## RANGE-ENERGY TABLES

Marvin Rich and Richard Madey

Radiation Laboratory, Department of Physics  
University of California, Berkeley, California  
March, 1954

## INTRODUCTION

The tables and graphs of this publication are essentially an expansion of the "Range-Energy Curves" of Aron, Hoffman, and Williams (AECU-663). The original work of Aron et al is extended to include pions, protons, deuterons, tritons, and  $\text{He}^3$  particles in selected absorber elements and in some compounds that are useful either as target materials or as scintillating materials. This extension is an outgrowth of needs that arose during the course of certain experiments that have been carried on for the past several years at the University of California Radiation Laboratory at Berkeley. Some of the work was done in a random fashion as needed chiefly for pion production experiments with scintillation counters. It seemed worthwhile to unify and complete this work for its utilitarian value to experimenters in high-energy physics, who have found similar needs.

The stopping media included in this publication are Be, C, Al, Cu, Pb,  $\text{H}_2$ ,  $\text{D}_2$ , air,  $\text{CH}_4$ ,  $\text{CH}_2$ ,  $\text{CD}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{D}_2\text{O}$ , plexiglass ( $\text{C}_5\text{H}_8\text{O}_2$ ) trans-stilbene ( $\text{C}_{14}\text{H}_{12}$ ), and phenyl-cyclo-hexane ( $\text{C}_{12}\text{H}_{16}$ ). The proton range-energy data for each element except aluminum were taken from Aron et al; that for aluminum from the article by J. H. Smith, Phys. Rev. 11, 32 (1947).

If the energy loss  $-\frac{dT}{dx}$  has the same velocity dependence for different particles, then the range in a given absorber is given by  $R = \frac{M}{Z^2} F(v)$ ,

where R is the range, M the mass, and Z the charge of the particle, and where  $F(v)$  is some function of the velocity of the particle. Two or more different particles moving in a given absorber will have the same  $F(v)$  if they have the same value of  $\frac{T}{M}$ , where T is the kinetic energy. Thus, for a singly charged particle of mass, M, the range and the energy loss in a given medium was obtained from that for protons in this medium by the relations

$$T = \frac{M}{M_{\text{proton}}} \quad T_{\text{proton}} = \frac{1}{r} \quad T_{\text{proton}} \quad r \equiv \frac{M_{\text{proton}}}{M} ,$$

$$R(T) = \frac{M}{M_{\text{proton}}} \quad R_{\text{proton}} (T_{\text{proton}}) = \frac{1}{r} \quad R_{\text{proton}} (r T_{\text{proton}}) ,$$

$$\left( \frac{dT}{dx} \right)_T = \frac{1}{r} \quad T_{\text{proton}} = \left( \frac{dT}{dx} \right)_{T_{\text{proton}}} ,$$

For doubly charged particles, the relations are

$$T = \frac{M}{M_{\text{proton}}} \quad T_{\text{proton}} = \frac{1}{r} \quad T_{\text{proton}} \quad r \equiv \frac{M_{\text{proton}}}{M} ,$$

$$R(T) = \frac{1}{4r} \quad R_{\text{proton}} (r T) ,$$

$$\left( \frac{dT}{dx} \right)_T = \frac{1}{r} \quad T_{\text{proton}} = 4 \left( \frac{dT}{dx} \right)_{T_{\text{proton}}} ,$$

The stopping power of molecular compounds for charged particles was obtained by assuming that each individual atom acts independently of all others in stopping the incident charged particle.<sup>1</sup> Since chemical binding energies of atoms bound in molecules are very small in comparison with the energy levels of the electrons in the absorber, the shifts in the energy levels should be small compared to the energies of the atomic levels themselves; thus, the effects of chemical binding on the stopping power should be small and it should be a good approximation to add atomic stopping powers. Proton ranges were obtained by numerical integration; the starting range was obtained first by extrapolating smoothly to zero the curve of  $d\xi/dT$  versus  $T$ , and then by integrating this curve for the molecular compound in question. The tables for the other particles were obtained as explained above.

The masses used in the various calculations are listed on page 8, except in the cases of pions in carbon, aluminum, and copper, where the pion mass was taken in these very early calculations as  $276 M_e$ .

