(Received 28 August 2007; revised manuscript received 14 March 2008; published 29 April 2008)

We present partial branching fractions for inclusive charmless semileptonic B decays $\bar{B} \rightarrow X_u \ell \bar{\nu}$, and the determination of the Cabibbo-Kobayashi-Maskawa matrix element $|V_{ub}|$. The analysis is based on a sample of $383 \times 10^6 Y(4S)$ decays into $B\bar{B}$ pairs collected with the BABAR detector at the SLAC PEP-II e^+e^- storage rings. We select events using the invariant mass M_X of the hadronic system, the invariant mass squared, q^2 , of the lepton and neutrino pair, the kinematic variable P_+ , or one of their combinations. We then determine partial branching fractions in limited regions of phase space: $\Delta\mathcal{B} = (1.18 \pm 0.09_{\text{stat}} \pm 0.07_{\text{syst}} \pm 0.01_{\text{theor}}) \times 10^{-3}$ ($M_X < 1.55 \text{ GeV}/c^2$), $\Delta\mathcal{B} = (0.95 \pm 0.10_{\text{stat}} \pm 0.08_{\text{syst}} \pm 0.01_{\text{theor}}) \times 10^{-3}$

($P_+ < 0.66 \text{ GeV}/c$), and $\Delta\mathcal{B} = (0.81 \pm 0.08_{\text{stat}} \pm 0.07_{\text{syst}} \pm 0.02_{\text{theor}}) \times 10^{-3} (M_X < 1.7 \text{ GeV}/c^2, q^2 > 8 \text{ GeV}^2/c^4)$. Corresponding values of $|V_{ub}|$ are extracted using several theoretical calculations.

DOI: 10.1103/PhysRevLett.100.171802

In the standard model the element V_{ub} of the Cabibbo-Kobayashi-Maskawa (CKM) quark-mixing matrix [1] plays a critical role in tests of the prediction of CP violation. Since the rate for charmless semileptonic decays, $\bar{B} \rightarrow X_u \ell \bar{\nu}$ [2], is proportional to $|V_{ub}|^2$, and the hadronic and leptonic currents are factorizable, the best method to extract this quantity is to measure branching fractions for such decays [3]. Experimentally, the principal challenge is to separate the rare $\bar{B} \rightarrow X_u \ell \bar{\nu}$ decays from the approximately 50 times larger $\bar{B} \rightarrow X_c \ell \bar{\nu}$ background. Given that the u quark is much lighter than the c quark, regions of phase space can be defined where the background is suppressed. To relate the decay rate of the B meson to $|V_{ub}|$, parton level calculations have to be corrected for perturbative and nonperturbative QCD effects. A variety of QCD calculations are available to determine these corrections [4–6].

In this Letter, we present a measurement of partial branching fractions for inclusive charmless semileptonic decays, $\bar{B} \rightarrow X_u \ell \bar{\nu}$ [7]. $Y(4S) \rightarrow B\bar{B}$ events are tagged by the full reconstruction of a hadronic decay of one of the B mesons (B_{reco}). The semileptonic decay of the second B meson (B_{recoil}) is identified by the presence of an electron or a muon. This technique results in a low event selection efficiency but allows the determination of the momentum, charge, and flavor of the B mesons.

We use three kinematic variables to separate $\bar{B} \rightarrow X_u \ell \bar{\nu}$ decays from the dominant $\bar{B} \rightarrow X_c \ell \bar{\nu}$ background: M_X , the invariant mass of the hadronic system $X_{u,c}$; q^2 , the invariant mass squared of the lepton-neutrino system; and $P_+ \equiv E_X - |\vec{P}_X|$ [4,5], where E_X and \vec{P}_X are the energy and momentum of the hadronic system $X_{u,c}$ calculated in the B rest frame. We measure the fraction of partial rates of charmless semileptonic decays $\Delta R_{u/sl} = \Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})/\mathcal{B}(\bar{B} \rightarrow X \ell \bar{\nu})$ in restricted phase-space regions, corrected for resolution effects. The resulting partial branching fractions are used to calculate $|V_{ub}|$ following theoretical prescriptions.

