To further understand the fundamental chemical processes governing the migration of transuranic contaminants in the environment, we are currently investigating the interactions between neptunium and manganese oxide/hydroxides. Manganese oxides, present as minor phases in the vadose zone, have been previously shown to sequester large quantities of plutonium under environmental conditions [1,2]. We are now continuing these studies with neptunium(V). Sorption onto manganite and hausmannite has been studied as a function of neptunium concentration and pH. XAFS spectra taken at the neptunium L_{III} edge, have been used to determine the oxidation state of the interacting neptunium as well as a structural probe. Neptunium is expected to sorb to these mineral surfaces in an inner-sphere coordination consistent with other actinides. Our preliminary experimental results indicate interesting redox behavior in this system.
