The Thue-Siegel method in diophantine geometry

Paul Vojta

Abstract. This mini-course described the Thue-Siegel method, as used in the proof of Faltings’ theorem on the Mordell conjecture. The exposition followed Bombieri’s variant of this proof, which avoids the machinery of Arakelov theory.

In the 1950s, K. F. Roth [Rot55] proved a much-anticipated theorem on diophantine approximation, building on work of Thue, Siegel, Gel’fond, Dyson, and others.

Theorem 0.1. Given an algebraic number \( \alpha \in \overline{\mathbb{Q}} \), a number \( C \in \mathbb{R} \), and \( \epsilon > 0 \), there are only finitely many \( p/q \in \mathbb{Q} \) (with \( p, q \in \mathbb{Z} \) and \( \gcd(p, q) = 1 \)) that satisfy

\[
\left| \frac{p}{q} - \alpha \right| \leq \frac{C}{|q|^{2+\epsilon}}.
\]

This theorem was proved using the Thue-Siegel method (which was described in M. Nakamaye’s course).

The goal for this course is to briefly describe how the Thue-Siegel method was adapted by Vojta [Voj91], Faltings [Fal91], and Bombieri [Bom90, Bom91] to give a proof of the Mordell conjecture (which had already been proved by Faltings):

Theorem 0.2. [Fal83] (Mordell’s conjecture) Let \( k \) be a number field and let \( C \) be a smooth projective curve over \( k \) of genus \( > 1 \). Then \( C(k) \) is finite.

Faltings’ original 1983 proof used results from the theory of moduli spaces of abelian varieties to prove a conjecture of Shafarevich on principally polarized abelian varieties of given dimension with good reduction outside of a fixed finite set of places of a number field. He then used “Parshin’s trick” to obtain the Mordell conjecture. In short, this was very different from the Thue-Siegel method.

Analogies with Nevanlinna theory suggested that there should be a common proof of both Roth’s theorem and the Mordell conjecture, and this led the author to try to prove the Mordell conjecture using the Thue-Siegel method. This led ultimately to the paper [Voj91], which gave another proof using the Thue-Siegel method, but which relied heavily on the Arakelov theory as developed by Gillet and Soulé. In particular, the use of Siegel’s lemma was replaced by an argument using an adaptation of the Riemann-Roch-Hirzebruch-Grothendieck theorem to Arakelov theory, due to Gillet and Soulé.

Shortly thereafter, Faltings [Fal91] managed to eliminate the use of the Gillet-Soulé Riemann-Roch theorem, replacing it with arguments on the Jacobian of the curve \( C \). This allowed him to make use of more than two rational points (as did...
Roth), as well as extend his result to prove a special case of a conjecture of Serge
Lang on rational points on closed subvarieties of abelian varieties not containing
any nontrivial translated abelian subvarieties. (He later succeeded in removing the
latter hypothesis [Fal94].)

Following that, Bombieri [Bom90] simplified the proof further, by removing
Arakelov theory altogether, at the (minor) cost of some clever geometrical argu-
ments. He was able to use the fact that Arakelov intersection numbers can be
realized more classically as heights. Then, he was able to avoid the use of the
Riemann-Roch theorem of Gillet and Soulé by applying a more classical theorem
of Riemann-Roch type (due to Hirzebruch), together with some clever geometrical
manipulations. In the end, he obtained a proof relying only on elementary facts
from algebraic geometry and the theory of heights.

This course describes Bombieri’s proof (but will omit some details, due to lack
of time). Another description of his proof appears in [HS00, Part E].

For those interested in the earlier proof [Voj91], a good place to start would
be an earlier paper [Voj89], which proved the function field variant of Mordell’s
conjecture (first proved by Manin [Man63]). This paper also used the Thue-Siegel
method, but used classical intersection theory instead of Arakelov theory, and the
Riemann-Roch-Grothendieck theorem in place of the Riemann-Roch theorem in
Arakelov theory due to Gillet and Soulé.

This paper is organized as follows. Section 1 gives an overview of the Thue-
Siegel method, as used to prove Roth’s theorem and its predecessors. Section 2
defines the basic geometrical objects to be used in Bombieri’s proof. Section 3
gives some basic information on curves and their Jacobians, as used by a result
of Mumford [Mum65], and which forms the core of Bombieri’s proof (and its
predecessors by Vojta and Faltings). Section 4 then gives an upper bound for the
height of a carefully chosen point \((P_1, P_2)\) on \(C \times C\), relative to a line bundle on
\(C \times C\) that is chosen based on properties of \(P_1\) and \(P_2\). Section 5 gives a lower
bound for the same height, depending on the height of a global section of the
line bundle. This global section plays a role comparable to that of the auxiliary
polynomial in the classical Thue-Siegel method. Section 6 constructs such a global
section with a bound on its height. In Section 7, the index of a local section of a
line bundle is defined; this generalizes the index used in the classical Thue-Siegel
method, and is a weighted order of vanishing. Finally, Section 8 concludes the
proof by comparing the two bounds for the height derived in Sections 4 and 5,
and deriving a contradiction to the assumption that \(C\) has infinitely many rational
points.

In this paper, \(\mathbb{N} = \{0, 1, 2, \ldots\}\) and \(\mathbb{Z}_{>0} = \{1, 2, 3, \ldots\}\). We will fix throughout
a number field \(k\), and work in the category of schemes (and morphisms) over \(k\).
A variety is an integral separated scheme of finite type over \(k\), and a curve is
a variety of dimension 1. When working with a product \(X \times Y\), the associated
projection morphisms are denoted \(p_1: X \times Y \to X\) and \(p_2: X \times Y \to Y\). On
\(\mathbb{P}^r \times \mathbb{P}^s\), \(\mathcal{O}(n, m) = p_1^*\mathcal{O}(n) \otimes p_2^*\mathcal{O}(m)\). A line sheaf is an invertible sheaf. If \(D_1\)
and \(D_2\) are divisors, then \(D_1 \sim D_2\) denotes linear equivalence. If \(D\) is a divisor on a
variety \(X\), the notations \(H^i(X, \mathcal{O}(D))\) and \(h^i(X, \mathcal{O}(D))\) are shortened to \(H^i(X, D)\)
and \(h^i(X, D)\), respectively. Finally, the function field of a variety \(X\) is denoted
\(K(X)\).
For the number field \( k \), the set \( M_k \) is the set of all places of \( k \); this is the disjoint union of the sets of real places, complex places, and non-archimedean places of \( k \). The real and complex places are in canonical one-to-one correspondence with the set of injections \( k \hookrightarrow \mathbb{R} \) and the set of unordered pairs \((\sigma, \overline{\sigma})\) of injections \( k \hookrightarrow \mathbb{C} \) with image not contained in \( \mathbb{R} \), respectively. The set of non-archimedean places is in canonical one-to-one correspondence with the set of nonzero prime ideals in the ring \( \mathcal{O}_k \) of integers of \( k \) \((\mathcal{O}_k \) is the integral closure of \( \mathbb{Z} \) in \( k \)). For each place \( v \in M_k \) we define a norm \( \| \cdot \|_v \), as follows:

\[
\|x\|_v = \begin{cases}
|\sigma(x)| & \text{if } v \text{ is real and corresponds to } \sigma : k \hookrightarrow \mathbb{R}; \\
|\sigma(x)|^2 & \text{if } v \text{ is complex and corresponds to } (\sigma, \overline{\sigma}); \\
(\mathcal{O}_k : p)^{-\text{ord}_v(x)} & \text{if } v \text{ is non-archimedean and corresponds to } p \subseteq \mathcal{O}_k.
\end{cases}
\]

(In the non-archimedean case, the formula assumes \( x \neq 0 \); of course \( \|0\|_v = 0 \) for all \( v \).) Note that these are called norms, not absolute values, because \( \| \cdot \|_v \) does not obey the triangle inequality when \( v \) is complex.

We have the product formula

\[
(0.3) \quad \prod_{v \in M_k} \|x\|_v = 1 \quad \text{for all } x \in k^*.
\]

Also, let

\[
N_v = \begin{cases}
1 & \text{if } v \text{ is real}, \\
2 & \text{if } v \text{ is complex}, \\
0 & \text{if } v \text{ is non-archimedean}.
\end{cases}
\]

Then

\[
(0.4) \quad \sum_{v \in M_k} N_v = [k : \mathbb{Q}]
\]

and

\[
(0.5) \quad \|a_1 + \cdots + a_n\|_v \leq n^{N_v} \max\{\|a_1\|_v, \ldots, \|a_n\|_v\}
\]

for all \( n \in \mathbb{Z}_{>0} \) and all \( a_1, \ldots, a_n \in k \). Finally, heights are always taken to be logarithmic and absolute. For example, the height of a point \( P \in \mathbb{P}^n(k) \) with homogeneous coordinates \([x_0 : x_1 : \cdots : x_n] \) is

\[
(0.6) \quad h(P) = \frac{1}{[k : \mathbb{Q}]} \sum_{v \in M_k} \log \max\{\|x_0\|_v, \ldots, \|x_n\|_v\}.
\]

For more information on the basic properties of heights (which we shall assume), see [HS00, Part B] or [Lan83, Ch. 4].

