#### Abstract

A new species of Alloionema Schneider, 1859, A. similis n. sp., and the known species $A$. appendiculatum Schneider, 1859 were isolated from cadavers of invasive slugs in California. Both species are described based on morphology, morphometrics and molecular data. Alloionema similis n . sp. is morphologically very similar to $A$. appendiculatum but can be distinguished by a more posterior position of the excretory pore in the Kleinform females and longer tail in the Kleinform males. Substantial differences between the two species are, however, found in both 18 S and 28 S rDNA sequences. Sequence analysis revealed unambiguous autapomorphies in nucleotide sequence and secondary structure of rRNA genes, separating $A$. appendiculatum and $A$. similis n . sp. Molecular phylogenies were inferred from concatenated secondary-

[^0]structure based multiple sequence alignments of nearly complete 18 S and the D1-D3 domains of the 28 S rRNA genes. Phylogenetic analyses placed these two species as sister taxa in a monophyletic clade, separately from Neoalloionema tricaudatum Ivanova, Pham Van Luc \& Spiridonov, 2016 and N. indicum Nermut', Půža \& Mráček, 2016.

## Introduction

Alloionema Schneider, 1859 (Rhabditida: Alloionematidae) was erected by Schneider (1859) for Alloionema appendiculatum Schneider, 1859, a nematode associated with the black slug Arion ater (Linneaus), in Germany. In a later paper, Schneider (1866) described the same species under the name Leptodera appendiculata Schneider, 1866 with a more detailed morphological description and some illustrations, apparently he erroneously marked it as a new species. Claus (1868) published an extensive account of its morphology and reproduction as well as the alternation of two different saprophytic generations previously reported by Schneider (1859). These two forms are distinguished mainly by their size and tail shape and Mengert (1953) referred to them as "Großform" and "Kleinform". Chitwood \& McIntosh (1934) described from the gastropod host Succinea avara Say a variety, A. appendiculatum var. dubia Chitwood \& McIntosh, 1934, intermediate in size
between the two forms. Nermut' et al. (2015) made a re-description of $A$. appendiculatum based on material isolated from the invasive slug Arion vulgaris Moquin-Tandon (= A. lusitanicus Mabille) collected in the Czech Republic.

The first report of the genus in the United States was A. appendiculatum var. dubia recovered in 1934 from Succinea avara in Piscataway, Maryland (Chitwood \& McIntosh, 1934). In 2007, surveys of slug nematode parasites in the USA (Ross et al., 2010) yielded a low nematode recovery ( $5.4 \%$ ) with the majority ( 10 of 14) of species of Rhabditidae Örley, 1880 unidentified. Although found most often ( $34 \%$ of all isolates), A. appendiculatum was reported only from the states of Oregon (four sites) and Washington (two sites) but from neither of two sites sampled in California.

The first population of Alloionema spp. from California was recovered in 2006 from Arion rufus (Linnaeus) collected in Eureka. Specimens belonging to Großform were prepared for morphological and molecular studies but the culture was lost, making it impossible to study Kleinform specimens. A subsequent statewide gastropod survey in 2013 resulted in the recovery of multiple Alloionema isolates from Deroceras reticulatum (Müller) (four isolates), Lehmannia valentiana (Férussac) (three isolates) and Arion hortensis species complex (the latter complex comprises A. hortensis Férussac, A. distinctus Mabille and A. owenii Davies) (four isolates) collected in San Mateo. The most recent population was isolated from Arion rufus collected in McKinleyville, California during a 2015 survey.

With the exception of one isolate (ITD225), which was lost before it could be subjected to sequencing, all populations from 2013 sampling were found to be genetically identical to each other on the basis of their rRNA genes (nearly full length 18 S rRNA gene and partial 5' section of 28 S rRNA gene encompassing D1, D2 and D3 domains), but different from previously described populations of Alloionema appendiculatum from Europe (Laznik et al., 2009, 2010; Nermut' et al., 2015; Ross et al., 2010; Spiridonov et al., personal communication) as well as from the populations collected in Eureka in 2006 and in McKinleyville in 2015.

