PREFACE AND ACKNOWLEDGMENTS

This paper analyzes the passenger trip length and fare patterns for each origin and destination market in the United States for the year of 1998. The U.S. Department of Transportation 10 percent origin and destination survey data for air passenger travel is used to evaluate the distribution of both passenger traffic and fares for different origin and destination distances.

The author wishes to acknowledge the guidance and suggestions of Dr. Geoffrey Gosling at the University of California at Berkeley during the conduct of the research, as well as the support of Safire Aircraft Company in sponsoring the work.

1. INTRODUCTION

At a national level it is common to express the amount of air travel in terms of the number of revenue passenger miles flown or the number of enplaned passengers. This provides a way to resolve the difficulty of how to aggregate measures of air travel in many different markets of many different distances. However, information about the distribution of trip lengths is lost in the process.

This information is of interest for a number of reasons. The type of aircraft that is most appropriate for different markets depends on the distances involved. The length of the trip is also likely to influence traveler behavior in terms of the importance of convenient access to airports, frequency of service, and willingness to make intermediate stops.

A related issue is how the cost of air travel varies with the length of the trip. The cost structure of airline service is such that the cost per mile flown reduces with increasing trip length, and this is reflected in typical airline fares. However, other factors also influence fares, such as airline competition, and the fare structure may or may not reflect the costs involved for trips of different lengths.

Therefore, this study examines the distribution of trip lengths and associated average fares in the U.S. domestic air travel market. For the purpose of this study, trip length is defined as the direct distance between the origin and destination of a trip. In practice, passengers may fly via intermediate stops, as when they take a connecting flight through an airline hub, and this will generally increase the distance flown. However, this aspect of trip length is not considered here.

2. DATA SOURCES

The research uses the U.S. Department of Transportation Origin-Destination Survey of Airline Passenger Traffic as the primary data source. The statistics generated by this survey result from a continuous sample of ten percent of all of the passengers traveling on U.S. certificated air carriers.

The collection of the data, mandated by the Federal Aviation Act of 1958, is a cooperative effort among the domestic air carriers, the Air Transport Association of America, and the Department of Transportation. The data resulting from the survey are compiled by the Data Administration Division of the Office of Aviation Information Management, Research & Special Programs Administration, of the United States Department of Transportation. [1]

The data collection effort itself is a continuous survey, not of passengers per se, but of ticket coupons. An airline ticket generally consists of a series of coupons. Each separate coupon represents an aircraft boarded. The flight coupons which are surrendered by passengers upon boarding a flight are the primary source of the survey.

From the set of all flight coupons collected by all certificated carriers, a constant ten percent sample is extracted. The sample is obtained as follows: whenever a participating carrier detaches the first flight coupon for travel on a participating carrier from any ticket, it retains and reports selected information from that ticket if the serial number of the ticket ends in a zero, or if the ticket represents 11 or more passengers. Coupons from tickets with serial numbers ending in any digit other than a zero are excluded from the survey. Also excluded are any coupons other than the very first coupon of the ticket which represents a participating carrier. (This coupon contains the full details of the ticket.)

The resulting Origin-Destination survey covers revenue passenger trips moving either in whole or in part via the scheduled services of certificated air carriers. The data collected encompass the full itinerary of the passenger, as it is reflected on the ticket, from initial origin to ultimate destination, including any carriage by nonparticipating carriers. [1]

O&D Plus®, a commercial product for the origin and destination survey of airline passenger traffic distributed by Data Base Products, Inc. [1], was used to retrieve required data for the research. After obtaining the required data, the statistical analysis software SAS® was used to process and generate results from the raw data.

In the research, we focus on the following data:

Trip length of an origin-destination pair:

The trip length of an origin-destination pair is the great circle distance between the airport that was the origin of travel to the airport that was the destination of travel, calculated in statute miles. In our data analysis, the trip length was expressed in 100-mile increments.

Market:

A market is defined as an airport pair that represents true-origin to true-destination. Therefore, passengers traveling from San Francisco to New York via Chicago and passengers traveling from New York to San Francisco via Chicago are defined as two different markets. A passenger traveled round trip from San Francisco to New York and back to San Francisco is considered as two trips recorded in separate markets.

Fared passenger:

The passengers consist of two passenger types: fared passengers and zero fare passengers. As the names imply, passengers who paid a fare are fared passengers and zero fare passengers are passengers who travel without paying a fare. These zero fare passengers can be people traveling on airline vouchers, people affiliated with airline industry, or people using their frequent flier mileage for free travel.

Average fare:

The average fare is the total revenue divided by total fared passengers. Here, the average fare is not the actual average fare a passenger paid but the amount after subtracting Federal Excise Tax from the reported “gross fare”. Therefore, this is the amount of revenue that the air carriers actually obtain from passengers.