1. The Thue-Siegel Method

This section briefly describes the Thue-Siegel method, which was originally used to prove Roth’s theorem (and its predecessors), and later was extended to consider hyperplanes in \( \mathbb{P}^n \) by W. M. Schmidt [Sch72, Lemma 7] (see also [Sch80, Ch. VI, Thm. 1F]), as well as to prove Mordell’s conjecture as described in the Introduction to this paper.

The Thue-Siegel method is as described in Nakamaye’s course, starting with Thue’s seminal paper [Thu09]. Basically, it involved constructing an auxiliary
Step − 1: Assume that there are infinitely many \( p/q \in \mathbb{Q} \) for which (0.1.1) is false.

Step 0: Choose two (or \( n \)) exceptions \( p_1/q_1, p_2/q_2 \) to (0.1.1) with certain properties.

Step 1: Using information about those exceptions, construct a polynomial \( f \) in two (or \( n \)) variables with certain properties.

Steps 2, 3: Show that the above choices, considerations, etc. imply that

\[ f \left( \frac{p_1}{q_1}, \frac{p_2}{q_2} \right) = 0, \]

and the same for certain partial derivatives of \( f \).

Step 4: Derive a contradiction.

In trying to adapt this to give a proof of the Mordell conjecture, some obstacles arise:

1. What should play the role of \( \alpha \)?
2. How do we work with polynomials, when we’re trying to prove something about points on a (non-rational) curve?

Let’s answer the second question first.

One can view a polynomial in \( x \) of degree \( d \) as a global section of a line sheaf \( \mathcal{O}(d) \) on \( \mathbb{P}^1 \); for example, \( ax^2 + bx + c \) corresponds to

\[ ax^2 + bx_0 x_1 + cx_0^2 \in \Gamma(\mathbb{P}^1, \mathcal{O}(2)). \]

Likewise, \( f \in \mathbb{Z}[x, y] \) of degree \( d_1 \) in \( x \) and \( d_2 \) in \( y \) corresponds to a global section of the line sheaf \( \mathcal{O}(d_1, d_2) := p_1^*\mathcal{O}(d_1) \otimes p_2^*\mathcal{O}(d_2) \) on \( \mathbb{P}^1 \times \mathbb{P}^1 \), where for \( i = 1, 2 \), \( p_i : \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1 \) is the projection to the \( i \)th factor. The line sheaf \( \mathcal{O}(d_1, d_2) \) corresponds to the divisor \( d_1([\infty] \times \mathbb{P}^1) + d_2(\mathbb{P}^1 \times [\infty]) \).

Having described that background, to answer the question let \( C \) be a smooth projective curve over \( k \) of genus \( g > 1 \), and fix \( P \in C(k) \). (If \( C(k) = \emptyset \), then there is nothing to prove.) The first thing to try is to look at sections of the line sheaf \( \mathcal{O}(d_1([P] \times C) + d_2(C \times [P])) \). As it turns out, though, this does not work.

However, the product \( C \times C \) has many other line sheaves. One possibility is to note that if \( Q \in C(k) \) and \( Q \neq P \), then \( \mathcal{O}(Q) \not\cong \mathcal{O}(P) \) (otherwise \( C \cong \mathbb{P}^1 \); see [Har77, II Example 6.10.1]). Therefore, one can create other line sheaves by allowing \( P \) to vary. This does not work, either.

Instead, what actually does work is to look at the diagonal \( \Delta \) on \( C \times C \). We have \( \deg (\mathcal{O}(\Delta)|_\Delta) = 2 - 2g \) (so \( \Delta^2 = 2 - 2g \)). Therefore \( \mathcal{O}(\Delta) \) is not isomorphic to \( p_1^*\mathcal{O}(D_1) \otimes p_2^*\mathcal{O}(D_2) \) for any divisors \( D_1 \) and \( D_2 \) on \( C \). This is because, for a closed rational point \( P \in C \), we have the intersection numbers

\[
\Delta \cdot (\{P\} \times C) = \Delta \cdot (C \times \{P\}) = 1, \\
(\{P\} \times C) \cdot (\{P\} \times C) = \deg D_2, \quad \text{and} \\
(\{P\} \times C) \cdot (C \times \{P\}) = \deg D_1.
\]
This would imply \( \deg D_1 = \deg D_2 = 1 \), so the divisor \( \Delta \) would need to be numerically equivalent to the divisor \( ([P] \times C) + (C \times [P]) \), and that would give
\[
2 - 2g = \Delta^2 = \left( ([P] \times C) + (C \times [P]) \right)^2 = 2,
\]
a contradiction since \( g > 1 \).

Here we have used intersection theory on \( C \times C \): There is a function \( (D_1, D_2) \) from \( \text{Div}(C \times C) \times \text{Div}(C \times C) \) to \( \mathbb{Z} \) that satisfies:

1. The pairing is symmetric: \( (D_1, D_2) = (D_2, D_1) \) for all \( D_1, D_2 \in \text{Div}(C \times C) \);
2. the pairing is bilinear: \( ((D_1 + D_2), D_3) = (D_1, D_3) + (D_2, D_3) \) for all \( D_1, D_2, D_3 \in \text{Div}(C \times C) \);
3. the kernels on the left and the right contain the subgroup of principal divisors (and hence this is actually a pairing \( \text{Pic}(C \times C) \times \text{Pic}(C \times C) \to \mathbb{Z} \));
4. if \( D_1 \) and \( D_2 \) are prime divisors on \( C \times C \) that cross transversally, then \( (D_1, D_2) \) is the number of points of intersection in \( (C \times C)(\overline{\mathbb{Q}}) \).

For more details on intersection theory, see [Har77, App. A].

So now let
\[
\Delta' = \Delta - \{ P \} \times C - C \times \{ P \}.
\]
This is a better divisor to work with than \( \Delta \), because (unlike \( \Delta \)) it has degree 0 on the fibers of \( p_1 \) and \( p_2 \), so it is orthogonal (in the intersection pairing) to the “obvious” divisors on \( C \times C \). We have
\[
(\Delta')^2 = \Delta^2 - 2\Delta(\{ P \} \times C) - 2\Delta(C \times \{ P \}) + 2(\{ P \} \times C)(C \times \{ P \})
= (2 - 2g) - 2 - 2 + 2
= -2g.
\]

For the actual proof of Faltings’ Theorem (Mordell’s conjecture), we will use a divisor of the form
\[
(1.1) \quad dY = d(\Delta' + a_1(\{ P \} \times C) + a_2(C \times \{ P \})) ;
\]
where \( a_1, a_2 \in \mathbb{Q}, \ d \in \mathbb{Z}, \ d > 0, \) and \( d \) is sufficiently divisible so that \( da_1, da_2 \in \mathbb{Z} \).

How will this divisor be used, and why is this form of \( Y \) useful?

Part of an answer to this question lies in Siegel’s lemma.

**Proposition 1.2. (Siegel’s lemma)** Let \( M \) and \( N \) be positive integers with \( N > M \), and let \( A \) be an \( M \times N \) matrix with integer entries whose absolute values are bounded by \( B \in \mathbb{Z} \). Then there is a nonzero element \( x \in \mathbb{Z}^N \) such that \( Ax = 0 \) and \( |x| \leq (NB)^{M/(N-M)} \).

Here \( |x| = \max\{|x_i|: 1 \leq i \leq N\} \).

**Proof (sketch).** For \( c \in \mathbb{N}, \) we have
\[
|\{ x \in \mathbb{Z}^N : 0 \leq x_i < c \ \forall i \}| = c^N.
\]
For \( x \) in this set, we have \( |x| < c \) and \( |Ax| < NBC \), so \( A \) maps a set of size \( c^N \) to a set of size \( < (2NBC)^M \). If \( c \) is large enough so that \( c^N > (2NBC)^M \), then there will be distinct \( x', x'' \in \mathbb{Z}^N \) with \( |x'|, |x''| < c \) and \( Ax' = Ax'' \). Let \( x = x' - x'' \). Then \( x \neq 0, \ |x| < c, \) and \( Ax = 0 \). The inequality \( c^N > (2NBC)^M \) is equivalent to \( c > (2NB)^{M/(N-M)} \).
With a little more work, a similar result can be obtained with \( c = (NB)^{M/(N-M)} \); see [HS00, Lemma D.4.1].

When using the Thue-Siegel method to prove Roth’s theorem (or, since we’ll be using only two variables, one of the earlier weaker versions of Roth’s theorem), Siegel’s lemma is used to construct a polynomial in two variables.

Given positive integers \( d_1 \) and \( d_2 \), Siegel’s lemma is used to construct a polynomial \( f \in \mathbb{Z}[x,y] \) of degree \( \leq d_1 \) in \( x \) and \( \leq d_2 \) in \( y \). The proof requires some vanishing conditions at \( (\alpha, \alpha) \); these conditions lead to a system of linear equations in which the variables are the coefficients. The number of variables is \( N = (d_1 + 1)(d_2 + 1) \).