The analysis uses a sample of 383×10^6 $Y(4S)$ decays into $B\bar{B}$ pairs, corresponding to an integrated luminosity of 347.4 fb^{-1} , collected with the *BABAR* detector [8]. Charmless semileptonic $\bar{B} \rightarrow X_u \ell \bar{\nu}$ decays are simulated as a combination of three-body decays ($X_u = \pi, \eta, \eta', \rho, \omega, \dots$) [9] and decays to nonresonant hadronic final states X_u [10]. The motion of the b quark inside the B meson is modeled with the shape function parametrization given in Ref. [10]. The simulation of the $\bar{B} \rightarrow X_c \ell \bar{\nu}$ background uses a heavy quark effective theory parametrization of form factors for $B \rightarrow D^* \ell \nu$ [11,12], and models for $\bar{B} \rightarrow D\pi\ell\bar{\nu}$, $D^* \pi\ell\bar{\nu}$ [13], and for $\bar{B} \rightarrow D\ell\bar{\nu}$, $D^{**}\ell\bar{\nu}$ [9]. The

simulation of the hadronization is performed by JETSET 7.4 [14]. We use GEANT4 [15] to simulate the detector response.

To reconstruct a large sample of hadronically decaying B mesons, $B_{\text{reco}} \rightarrow \bar{D}^{(*)} Y^\pm$ are selected. Here, the system Y^\pm consists of hadrons with a total charge of ± 1 , composed of $n_1 \pi^\pm n_2 K^\pm n_3 K_S^0 n_4 \pi^0$, where $n_1 + n_2 \leq 5$, $n_3 \leq 2$, and $n_4 \leq 2$. The kinematic consistency of B_{reco} candidates is checked with two variables, $m_{\text{ES}} = \sqrt{s/4 - \vec{p}_B^2}$ and $\Delta E = E_B - \sqrt{s}/2$. Here \sqrt{s} is the total energy in the $Y(4S)$ center of mass frame, and \vec{p}_B and E_B denote the momentum and energy of the B_{reco} candidate in the same frame. We require $\Delta E = 0$ within 3 standard deviations as measured for each decay mode. For each of the B_{reco} decay modes, the purity \mathcal{P} is estimated using Monte Carlo (MC) simulation. \mathcal{P} is defined as the ratio of signal over background events with $m_{\text{ES}} \geq 5.27 \text{ GeV}/c^2$. Only modes for which \mathcal{P} exceeds 20% are used. On average, we reconstruct at least one B candidate in 0.3% (0.5%) of the $B^0\bar{B}^0$ (B^+B^-) events. For events with more than one reconstructed B decay, the decay mode with the highest purity is selected.

We determine the number of B_{reco} candidates from an unbinned maximum likelihood fit to the m_{ES} distribution. The data are fit to the sum of three contributions: signal B_{reco} decays, combinatorial background from $B\bar{B}$ events, and continuum ($e^+e^- \rightarrow q\bar{q}$, $q = u, d, s, c$) events. A threshold function [16] is used to describe the combinatorial and continuum backgrounds. To obtain a good description of the signal m_{ES} distribution, we adopt the modified Gaussian function used in Ref. [17] to account for energy losses of photons in the detector. Fits to the m_{ES} distribution are shown in Fig. 1. Semileptonic decays $\bar{B} \rightarrow X\ell\bar{\nu}$ of

FIG. 1. The m_{ES} distribution for data (full circles) is shown together with the results of the fit (solid line) for selected semileptonic decays from B^+B^- events (a) and $B^0\bar{B}^0$ events (b). The dashed line shows the contribution from combinatorial and continuum background.

the B_{recoil} candidate are identified by an electron or muon with momentum, p_ℓ^* , defined in the \bar{B} rest frame, greater than 1 GeV/c. For charged B_{recoil} candidates, we require the charge of the lepton to be consistent with a prompt semileptonic \bar{B} decay. For neutral B_{recoil} candidates, both charge-flavor combinations are retained and the known average B^0 - \bar{B}^0 mixing rate [18] is used to extract the prompt lepton yield.

