CASE PRESENTATION

A 19-year-old man was brought by ambulance to the emergency department with left-sided testicular pain. He reported sudden severe, non-radiating left testicular pain that woke him from sleep 30 minutes prior to arrival. He presented in severe pain, tremulous from discomfort. His exam revealed a high-riding, firm, left testicle in a horizontal lie with absent cremasteric reflex. Urology was consulted and a comprehensive ultrasound ordered. The patient’s testicles were immediately examined with point-of-care ultrasound (POCUS) (Image 1). After receiving 100 micrograms of fentanyl, manual detorsion was conducted, and repeat ultrasonography was performed (Image 2). The patient was then transported for comprehensive ultrasonography (Image 3).

DISCUSSION

Testicular torsion is a urologic emergency in which the testicle rotates 180–720 degrees, compromising venous and ultimately arterial circulation, leading to ischemia, necrosis, and nonviability. The literature has demonstrated good survivability at six hours, although it is time dependent with improved
CPC-EM Capsule

What do we already know about this clinical entity?

Testicular torsion is a time-sensitive emergent condition for which point-of-care ultrasound has emerged as a potential tool for both identification and management.

What is the major impact of the image(s)?

These images illustrate classic ultrasound findings of testicle edema, and absence of Doppler flow and demonstrate return of Doppler flow after attempted detorsion.

How might this improve emergency medicine practice?

Depending on resources, providers should consider point-of-care ultrasound, paired with comprehensive studies, to identify testicular torsion and confirm detorsion.

outcomes at quicker intervention. Classic history and exam features include sudden onset of pain, and a firm, horizontally oriented testicle with absent cremasteric reflex. Conventional teaching invokes early urologic consultation in highly suspicious cases prior to comprehensive ultrasonography.

POCUS has emerged as an important diagnostic tool, with up to 100% sensitivity reported in small-sample studies for both fellowship- and non-fellowship trained emergency physicians. Ultrasonographic features can include the following: an enlarged edematous hypoechoic testicle without Doppler flow; a whirlpool sign (spiral twist of the spermatic cord at the external inguinal ring or scrotal sac); and epidydimal enlargement without hyperemia. This patient underwent bedside manual detorsion with return of flow after approximately two lateral rotations. Comprehensive ultrasound demonstrated a hyperemic testicle consistent with recent detorsion. Depending on availability of resources and timing, POCUS can be an important tool in identifying testicular torsion and helping guide adequacy of reduction in conjunction with comprehensive ultrasonography.