As for the number \( M \) of equations, let’s first look at a polynomial for which \( d_2 = 1 \). We will want this to be a polynomial of the form

\[
 f(x, y) = (x - \alpha)^n G(x) - (y - \alpha) H(x) .
\]

A polynomial \( f \) will be of this form if and only if

\[
 f(\alpha, \alpha) = \frac{\partial}{\partial x} f(\alpha, \alpha) = \left( \frac{\partial}{\partial x} \right)^2 f(\alpha, \alpha) = \cdots = \left( \frac{\partial}{\partial x} \right)^{n-1} f(\alpha, \alpha) = 0 .
\]

For larger values of \( d_2 \), the linear conditions will come from requiring the vanishing of \( \left( \frac{\partial^i}{\partial x} \right)^j f(\alpha, \alpha) \) for certain pairs \( (i, j) \in \mathbb{N}^2 \).

Returning to the context of a proof of Mordell’s conjecture, we need to find out what \( N \) is in this case. This amounts to finding \( \dim_k H^0(C \times C, Y) \).

A useful way to find this dimension (or at least a lower bound for it) is the following special case of the Riemann-Roch-Hirzebruch theorem.

**Theorem 1.3.** Let \( \mathcal{L} \) be a line sheaf on a nonsingular complete surface \( X \) over a field \( k \), and let \( d \in \mathbb{N} \). Then

\[
 (1.3.1) \quad h^0(X, \mathcal{L} \otimes d) - h^1(X, \mathcal{L} \otimes d) + h^2(X, \mathcal{L} \otimes d) = \frac{d^2}{2} (\mathcal{L} \cdot \mathcal{L}) + O(d) .
\]

(Here \( h^i(X, \mathcal{L} \otimes d) = \dim_k H^i(X, \mathcal{L} \otimes d) \).)

When \( \mathcal{L} = \mathcal{O}(Y) \), the right-hand side of (1.3.1) is

\[
 \frac{d^2}{2} (-2g + 2a_1a_2 + o(1)) = d^2(-g + a_1a_2 + o(1)) .
\]

As long as this is positive, \( H^0(C \times C, dY) \) will be nonzero. This is because \( h^1(C \times C, dY) \geq 0 \), and \( h^2(C \times C, dY) = h^0(C \times C, K_{C \times C} - dY) = 0 \) for \( d \gg 0 \) by duality and the fact that \( Y \) will have intersections \( a_2 > 0 \) and \( a_1 > 0 \) with the fibers of \( p_1 \) and \( p_2 \), respectively.

To give a little more information about the definition (1.1) of \( Y \), \( a_1 \) and \( a_2 \) are positive rational numbers chosen such that \( a_1a_2 > g \) (but is very close to \( g \)) and \( a_1/a_2 \) is close to \( h(P_2)/h(P_1) \), where \( P_1 \) and \( P_2 \) will be two suitably chosen rational points on \( C \) and \( h(P_1) \) and \( h(P_2) \) are their heights (using a height function that will be described later).

In summary, the answer to the second question, about what object replaces the auxiliary polynomial in the proofs of Thue, Siegel, etc., is that the replacement is the line sheaf \( \mathcal{O}(dY) \) (for large \( d \)).

Let us now return briefly to the first question: What replaces \( a \)? Mordell’s conjecture does not contain any diophantine inequality, so this was perhaps the hardest question that came up when trying to find a proof.
The quick answer is that nothing replaces $\alpha$, because $h_0(C \times C, dY)$ (which replaces $N - M$, a lower bound for the dimension of the solution space in Siegel’s lemma) is already small.

But this is not all of the answer. In the proofs of Thue, Siegel, etc., as $N - M \to 0$ the bound on $|x|$ becomes larger, so Steps 2 and 3 become harder. That phenomenon occurs in the proof of Mordell, too—see (6.1.1) as $\gamma \to 0$.

Note that the Riemann-Roch-Hirzebruch theorem does not say anything that corresponds to the bound on the coefficients in Siegel’s lemma. This is a necessary aspect of the proof, yet it is handled differently in the three major variants of the proof:

- My own proof used Arakelov theory (as developed by Gillet and Soulé), in particular the “Riemann-Roch-Hirzebruch-Grothendieck-Gillet-Soulé” theorem, which extended the Riemann-Roch-Hirzebruch theorem by encompassing families of varieties (Riemann-Roch-Hirzebruch-Grothendieck) and further incorporated Arakelov theory.
- Faltings’ proof replaced the Riemann-Roch-...-Gillet-Soulé Theorem with a fancier Siegel’s lemma (and also extended the theorem to higher dimensions).
- Bombieri’s proof also put Siegel’s lemma back in, but used the basic Siegel lemma and used it in a different way.

This paper will follow Bombieri’s proof.

Getting back to the question about what replaces $\alpha$, for simplicity we restrict to considering the proof, in the classical Thue-Siegel method, that the auxiliary polynomial $f$ vanishes at $\left(\frac{p_1}{q_1}, \frac{p_2}{q_2}\right)$. Assume that it is nonzero there. The approximation conditions, together with vanishing conditions for $f$ at $(\alpha, \alpha)$ and the bounds on the coefficients of $f$, imply an upper bound on $\|f(p_1/q_1, p_2/q_2)\|$ when $v = \infty$. By the product formula (0.3), this gives a lower bound on the product

$$\prod_{v \neq \infty} \left\| f \left( \frac{p_1}{q_1}, \frac{p_2}{q_2} \right) \right\|_v .$$

However, since the coefficients of $f$ are integers, the denominator of $f(p_1/q_1, p_2/q_2)$ is bounded by $|q_1^d q_2^d|$. The proof obtains a contradiction from these two facts to conclude that $f(p_1/q_1, p_2/q_2) = 0$.

In the case of Mordell’s conjecture, there is no $\alpha$, so we can consider the equivalent of the product (1.4) over all places of the number field $k$. The geometry of the curve $C$ (or, more precisely, of its Jacobian), implies a lower bound on this product. This is equivalent to an upper bound on minus the logarithm of such a product, which is closely related to the height of a point $(P_1, P_2)$ on $C \times C$ relative to a certain line sheaf. The proof then proceeds to a contradiction by finding a contradictory lower bound for this height.

Thus, it is the geometry of the Jacobian that replaces $\alpha$. This is very natural, from the point of view that the approximation conditions in the Thue-Siegel proof can be viewed as taking place on the log Jacobian of $\mathbb{P}^1$ minus the Galois conjugates of $\alpha$. 
2. Basic Constructions in Bombieri’s Proof

Bombieri avoids Arakelov theory in his proof by taking suitable embeddings into projective space and suitable linear projections, and by expressing the divisor $dY$ as a difference of two suitably chosen divisors on $C \times C$.

Here is the basic geometric construction used in Bombieri’s proof. Recall that $C$ is a smooth projective curve of genus $g > 1$ over a number field $k$. We are assuming (by way of contradiction) that $C(k)$ is infinite.

Step 0. Fix a divisor $A$ of degree 1 on $C$, chosen so that $(2g - 2)A \sim K_C$, where $K_C$ is the canonical divisor on $C$. (The reason for this condition will be explained in Section 3.) (This may require extending the base field $k$.) By abuse of notation, we write $p^*_1 A$ and $p^*_2 A$ as $A \times C$ and $C \times A$, respectively, instead, where $p_1, p_2: C \times C \to C$ are the two projection morphisms.

Let
\[(2.1) \quad \Delta' = \Delta - A \times C - C \times A.\]

Step 1. Fix $s \in \mathbb{Z}$ sufficiently large such that the divisor
\[(2.2) \quad B := s(A \times C) + s(C \times A) - \Delta'\]
is very ample. Choose a projective embedding
\[\phi_B: C \times C \to \mathbb{P}^m\]
associated to the complete linear system $|B|$, and use $\phi_B$ to define a height $h_B$ on $C \times C$:
\[(2.3) \quad h_B(P_1, P_2) = \text{height}(\phi_B(P_1, P_2)),\]
where the second height $\text{height}(\cdot)$ is the standard Weil height (0.6) on $\mathbb{P}^m$.

Step 2. Choose $d \in \mathbb{Z}$ sufficiently large so that the map
\[(2.4) \quad H^0(\mathbb{P}^m, \mathcal{O}(d)) \to H^0(C \times C, dB)\]
is surjective. (This can be done by choosing $d$ such that $H^1(\mathbb{P}^m, \mathcal{I}_{C \times C} \otimes \mathcal{O}(d)) = 0$, where $\mathcal{I}_{C \times C}$ is the ideal sheaf on $\mathbb{P}^m$ corresponding to the image of $\phi_B$, with reduced induced subscheme structure. This condition on $d$ is true for sufficiently large $d$ by [Har77, III 5.2].)

