Abstract

Objectives: To enable interactive visualization of the vaginal microbiome across the pregnancy and facilitate discovery of novel insights and generation of new hypotheses.

Material and Methods: Vaginal Microbiome Atlas during Pregnancy (VMAP) was created with R shiny to generate visualizations of structured vaginal microbiome data from multiple studies.

Results: VMAP (http://vmapapp.org) visualizes 3880 vaginal microbiome samples of 1402 pregnant individuals from 11 studies, aggregated via open-source tool MaLiAmPi. Visualized features include diversity measures, VALENCIA community state types, and composition (phylotypes, taxonomy) that can be filtered by various categories.

Discussion: This work represents one of the largest and most geographically diverse aggregations of the vaginal microbiome in pregnancy to date and serves as a user-friendly resource to further analyze vaginal microbiome data and better understand pregnancies and associated outcomes.

Conclusion: VMAP can be obtained from https://github.com/msirota/vmap.git and is currently deployed as an online app for non-R users.

Lay Summary

The vaginal microbiome plays a significant role in birth outcomes, including preterm and spontaneous labor. Despite the increasing number of microbiome studies being performed, the information remains separated and difficult to compare due to technical challenges in its aggregation. This fact hinders analyses of large and widely-representative data. To address this drawback, we present the Vaginal Microbiome Atlas during Pregnancy (VMAP), a web application that enables the visualization of 11 different microbiome studies, including a total of 3880 vaginal microbiome samples aggregated leveraging an open-source tool, MaLiAmPi. VMAP offers an online platform for exploring robust vaginal microbiome data in the context of pregnancy from multiple studies, providing interactive visualization of diverse microbiome features, allowing a better understanding of the role of the vaginal microbiome in preterm birth, and facilitating the generation of new research hypotheses.

Key words: bioinformatics; 16S rRNA sequencing; microbiome; visualization; data integration.

Introduction

The vaginal microbiome plays a significant role in birth outcomes, including spontaneous and preterm labor.[1–7] An increasing number of microbiome studies in the past decade, thanks to advances in high-throughput sequencing, have permitted greater insights into the role of the microbiome in human health and disease[8]; however, efforts to aggregate microbiome datasets to better understand the microbiome through analysis of large, widely-representative data has been precluded by technical challenges.[9] In particular, the dominant approach to harmonize microbiome data include closed reference operational taxonomic units (OTUs) and projection to taxonomy. The main drawback is this technology is highly dependent on the matching of microbiome communities to the reference which hinders the process of harmonization.[10] In this work, we present an atlas of the vaginal microbiota during pregnancy leveraging data across 11 studies harmonized by the open-source tool, MaLiAmPi.[10] This algorithm places 16S rRNA gene variable region amplicon sequence variants onto a common phylogenetic tree, successfully correcting for the technical differences and retaining more true entropy. Although other microbiome atlases exist, such as microbioTA,[11] here we present a specific atlas of vaginal microbiome across pregnancy that encompasses a total of 11 projects. This dataset represents one of the largest and most geographically diverse aggregations of the vaginal microbiome in pregnancy to date—3880 samples from 1402 pregnant individuals—harmonized into a set of generalizable features suitable for integration of new microbiota data post-hoc. A rich set of paired metadata is included, including collection week during gestation (by specimen), week of delivery, and maternal NIH racial category. Approximately one-third of the pregnancies in this data set were of women delivering preterm, including just over 1/8th who delivered early preterm. This dataset and features derived from these data can be interactively visualized via our Vaginal Microbiome Atlas during Pregnancy (VMAP) application, a resource for understanding the vaginal microbiome in the context of pregnancy (http://vmapapp.org).