In order to avoid possible confusion or error in using this report, the following facts should be noted. First, the unit for the rate of energy loss in these tables and graphs are Mev per gram-cm<sup>-2</sup> and is denoted by  $-\frac{dT}{d\xi} = -\frac{1}{\rho} \frac{dT}{dx}$ ,

where  $\xi$  is the thickness in grams per cm<sup>2</sup>, and  $x$  is the thickness in cm, and  $\rho$  is the density in grams per cm<sup>3</sup>. Second, for each range-energy graph, note that the number on the horizontal range scale must be multiplied by the proper factor of ten, given at the right hand end of that curve, to obtain the actual range. Finally, as explained in the Aron report (AECU-663), the values computed have been the rate of energy loss and range corresponding to a loss of energy by ionization only. There are a number of neglected effects such as nuclear interactions, meson production, bremsstrahlung, and polarization effects, which will play an increasingly important role at higher energies. In the tables of Aron, et al, the mean excitation potential,  $I$ , of the atoms in the absorber was chosen to be 17.5 ev for hydrogen and 44 ev for helium, in accordance with the theoretical calculation of Williams<sup>2</sup>; for all other elements, the mean excitation potential was taken proportional to  $Z$ , in accordance with Bloch's theory<sup>3</sup>, which is based on the FermiThomas model of the atom with several electrons. The value of the Bloch constant  $I/Z$  was taken to be 11.5 ev in accordance with measurements by Wilson<sup>4</sup>. Recent measurements<sup>5-11</sup> of the mean excitation potential and of ranges have indicated that this value may be considerably in error. For example, the various measurements of the mean excitation potential,  $I$ , of Be seem to be between 59 ev and 64 ev, whereas the value used in the calculations for the Aron report is 46 ev. Thus, although the tables in this report are calculated on the basis of the Aron report (AECU-663) to four significant figures, the tabulated values may differ from the experimental values by several percent. The order of magnitude of the discrepancies between the measured range,  $R_M$ , and the interpolated tabulated range,  $R_T$ , for protons at various energies and absorbers may be seen from Table A. Another estimate of the errors in the tabulated values can be obtained by comparing them directly with some later tabulated values; these newer tabulated values were recalculated by Aron<sup>12</sup> with values of the mean excitation potential,  $I$ , that were obtained by Bakker and Segre<sup>6</sup> and by Mather and Segre<sup>7</sup>. This comparison is made in Table B through Table E for Be, C, Cu, and Pb as a function of proton energy. The manner of graphical presentation of the range-energy curves is due to Dr. W. J. Frank.

We wish to thank Dr. W. A. Aron and Dr. H. Bichsel for their interest and constructive criticism of the introduction to this work; to acknowledge the work done by Mr. Richard Mitchell in performing the numerical integrations; and finally, to express our gratitude to Dr. B. J. Moyer for his support of this program.

This work was performed under the auspices of the Atomic Energy Commission.

MASSES OF VARIOUS PARTICLES

1.	Mass of proton	=	$m_p$	=	938.17 Mev.	(1)
2.	Mass of neutron	=	$m_n$	=	939.43 Mev.	(1)
3.	Mass of deuteron	=	$m_o$	=	1875.38 Mev.	(2)
4.	Mass of $H^3$	=	$m_T$	=	2808.54 Mev.	(3)
5.	Mass of $He^3$	=	$m_{He}$	=	2808.04 Mev.	(3)
6.	Mass of positive pion	=	$m_{\pi^+}$	=	139.71 Mev.	(4)

REFERENCES:

(1) Physical Constants UCRL-422 (1949)

(2) From Snow: Phys. Rev. 78, 21 the binding energy of deuterium is 2.225 Mev. Thus

$$m_o = m_p + m_n - 2.225 = 1875.38 \text{ Mev.}$$

(3) From Blatt and Weisskopf: Theoretical Nuclear Physics, page 204  
the binding energies of  $H^3$  and  $He^3$  are

$$B_{H^3} = 8.492 \text{ Mev.} \quad \text{and} \quad B_{He^3} = 7.728 \text{ Mev.}$$

Thus

$$m_T = m_p + 2m_n - B_{H^3} = 2808.54 \text{ Mev.}$$

$$m_{He} = 2m_p + m_n - B_{He^3} = 2808.04 \text{ Mev.}$$

(4) From W. Barkas (June 1953):

$$m_{\pi^+} = 273.5 \pm 1.2 \text{ electron masses}$$