Step 3. Fix $N \in \mathbb{Z}$ such that $NA$ is very ample. Let
\[(2.5) \quad \phi_{NA}: C \hookrightarrow \mathbb{P}^n\]
be some associated projective embedding, chosen suitably generically to satisfy conditions to be described later (see Section 6). As with $h_B$, let $h_{NA}$ be the height on $C$ defined by $\phi_{NA}$:
\[(2.6) \quad h_{NA}(P) = h(\phi_{NA}(P)),\]
and also let $h_A(P) = \frac{1}{N} h_{NA}(P)$, for all $P \in C(\bar{k})$.

Step 4. As before, the natural map
\[(2.7) \quad H^0(\mathbb{P}^n \times \mathbb{P}^n, \mathcal{O}(\delta_1, \delta_2)) \to H^0(C \times C, \delta_1(NA \times C) + \delta_2(C \times NA))\]
is surjective for all sufficiently large $\delta_1, \delta_2 > 0$. (In fact, it is true for all $\delta_1, \delta_2$ with $\min\{\delta_1, \delta_2\}$ sufficiently large, but for our purposes it suffices to know that for each positive $r \in \mathbb{Q}$ it is true for all sufficiently large $\delta_1, \delta_2$ with $\delta_1/\delta_2 = r$, with the
Step 5. We will be working with points $P_1, P_2 \in C(k)$, chosen such that $h_{NA}(P_1)$ and $h_{NA}(P_2)/h_{NA}(P_1)$ are large. Given such $P_1$ and $P_2$, choose rational $a_1$ and $a_2$ such that

\[(2.8) \quad a_1^2 \approx (g + \gamma) \frac{h_{NA}(P_2)}{h_{NA}(P_1)} \quad \text{and} \quad a_2^2 \approx (g + \gamma) \frac{h_{NA}(P_1)}{h_{NA}(P_2)},\]

so that

\[\frac{a_1}{a_2} \approx \frac{h_{NA}(P_2)}{h_{NA}(P_1)}.\]

Here $\gamma > 0$ is small (to be determined later). Let

\[(2.9) \quad \delta_1 = (a_1 + s) \frac{d}{N} \quad \text{and} \quad \delta_2 = (a_2 + s) \frac{d}{N},\]

and let

\[(2.10) \quad Y = \delta_1 NA \times C + C \times \delta_2 NA - dB
\]

\[= d(a_1 A \times C + a_2 C \times A + \Delta'),\]

where $d$ is an integer chosen sufficiently divisible so that $\delta_1, \delta_2 \in \mathbb{Z}$. (This differs by a factor of $d$ from the $Y$ of (1.1).) Define

\[(2.11) \quad h_Y(P_1, P_2) = \delta_1 h_{NA}(P_1) + \delta_2 h_{NA}(P_2) - dh_B(P_1, P_2).\]

By definition, the height $h_Y$ behaves well as $a_1, a_2,$ and $d$ vary.

Bombieri’s proof avoids Arakelov theory by using clever manipulations in the heights $h_B$, $h_{NA}$, and $h_Y$ instead.

### 3. Divisors, Heights, and Jacobians

This section describes the connections with the Jacobian of $C$, which are central to all three variants of the proof discussed here.

Let $J$ be the Jacobian of $C$, and define

\[j: C \hookrightarrow J\]

to be the map $j(x) = (x) - A \in J$. (More precisely, it is defined by taking a point $x \in C \times_k \mathbb{K}$ to the divisor $(x) - A$ in $J \times_k \mathbb{K}$, but this map comes from a morphism $C \to J$ over $k$; see [Mil86, Thm. 1.1].) Also let $\Theta$ be the associated theta divisor; this is the sum $j(C) + \cdots + j(C)$ with $g - 1$ terms (under the group operation).

The following is a well-known fact about the theta divisor.

**Lemma 3.1.** [HS00, Lemma E.2.1] With notation as above, we have

(a). $\Theta$ is a symmetric divisor; i.e., $[-1]^*\Theta \sim \Theta$, where $[-1]$ denotes taking the inverse under the group operation;

(b). $j^*\Theta \sim gA$; and

(c). if $s: J \times J \to J$ is the group operation, then

\[(3.1.1) \quad (j \times j)^*(s^*\Theta - p_1^*\Theta - p_2^*\Theta) = -\Delta'.\]

In addition, $\Theta$ is ample; see [Mil86, Thm. 6.6 and the preceding paragraph].

Since $\Theta$ is ample and symmetric, it gives rise to a (Néron-Tate) **canonical height** $h_\Theta$ on $J$:
Theorem 3.2. [HS00, Thm. B.5.1] Let $J$ be an abelian variety over a number field $k$, and let $D$ be a symmetric divisor on $J$. Then there exists a unique canonical height $\hat{h}_D: J(\mathbb{K}) \to \mathbb{R}$ such that

$$\hat{h}_D([m]P) = m^2\hat{h}_D(P) \quad \text{for all } P \in J(\mathbb{K}) \text{ and all } m \in \mathbb{Z}$$

and for all (conventional) Weil heights $h_D$ on $J$ relative to $D$,

$$\hat{h}_D(P) = h_D(P) + O(1) \quad \text{for all } P \in J(\mathbb{K}) \, ,$$

with the implicit constant depending on $h_D$. Moreover:

(a). (Parallelogram Law)

$$\hat{h}_D(P + Q) + \hat{h}_D(P - Q) = 2\hat{h}_D(P) + 2\hat{h}_D(Q) \quad \text{for all } P, Q \in J(\mathbb{K}) \, .$$

(b). The canonical height $\hat{h}_D$ is a quadratic form. The associated pairing

$$\langle \cdot, \cdot \rangle_D: J(\mathbb{K}) \times J(\mathbb{K}) \to \mathbb{R}$$

defined by

$$(3.2.1) \quad \langle P, Q \rangle_D = \frac{\hat{h}_D(P + Q) - \hat{h}_D(P) - \hat{h}_D(Q)}{2}$$

is bilinear and satisfies $\langle P, P \rangle_D = \hat{h}_D(P)$.

Since $\Delta$ is an effective divisor on $C \times C$, we have $h_\Delta(P_1, P_2) \geq O(1)$ for all $P_1, P_2 \in C(\mathbb{K})$ with $P_1 \neq P_2$. This fact can be combined with (3.1.1) to give information on the canonical heights of rational points on $C$, as follows.

Since the bilinear form $\langle \cdot, \cdot \rangle_0$ is positive definite on $J(\mathbb{K}) \otimes_{\mathbb{Z}} \mathbb{R}$, the latter is an (infinite dimensional) Euclidean space, and in particular

$$(3.3) \quad \langle x, y \rangle_0 = (\cos \theta) \sqrt{|x|^2|y|^2}$$

for all $x, y \in J(\mathbb{K}) \otimes_{\mathbb{Z}} \mathbb{R}$, where

$$|x|^2 = \langle x, x \rangle_0 = \hat{h}_\Theta(x)$$

and $\theta$ is the angle between $x$ and $y$. In particular, let $x = j(P_1)$ and $y = j(P_2)$.

Then, by (3.3), (3.2.1), (3.1.1), functoriality of heights, and Lemma 3.1b,

$$\langle \cos \theta \rangle \sqrt{|x|^2|y|^2} = \langle x, y \rangle_0$$

$$\frac{\hat{h}_\Theta(x + y) - \hat{h}_\Theta(x) - \hat{h}_\Theta(y)}{2}$$

$$(3.4) \quad = -\frac{1}{2}h_\Delta(P_1, P_2) + O(1)$$

$$= -\frac{1}{2}h_\Delta(P_1, P_2) + \frac{1}{2}h_A(P_1) + \frac{1}{2}h_A(P_2) + O(1)$$

$$\leq \frac{|x|^2}{2g} + \frac{|y|^2}{2g} + O(1) \, .$$

Since $\sqrt{|x|^2|y|^2}$ can be as large as $(|x|^2 + |y|^2)/2$ (when $|x| = |y|$) and $g > 1$, this means that $\cos \theta$ is bounded away from 1 (so $\hat{\theta}$ is bounded away from 0) when $|x|$ and $|y|$ are close to each other.

When $P_1$ and $P_2$ are rational over $k$, we have $x, y \in J(k)$. By the Mordell-Weil theorem [HS00, Thm. C.0.1], $J(k)$ is finitely generated, so $J(k) \otimes_{\mathbb{Z}} \mathbb{R}$ is finite dimensional. Since the angle $\theta$ is bounded from below when $|x|$ and $|y|$ are close,
this implies that not too many points in $C(k)$ can have heights sufficiently large and in a sufficiently small range. This is the analogue for Mordell’s conjecture of the “gap principle” in the context of diophantine approximation [HS00, Exercises D.12 and D.13], and was originally discovered by Mumford [Mum65]; see also [HS00, Prop. B.6.6].

This idea will be used in the next section, using a different effective divisor in place of $\Delta$.

4. An Upper Bound for the Height

The purpose of this section is to find an upper bound for the height $h_Y(P_1, P_2)$, which will be compared with the lower bound (5.5.1) to ultimately derive a contradiction in the proof of the theorem.