3. DATA ANALYSIS

In 1998, the O&D survey data recorded 110,864 markets in the United States. From the data, more than 387 million passengers used the air transportation system for their trips. Among these passengers, 369 million passengers were fare-paying passengers. The total revenue from fares is 55 billion dollars. On average, a passenger paid 151 dollars per trip in 1998.

Figure 1 Percentage of Markets for Different Trip Lengths

For operation within the 48 continental states, the furthest trip length is around 2800 miles. All operations with a trip length more than 2800 miles are operations between Hawaii, Alaska and the Continental US. More than half of the markets have trip lengths within 1000 miles. Twenty percents of markets fell into the range between 1000 to 1499 miles. Figure 1 shows the percentage of markets for different trip lengths. The number of markets is related to the population distribution. In the mid-west, most population is concentrated in several major

metropolitan areas, therefore, the number of markets to and from this region will be less than that between the east and west coasts.

Figure 2 shows the distribution of fared passengers by trip length. 64 percent of these passengers have an OD trip length less than 1000 miles. The passengers' share for trip lengths between 1000 and 1999 miles is 25.5 percent, which is smaller than the proportion of markets for this distance range, 33 percent. One reason why the passenger share is less than the market share is that most markets between 1000 and 1999 miles are markets between the west and east coasts and the mid-west, which do not have as many passengers.

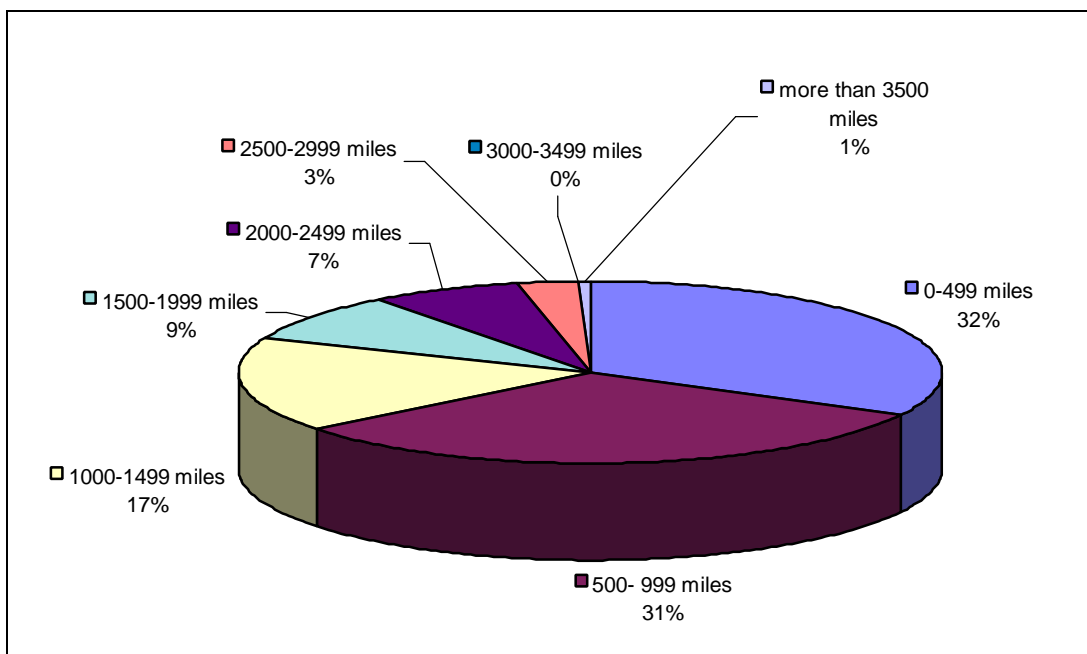

Figure 2 Fared Passenger Share for Different O&D Trip Lengths

Figure 3 shows the number of fared passengers for different trip lengths. More than 37 million passengers have trip lengths between 300 and 399 miles. In general, the number of passengers decreases with increasing trip length. However, a secondary peak occurs between 2200 miles and 2800 miles. This is because concentration of U.S. population on the east and west

coasts results in higher traffic levels for coast-to-coast operations that fall into this distance range. For trip lengths over 2800 miles, the OD pairs are from Hawaii and Alaska to the continental US, which have less traffic than the domestic flights. Therefore, as shown in Figure 3, the number of passengers decreases dramatically after 2800 miles.