Materials and methods

The dataset was constructed by aggregating and processing vaginal microbiome data from the public domain[12–16] in addition to including newly generated data not yet released to the public. The publicly available data were from 9 studies, representing 3578 samples across 1268 individuals of whom 851 delivered term and 247 preterm (32-37 weeks of gestation) and 170 early preterm (before 32 weeks of gestation). Two additional unpublished datasets are included. One is from Wayne State University consisting of 159 samples

across 60 individuals among whom 40 (66.7%) had term deliveries and 15 (25.0%) had preterm deliveries and 5 (8.3%) who had early preterm deliveries. A newly generated dataset which comprises 143 vaginal microbiome samples from 74 individuals, up to 3 samples (one sample per trimester) for each individual, with 44 individuals (59.5%) having term deliveries, 25 individuals (33.8%) having preterm deliveries, and 5 individuals (6.8%) having early preterm deliveries.[17]

To harmonize the raw amplicon sequence reads from such a diverse set of underlying approaches, we developed a novel phylogenetic-based approach implemented in an open source workflow called MaLiAmPi.[10] Briefly, MaLiAmPi is a Nextflow pipeline based on 4 important steps: (1) The generation of ASVs from FASTQ files, (2) The selection of a repository of 16S rRNA alleles, (3) The generation of a reference package containing a phylogenetic tree, and (4) The placement of these ASVs onto the reference phylogenetic tree. This pipeline is a promising approach for harmonizing microbiome data improving the current techniques such as those based on closed-OTUs.

We further compute the alpha-diversity of communities (diversity measures include Shannon, Inverse Simpson, Balance weighted phylogenetic diversity [bwpd], phylogenetic entropy, quadratic, unrooted phylogenetic diversity, and rooted phylogenetic diversity), weighted phylogenetic (KR) distance between communities, provide taxonomic assignments to each ASV, and cluster ASVs into phylotypes which serve as a taxonomy-independent representative of (phylogenetically) closely related organisms. In addition, VALENCIA[18] was used to provide the microbiome community state type (CST) of each sample.

VMAP is an interactive web application implemented in R shiny (version = 1.7.5.1) and HTML 5 to visualize, filter, and explore microbiome data.

Results

VMAP (http://vmapapp.org) interactively visualizes vaginal microbiome features during healthy term or adverse-outcome associated pregnancies across 11 studies, representing 3880 samples from 1402 individuals, of whom 935 delivered at term, 287 delivered at preterm, and 180 whose deliveries were early preterm. The demographics and information about the source studies are presented in Table 1. The vaginal microbiome data are from individuals of different racial backgrounds, including Black or African American, White, American Indian, Alaska native, Asian, and unknown, and of varying age. Additionally, samples were collected during the 3 pregnancy trimesters allowing insight into microbiome changes across time (Table S1). Figure 1 depicts a schematic of all the features that are captured by the atlas.

	Instruments	454 GS FLX Titanium, Illumina HiSeq 2500, Illumina HiSeq 4000, Illumina MiSeq, or Illumina NextSeq 550

This tool allows customizable visualization of the data at several levels including demographics of the cohort at the sample or individual level organized by outcome (term, preterm, early preterm), race and ethnicity distributions, as well as breakdown per project (see web tutorial). Demographics are shown as stacked barplots where the relative frequency of each type of category selected can be seen. Furthermore, stacked barplots are updated according to the demographic feature selected (Figure S1). Alpha-diversity measures are also shown in several ways including overall correlation plots of the individual measures and their distribution as well as violin plots across various stratifications (Figure S2). Different diversity measures are customizable allowing users to select their measures of interest with a legend below the chart explaining each of them. CSTs are visualized via alluvial plots longitudinally across trimesters allowing for various stratifications of interest. The alluvial plots allow the observation of changes in the relative composition of CSTs across trimesters according to the feature selected, representing each stream as an individual CST (Figure S3A). The prevalence and relative abundance of closely related microbes (as represented by phylotypes) or taxa are displayed as heatmaps (Figure S3B). Dimensionality reduction plots, namely Uniform Manifold Approximation and Projections (UMAPs), are used to visualize phylotype data per sample or individual comparing different features (Figure S4). Finally, it is worth noting that VMAP contains a tutorial on what each chart represents and how to use the filters to facilitate the use of this application.