This will be done using the results of Section 3 on canonical heights on the Jacobian of $C$.

To begin, let $a_1$ and $a_2$ be positive rational numbers, to be determined later, and let $d_i = a_id$ for $i = 1, 2$.

**Lemma 4.1.** There is a constant $c_1$, depending only on $C$, $A$, $\phi_{NA}$, and $\phi_B$ (but not on $P_1$ or $P_2$), such that

\begin{equation}
(4.1.1) \quad h_Y(P_1, P_2) \leq \frac{d_1}{g} |j(P_1)|^2 + \frac{d_2}{g} |j(P_2)|^2 - 2dl(j(P_1), j(P_2))\Theta + c_1(d_1 + d_2 + d)
\end{equation}

for all $P_1, P_2 \in C(\bar{k})$.

**Proof.** Recall from (2.11) that $h_Y$ is defined using $h_{NA}$ and $h_B$. We also use (2.2) to define $h_{\Delta'}$:

$$h_B(P_1, P_2) = \frac{s}{N}h_{NA}(P_1) + \frac{s}{N}h_{NA}(P_2) - h_{\Delta'}(P_1, P_2).$$

With this definition, (2.9) and (2.11) give

\begin{equation}
(4.1.2) \quad h_Y(P_1, P_2) = d \left( h_{\Delta'}(P_1, P_2) + \frac{a_1}{N}h_{NA}(P_1) + \frac{a_2}{N}h_{NA}(P_2) \right).
\end{equation}

Note that this holds exactly (i.e., not up to $O(1)$), by the various definitions. By Theorem 3.2 and Lemma 3.1b,

$$|j(P)|^2 = \hat{h}_\Theta(j(P)) = \frac{g}{N}h_{NA}(P) + O(1)$$

for all $P \in C(\bar{k})$. In addition, by (3.1.1) and (3.2.1),

$$h_{\Delta'}(P_1, P_2) = -2\langle j(P_1), j(P_2) \rangle\Theta + O(1)$$

for all $P_1, P_2 \in C(\bar{k})$.

Applying these two equations to (4.1.2) gives (4.1.1). (Actually, (4.1.1) is an equality up to $O(d_1 + d_2 + d)$.)\(\square\)

The next step is to use (3.4) to get the right-hand side of (4.1.1) to be negative (for sufficiently large $d_1 + d_2 + d$).

As noted at the end of Section 3, $J(k) \otimes \mathbb{R}$ is a finite-dimensional vector space. Therefore, since we have assumed that $C(k)$ is infinite, there is an infinite subset $\Sigma'$ of $C(k)$ such that, for all $P_1, P_2 \in \Sigma'$, the angle between $j(P_1)$ and $j(P_2)$ in $J(k) \otimes \mathbb{R}$ is at most $\cos^{-1}(3/4)$; therefore

$$\langle j(P_1), j(P_2) \rangle\Theta \geq \frac{3}{4} \sqrt{\hat{h}_\Theta(j(P_1))\hat{h}_\Theta(j(P_2))}.$$
Incorporating this into (4.1.1) gives
\[
(4.2) \quad h_Y(P_1, P_2) \leq \frac{d_1}{g} |j(P_1)|^2 + \frac{d_2}{g} |j(P_2)|^2 - \frac{3}{2} d |j(P_1)||j(P_2)| + c_1(d_1 + d_2 + d)
\]
for all \(P_1, P_2 \in \Sigma'\).

5. A Lower Bound

In Section 3, since \(\Delta\) is an effective divisor and \(P_1 \neq P_2\) (hence \((P_1, P_2) \notin \Delta\)), the height \(h_\Delta(P_1, P_2)\) is trivially bounded from below. In the present case, though, \(\Delta\) will be replaced by an effective divisor associated to a global section \(s\) of \(\mathcal{O}(Y)\). The section \(s\) will be constructed using Siegel’s lemma, and it will be hard to guarantee that \(s\) will not vanish at \((P_1, P_2)\). In fact, in general \(s\) will vanish there, but we will derive a contradiction based on its (weighted) multiplicity at \((P_1, P_2)\).

Since \(Y\) depends on \(P_1\) and \(P_2\), it will be necessary to control the constant \(O(1)\) in (3.4), and this is a major part of the proof.

We start by defining a notion of the height of a global section \(s\) of \(\mathcal{O}(Y)\), which plays the role of the height of the auxiliary polynomial in the classical Thue-Siegel method.

**Lemma 5.1.** Let \(Y\) be a divisor on \(C \times C\) as in (2.10). Let \(y_0, \ldots, y_m\) be the global sections of \(\mathcal{O}(B)\) corresponding to the coordinates of \(\phi_B\). Also let \(x_0, \ldots, x_n\) and \(x'_0, \ldots, x'_n\) be bases for the global sections on \(C \times C\) of \(p_1^* \mathcal{O}(NA)\) and \(p_2^* \mathcal{O}(NA)\), respectively. Then, for each global section \(s\) of \(\mathcal{O}(Y)\) there are polynomials
\[
F_0(x, x'), \ldots, F_m(x, x')
\]
such that
\[
\begin{align*}
(i) & \quad \text{each of the } F_i \text{ is homogeneous of degree } \delta_1 \text{ in the variables } x = (x_0, \ldots, x_n) \\
& \quad \text{and homogeneous of degree } \delta_2 \text{ in } x' = (x'_0, \ldots, x'_n), \\
(ii) & \quad \text{for all } i \in \{0, \ldots, m\}, \\
& \quad F_i(x, x') = y_i^d s, \\
(iii) & \quad \text{for all } i, j \in \{0, \ldots, m\}, \\
& \quad \left(\frac{F_i(x, x')}{{y_i^d}}\right) = \left(\frac{F_j(x, x')}{{y_j^d}}\right)
\end{align*}
\]
everywhere on \(C \times C \setminus \{y_i y_j = 0\}\).

Conversely, each set of polynomials \(F_0, \ldots, F_m\) satisfying (i) and (iii) uniquely determines a global section \(s\) of \(\mathcal{O}(Y)\) that satisfies (ii). Thus, there is a one-to-many correspondence between global sections \(s\) and systems \((F_0, \ldots, F_m)\) of polynomials satisfying (i) and (iii).

**Proof.** Let \(s\) be a global section of \(\mathcal{O}(Y)\) on \(C \times C\). For each \(i\), the global section
\[
y_i^d s \in \Gamma(C \times C, \delta_1 NA \times C + C \times \delta_2 NA),
\]
lifts by surjectivity of (2.7) to
\[
F_i(x, x') \in \Gamma(\mathbb{P}^n \times \mathbb{P}^n, \mathcal{O}(\delta_1, \delta_2)).
\]
These \(F_i\) are polynomials in \(x\) and \(x'\) that satisfy (i) and (ii) by construction. They also satisfy (iii), because the two sides of (5.1.1) are equal to \(s\) everywhere.
Conversely, let $F_0, \ldots, F_m$ be polynomials satisfying conditions (i) and (iii). For each $i$, $F_i(x, x')|_{C \times C}$ is a global section of $O(\delta_1 NA \times C + C \times \delta_2 NA)$ on $C \times C$, and $y_i|_{C \times C}$ is a global section of $O(B)$ on $C \times C$. Therefore

(5.1.2) \[ F_i \frac{y_i^d}{y_i} \in \Gamma((C \times C) \setminus \{y_i = 0\}, Y). \]

Since $y_0, \ldots, y_m$ are never simultaneously zero, the sections (5.1.2) glue together to give a global section $s$ of $O(Y)$ on $C \times C$, by (5.1.1).

**Lemma 5.2.** Let $s$ be a global section of $O(Y)$ that does not vanish at $(P_1, P_2)$, let $F = (F_0, \ldots, F_m)$ be as in Lemma 5.1 (as determined by $s$), and define

\[ h(F) = \frac{1}{[k : Q]} \sum_{v \in M_k} \max_i \max_{c \in \{\text{coefficients of } F_i\}} \|c\|_v. \]

Then

(5.2.1) \[ h_Y(P_1, P_2) \geq -h(F) - n \log((\delta_1 + n)(\delta_2 + n)). \]

(Recall that $n = h^0(C, NA) - 1$.)

**Proof.** Let $\tilde{x} = \phi_{NA}(P_1)$ and let $\tilde{x}_0, \ldots, \tilde{x}_n \in k$ be homogeneous coordinates for $\tilde{x}$. Define $\tilde{y} = \phi_B(P_1, P_2)$ and $\tilde{y}, \tilde{y}_0, \ldots, \tilde{y}_m \in k$

Then, by definition,

\[ h_Y(P_1, P_2) = \frac{\delta_1}{[k : Q]} \sum_j \max_j \|\tilde{x}_j\|_v + \frac{\delta_2}{[k : Q]} \sum_j \max_j \|\tilde{y}_j\|_v - d \sum_i \max_i \|\tilde{y}_i\|_v \]

(5.2.2) \[ = \frac{1}{[k : Q]} \sum_i \min_{j, j'} \max_{\delta, \delta'} \left\| \frac{x_j (x'_j)^{\delta}}{x'_0} \right\|_v, \]

where all sums are over all $v \in M_k$.