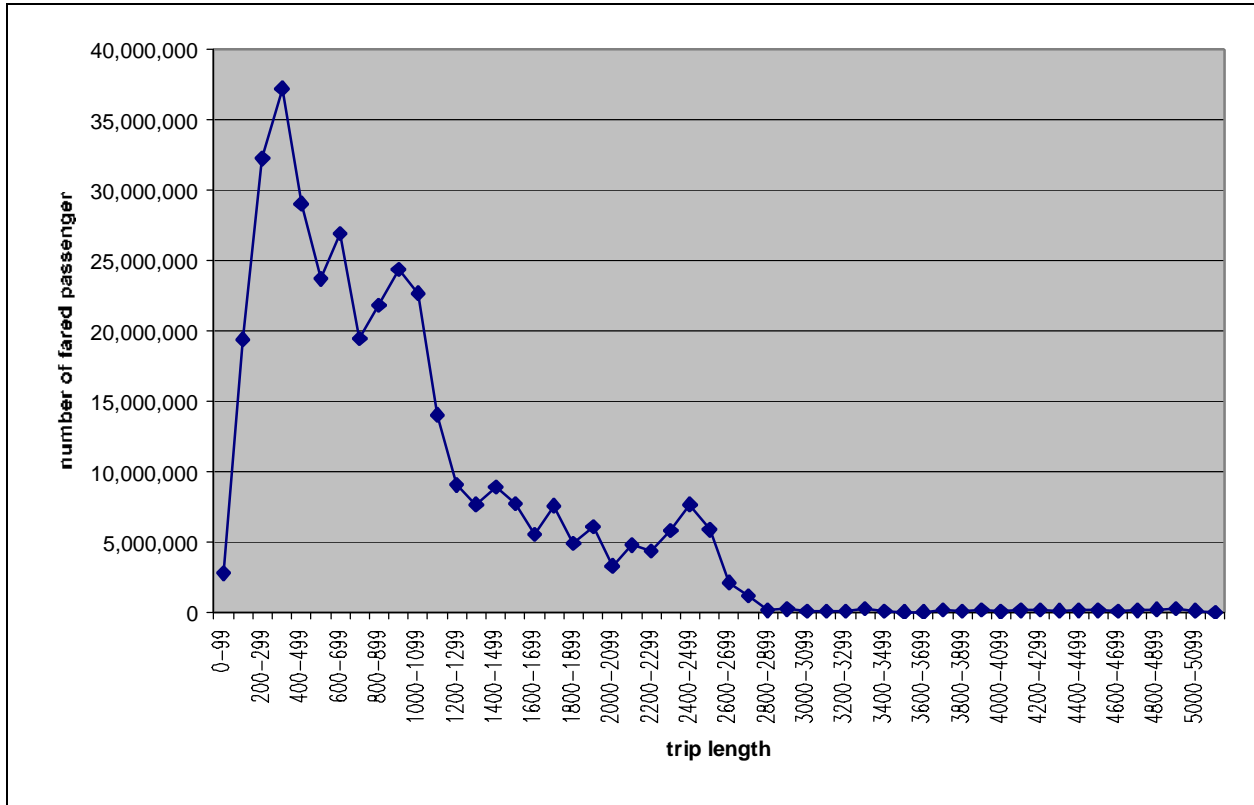

Figure 3 Relationship between Numbers of Fared Passenger and Trip Length

Figure 4 illustrates the average fare passengers paid for each trip length range. As can be expected, the longer the trip length, the more expensive the average passenger fare is. However, the marginal increment in average fare decreases with trip length. This is due to the nature of the cost function for flight operations, which has a substantial fixed cost and relatively smaller variable cost. For each flight, the fixed costs include station costs and fuel burn for take-off and

landing. The variable costs are largely the labor costs of the flight and cabin crew and the cost for airborne fuel, which increase with distance flown.

Figure 4 Average Fare Passengers Paid for Each Trip Length segment

When expressed as an average fare per mile, as shown in Figure 5, the average cost decreases rapidly increasing trip length for trip lengths under 1000 miles. For trip lengths between 0 and 99 miles, the average cost is 1.01 dollars per mile. For these short trips, the fixed costs dominate the average cost. For most coast-to-coast operations with trip lengths between 2200 and 2800 miles, the average cost per mile is only about 10 cents, since the fixed costs for these trip lengths ranges are a much smaller part of total costs.

Figure 5 Average Cost per Mile for Each Trip Length Segment

4. SUMMARY

An analysis of data in the Origin-Destination Survey of Airline Passenger Traffic for 1998 shows that:

1. Over half of the US markets are under 1000 miles
2. More than 60 percent of passengers have trip lengths under 1000 miles
3. On average, passengers paid 151 dollars for a trip length
4. In general, the number of passengers decreases with increasing trip length. However, a secondary peak in the distribution occurs in the range between 2200 miles and 2800 miles due to coast-to-coast operations
