Abstract: Can human-normed personality scales alone give us a full picture of the attribution of personality to virtual agents? In humans, personality traits are often immediately ascribed: first impressions, influenced by posture and gesture, can be strong, lasting and accurate. Is there a similar immediate attribution of personality for virtual agents that can be similarly influenced by posture and gesture? Our study uses an open-ended question alongside a traditional Big Five personality through gesture. Though inventory scores show that considered impressions are in line with the agent's intended personality trait, we also show a mismatch between initial and considered impressions in virtual agent personality perception. We suggest that first impressions derived from open-ended questions provide information complementary to the traditional personality inventory.