The objectives of this paper were: (i) to describe the two genotypes of Alloionema from California, giving additional information on morphology, morphometrics and genetic variability of the genus; (ii) to
compare the present material with previously described populations of A. appendiculatum; and (iii) to designate a new species for the genetically divergent population of Alloionema collected in San Mateo in 2013.

## Materials and methods

## Collection and maintenance of gastropods

Statewide invasive slug and snail surveys were conducted during 2006, 2007, 2013, 2014 and 2015 in California. Gastropods were collected primarily from nurseries and garden centers by examining the area under potted plants and taxa were identified using Mc Donnell et al. (2009). Gastropod specimens collected during these surveys yielded a total of 13 strains of Alloionema (Table 1). The first population was collected in 2006 from Arion rufus in Eureka while the most recent sample was also recovered from A. rufus collected in McKinleyville in 2015. In addition to $A$. rufus, specimens of Alloionema were recovered from A. hortensis agg., D. reticulatum and L. valentiana in California. Slugs and snails were reared on organic carrots in plastic containers $(26.5 \times$ $15.5 \times 6.5 \mathrm{~cm}$ ) lined with damp paper towel, and following death of the animals, the cadavers were placed on $1 \%$ plain agar. Nematodes that emerged were isolated, subcultured, and subsequently maintained on fresh plain agar and nutrient agar (Tandingan De Ley et al., 2014). Our attempts to obtain a Großform by inoculating slugs with Kleinform specimens (isolates 175 and 295) failed; nematodes continued to propagate, the host died, but no Großform could be found in our cultures after the death of the host.

## Light and scanning electron microscopy

Nematodes were picked from dead slugs and culture plates, relaxed by gentle heat and fixed in cold $4 \%$ formaldehyde solution. For light microscopy (LM), specimens were transferred to pure glycerine by a slow evaporation method and mounted on permanent slides in glycerine with paraffin wax as support for the coverslip. Specimens used in this study are deposited in the general invertebrate collection (slides \# SMNH-153525-SMNH-153536) of the Department of Zoology, Swedish Museum of Natural History, Stockholm, Sweden. For scanning electron microscopy (SEM),

specimens from the isolate ITD176 were post-fixed in $1 \%$ osmium tetroxide $\left(\mathrm{OsO}_{4}\right)$ and transferred to pure acetone through an acetone/distilled water series. Specimens were critical point dried in liquid $\mathrm{CO}_{2}$, mounted on stubs, gold-plated under vacuum to a thickness of $200 \AA$ An an Agar High Resolution Sputter Coater Model 20, and examined in a Hitachi S-4300 SEM at an accelerating voltage of 5 kV . All measurements in the descriptions and tables are in micrometres unless otherwise indicated.

## Molecular procedures

DNA extraction and amplification were performed as described in Tandingan De Ley et al. (2007) for the 5' section of the 28 S (covering either D2-D3 or D1-D2D3 expansion segments) and the 18 S rRNA genes (Tandingan De Ley et al., 2002). Genomic template DNA ( $2-3 \mu \mathrm{l}$ ) was used in a $25 \mu \mathrm{l}$ PCR reaction using Illustra PuReTaq Ready-To-Go ${ }^{\text {TM }}$ PCR beads (GE Healthcare, 800 Centennial Ave., P.O. Box 1327, Piscataway, NJ, USA) under the same PCR conditions, and using the same amplification and sequencing primers previously described (Blaxter et al., 1998; Tandingan De Ley et al., 2002). Contiguous sequences were assembled and compared with published sequences in the GenBank database using CodonCode Aligner (CodonCode Corp., 58 Beech Street, Dedham, MA, USA).

