Hepatocyte Nuclear Factor 4 $\alpha$  (HNF4 $\alpha$ ), a master regulator of hepatocyte differentiation, is regulated by two promoters (P1 and P2) which drive the expression of different isoforms. P1-HNF4 $\alpha$  is the major isoform in the adult liver while P2-HNF4 $\alpha$  is thought to be expressed only in fetal liver and liver cancer. Here, we show that P2-HNF4 $\alpha$  is indeed expressed in the normal adult liver at Zeitgeber time (ZT)9 and ZT21. Using exon swap mice that express only P2-HNF4 $\alpha$  we show that this isoform orchestrates a distinct transcriptome and metabolome via unique chromatin and protein-protein interactions, including with different clock proteins at different times of the day leading to subtle differences in circadian gene regulation. Furthermore, deletion of the *Clock* gene alters the circadian oscillation of P2- (but not P1-)HNF4 $\alpha$  RNA, revealing a complex feedback loop between the HNF4 $\alpha$  isoforms and the hepatic clock. Finally, we demonstrate that while P1-HNF4 $\alpha$  drives gluconeogenesis, P2-HNF4 $\alpha$  drives ketogenesis and is required for elevated levels of ketone bodies in female mice. Taken together, we propose that the highly conserved two-promoter structure of the *Hnf4a* gene is an evolutionarily conserved mechanism to maintain the balance between gluconeogenesis and ketogenesis in the liver in a circadian fashion.

cytochrome P450, metabolic switch, sex-specific gene expression, fasting, circadian clock, ketogenesis, alternative promoter, nuclear receptor

## Introduction

Roughly 30% of human genes contain alternative promoters and yet the functional significance of the majority of those promoters, and the transcripts they generate, is woefully understudied. One such gene is the nuclear receptor (NR) Hepatocyte Nuclear Factor 4 alpha (HNF4 $\alpha$ ), a liver-enriched transcription factor (TF) best known as a master regulator of liver-specific gene expression and mutated in Maturity Onset Diabetes of the Young 1 (MODY1) (1, 2). In mice, HNF4 $\alpha$  is essential for fetal liver function (3) and liver knockout (KO) mice die within six weeks of birth with a fatty liver (4).

The human *HNF4A* and mouse *Hnf4a* genes are highly conserved and regulated by proximal P1 and distal P2 promoters. P1 drives the expression of transcripts containing exon 1A while P2 transcripts contain exon 1D, resulting in a loss of the N-terminal activation function 1 (AF-1). In the adult liver P1 is presumed to be the only active promoter, while during fetal liver development both P1 and P2 are active (5, 6). The first P2-HNF4 $\alpha$  transcript cloned, HNF4 $\alpha$ 7, was from the embryonal carcinoma cell line F9 (7), suggesting that it might play a role in cancer as well as fetal development. P1-HNF4 $\alpha$  is downregulated in liver cancer and acts as a tumor suppressor (8–12), while overexpression of P2-HNF4 $\alpha$  is linked to poor prognosis in hepatocellular carcinoma (HCC) (13).

The circadian clock regulates all aspects of physiology, including lipid metabolism. The liver is a major driver of the peripheral clock which is entrained by feeding and plays a role in fatty liver disease as well as hormonal homeostasis (14–19). While P2-HNF4 $\alpha$  is not typically found in normal adult liver, it is expressed under certain stress conditions that involve metabolic adaptation by cells, such as cancer and high fat diet (HFD) feeding (12, 20). Furthermore, both cancer and HFD-induced obesity are known to be exacerbated by disruption of circadian rhythms (21, 22). Since HNF4 $\alpha$  is a known driver of liver metabolism and has been shown to play a role in hepatic circadian rhythms (2), we hypothesized that P2-HNF4 $\alpha$  may play a unique role in liver metabolism and may intersect with the circadian clock.