The hadronic system X in the decay $\bar{B} \rightarrow X\ell\bar{\nu}$ is reconstructed from charged tracks and energy depositions in the calorimeter that are not associated with the B_{recoil} candidate or the identified lepton. We reconstruct K_S^0 by performing a mass-constrained fit to $\pi^+\pi^-$ pairs with an invariant mass in the range 0.473–0.523 GeV/c². The neutrino four-momentum p_ν is estimated from the missing momentum four-vector $p_{\text{miss}} = p_{Y(4S)} - p_{B_{\text{recoil}}} - p_X - p_\ell$, where all momenta are measured in the laboratory frame and $p_{Y(4S)}$ refers to the $Y(4S)$ meson.

To select $\bar{B} \rightarrow X_u\ell\bar{\nu}$ candidates, we require exactly one charged lepton with $p_\ell^* > 1$ GeV/c, charge conservation ($Q_X + Q_\ell + Q_{B_{\text{recoil}}} = 0$), and a missing mass consistent with zero ($m_{\text{miss}}^2 < 0.5$ GeV²/c⁴). These criteria suppress the dominant $\bar{B} \rightarrow X_c\ell\bar{\nu}$ decays, many of which contain additional leptons or an undetected K_L^0 meson. We suppress the $B \rightarrow D^*\ell\nu$ background by reconstructing the low momentum π^+ from the $D^{*+} \rightarrow D^0\pi^+$ decay. Since the momentum of the π^+ is almost collinear with the D^{*+} momentum $p_{D^{*+}}$, we can approximate the D^{*+} energy as $E_{D^{*+}} \simeq m_{D^{*+}} \times E_\pi/145$ MeV/c². The neutrino mass $m_{\text{veto}}^2 = (p_B - p_{D^{*+}} - p_\ell)^2$ is peaked at zero for background events. The requirement $m_{\text{veto}}^2 < -3$ GeV²/c⁴ reduces the $B \rightarrow D^*\ell\nu$ background by about 36% while keeping more than 90% of signal events. We reject events with charged kaons or K_S^0 in the B_{recoil} to reduce the background from $\bar{B} \rightarrow X_c\ell\bar{\nu}$ decays.

To extract the distribution in the variables M_X , P_+ , and the combination of M_X and q^2 , we perform fits to the B_{recoil} m_{ES} distributions for subsamples of events in individual bins for each of the variables, and subsequently separate the signal from the combinatorial and continuum backgrounds for the three distributions. The resulting distributions are presented in Fig. 2. To reduce the systematic uncertainties in the derivation of the branching fractions, we determine the ratios of the partial branching fractions to the total semileptonic branching fraction. This is done for restricted regions of phase space, $M_X < 1.55$ GeV/c², $P_+ < 0.66$ GeV/c, and $(M_X < 1.7$ GeV/c², $q^2 > 8.0$ GeV²/c⁴). Specifically, we define this ratio as

$$\frac{\Delta\mathcal{B}(X_u\ell\bar{\nu}_\ell)}{\mathcal{B}(X\ell\bar{\nu}_\ell)} = \frac{(N_u - N_u^{\text{out}} - BG_u)/(\epsilon_{\text{sel}}^u \epsilon_{\text{kin}}^u)}{(N_{\text{sl}} - BG_{\text{sl}})} \frac{\epsilon_\ell^{\text{sl}} \epsilon_t^{\text{sl}}}{\epsilon_\ell^u \epsilon_t^u}, \quad (1)$$

where N_u refers to the number of observed events, BG_u to the estimated number of background events, and N_u^{out} to the signal events that migrate from outside the kinematic region into the signal region. They are determined by a χ^2 fit to the measured spectra with signal and background shapes determined from MC simulation. $N_{\text{sl}} = 181074 \pm 706$ and $BG_{\text{sl}} = 12185 \pm 78$ are the number of semileptonic events, extracted with a m_{ES} fit, and the corresponding background, determined from simulation. The efficiency ϵ_{sel}^u denotes the fraction of selected B_{recoil} -tagged signal events with a high-energy lepton. The model-dependent efficiency ϵ_{kin}^u accounts for the loss of selected events generated in the kinematic region that migrate outside this region. The efficiency of the tag and lepton selection, ϵ_t and ϵ_ℓ , differ slightly for the signal and the semileptonic samples, due to differences in the lepton momentum distribution and the multiplicity of the recoiling B meson. To convert the ratio in Eq. (1) to partial branching fractions, we use the total semileptonic branch-