## Sequence alignment

The secondary structure alignment was created based on existing secondary structure models of nearly complete 18 S and partial 28 S rRNA genes as described in Holovachov et al. (2015). New rRNA sequences (Table 2) were added to existing secondary structure-based alignments and aligned to maximize apparent positional homology of nucleotides. Secondary structure annotation was manually added to nonannotated sequences using 4SALE (Seibel et al., 2006); complementarity of base pairings in stem regions was manually verified for all sites.

## Sequence comparison

Secondary structure-based alignments of all recent and published 18 S and 28 S rDNA sequences of Alloionema and Neoalloionema Ivanova, Pham Van Luc \& Spiridonov, 2016 (Table 3) were visually compared in SeaView (Gouy et al., 2010). For comparative analysis, consensus sequences were created for A. appendiculatum and A. similis n. sp. Common sites were excluded from all sequences of $A$. similis n. sp., Neoalloionema indicum and N. tricaudatum, while variable sites were retained.

## Visualization of rRNA secondary structure

Secondary structures of selected domains of both 18 S rRNA and 28S rRNA were visualized with the aid of

## Phylogenetic analysis

The concatenated alignment was analyzed with Bayesian phylogenetic inference using the mcmcphase program in the PHASE 2.0 package (Gowri-Shankar \& Jow, 2006). The entire concatenated alignment was partitioned into 18 S rDNA and 28 S rDNA partitions. Furthermore, each partition was divided into secondary partitions of "stems" (paired sites) and "loops" (non-paired sites) to account for the potential phylogenetic importance of compensatory substitutions. The REV nucleotide substitution model (Tavaré, 1986) was used for non-paired sites, whereas RNA7A (Higgs, 2000) nucleotide substitution model was used for paired sites. Model parameters were estimated independently for all sub-partitions (non-paired and paired sites of 18S rRNA gene and non-paired and paired sites of partial 28 S rRNA gene). Chains were allowed to burn in for 500,000 generations, followed by 5 million generations (total 5.5 million generations) during which tree topologies, branch length and model parameters were sampled every 200 generations. The tree was rooted using Rhabditophanes sp. KR3021.

## Family Alloionematidae Chitwood \& McIntosh, 1934

Genus Alloionema Schneider, 1859

## Alloionema appendiculatum Schneider, 1859

Description of Großform from Arion rufus
(Figs. 1A, C, 2A-C)

Host: Arion rufus (Linnaeus).
Locality: Potted plant in a garden center in Eureka, California, on 26.vi. 2006 (GPS coordinates: $\left.40^{\circ} 46^{\prime} 06^{\prime \prime} \mathrm{N}, 124^{\circ} 11^{\prime} 33^{\prime \prime} \mathrm{W}\right)$.
Voucher material: Two females and four males on slides \# SMNH-153527-SMNH-153528 deposited in the general invertebrate collection of the Department of Zoology, Swedish Museum of Natural History, Stockholm, Sweden.

General [Based on six specimens; see measurements in Table 4.] Body 2.0-2.4 mm long in females and 1.3-
1.5 mm long in males. When killed by heat, females slightly arcuate ventrad and males more strongly arcuate ventrad, especially in posterior end. Cuticle finely annulated, annules less prominent in LM, in anterior body region $2.2-2.4$ wide and $1.6-1.7$ wide in females and males, respectively. Lateral field not seen in LM or SEM. Lip region rounded, continuous with body contour. Anterior end gradually tapering. Six rounded lips grouped in 3 pairs, 1 dorsal and 2 ventrolateral, carrying 6 inner labial, 6 outer labial and 4 cephalic papilliform sensilla and 2 small oval amphids. Stoma less than one lip region diameter long. Cheilostom broad, with thick rounded rhabdia; gymnostom short; stegostom funnel-shaped, with strongly sclerotised lining. Pharynx muscular; corpus cylindrical, 1.5-2.1 times as long as isthmus, widening posteriorly to a non-valvular metacorpus; isthmus narrower, demarcated by a break in muscular tissue; basal bulb oval, with weakly developed valves. Nervering surrounding isthmus. Excretory pore somewhat more posterior, opening in posterior part of isthmus, at isthmus-bulb junction or at terminal bulb. Deirids not observed.

