The strong features in the absorption spectrum and the laser excited fluorescence spectrum have been interpreted as arising from levels of Pr³⁺ in the D_{2d} symmetry site of ThBr₄. 43 energy levels have been fitted to the parameters with an RMS deviation of 61 cm⁻¹. The values of the crystal field parameters are: B₀² = 260.0 cm⁻¹, B₀⁴ = - 644.2 cm⁻¹, B₄⁴ = 929.2 cm⁻¹, B₀⁶ = 1089.0 cm⁻¹ and B₄⁶ = 240.6 cm⁻¹. The presence of other crystal symmetry sites is observed.

I - INTRODUCTION

Thorium tetrabromide is of interest as a matrix for tetravalent ions of the actinide elements because it can be prepared in large, optically clear crystals^{1,2}. At room temperature, ThBr₄ is tetragonal and isostructural with UCl₄, the thorium ion is at a site of D_{2d} symmetry. In an attempt to find a simpler and better understood system to confirm U⁴⁺(5f²) work, we have studied Pr³⁺ (4f²) diluted in ThBr₄. We assume the Pr³⁺ substitutes into the crystal at Th⁴⁺ sites and therefore the most important symmetry seen by the Pr³⁺ is D_{2d}. The fact that it is a 3⁺ ion in a tetravalent matrix presents some complications which are overcome because the Pr³⁺ system is so well known.

II - EXPERIMENTAL PROCEDURES

The crystals were prepared varying in size from 6 mm in diameter to 40mm in diameter and using approximately 1% by weight PrBr_3 or Pr_6O_{11} as starting materials. The larger crystals yielded pieces 10 x 10 x 5mm that were optically clear and the optical axis could be easily found and positioned for the spectral studies. The spectra obtained from the two different Pr compounds were identical.

The absorption spectra were recorded in both Orsay and Berkeley. In Orsay, we used a 1 meter Jobin-Yvon "HR1000" spectrophotometer with a 1200lines/mm grating. The Berkeley work was done with a 0.75 meter photographic instrument. Polarized spectra were recorded between 4000 Å and 2 μm at room temperature, 77 K and 4.2 K. Spectra were also recorded on a Cary 17 at 77 K and 4.2 K in the wavelength region from 4000 Å to 2.5 μm.

Fluorescence of the crystals was excited with a nitrogen laser and with a nitrogen pumped dye laser. The dye laser produces a wavelength about 1 Å FWHM and was varied in 1 Å steps. The fluorescence spectra were recorded photographically with exposure times of 15 minutes.

III - RESULTS

The spectra contained many more lines than can be explained by electric dipole transitions between allowed levels in D_{2d} symmetry. The extra lines become sharper at low temperature and are found within less than 50 cm^{-1} on both sides of the strong lines. Over all, the strong lines resemble the expected Pr^{3+} spectrum and it is these that were used in the analysis of the data. In table 1 the absorption lines obtained at 4.2 K are listed.

The $^3\text{P}_0$ contains only a Γ_1 state and according to the D_{2d} selection rules^{3,4,5} gives a π line for a transition with the Γ_4 state of the $^3\text{H}_4$ ground multiplet or a σ line when the transition is to a Γ_5 state. In our experiment the $^3\text{P}_0$ line was very clearly polarized σ , thus supports a Γ_5 to Γ_1 transition. Fig. 1 shows the structure around the $^3\text{P}_0$ at 77 K in both the π and σ

Figure 1

Figure 2

polarization and Fig. 2 shows the change in structure of the π polarization with the change of the temperature from 77 to 4.2 K.

The absorption spectrum at room temperature has a line at 304 cm^{-1} to the low energy side of the 3P_0 . This was observed in a crystal perpendicular to the c-axis but was not polarized. Since this agrees with a laser fluorescence line and the only other line possible is to the Γ_4 level, it is taken as the Γ_4 to Γ_1 transition.

This assignment is supported by the transitions to the 1D_2 . We see four lines : 3σ lines and a π line which is the case only for a Γ_5 ground state. A Γ_1 , Γ_2 or Γ_4 ground state would allow only two lines, a π and a σ , and a Γ_3 ground state permits only one σ line. None of these ground states would allow transitions to the 3P_0 .