As before, we continue to let $x_0, \ldots, x_n$ and $y_0, \ldots, y_m$ be the global sections of $O(NA)$ and $O(B)$, respectively, corresponding to the coordinates of $\phi_{NA}$ and $\phi_B$, respectively. We assume that $x_0$ does not vanish at $P_1$ or $P_2$, and that $y_0$ does not vanish at $(P_1, P_2)$. Then $\tilde{x}_0 \neq 0$, $\tilde{x}'_0 \neq 0$, and $\tilde{y}_0 \neq 0$. Assume that $\tilde{x}_0 = \tilde{x}'_0 = \tilde{y}_0 = 1$. For each $j$, $x_j/x_0$ is a rational function on $C$ that is regular at $P_1$ and at $P_2$, and we have

(5.2.3) \[ \left( \frac{x_j}{x_0} \right)(P_1) = \frac{\tilde{x}_j}{\tilde{x}_0} = \tilde{x}_j \quad \text{and} \quad \left( \frac{x_j}{x_0} \right)(P_2) = \frac{\tilde{x}_j}{\tilde{x}_0} = \tilde{x}'_j. \]

Similarly, for each $i$, $y_i/y_0$ is a rational function on $C \times C$ that is regular at $(P_1, P_2)$, and

(5.2.4) \[ \left( \frac{y_i}{y_0} \right)(P_1, P_2) = \tilde{y}_i. \]

Since $s$ and $p_1^*(x_0^{\delta_1})p_2^*(x_0^{\delta_2})/y_0^{\delta}$ are both regular sections of $O(Y)$ in a neighborhood of $(P_1, P_2)$ and the latter section does not vanish at $(P_1, P_2)$, the ratio

\[ s(P_1, P_2) \left/ \frac{x_0(P_1)^{\delta_1}x_0(P_2)^{\delta_2}}{y_0(P_1, P_2)^{\delta}} \right. \]
is a well-defined element of \( k \), and it is nonzero at \((P_1, P_2)\) by the assumption that \( s \) also does not vanish at \((P_1, P_2)\). Therefore, by the product formula (0.3),

\[
\frac{1}{[k : \mathbb{Q}]} \sum_v \log \left\| \frac{s(P_1, P_2)}{y_0(P_1, P_2)^d} \right\|_v = 0.
\]

Subtracting this from (5.2.2) and applying (5.2.3) and (5.2.4) then gives

\[
h_Y(P_1, P_2) = \frac{1}{[k : \mathbb{Q}]} \sum_v \min_i \max_{j,j'} \left\| \frac{x_j(P_1)^{\delta_1} x_j(P_2)^{\delta_2}}{s(P_1, P_2)y_0(P_1, P_2)^d} \right\|_v
\]

\[
= \frac{1}{[k : \mathbb{Q}]} \sum_v \min_i \max_{j,j'} \left\| \frac{x_j(P_1)^{\delta_1} x_j(P_2)^{\delta_2}}{F_i(x(P_1), x(P_2))} \right\|_v
\]

\[
= -\frac{1}{[k : \mathbb{Q}]} \sum_v \max_i \min_{j,j'} \left\| F_i \left( \frac{x(P_1)}{x_j(P_1)}, \frac{x(P_2)}{x_j(P_2)} \right) \right\|_v,
\]

where \( x = (x_0, \ldots, x_n) \).

For each \( v \) and \( i \) let \( j_{v,i} \) and \( j'_{v,i} \) be the values of \( j \) and \( j' \), respectively, where the minimum occurs; i.e.,

\[
\min_{j,j'} \left\| F_i \left( \frac{x(P_1)}{x_j(P_1)}, \frac{x(P_2)}{x_j(P_2)} \right) \right\|_v = \left\| F_i \left( \frac{x(P_1)}{x_{j_{v,i}}(P_1)}, \frac{x(P_2)}{x_{j_{v,i}}(P_2)} \right) \right\|_v.
\]

Then, by bihomogeneity of \( F_i \), \( \|x_j/x_{j_{v,i}}\|_v \leq 1 \) and \( \|x_j'/x_{j'_{v,i}}\|_v \leq 1 \) for all \( j \) and \( j' \) (respectively). Since the number of nonzero terms in \( F_i \) is at most \((\delta_1 + n)^n (\delta_2 + n)^n\),

\[
\min_{j,j'} \left\| F_i \left( \frac{x(P_1)}{x_j(P_1)}, \frac{x(P_2)}{x_j(P_2)} \right) \right\|_v \leq \left( (\delta_1 + n)^n (\delta_2 + n)^n \right)^{N_c} \max_{c \in \{\text{coefficients of } F_i\}} \|c\|_v
\]

for all \( v \in M_k \) and all \( i \), by (0.5).

The inequality (5.2.1) then follows from (5.2.5), (5.2.6), (0.4), and the definition of \( h_Y \).

This will be used to do the equivalent of controlling the constant \( O(1) \) in (3.4), because \( Y \) here will play the role of \( \Delta \) later on.

However, things are a bit more complicated than that, because it is possible that \( s \) may vanish at \((P_1, P_2)\). In general, what will be needed is a similar argument using “partial derivatives” of \( s \). Since \( s \) is a section of a line bundle, as opposed to a function, the meaning of partial derivative is not so clear. However, as with \( s \) itself, under certain conditions it is possible to obtain a well-defined notion of whether certain partial derivatives of \( s \) are zero.

**Definition 5.3.** Let \( s \) be a rational section of some line sheaf \( \mathcal{L} \) on \( C \times C \), and let \( P_1, P_2 \in C(k) \) be points such that \( s \) is regular at \((P_1, P_2)\). Fix a rational section \( s_0 \) of \( \mathcal{L} \) that generates \( \mathcal{L} \) in a neighborhood of \((P_1, P_2)\), and let \( \zeta_1 \) and \( \zeta_2 \) be local coordinates on \( C \) at \( P_1 \) and \( P_2 \), respectively. Then we say that a pair \((i_1^*, i_2^*) \in \mathbb{N}^2\) is admissible if

\[
\left( \frac{\partial}{\partial \zeta_1} \right)^{i_1} \left( \frac{\partial}{\partial \zeta_2} \right)^{i_2} \left( \frac{s}{s_0} \right)(P_1, P_2) = 0
\]

for all pairs \((i_1, i_2) \in \mathbb{N}^2\) such that \( i_1 \leq i_1^*, i_2 \leq i_2^*, \) and \((i_1, i_2) \neq (i_1^*, i_2^*)\).
We note that, by elementary computations and induction on \((i_1, i_2)\), the condition (5.3.1) is independent of the choices of \(s_0, \zeta_1, \) and \(\zeta_2\) when \((i_1, i_2)\) is admissible. Therefore admissibility itself is independent of these choices.

The usefulness of admissibility of pairs stems from the following lemma.

**Lemma 5.4.** Let \(s, \mathcal{L}, P_1, P_2, s_0, \zeta_1, \) and \(\zeta_2\) be as in Definition 5.3, and let \((i_1^*, i_2^*)\) be an admissible pair. Then the quantity

\[
(\frac{\partial}{\partial \zeta_1})^{i_1^*} \left( \frac{\partial}{\partial \zeta_2} \right)^{i_2^*} \left( \frac{s}{s_0} \right) (P_1, P_2) \cdot \left( s_0 \otimes (d\zeta_1)^{\otimes i_1^*} \otimes (d\zeta_2)^{\otimes i_2^*} \right)_{(P_1, P_2)}
\]

is independent of the choices of \(s_0, \zeta_1\) and \(\zeta_2\).

**Proof.** Independence of \(s_0\) is easy to see from the Leibniz rule and admissibility of \((i_1^*, i_2^*)\), and independence of \(\zeta_1\) and \(\zeta_2\) follows from formalisms of differential geometry.

For admissible pairs \((i_1^*, i_2^*)\), we can then define

\[
\left( \frac{\partial}{\partial \zeta_1} \right)^{i_1^*} \left( \frac{\partial}{\partial \zeta_2} \right)^{i_2^*} s(P_1, P_2)
\]

to be the section of (5.4.1).

With more work, one can then generalize Lemma 5.2 as follows.

**Lemma 5.5.** Let \(s\) be a global section of \(\mathcal{O}(Y)\), let \(\mathcal{F} = (F_0, \ldots, F_m)\) be as in Lemma 5.1 (as determined by \(s\)), and let \((i_1^*, i_2^*)\) be an admissible pair at \((P_1, P_2)\) for \(s\). Assume that \((\partial/\partial \zeta_1)^{i_1^*} (\partial/\partial \zeta_2)^{i_2^*} s(P_1, P_2) \neq 0\). Then there are constants \(c_2\) and \(c_3\), depending only on \(C, \phi_{NA}, \) and \(\phi_B\), such that

\[
h_Y(P_1, P_2) \geq -h(\mathcal{F}) - c_2(i_1^* h_A(P_1) + i_2^* h_A(P_2)) - c_3(i_1^* + i_2^*) - (1 + o(1))(\delta_1 + \delta_2)
\]

The proof of this is quite technical, so it will not be included here. The interested reader is referred to [Bom90, Lemma 6] for a detailed proof.