Female. Reproductive system didelphic, amphidelphic, ovaries reflexed. Oviducts filled with sperm. Gonads filled with oöcytes and hatched juveniles. Vulva a transverse slit, vulval lips not protruding; vagina $c .1 / 8$ of vulval body diameter (VBD). Tail conoid, tapering rapidly posteriorly to a minutely rounded terminus. Rectum short, less than one time anal body diameter (ABD) long. Phasmids in the shape of large transverse slits located at posterior third of tail length.

Male. Similar to female in most respects, except for the sexual characters. Reproductive system monorchic, testis reflexed dorsad anteriorly. Spicules paired, with weakly arcuate shaft and manubria bent sideways. Gubernaculum with robust dorsal apophysis. Genital papillae distributed as follows: a single midventral large pad-like precloacal papilla 74-88 anterior to cloaca; 2 subventral precloacal pairs (at 59-64 and 16-22 anterior to cloaca, respectively); single subventral adcloacal pair; other papillae indistinct, if present. Phasmids are not discernible in our specimens. Tail differently shaped than in female, strongly curved ventrad, conoid

Fig. 1 Light microscopy photomicrographs of Alloionema appendiculatum Schneider, 1859 and A. similis n . sp . Entire specimens. A, A. appendiculatum, Großform, male; B, A. appendiculatum, Kleinform, male; C, A. appendiculatum, Großform, female; D, A. appendiculatum, Kleinform, female; E, A. similis n. sp., Kleinform, male; F, A. similis n. sp., Kleinform, female. Scale-bar: $200 \mu \mathrm{~m}$
with an 18-20 long mucro ending in a pointed terminus.

## Remarks

The present material agrees well with the description of the Großform of A. appendiculatum by Mengert (1953) (see Table 4). Our study of the Californian specimens also largely corroborates the results obtained by Nermut' et al. (2015) based on Czech material, but there is one notable difference: larger anal body diameter in females and males from California (72-85 vs 23-43 $\mu \mathrm{m}$ and 45-48 vs 23-38 $\mu \mathrm{m}$, respectively).

## Description of Kleinform from Arion rufus strain

ITD792 (Figs. 1B, D, 2D-F)
Host: Arion rufus (Linnaeus).
Locality: Garden center in McKinleyville town center in Northern California on 18.v. 2015 (GPS coordinates: $\left.40^{\circ} 56^{\prime} 16^{\prime \prime} \mathrm{N}, 124^{\circ} 06^{\prime} 05^{\prime \prime} \mathrm{W}\right)$.
Voucher material: Twenty females and seventeen males on slides \# SMNH-153529-SMNH-153536 deposited in the general invertebrate collection of the Department of Zoology, Swedish Museum of Natural History, Stockholm, Sweden.
General [Based on 22 specimens; see measurements in Table 5.] Body $0.7-0.9 \mathrm{~mm}$ long in females and $0.6-0.8 \mathrm{~mm}$ long in males. When killed by heat, females almost straight and males slightly arcuate ventrad, more strongly arcuate in the posterior end. Cuticle finely annulated, annules less prominent in LM, c. 0.5 wide. Lateral field not seen in LM. Anterior end gradually tapering. Lip region rounded, continuous with body contour. Six rounded lips grouped in 3 pairs, 1 dorsal and 2 ventrolateral, carrying 6 inner labial, 6 outer labial and 4 cephalic papilliform sensilla and 2 small oval amphids. Stoma somewhat longer than lip region diameter. Cheilostom broad, with thick rounded rhabdia; gymnostom short; stegostom funnelshaped, with strongly sclerotised lining and small denticles in its dorsal sector. Pharynx muscular; corpus cylindrical, 1.9-2.8 times as long as isthmus, widening posteriorly to a non-valvular metacorpus; isthmus narrower, demarcated by a break in muscular tissue; basal bulb oval, with strongly developed valves. Nerve-ring surrounding isthmus. Excretory
pore opening at middle or posterior part of isthmus or anterior part of basal bulb. Deirids not observed.