The absorption lines were then used as data in a fitting program which adjusted the various parameters. At first the electrostatic parameters, F^2 , F^4 , F^6 , the spin orbit parameter ξ , and the configuration interaction parameters α, β, γ were fixed at the values for aqueous ion⁶. The crystal field parameters, B_0^2 , B_0^4 , B_4^4 , B_0^6 and B_4^6 were varied starting with the values for Pr^{3+} in Li YF_4 . The ground state is different for the two matrices but otherwise the order of magnitude was correct. Once reasonable B^K values were obtained they were fixed and the $F^{K'}$'s and ξ were varied. At this point, the calculated values were compared to the lines determined from the laser fluorescence experiments. These lines were not polarized, and because the levels have some vibronic components, all possible lines appeared. Thus all 7 possible lines from the 3P_0 to the 3H_4 were seen regardless of selection rules. All 10 lines from the 3H_6 and 4 lines from the 3F_2 are also seen (Table 2). These fluorescence levels were then assigned in the order derived from the fit. The $B^{K'}$'s were then varied, fixing the $F^{K'}$'s, ξ ; then the $F^{K'}$'s varied with the $B^{K'}$'s fixed and finally the $B^{K'}$'s were varied again. The final parameter values are listed in table 3. Table 4 gives the values of the experimental and calculated energies together with the irreducible representations and the L-S states.

IV - CONCLUSIONS

The strong lines in the spectrum of Pr^{3+} in ThBr_4 resemble the structure of Pr^{3+} ion in other situations such as the aqueous solution. The data have been successfully fitted to the symmetry of the ThBr_4 , D_{2d} .

However it should be mentioned that the Pr^{3+} ion in ThBr_4 is not that simple and there are many processes going on that we cannot explain and probably some of which we are not aware. A few examples should be mentioned. The 3P_0 shows vibronic structure with several satellite lines on both sides of the main line. In crystals which were not as optically good as those used there was a satellite line at 89 cm^{-1} to the low energy side of this line which varied in intensity in different parts of the crystal and in different crystals. When this line was excited by the laser, it gave a very complicated spectrum in the region of the strong 3F_2 and 3H_6 transitions. Therefore it was due to Pr^{3+} but of a very different nature from the stronger 3P_0 line. Also, as the laser excitation wavelength was varied over the 3P_0 absorption peak, we saw four strong lines to the 3F_2 levels but a change of 2 \AA to higher energy produced a doubling of each of the four lines separated by about 5 cm^{-1} . The 3H_6 lines were broader and did not show this splitting. We interpret this as two different sites of the same symmetry. As we scanned further from the peak the four lines faded and as many as eight other weaker lines appeared, probably due to Pr^{3+} ion in other symmetries. The 3H_6 showed this fading of the original lines into a complex pattern of many lines. Excitation into the absorption peaks of the 3P_1 and 3P_2 yielded the same fluorescence as the 3P_0 , four strong lines. This is a radiationless transition from the upper levels to the lower 3P_0 . We did not look for fluorescence from the 1D_2 as it would be too far in the red to be easily observed.

There is a moderately intense line at 4525 \AA which is unpolarized and does not fit into D_{2d} system. One possible explanation is that it is a 3P_2 line of a different symmetry and is the only such line seen because of the great intensity of the $^3H_4 - ^3P_2$ transition.

It appears that in addition to the strong features which can be interpreted as belonging to the D_{2d} symmetry site of ThBr_4 , there is another D_{2d} site and at least two other symmetries exist in this crystal. There is also an unexplained feature due to Pr^{3+} which depends on the perfection of the quality of the crystal.

Moreover we have not been able to index the vibronic structure of the $^3P_{0,1,2}$ lines even though vibronic frequencies are known for both infrared and Raman active vibrations⁷.

ACKNOWLEDGMENTS

We are grateful to Dr. Norman Edelstein for providing us the least square program, the matrix elements and for very fruitful discussions.

a) The three absorption lines were used to find the value of the level from which fluorescence originated : the difference between the levels in absorption and fluorescence is between 1 and 3 cm^{-1} . The origin of fluorescence is 45 cm^{-1} higher than the absorption value. However, there is a very weak satellite line at 4882 Å which is probably the origin of the fluorescence.