FIG. 2 (color online). Upper row: measured M_X (a), P_+ (b), and q^2 with $M_X < 1.7$ GeV/c² (c) spectra (data points). The result of the fit to the sum of three MC contributions is shown in the histograms: $\bar{B} \rightarrow X_u\ell\bar{\nu}$ decays generated inside (no shading) and outside (dark shading) the selected kinematic region, and $\bar{B} \rightarrow X_c\ell\bar{\nu}$ and other background (light shading). Lower row: corresponding spectra for $\bar{B} \rightarrow X_u\ell\bar{\nu}$ after $\bar{B} \rightarrow X_c\ell\bar{\nu}$ and other background subtraction; they have been rebinned in order to show the shape of the kinematic variables.

TABLE I. Summary of the fitted number of events and efficiencies, $\Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})$, and extracted $|V_{ub}|$ for the three kinematic cuts. The first uncertainty is statistical, the second systematic. For $\Delta\mathcal{B}$, the third uncertainty is due to the theoretical knowledge of the signal efficiency; for the $|V_{ub}|$ values, it comes from the theoretical uncertainty on $\Delta\zeta$. For Ref. [4] we use the exponential parametrization of the shape function.

Method	N_u	N_u^{out}	BG_u	$\epsilon_{\text{sel}}^u \epsilon_{\text{kin}}^u$	$\frac{\epsilon_7^{\text{sl}} \epsilon_7^{\text{sl}}}{\epsilon_7^u \epsilon_7^{\text{sl}}}$	$\Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})(10^{-3})$	$ V_{ub} \times (10^{-3})$
M_X	803 ± 60	27 ± 2	923 ± 21	0.331 ± 0.003	0.76 ± 0.02	$1.18 \pm 0.09 \pm 0.07 \pm 0.01$	$4.27 \pm 0.16 \pm 0.13 \pm 0.30$ [4] $4.56 \pm 0.17 \pm 0.14 \pm 0.32$ [5] $3.88 \pm 0.19 \pm 0.16 \pm 0.28$ [4]
P_+	633 ± 63	48 ± 5	1183 ± 27	0.344 ± 0.003	0.81 ± 0.02	$0.95 \pm 0.10 \pm 0.08 \pm 0.01$	$3.99 \pm 0.20 \pm 0.16 \pm 0.24$ [5] $4.57 \pm 0.22 \pm 0.19 \pm 0.30$ [4]
M_X, q^2	562 ± 55	32 ± 2	789 ± 9	0.353 ± 0.005	0.79 ± 0.03	$0.81 \pm 0.08 \pm 0.07 \pm 0.02$	$4.64 \pm 0.23 \pm 0.19 \pm 0.25$ [5] $4.93 \pm 0.24 \pm 0.20 \pm 0.36$ [6]

ing fraction, $\mathcal{B}(\bar{B} \rightarrow X \ell \bar{\nu}_\ell) = (10.75 \pm 0.15)\%$ [18]. The resulting partial branching fractions for the three selected kinematic regions, along with parameters in Eq. (1), are listed in Table I. The statistical correlations between the M_X and (M_X, q^2) , P_+ analyses are 65%, 67%, 38%, respectively.

We consider several sources of systematic uncertainties. Detector-related uncertainties take into account particle (e , μ , K) identification (efficiency, misidentification), charged particle tracking efficiency, photon reconstruction efficiency, and K_L^0 interactions. We estimate the uncertainty due to signal and background modeling. The uncertainty on the signal modeling is due to the modeling of exclusive charmless semileptonic decays and gluon splitting into $s\bar{s}$ -quark pairs. We also calculate the uncertainties due to the nonperturbative parameters and the functional form of the shape function. The background simulation depends on the B and D branching fractions and $B \rightarrow D^* \ell \bar{\nu}$ form factors; the corresponding systematic uncertainties are calculated by varying all these quantities within their experimental errors. We estimate the error due to m_{ES} fits, coming from the uncertainty in the parametrization ansatz. Finally, we estimate the error due to MC statistics. The fractional contribution of each uncertainty is shown in Table II together with the total error.