Female. Reproductive system didelphic, amphidelphic, ovaries reflexed, ovary flexures reaching vulval region. Oviducts filled with sperm. Gonads filled with oöcytes and hatched juveniles. Vulva a transverse slit, vulval lips not protruding, with epiptygmata; vagina $c .1 / 4-1 / 3$ of VBD. Tail conoid, elongate, tapering to a finely pointed terminus. Rectum short, less than one time ABD long. Phasmids are not discernible in our specimens.

Male. Similar to female in most respects, except for the sexual characters. Reproductive system monorchic, testis reflexed dorsad anteriorly. Spicules paired with weakly arcuate shaft and manubria bent sideways. Gubernaculum with robust dorsal apophysis. Pads on posterior lip of cloaca indistinct. Genital papillae distributed as follows: a single midventral large pad-like precloacal papilla 42-66 anterior to cloaca; 2 subventral precloacal pairs; 1 subventral adcloacal pair; 1 lateral pair near cloaca; and 1 subventral and 1 subdorsal caudal pair at midtail; other papillae indistinct. Phasmids are not discernible in our specimens. Tail differently shaped than in female, strongly curved ventrad, conoid with a 36-48 long mucro ending in a pointed terminus.

## Remarks

As in the Großform, the present material of the Kleinform of $A$. appendiculatum agrees well with the description by Mengert (1953) (see Table 5). Likewise, our study of the Californian specimens also largely corroborates the results obtained by Nermut' et al. (2015) with the Czech material. There are however some notable differences: the Czech specimens are generally of bigger size than the Californian specimens (body length 889-1,454 vs 781-905 $\mu \mathrm{m}$ for females; 848-1,010 vs 651-806 $\mu \mathrm{m}$ for males), and have longer spicules ( $28-35$ vs 26-29 $\mu \mathrm{m}$ ) and gubernaculum (25-37 vs 24-27 $\mu \mathrm{m}$ ).

Type-locality: Potted plant in a garden center in San Mateo, California, on 27.i. 2013 (GPS coordinates: $\left.37^{\circ} 34^{\prime} 18.62^{\prime \prime} \mathrm{N}, 122^{\circ} 18^{\prime} 56.62^{\prime \prime} \mathrm{W}\right)$.
Type-material: Holotype female, four paratype females and six paratype males on slide \# SMNH-Type- 8790 deposited in the invertebrate type collection of the Department of Zoology, Swedish Museum of Natural History, Stockholm, Sweden.

Description of Kleinform cultured on agar
(Figs. 1E-F, 3-5)

General [Based on 11 specimens; see measurements in Table 5.] Body $1.2-1.3 \mathrm{~mm}$ long in females and $0.9-1.0 \mathrm{~mm}$ long in males. When killed by heat, females almost straight and males slightly arcuate ventrad, more strongly arcuate in the posterior end. Cuticle finely annulated, annules less prominent in LM, $c .1$ wide. Lateral field not seen in LM or SEM. Anterior end gradually tapering. Lip region rounded, continuous with body contour. Six rounded lips grouped in 3 pairs, 1 dorsal and 2 ventrolateral, carrying 6 inner labial, 6 outer labial and 4 cephalic papilliform sensilla and 2 small oval amphids. Stoma somewhat longer than the lip region diameter. Cheilostom broad, with bacilliform rhabdia; gymnostom short; stegostom funnel-shaped, with strongly sclerotised lining and prominent denticles in its dorsal sector. Pharynx muscular; corpus cylindrical, 2.1-2.4 times as long as isthmus, widening posteriorly to a non-valvular metacorpus; isthmus narrower, demarcated by a break in muscular tissue; basal bulb oval, with strongly developed valves. Nerve-ring surrounding isthmus. Excretory pore opening at isthmus-bulb junction or at terminal bulb. Deirids not observed.

