## ABSTRACT

Solutions of Laplace's equation for azimuthally symmetrical potentials in cylindrical coordinates are found which can be correlated with two-dimensional multipoles in planes  $\theta = \text{const.}$  Formulas are presented by which the coefficients for linear combinations of these solutions can be calculated to describe fields whose values are known along given axial or radial lines.

---

\* Work performed under the auspices of the Energy Research and Development Administration.

An azimuthally symmetrical electrostatic or magnetostatic field is described in a cylindrical coordinate system  $\rho, \zeta, \theta$  by a scalar potential  $\phi$  which is a function of  $\rho$  and  $\zeta$  only. Set up a rectangular coordinate system in a  $\rho, \zeta$  plane with the origin at  $\rho = \rho_0, \zeta = 0$  and having the dimensionless coordinates  $r, x, y$ , where  $r = \rho/\rho_0, x = r-1, y = \zeta/\rho_0$ . It is the purpose of this note to find a set of functions of these variables which are solutions of Laplace's equation in cylindrical coordinates but which, when expanded in power series in  $x$  and  $y$ , are equal to two-dimensional multipoles plus additional higher terms. The two-dimensional multipole potentials can be obtained from the complex expression  $(x + iy)^m$ , which is expanded and the real and imaginary parts separated, the real part giving a  $2m$ -pole with the field along the  $x$ -axis at  $y=0$ , and the imaginary part giving a  $2m$ -pole with the field perpendicular to the  $x$ -axis at  $y=0$ ; for example, the quadrupole potentials  $x^2 - y^2$  (real part) and  $2xy$  (imaginary part).

The procedure followed is to seek solutions of Laplace's equation:

$$\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \phi}{\partial r} \right) + \frac{\partial^2 \phi}{\partial y^2} = 0 \quad (1)$$

in the form:

$$\phi = f_m(r) + f_{m-1}(r)y - f_{m-2}(r) \frac{y^2}{2!} - f_{m-3}(r) \frac{y^3}{3!} + \dots \quad (2)$$

with the signs alternating in pairs.

It is found that Eq. (2) separates into independent even and odd series, and that the functions  $f_n(r)$  obey the recursion relation:

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{df_n}{dr} \right) = f_{n-2} \quad (3)$$

If any one of the functions  $f_n(r)$  is given an assigned form, the functions to the right in the series are found by differentiation and to the left (i.e., in order of increasing  $n$ ) by integration, involving two constants of integration at each step. Now an additional condition is put on the solutions; the series are made to terminate at  $f_0(r)$  and  $f_1(r)$ . According to Eq. (3), this occurs if  $f_0(r) = 1$  or  $\ln r$  and  $f_1(r) = 1$  or  $\ln r$ . These four possibilities lead to a redundancy in the set of solutions obtained by considering all values of  $m$  in Eq. (2), and it is sufficient to take  $f_0(r) = 1$ ,  $f_1(r) = \ln r$ .

The continuation to higher orders of  $f_n(r)$  by integration gives a branching sequence because of the constants of integration, but no generality is lost if a particular choice of the constants is made; the general case can be represented as a linear combination of the resulting set of solutions. The choice made is to treat the integrations as definite integrals starting at  $r = 1$ , i.e.,

$$f_n = \int_1^r \frac{1}{r} \left[ \int_1^r r f_{n-2} dr \right] dr \quad (4)$$

This choice has the valuable consequence that the leading term in the power series expansion in  $x$  of  $f_n(r)$  is  $\frac{1}{n!} x^n$ , satisfying the condition set in the beginning that the solutions should equal the two-dimensional multipoles in the lowest order.