The results of the partial branching fractions are translated into $|V_{ub}|$ in the context of recent QCD calculations [4–6], including estimates of theoretical uncertainties (see Table I). The hadronic input parameters, the b -quark mass m_b and the kinetic energy expectation value μ_π^2 , are ex-

tracted from moment measurements in $B \rightarrow X_s \gamma$ and $\bar{B} \rightarrow X_c \ell \bar{\nu}$. Their values in the kinetic scheme [19] are $m_b = (4.59 \pm 0.04) \text{ GeV}/c^2$ and $\mu_\pi^2 = (0.40 \pm 0.04) \text{ GeV}^2/c^2$ [20] and are translated into values in different schemes, as needed [4–6]. The partial branching fraction $\Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})$ is related directly to $|V_{ub}|$ by the relation $|V_{ub}| = [\Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})/\tau_b \Delta\zeta]^{1/2}$, where τ_b is the average B lifetime [18], and $\Delta\zeta$ is the prediction for the partial rate for $\bar{B} \rightarrow X_u \ell \bar{\nu}$ in the given phase-space region [4–6].

In summary, we have measured the branching fractions for inclusive charmless semileptonic B decays $\bar{B} \rightarrow X_u \ell \bar{\nu}$ in three overlapping regions of phase space. Relying on theoretical predictions, we extract values for the CKM matrix element $|V_{ub}|$ from our measured $\Delta\mathcal{B}$.

We find that the determinations of $|V_{ub}|$ agree at 1σ level in the BNLP [4] framework for the M_X and combined (M_X, q^2) analyses. The analysis based on P_+ differs from the two others at a 2.5σ level, as indicated also by other experiments [21]. The M_X analysis captures the largest portion of phase space and gives the most precise determination of $|V_{ub}|$. Within their stated theoretical uncertainties, the results based on BLNP and DGE [5] give consistent results. The result, based on the hadronic mass spectrum, supersedes our previously published measurement [3], reducing the relative uncertainty by 40%. These values are in good agreement with other inclusive $|V_{ub}|$ determinations, and they are somewhat higher, though compatible, than the results based on exclusive charmless semileptonic decays [18].

TABLE II. Contributions to the systematic uncertainty on the measured $\Delta\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})$, shown in percent (%) for the three kinematic cuts, from detector, shape function (input parameters and functional form), exclusive $\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})$, gluon splitting, exclusive $\mathcal{B}(\bar{B} \rightarrow X_c \ell \bar{\nu})$, $B \rightarrow D^* \ell \bar{\nu}$ form factors, $\mathcal{B}(D)$, m_{ES} fit, MC statistics. The last column gives the total systematic uncertainty.

Method	Detector	Shape function	$\mathcal{B}(\bar{B} \rightarrow X_u \ell \bar{\nu})$ $X_u = \pi, \rho, \dots$	Gluon splitting	$\mathcal{B}(\bar{B} \rightarrow X_c \ell \bar{\nu})$	$B \rightarrow D^* \ell \bar{\nu}$ form factors	$\mathcal{B}(D)$	m_{ES} fit	Monte Carlo statistics	Total
M_X	1.92	0.90	2.08	1.62	0.87	0.21	0.44	3.71	3.22	6.07
P_+	3.88	1.31	2.22	1.47	2.80	0.39	0.73	3.98	4.62	8.38
M_X, q^2	3.83	2.43	2.71	1.02	1.17	0.55	0.79	5.17	4.29	8.81

We would like to thank the many theorists with whom we have had valuable discussions, in particular, J. R. Andersen, E. Gardi, B. Lange, Z. Ligeti, M. Neubert, and G. Paz. We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing organizations that support *BABAR*. The collaborating institutions wish to thank SLAC for its support and kind hospitality. This work is supported by DOE and NSF (USA), NSERC (Canada), CEA and CNRS-IN2P3 (France), BMBF and DFG (Germany), INFN (Italy), FOM (The Netherlands), NFR (Norway), MIST (Russia), MEC (Spain), and STFC (United Kingdom). Individuals have received support from the Marie Curie EIF (European Union) and the A. P. Sloan Foundation.