Female. Reproductive system didelphic, amphidelphic, ovaries reflexed, posterior ovary flexure reaching almost to vulva. Oviducts filled with sperm. Gonads filled with oöcytes and hatched juveniles. Vulva a transverse slit, vulval lips not protruding, with epiptygmata; vagina $c .1 / 3$ of VBD. Tail conoid, elongate, tapering to a finely pointed terminus. Rectum short, about one time ABD long. Phasmids at one-third to half of tail length.

Male. Similar to female in most respects, except for the sexual characters. Reproductive system

monorchic, testis reflexed dorsad anteriorly. Spicules paired, with weakly arcuate fusiform shaft and manubria bent sideways. Gubernaculum with robust dorsal apophysis. Two sublateral pads on the posterior lip of cloaca. Genital papillae distributed as follows: a single midventral large pad-like precloacal papilla

58-74 anterior to cloaca; 2 subventral precloacal pairs (at 54-66 and 15-22 anterior to cloaca, respectively); 1 subventral adcloacal pair; 1 lateral pair short distance posterior to cloaca; and 1 subventral and 1 subdorsal caudal pair at midtail. Phasmids at about half of tail length, between subventral and subdorsal

Fig. 7 Secondary structure-based multiple sequence alignment of partial 28S rRNA of four species of the family Alloionematidae (consensus sequences of Alloionema appendiculatum and A. similis n. sp.), showing differences between species; dots indicate nucleotides identical to those in the top sequence, dashes indicate alignment gaps (indels)
caudal papillae. Tail differently shaped than in female, strongly curved ventrad, conoid with a 33-45 long mucro ending in a pointed terminus.

## Remarks

The new species is morphologically very similar to Alloionema appendiculatum, hence it is given the name Alloionema similis n . sp. Morphologically, it agrees well with the description by Mengert (1953) (see Table 5), except for the size of the Kleinform which are generally bigger in this study (body length 1,189-1,309 vs 922-1,073 $\mu \mathrm{m}$ for females; $910-1,029$ vs $561-926 \mu \mathrm{~m}$ for males). Similar size differences were obtained by Nermut' et al. (2015) and a reason for these variations could be the food source or culture media used. Another difference is the number of male genital papillae, which
were recorded as being five by Mengert (1953), but were revealed by SEM to be six (Nermut' et al., 2015; this paper). The new species is morphologically very similar to the Czech specimens of $A$. appendiculatum described by Nermut' et al. (2015), but there are some differences: (i) more posterior position of the excretory pore in the Kleinform females (169-188 vs 117-164 $\mu \mathrm{m}$ from anterior end); (ii) smaller anal body diameter in Kleinform females (24-26 vs 27-39 $\mu \mathrm{m}$ ); and (iii) longer tail in Kleinform males (98-112 vs 56-79 $\mu \mathrm{m}$; с $=9.2-9.9$ vs $11.4-17.8 ; c^{\prime}=3.0-3.4$ vs $3.9-6.9$ ). There are some problems with the latter comparison since the tail length 56-79 $\mu \mathrm{m}$ and anal body diameter $27.4-35.2 \mu \mathrm{~m}$ will give a c' of about 2 and not 3.9-6.9, thus a mistake is possibly made in Table 1 of Nermut' et al. (2015). There are, however, substantial differences in both 18 S and 28 S rDNA sequences between Alloionema similis n . sp. and

A. appendiculatum

A. similis A.

B
A. appendiculatum

A. appendiculatum

males, we are confident that Alloionema similis n . sp. does not represent the same organism as the nematode described by Chitwood \& McIntosh (1934). It is also worth noting that these authors illustrated the lip region and subcephalic region of A. appendiculatum var. dubia as being cylindrical rather than clearly tapering, which is a condition not seen in any of our material nor shown in any of the illustrations by Nermut' et al. (2015). For the time being we therefore consider it best to neither elevate A. appendiculatum var. dubia to a separate species, nor to treat as a match with A. appendiculatum (sensu stricto). The resolution of its status must await new collections from Succinea snails obtained near the location reported by Chitwood \& McIntosh (a swamp near Piscataway in Maryland).