It is convenient to introduce the notation  $F_n(r) = n! f_n(r)$ ; then the set of solutions can be represented in the format used for the two-dimensional case, i.e., expand  $(x + iy)^m$ , separate the real and imaginary parts, and replace  $x^n$  by  $F_n(r)$ , giving the solutions that will be called

$\phi_m^r$  and  $\phi_m^i$ . The functions  $F_n(r)$  up to  $n=6$  are given below, with the power series expansions of  $F_n(1+x)$  through  $x^7$ .

$$F_0 = 1$$

$$F_1 = \ln r = x - \frac{1}{2} x^2 + \frac{1}{3} x^3 - \frac{1}{4} x^4 + \frac{1}{5} x^5 - \frac{1}{6} x^6 + \frac{1}{7} x^7 + \dots$$

$$F_2 = \frac{1}{2}(r^2 - 1) - \ln r = x^2 - \frac{1}{3} x^3 + \frac{1}{4} x^4 - \frac{1}{5} x^5 + \frac{1}{6} x^6 - \frac{1}{7} x^7 + \dots$$

$$F_3 = \frac{3}{2} \left[ -(r^2 - 1) + (r^2 + 1) \ln r \right] = x^3 - \frac{1}{2} x^4 + \frac{7}{20} x^5 - \frac{11}{40} x^6 + \frac{8}{35} x^7 + \dots$$

$$F_4 = 3 \left[ \frac{1}{8}(r^4 - 1) + \frac{1}{2}(r^2 - 1) - (r^2 + \frac{1}{2}) \ln r \right] = x^4 - \frac{2}{5} x^5 + \frac{3}{10} x^6 - \frac{17}{20} x^7 + \dots$$

$$F_5 = \frac{15}{2} \left[ -\frac{3}{8}(r^4 - 1) + (\frac{1}{4}r^4 + r^2 + \frac{1}{4}) \ln r \right] = x^5 - \frac{1}{2} x^6 + \frac{5}{14} x^7 + \dots$$

$$F_6 = \frac{45}{4} \left[ \frac{1}{36}(r^6 - 1) + \frac{1}{2}(r^4 - 1) - \frac{1}{4}(r^2 - 1) - (\frac{1}{2}r^4 + r^2 + \frac{1}{6}) \ln r \right] = x^6 - \frac{3}{7} x^7 + \dots$$

The magnetostatic field can equally well be represented by a vector potential  $A$ , which can be simply represented in terms of the functions  $F_n(r)$  by the following procedure: expand  $-i(x+iy)^m$ , separate the real and imaginary parts, and replace  $x^n$  by  $\frac{1}{n+1} \frac{d}{dr} F_{n+1}(r)$ , including the replacement of  $x^0$  by  $\frac{d}{dr} F_1(r) = \frac{1}{r}$ . The real part of this is a vector potential  $A_m^r$  which gives the same field as the scalar potential  $\phi_m^r$ , and similarly for the imaginary parts.

Thus, for the quadrupole,  $(x+iy)^2 = x^2 - y^2 + 2ixy$  and  $-i(x+iy)^2 = 2xy + i(y^2 - x^2)$ , from which:

$$\phi_2^r = F_2 - F_0 y^2 = \frac{1}{2} (r^2 - 1) - \ln r - y^2$$

$$\phi_2^i = 2F_1 y = 2y \ln r$$

$$A_2^r = 2 \cdot \frac{1}{2} \frac{dF_2}{dr} y = \left(r - \frac{1}{r}\right) y$$

$$A_2^i = \frac{dF_1}{dr} y^2 - \frac{1}{3} \frac{dF_3}{dr} = \frac{1}{2} \left(r - \frac{1}{r}\right) - r \ln r + \frac{y^2}{r}$$

The field components are, for the real part:

$$-B_x = \frac{\partial \phi}{\partial r} = \frac{\partial A}{\partial y} = r - \frac{1}{r} = 2x - x^2 + x^3 + \dots$$

$$-B_y = \frac{\partial \phi}{\partial y} = -\frac{1}{r} \frac{\partial(rA)}{\partial r} = -2y$$

and for the imaginary part:

$$-B_x = 2 \frac{y}{r} = 2y - 2xy + 2x^2y + \dots$$

$$-B_y = 2 \ln r = 2x - x^2 + \frac{2}{3} x^3 + \dots$$

Any field expandable as a power series in  $x$  and  $y$  can be represented by a linear combination of these solutions, which can be written:

$$\phi = \sum_{m=1} \left[ A_m \phi_m^r + B_m \phi_m^i \right] \quad (5)$$

where  $A_m$  and  $B_m$  are numerical coefficients. The field components  $B_x$  and  $B_y$  at  $x=0$  are then given by:

$$-B_x = A_1 + 2B_2y - 3A_3y^2 - 4B_4y^3 + 5A_5y^4 + 6B_6y^5 + \dots \quad (6)$$

$$-B_y = B_1 - 2A_2y - 3B_3y^2 + 4A_4y^3 + 5B_5y^4 - 6A_6y^5 + \dots$$

and at  $y=0$  by:

$$-B_x = \frac{d}{dr} \sum_{m=1} A_m F_m(r)$$

$$-B_y = \sum_{m=1} m B_m F_{m-1}(r) \quad (7)$$

From Eq. (6) it is seen that there is a one-to-one relation between the coefficients  $A_m$  and  $B_m$  and the coefficients in the power series expansions in  $y$  of the field components at  $x=0$ , showing that any field can be fitted by these solutions.

At  $y=0$ , letting  $-B_x = \sum_{k=0} a_k x^k$  and  $-B_y = \sum_{k=0} b_k x^k$ , and using in Eq. (7) the series expansions in  $x$  of  $F_n(r)$ , the following relations between the coefficients  $A_m, B_m$  and  $a_k, b_k$  are found:

$$A_1 = a_0$$

$$A_2 = \frac{1}{2} a_0 + \frac{1}{2} a_1$$

$$A_3 = -\frac{1}{6} a_0 + \frac{1}{6} a_1 + \frac{1}{3} a_2$$

$$A_4 = \frac{1}{24} a_0 - \frac{1}{24} a_1 + \frac{1}{6} a_2 + \frac{1}{4} a_3$$

$$A_5 = -\frac{1}{40} a_0 + \frac{1}{40} a_1 - \frac{1}{20} a_2 + \frac{1}{10} a_3 + \frac{1}{5} a_4$$

$$A_6 = \frac{1}{80} a_0 - \frac{1}{80} a_1 + \frac{1}{60} a_2 - \frac{1}{40} a_3 + \frac{1}{10} a_4 + \frac{1}{6} a_5$$

$$A_7 = -\frac{1}{112} a_0 + \frac{1}{112} a_1 - \frac{3}{280} a_2 + \frac{1}{70} a_3 - \frac{1}{35} a_4 + \frac{1}{14} a_5 + \frac{1}{7} a_6$$

$$B_1 = b_0$$

$$B_2 = \frac{1}{2} b_1$$

$$B_3 = \frac{1}{6} b_1 + \frac{1}{3} b_2$$

$$B_4 = -\frac{1}{24} b_1 + \frac{1}{12} b_2 + \frac{1}{4} b_3$$

$$B_5 = \frac{1}{120} b_1 - \frac{1}{60} b_2 + \frac{1}{10} b_3 + \frac{1}{5} b_4$$

$$B_6 = -\frac{1}{240} b_1 + \frac{1}{120} b_2 - \frac{1}{40} b_3 + \frac{1}{15} b_4 + \frac{1}{6} b_5$$

$$B_7 = \frac{1}{560} b_1 - \frac{1}{280} b_2 + \frac{1}{140} b_3 - \frac{1}{70} b_4 + \frac{1}{14} b_5 + \frac{1}{7} b_6$$

Any power of  $x$  in the fields thus introduces solutions of that order and higher. It is not possible to find any combination of solutions that equals the two-dimensional multipoles for more than one order, the lowest one occurring.

The solutions  $\phi_m^r$  and  $\phi_m^i$  can be related to solutions in terms of Bessel functions. As an example, consider the potential  $\phi = J_0(r) \sinh y$ . The field components at  $x=0$  ( $r=1$ ) are compared with Eq. (6), with the result that:

$$\phi = J_0(1) \left( \phi_1^i - \frac{1}{3!} \phi_3^i + \frac{1}{5!} \phi_5^i + \dots \right) - J_1(1) \left( \frac{1}{2!} \phi_2^i - \frac{1}{4!} \phi_4^i + \frac{1}{6!} \phi_6^i + \dots \right)$$

(I wish to express my gratitude to Frank Krienen of CERN, whose solution in the case here called  $\phi_2^r$  led me to seek a generalization to other cases.)