Discussion

VMAP provides a means to view a rich set of features derived from vaginal microbiota data (including alpha-diversity, CSTs, and the composition of specific microbes and taxa) associated with core outcomes (delivery group) and metadata (eg, NIH racial categories, maternal age) that can be sliced and viewed interactively. VMAP can be a resource for those wishing to relate and understand vaginal microbiota data within the context of pregnancy. The generalizability of these features across studies using distinct underlying techniques
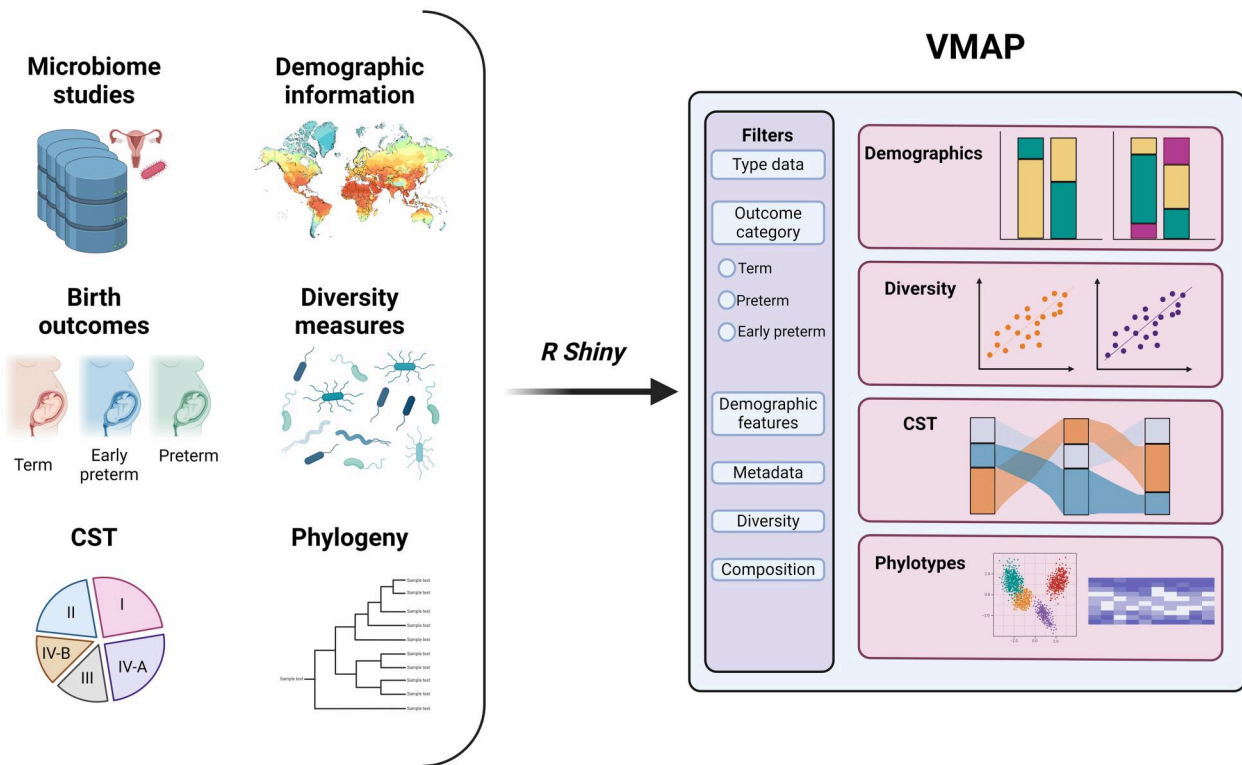

Figure 1. VMAP RShiny App. VMAP encompasses information from different microbiome studies gathering demographic information, birth outcomes, diversity measures, CST, and phylogeny (left). A user can visualize demographic features of the cohort, diversity measures (including correlations between them) by outcome of interest, alluvial plots of CSTs, dimensionality reduction plots of phylogeny, and heatmaps of taxonomical features (right). The visualizations are customizable by the filters in the bar on the left, allowing one to choose which projects and samples to visualize. Abbreviation: CST = community state types. Created with BioRender.com.