## Discussion

Interspecific variability of ribosomal RNA gene sequences

The four-taxa secondary-structure based multiple sequence alignments of 18 S and 28 S rRNA genes of all current members of the family Alloionematidae contained 1,544 and 893 positions respectively. There
were 27 ( 12 within 18 S and 15 within 28 S rDNA) unambiguous autapomorphies for Alloionema similis n. sp.; 26 ( 20 within 18 S and 6 within 28 S rDNA) for A. appendiculatum; 31 ( 21 within 18 S and 10 within 28 S rDNA) for Neoalloionema indicum; and 24 (14 within 18 S and 10 within 28 S rDNA) for $N$. tricaudatum (Figs. 6-7). Not all apomorphies can be accounted for within the 28 S rRNA gene due to the fact that large part of the gene was not sequenced for $N$. tricaudatum. Molecular differences between Alloionema appendiculatum and $A$. similis n . sp. are not limited to random mutations, but include a number of compensatory substitutions in the hairpins $18,23 \mathrm{e} / 1-$ 23e/2, b13_1, c2_b, c2_c and d5 of the secondary structure of both 18S and 28S rRNA genes (Fig. 8).

Phylogenetic analysis
The combination of characters: stoma short with sclerotised anterior part and non-sclerotised funnelshaped posterior part, median bulb without valves, basal bulb with valves, female reproductive system didelphic and amphidelphic with reflexed ovaries, and male tail without bursa, makes the systematic position of Alloionema somewhat uncertain. For Alloionema and Rhabditophanes Fuchs, 1930, Chitwood \&

Fig. 9 Majority-rule consensus tree of the Bayesian phylogenetic analysis of concatenated alignment of 18S rRNA and D1-D2-D3 domains of 28 S rRNA, rooted using Rhabditophanes sp. KR3021, branch lengths represent the mean posterior estimates of the expected number of substitutions per site

McIntosh (1934) proposed a new subfamily in the family Diplogastridae Micoletzky, 1922, the Alloionematinae Chitwood \& McIntosh, 1934, differing from Diplogastrinae by the presence of a basal bulb with valves. Goodey (1963) placed Alloionematinae in the family Rhabditidae Örley, 1880 while Andrássy (1976) raised it to superfamily and family level (Alloionematoidea Chitwood \& McIntosh, 1934 and Alloionematidae Chitwood \& McIntosh, 1934) in Rhabditina. Based on molecular characters, De Ley \& Blaxter (2004) placed Alloionematidae in the superfamily Strongyloidoidea Chitwood \& McIntosh, 1934 in the infraorder Panagrolaimomorpha De Ley \& Blaxter, 2004. In a study on the molecular phylogeny of slug-parasitic nematodes, based on 18S rRNA gene sequences, $A$. appendiculatum clustered in a clade with species of Strongyloides Grassi, 1879 and Rhabditophanes Fuchs, 1930 (see Ross et al., 2010). In the study by Nermut' et al. (2015), the molecular evidence from several ribosomal genes also generated a strongly supported clade including A. appendiculatum and species of Strongyloides, Parastrongyloides Morgan, 1928 and Rhabditophanes. In our analysis (Fig. 9) both A. appendiculatum and $A$. similis were placed as sister taxa in a strongly supported clade. Neoalloionema tricaudatum Ivanova, Pham Van Luc \& Spiridonov, 2016 and N. indicum Nermut', Půžà \& Mráček, 2016. formed a distinct strongly supported clade, in agreement with a recent study published by Nermut' et al. (2016).

Funding This research was partially funded by the California Department of Food and Agriculture 2012 Specialty Crop Block Grant SCB12059 and by the United States Department of Agriculture National Institute of Food and Agriculture, MultiState Project CA-R-ENT-7607-MS.