## 6. Construction of a Global Section

This section gives Bombieri’s construction of a global section of \(\mathcal{O}(Y)\) with bounds on its height \(h(\mathcal{F})\). This is the core of Bombieri’s additions to earlier proofs, as it replaces the use of advanced Arakelov theory with arguments using more classical algebraic geometry.

**Lemma 6.1.** Let \(\gamma > 0\) and let \(a_1\) and \(a_2\) be positive rational numbers with \((1 - \gamma)a_1a_2 > g\).

Let \(Y\) be the divisor defined by (2.10) for a suitable \(d > 0\). Then there exist a nonzero global section \(s\) of \(\mathcal{O}(Y)\); a constant \(c_4\) depending only on \(C, \phi_{NA}, \) and \(\phi_B\); and a representation \(\mathcal{F} = (F_i)_{0 \leq i \leq m}\) of \(s\), such that

\[
h(\mathcal{F}) \leq c_4(d_1 + d_2)/\gamma + o(d_1 + d_2)
\]

**Proof.** The section \(s\) will be constructed by finding \(\mathcal{F}\) that satisfies the conditions of Lemma 5.1.
By the Riemann-Roch theorem for projective algebraic surfaces,
\[ h^0(C \times C, Y) = d^2(a_1 a_2 - g) + O(d_1 + d_2 + d) \]
\[ \geq d^2(a_1 a_2 \gamma) - O(\delta_1 + \delta_2) . \]  
(6.1.2)

By Riemann-Roch for curves,
\[ h^0(C \times C, \delta_1 NA \times C + C \times \delta_2 NA) = (N \delta_1 + 1 - g)(N \delta_2 + 1 - g) , \]
and therefore the space of all possible \( \phi \) has dimension
\[ (m + 1)(N^2 \delta_1 \delta_2 - N(g - 1)(\delta_1 + \delta_2) + (g - 1)^2) . \]  
(6.1.3)

(Here (6.1.2) and (6.1.3) are close to the values of \( N - M \) and \( N \), respectively, in the application of Siegel’s lemma; see the details later in this proof.)

We will work using (local) affine coordinates \( \xi_j := (x_j/x_0) \circ p_1, \xi_j' := (x_j/x_0) \circ p_2, \) and \( \eta_i := (y_i/y_0)|_{C \times C} \) on \( C \times C \).

For suitably generic choice of \( \phi_{NA} \) (which we assume has been chosen), the rational map \( \pi_1: \mathbb{P}^n \rightarrow \mathbb{P}^1 \) given by \( [x_0 : x_1 : \cdots : x_n] \mapsto [x_0 : x_1] \) is a morphism on \( \phi_{NA}(C) \). Likewise, we assume that \( \phi_{NA} \) has been chosen such that the projection \( \pi_{1,2}: [x_0 : x_1 : \cdots : x_n] \mapsto [x_0 : x_1 : x_2] \) maps \( \phi_{NA}(C) \) birationally to its image in \( \mathbb{P}^2 \) (which is therefore a curve of degree \( N \)), and \( \xi_2 \) is integral over the ring \( k[\xi_1] \).

Since the morphism \( \phi_{NA} \times \phi_{NA}: C \times C \rightarrow \mathbb{P}^n \times \mathbb{P}^n \) is a closed immersion, composing with \( \pi_{1,2} \times \pi_{1,2} \) gives a birational map from \( C \times C \) to its image in \( \mathbb{P}^2 \times \mathbb{P}^2 \), so we have
\[ K(C \times C) = k(\xi_1, \xi_2, \xi_1', \xi_2') \]
and therefore, for all \( i \),
\[ \eta_i = \frac{P_i(\xi_1, \xi_2, \xi_1', \xi_2')}{Q_i(\xi_1, \xi_2, \xi_1', \xi_2')} \]
for polynomials \( P_i \) and \( Q_i \) with coefficients in \( k \). The conditions \( F_i/y_i^d = F_j/y_j^d \)
then become
\[ ((P_i Q_j)^d F_j)|_{C \times C} = ((P_j Q_i)^d F_i)|_{C \times C} \quad \text{for all } i, j . \]

Note that the height of \( (P_i Q_j)^d \) is \( O(d) \) for all \( i, j \).

In order to apply Siegel’s lemma, it is necessary to find a basis for the set of all possible \( \phi \) such that the linear conditions relative to this basis do not become much larger than the heights of \( (P_i Q_j)^d \). The easiest way to do this is to use a linear subspace of slightly smaller dimension. This will change \( N \) and \( N - M \) in Siegel’s lemma by \( O(\delta_1 + \delta_2) \), which is small enough not to change the outcome appreciably.

The details of this are as follows. The image of the morphism \( \pi_{1,2} \circ \phi_{NA}: C \rightarrow \mathbb{P}^2 \) is a curve of degree \( N \), and is birational to \( C \). Moreover, the field extension \( K(C)/k(\xi_1) \) is also of degree \( N \), generated by \( \xi_2 \). We then restrict our choices of the \( F_i \) to the space generated by the monomials
\[ x_0^{\delta_1 - w_1} x_1^{u_1} x_2^{w_1} (x_0')^{\delta_2 - u_2} x_2 (x_2')^{w_2} , \quad 0 \leq w_1 \leq N , \quad 0 \leq u_1 \leq \delta_1 - w_1 , \]
\[ 0 \leq w_2 \leq N , \quad 0 \leq u_2 \leq \delta_2 - w_2 . \]
The number of ordered pairs \((w_1, u_1)\) is
\[
(\delta_1 + 1) + (\delta_1 + 1 - 1) + \cdots + (\delta_1 + 1 - (N - 1)) = N\delta_1 + N - \frac{N(N-1)}{2}
= N\left(\delta_1 - \frac{N-3}{2}\right),
\]
and similarly for the number of pairs \((w_2, u_2)\). Therefore the dimension of this subspace is
\[
(m + 1)N^2 \left(\delta_1 - \frac{N-3}{2}\right) \left(\delta_2 - \frac{N-3}{2}\right),
\]
which differs from (6.1.3) by \(O(\delta_1 + \delta_2)\).

With the setup described above, the height of the linear forms remains \(O(d)\), and therefore Siegel’s lemma constructs \(\mathcal{F}\) satisfying the conditions of Lemma 5.1 with
\[
h(\mathcal{F}) \leq O \left( \frac{(m + 1)N^2 \delta_1\delta_2}{\gamma d_1 d_2} \right) = O \left( \frac{d_1 + d_2}{\gamma} \right).
\]
(Recall that \(N\delta_i = d(a_i + s)\) and \(d_i = d a_i\) \((i = 1, 2)\). Then \(a_1 \to \infty\) and \(a_2 \to 0\) as \(h(P_2)/h(P_1) \to \infty\); therefore \(N\delta_1/d_1 \to \text{constant}\) and \(N\delta_2/d_2\) grows like \(h(P_2)/h(P_1)\) as \(h(P_2)/h(P_1) \to \infty\).)

\(\square\)

The above proof omits many of the details that determine the bounds on \(h(\mathcal{F})\). For a complete proof see [Bom90, §8].

7. The Index

Since the inequality (5.5.1) will be applied when \(h(P_2)/h(P_1)\) and \(h(P_1)\) are large, the effect of an increase in \(i_2^*\) will be much greater than the effect of the same increase in \(i_1^*\). Therefore it will be useful to work with a measure of vanishing of \(s\) at \((P_1, P_2)\) that assigns more weight to \(\zeta_2\) than to \(\zeta_1\).

This is consonant with the fact that the ratio \(\delta_1/\delta_2\) is large, which stems from the fact that \(a_1\) and \(a_2\) are chosen such that their ratio \(a_1/a_2\) is close to \(h_A(P_2)/h_A(P_1)\) (see (2.8)). This ensures that the two components of the term \(c_2(i_1^* h_A(P_1) + i_2^* h_A(P_2))\) in (5.5.1) have approximately the same size.

With this in mind, the Thue-Siegel method relies heavily on the “index” of a polynomial or a global section, which may be regarded as a weighted order of vanishing at a point.