(eg, targeting different 16S rRNA gene variable regions or novel sequencing platforms) and the ability to integrate new data into the existing set of features are significant advances for microbiome research. For example, this data set and approach were successfully employed as the basis for a machine learning ("DREAM") challenge predicting preterm and early-preterm birth where over 300 teams participated with the goal of building machine learning models to predict which women would deliver preterm.[17] This challenge used this novel approach to integrate data *post-hoc* to validate machine learning models against datasets unavailable to participants. VMAP will enable the scientific community to visualize and study all of this information, both to better understand the role of the microbiome in preterm birth and to generate new research hypotheses. In addition, filtering by metadata information can reveal trends in microbiome data in specific groups of interest, such as age groups or trimesters.

The resource has limitations that should be considered. It is based on publicly available data which might not have full clinical or demographic annotations of the samples in the metadata. While the sample size of the study is considerable with representation of individuals of diverse backgrounds, it may not be representative of the entire population of pregnant women from around the world.

This work serves as the basis for several potential follow-up opportunities. Our VMAP visualization resource can further be extended to include non-pregnancy datasets as well as microbiome data across body sites by leveraging the MaLiAmPi harmonization technique that can incorporate additional datasets post hoc.[10] In addition, other adverse pregnancy outcomes such as recurrent pregnancy loss can be investigated and included in the expansion of this resource with the aim of observing differences and similarities as well as improving the understanding of these reproductive conditions. Finally, the microbiome data can further be integrated with other omics measures to better understand healthy human pregnancy and those associated with adverse outcomes. VMAP will be valuable for more robust interpretation of novel datasets seeking to relate the vaginal microbiome to pregnancy outcomes—serving as a large and regularized set of data and metadata for comparison.

Conclusion

VMAP offers a platform for exploring robust vaginal microbiome data in the context of pregnancy from multiple studies, providing interactive visualization and assessment of diverse features. Despite current limitations such as clinical annotation accuracy, VMAP opens avenues into further work—extending to other outcomes and incorporating additional microbiome data including non-pregnancy datasets, data from other body sites, and other omics measures—for a deeper understanding of human health.

Conflicts of interest

Antonio Parraga-Leo and Patricia Diaz-Gimeno are receiving hononaria from the IVI Foundation. All other authors declare no financial or non-financial competing interests.

Data availability

The RShiny app is available: http://vmapapp.org.

Datasets were downloaded from ImmPort[13] via the March of Dimes Preterm Birth database[12] (Study SDY465), from the NCBI Sequence Read Archive[15] (BioProjects PRJNA242473, PRJNA294119, PRJNA393472, and PRJNA430482), the Sequence Read Archive of the European Nucleotide Archive[16] (Projects PRJEB11895, PRJEB12577, PRJEB21325, and PRJEB30642), and the database of Genotypes and Phenotypes (dbGaP)[14] (accession number phs001739.v1.p1).

Additional associated metadata were requested and obtained from the RAMS Registry (https://ramsregistry.vcu.edu) (PRJNA430482) or from the senior author (Projects PRJEB 11895, PRJEB12577, PRJEB21325, and PRJEB30642), or downloaded from the publication by the Kindinger et al[4,5] (PRJEB11895 and PRJEB12577).

Data for accession number phs001739.v1.p1 are exclusively available via dbGaP after following the application procedures there.

The aggregated vaginal microbiome dataset can be downloaded from the March of Dimes Prematurity Research Database excluding the datasets that we are unable to share due to legal restrictions (**SDY2187**).

Ethics statement

This work was approved by the National Heart, Lung, and Blood Institute (NHLBI) Clinical Data Science Institutional Review Board (CDS-IRB) in study number 2021-040, and reliance was granted to the NHLBI CDS-IRB by the University of California, San Francisco Institutional Review Board in study number 21-35274.
