ABSTRACT

Measurements of equilibrium constants for the reactions: SmCl_{3(s)} + H₂O_(g) = SmOCl_(s) + 2HCl_(g) and GdCl_{3(s)} + H₂O_(g) = GdOCl_(s) + 2HCl_(g) at various temperatures give the free energy functions $\Delta F^{o}_{(kcal)} = 21.56 + \frac{6.4 \text{ T} \log \text{ T}}{1000} + 1.8 \times 10^{-7} \text{ T}^{2} - \frac{22}{\text{ T}} - \frac{53.01 \text{ T}}{1000}$, and $\Delta F^{o}_{(kcal)} = 19.96 + \frac{6.4 \text{ T} \log \text{ T}}{1000} + 1.8 \times 10^{-7} \text{ T}^{2} - \frac{22}{\text{ T}} - \frac{51.88 \text{ T}}{1000}$, respectively, using an estimated ΔCp function of $-2.8 - 0.36 \times 10^{-3} \text{ T} + 0.44 \times 10^{5} \text{ T}^{-2}$ for both reactions. Within the experimental temperature range of about 700-900° K these functions are consistent with the experimental measurements within an average deviation

of about ± 0.07 kcal. Because of the possible error in the estimated ΔCp function, however, extrapolation to 298° K involves a much larger uncertainty.

THE VAPOR PHASE HYDROLYSIS OF THE RARE EARTH HALIDES II. Heat and Free Energy of the Reactions: $SmCl_3(s) + H_2O(g) = SmOCl(s) + 2HCl(g)$ and $GdCl_3(s) + H_2O(g) = GdOCl(s) + 2HCl(g)$

Introduction

An experimental method of measuring equilibrium constants for the reaction: $LaCl_{3(s)} + H_{2^{0}(g)} = LaOCl_{(s)} + 2HCl_{(g)}$ at various temperatures has been described in a previous paper.¹ The method has now

1. C. W. Koch, A. Broido, and B. B. Cunningham, J. Am. Chem. Soc. <u>74</u>, 2349 (1952).

been applied to an investigation of the corresponding reactions of samarium and gadolinium. The results are of interest because they furnish thermodynamic data not previously available for the rare earth oxychlorides and also because they provide information for a consideration of the influence of crystal geometry on the thermodynamic properties of compounds of close structural similarity. This latter subject will be considered in a subsequent paper.

-4-

<u>Apparatus and Technique</u>.--A detailed description of the apparatus and experimental technique used for the hydrolysis measurements on lanthanum trichloride has been given previously.¹ No modifications of apparatus or technique were necessary for the measurements reported here. However, a platinum foil radiation shield some four inches in length has now been placed around the central portion of the reaction chamber, although it was found that the apparent temperature of the sample was not affected significantly by this change in the experimental set-up.

<u>Materials</u>.--Samarium was obtained as the sesquioxide from Dr. Frank Spedding of Iowa State College. Spectrographic analysis by Mr. John Conway of the Radiation Laboratory gave the following results: europium - 0.01-0.1%, calcium - 0.01-0.1%, lanthanum - 0.01-0.1%.

Gadolinium sesquioxide was purchased from Adam Hilger and Sons, London, England. The results of a spectrographic analysis of a sample of this material were as follows: iron = 0.01=0.1%, magnesium = 0.01=0.1%, and no other rare earth detected.

<u>X-Ray Diffraction Data</u>.--Powder patterns of rare earth trichlorides and oxychlorides prepared by the methods described in this paper were obtained by Mrs. Carol Dauben and Mrs. Helena Rubin of the x-ray diffraction group. Estimates of the crystallite size of some of our preparations were made by Professor D. H. Templeton from measurements of the line broadening of the diffraction patterns.

RESULTS

The results of the hydrolysis measurements on solid SmCl₃ and GdCl₃ are summarized in Tables I and II below. Calculated free energy Values based on the function:

$$\Delta F_{\rm T}^{\rm O} = \Delta H_{\rm O} + \frac{6.4 \, \text{T} \, \log \, \text{T}}{1000} + 1.8 \, \text{x} \, 10^{-6} \, \text{T}^2 - \frac{22}{\text{T}} + \text{I} \, \text{T}$$

are given for comparison. This function assumes the same ΔCp equation as that estimated for lanthanum:¹

$$\Delta Cp = -2.8 - 0.36 \times 10^{-3} T + 0.44 \times 10^{5} T^{-2}.$$

The constants ΔH_0 and I were evaluated for the samarium and gadolinium reactions by taking the mean of individual values calculated from various pairs of free energy values derived from experimentally observed equilibrium constants.

The right hand columns of Tables I and II give the deviations of the experimental ΔF^{0} values from the ΔF^{0} values calculated from the free energy functions. Within the experimental temperature range the agreement is reasonably satisfactory.

It should be emphasized, however, that heat capacity data for the rare earth chlorides and oxychlorides are not available and the uncertainty in our estimated Δ Cp equation therefore is considerable. This leads to an uncertainty of perhaps 1.5 kcal and 2-3 entropy units in the extrapolation of our data to room temperature.

The thermodynamic constants for the hydrolysis of the solid trichlorides of lanthanum, samarium and gadolinium by water vapor are summarized in Table III.

The above values are in kcal per mole and cal per degree per mole.

Neglecting electronic contributions it would be expected that ΔS for the various reactions would be very nearly the same at a given temperature.

However, since the electrical fields within the trichloride and oxychloride crystals are not of the same symmetry, the difference between the contributions of low lying energy states to the entropies of the trichloride and oxychloride of the same element, may be appreciably different for different rare earths. Such effects cannot be calculated with confidence at present, and we prefer to attribute the differences in the observed AS values principally to experimental error.

The most noticeable feature of the hydrolysis reactions is that their free energies become progressively more negative with increasing atomic number. A detailed consideration of this effect in terms of the crystal energies of the trichlorides and oxychlorides of lanthanum, samarium, and gadolinium will be presented in a subsequent paper.

In a previous paper¹ on the reaction of lanthanum trichloride with water vapor, we combined our thermochemical data with data given

-8-

in the Bureau of Standard's "Selected Values of Chemical Thermodynamic Properties" (Series I, Table 76-1, December 31, 1949) to calculate a heat and free energy of formation of LaOC1. It now appears^{2,3} that the

heats of formation of the rare earth trichlorides given in the source referred to are substantially in error. It does not seem worthwhile therefore to attempt to calculate heats and free energies of formation of SmOCl and GdOCl from our data until reliable thermochemical values are available for the trichlorides.

Crystallite size estimates of some of our preparations indicated a particle size in excess of 500 Å. It seems unlikely that the thermodynamic properties of the solid trichlorides and oxychlorides used in the equilibrium measurements were sufficiently different from those of macro crystals to have affected our results significantly.

This work was performed under the auspices of the U.S. Atomic Energy Commission.