**Definition 7.1.** Let \(k\) be a field, let \(d_1\) and \(d_2\) be positive integers, let \(f \in k[x_1, x_2]\) be a nonzero polynomial, and let \(\alpha_1, \alpha_2 \in k\). Write
\[
f(x_1, x_2) = \sum_{i_1, i_2 \in \mathbb{N}} a_{i_1, i_2} (x_1 - \alpha_1)^{i_1} (x_2 - \alpha_2)^{i_2}.
\]
Then the **index** of \(f\) at \((\alpha_1, \alpha_2)\) relative to \((d_1, d_2)\) is the (rational) number
\[
\text{ind}_{d_1, d_2}(f, (\alpha_1, \alpha_2)) = \min \left\{ \frac{i_1}{d_1} + \frac{i_2}{d_2} : i_1, i_2 \in \mathbb{N}, a_{i_1, i_2} \neq 0 \right\}
= \min \left\{ \frac{i_1}{d_1} + \frac{i_2}{d_2} : i_1, i_2 \in \mathbb{N}, \left(\frac{\partial}{\partial x_1}\right)^{i_1} \left(\frac{\partial}{\partial x_2}\right)^{i_2} f(\alpha_1, \alpha_2) \neq 0 \right\},
\]
where the second expression is valid only if char $k = 0$.

This definition is used in the proofs of Thue and Siegel. In those proofs, $d_1 / d_2$ is taken close to $(h(p_1 / q_1) / h(p_2 / q_2))^{-1}$ (with notation as in Section 1), so that $d_i h(p_i / q_i)$ is approximately independent of $i$. In addition, $|q_i|^{d_i} \approx |q_2|^{d_2}$, so since $f$ has degree $d_1$ in $x_1$ and degree $d_2$ in $x_2$, the contributions to the denominators from each variable in the expression $f(p_1 / q_1, p_2 / q_2)$ are approximately the same.

In Bombieri’s (and my) proof of the Mordell conjecture, $d_1 = a_1 d$ and $d_2 = ad_2$, which are approximately the intersection numbers of the divisor $Y$ with fibers $A \times C$ and $C \times A$, respectively.

In the above definition, $f$ may be a power series, and may be further extended to the index of a global section of $\mathcal{O}(Y)$ at $(P_1, P_2)$ (by dividing by a local generator of $\mathcal{O}(Y)$ at $(P_1, P_2)$ and expressing the quotient as a power series in local coordinates on the factors). This is easily seen to be well defined, for the same reason that admissibility is well defined.

8. The End of the Proof

So far we have constructed a global section $s$ of $\mathcal{O}(Y)$ whose height $h(\mathfrak{F})$ is bounded by (6.1.1), and obtained upper and lower bounds for the height $h_Y(P_1, P_2)$.

In more detail, combining (5.5.1) with (6.1.1) gives the lower bound

$$h_Y(P_1, P_2) \geq -c_4 \left( \frac{d_1 + d_2}{\gamma} \right) - c_2 (i_1^* h_A(P_1) + i_2^* h_A(P_2)) - c_3 (i_1^* + i_2^*) - \left( 1 + o(1) \right) (\delta_1 + \delta_2).$$

Recall that the upper bound (4.2) is

$$h_Y(P_1, P_2) \leq \frac{d_1}{g} |j(P_1)|^2 + \frac{d_2}{g} |j(P_2)|^2 - \frac{3}{2} d |j(P_1)||j(P_2)| + c_1 (d_1 + d_2 + d).$$

Combining these two bounds then gives

$$c_2 \max\left\{ d_1 h_A(P_1), d_2 h_A(P_2) \right\} \left( \frac{i_1^*}{d_1} + \frac{i_2^*}{d_2} \right) \left( \frac{d_1 + d_2}{\gamma} \right) - c_3 (i_1^* + i_2^*) - c_4 \left( \frac{d_1 + d_2}{\gamma} \right) - O(d_1 + d_2).$$

The first thing to notice about this inequality is that the quantity $i_1^*/d_1 + i_2^*/d_2$ on the left-hand side is the index $\text{ind}_{d_1, d_2}(s, (P_1, P_2))$ of $s$ at $(P_1, P_2)$ relative to $d_1$ and $d_2$ (for suitable choices of $i_1^*$ and $i_2^*$, which we now assume).

Another important fact about (8.1) is that all of the terms on the right-hand side grow linearly with $d$, as does the coefficient $c_2 \max\left\{ d_1 h_A(P_1), d_2 h_A(P_2) \right\}$ on the left. Therefore, (8.1) implies a lower bound on the index that does not depend on $d$.

Of course, such a lower bound is not useful if it is negative. However, since

$$|j(P)|^2 = h_{\mathfrak{O}}(j(P)) = g h_A(P) + O(1) \quad \text{for all } P \in C(\overline{k}),$$

$$-\frac{d_1}{g} |j(P_1)|^2 - \frac{d_2}{g} |j(P_2)|^2 + \frac{3}{2} d |j(P_1)||j(P_2)| = dg \sqrt{h_A(P_1)h_A(P_2)} \left( -2 \frac{\sqrt{g + \gamma}}{g} + \frac{3}{2} \right).$$

(8.2)
Since \( g \geq 2 \) (this is where the assumption on the genus is used), one can take \( \gamma > 0 \) sufficiently small so that \( \sqrt{g + \gamma}/g < 3/4 \), so this term is positive. Moreover, it grows at the same rate as \( \max\{d_1 h_A(P_1), d_3 h_A(P_2)\} \).

Thus, if \( h_A(P_1) \) and \( h_A(P_2) \) are sufficiently large, then the last three terms of (8.1) are insignificant, and we have a lower bound
\[
(\text{8.3}) \quad \text{ind}_{d_1, d_2}(s_i(P_1, P_2)) \geq \epsilon ,
\]
where \( \epsilon > 0 \) depends only on \( C, N, A, \phi_{N_A}, \phi_B, \) etc., but not on \( P_1, P_2, \) or \( d \).

The final contradiction will be obtained using Roth’s lemma:

**Theorem 8.4.** Let \( f \) be a nonzero polynomial in \( m \) variables \( x_1, \ldots, x_m \), of degree at most \( r_i \in \mathbb{Z}_{>0} \) in \( x_i \) for each \( i \), and with coefficients in \( \overline{\mathbb{Q}} \). Let \( (b_1, \ldots, b_m) \) be an algebraic point. Finally, let \( \epsilon > 0 \) be such that
\[
(\text{8.4.1}) \quad \frac{r_{i+1}}{r_i} \leq e^{2^{m-1}}, \quad \text{for all } i = 1, \ldots, m - 1
\]
and
\[
(\text{8.4.2}) \quad r_i h(b_i) \geq \epsilon^{-2^{m-1}}(h(P) + 2mr_1), \quad \text{for all } i = 1, \ldots, m.
\]
Then the index of \( f \) at \( (b_1, \ldots, b_m) \) satisfies
\[
\text{ind}_{r_1, \ldots, r_m}(P, (b_1, \ldots, b_m)) \leq 2mc .
\]

This lemma appears (with proof) in [HS00, Prop. D.6.2] (and in many other places), and will not be proved here.

Of course we will use \( m = 2 \) in applying Theorem 8.4, and will also need to adjust \( \epsilon \) in (8.3). But first, it will be necessary to address the fact that \( f \) is a polynomial in two variables (which can be regarded as a global section of \( \mathcal{O}(r_1, r_2) \) on \( \mathbb{P}^1 \times \mathbb{P}^1 \)), whereas \( s \) is a global section of a line sheaf on \( C \times C \).

This difference can be handled as follows. For suitable \( a \) and \( b \), fix finite maps \( C \to \mathbb{P}^1 \) given by the rational functions \( x_a/x_0 \) and \( x_b/x_0 \), and let \( g = F_0/\eta_0^d \), which has poles only along \( x_0 = 0 \) and \( x'_0 = 0 \). Now, recalling that \( \xi_a = (x_a/x_0) \circ p_1 \) and \( \xi'_b = (x_b/x_0) \circ p_2 \), take the norm
\[
f = N_{K(C \times C)/K(\xi_a, \xi'_b)} \ g
\]
to get a section of \( \mathcal{O}(N^2 \delta_1, N^2 \delta_2) \) on \( \mathbb{P}^1 \times \mathbb{P}^1 \). This is the polynomial \( f \), and one can bound its height by
\[
h(P) \leq O \left( \frac{d_1 + d_2}{\gamma} \right) + O(d_1 + d_2);
\]
see [Bom90, §9].

One will have \( b_1 = \xi_a(P_1) \) and \( b_2 = \xi_b(P_2) \), so \( h(b_1) = h_{N_A}(P_1) + O(1) \) and \( h(b_2) = h_{N_A}(P_2) + O(1) \) by elementary properties of heights [HS00, Thm. B.3.2(b) or Cor. B.2.6]. Therefore, one can choose \( P_1 \in \Sigma' \) with \( h_A(P_1) \) sufficiently large so that (8.3) and (8.4.2) hold, and subsequently choose \( P_2 \in \Sigma' \) with \( h_A(P_2)/h_A(P_1) \) sufficiently large so that (8.4.1) is true.

This then gives a contradiction, so the assumption that \( C(k) \) is infinite must be false.

Note that much has been left out of the proof, most notably the derivations of the bounds of the heights in the application of Siegel’s lemma, as well as the height inequalities in this section. The interested reader is referred to [Bom90] for more explicit details.