To address the physiological role of P2-HNF4 $\alpha$ , we employed exon swap mice ( $\alpha$ 7HMZ), which substitute exon 1A with exon 1D in the P1 promoter and demonstrate a role for the AF-1 domain *in vivo* (23). We compared the  $\alpha$ 7HMZ adult mice (express only P2-HNF4 $\alpha$ ) to wildtype (WT) mice (express P1-HNF4 $\alpha$ ) using RNA-seq, ChIP-seq, rapid immunoprecipitation mass spectrometry of endogenous proteins (RIME), protein binding microarrays (PBMs) and metabolomics. An orchestrated, altered hepatic transcriptome in P2-HNF4 $\alpha$  livers reveals large, significant differences in several cytochrome P450 transcripts and small but significant differences in key clock regulators, as well as expression of female-specific genes in the male livers. The distinct P2-HNF4 $\alpha$  transcriptome appears to be due to altered protein-protein interactions, as well as altered chromatin binding but not differences in innate DNA binding specificity. Expression of P2-HNF4 $\alpha$  is observed at Zeitgeber time (ZT) 9 and ZT21 in WT adult livers, and is upregulated in *Clock*-

deficient mice. The P2-HNF4 $\alpha$  hepatic metabolome is enriched in lipids and ketone bodies while mice expressing only P1-HNF4 $\alpha$  exhibit enhanced gluconeogenesis and lack the elevated levels of ketone bodies normally found in females (24). Given that the P1/P2 promoter structure of the *Hnf4a* gene and many of its target genes are conserved across more than 90 million years (2, 25), our results suggest that expression of P2-HNF4 $\alpha$  in the liver is an evolutionarily conserved mechanism to balance carbohydrate and fatty acid metabolism during the circadian cycle.

## Results

### The P2-HNF4 $\alpha$ transcriptome has neither a fetal nor a cancer profile

Exon swap  $\alpha$ 7HMZ mice were verified to express P2-HNF4 $\alpha$ , but not P1-HNF4 $\alpha$ , RNA and protein in adult liver (Figures 1A–C). RNA-seq of adult male livers revealed a significant difference ( $\text{padj} \leq 0.01$ ) in ~1600 genes between WT and  $\alpha$ 7HMZ, both up- (831) and downregulated (792) in  $\alpha$ 7HMZ (Figure 1D). The most downregulated (e.g., *Scnn1a*, *Cyp2c50*, *Rdh16f2*, *Ces2e*) and upregulated genes (e.g., *Rad51b*, *Pcp4l1*, *Cyp2b13*, *Cyp2b9*) exhibited nearly 30-fold effects (Figure 1E). Kegg pathway analysis revealed discrete metabolic pathways upregulated in  $\alpha$ 7HMZ versus WT livers (e.g., oxidative phosphorylation and non-alcoholic fatty liver disease), suggesting a purposeful alteration in gene expression (Figure 1F). For example, cell adhesion molecules, drug and linoleic acid metabolism and steroid hormone biosynthesis genes were enriched in WT mice while the ribosome, oxidative phosphorylation and RNA transport and processing were enriched in  $\alpha$ 7HMZ. Several disease pathways were also enriched among the P2-specific genes, including non-alcoholic fatty liver disease (NAFLD), viral carcinogenesis, alcoholism and neurological diseases (Parkinson's, Huntington's, Alzheimer's) (Figure 1F). Comparison of  $\alpha$ 7HMZ versus WT differentially expressed genes (DEGs) with HNF4 $\alpha$  liver KO expression data (26) revealed that ~100 of the WT-specific genes (but none of the  $\alpha$ 7HMZ-specific genes) were downregulated in the HNF4 $\alpha$  KO (Supplementary Figure 1A), confirming P1-HNF4 $\alpha$  predominance in the adult liver.

The  $\alpha$ 7HMZ versus WT DEGs were compared with adult versus fetal (E14.5) liver DEGs (Figure 1G). More than two thirds of the genes upregulated in WT livers were also upregulated in the adult liver, while ~10% were enriched in fetal livers (562 versus 87, respectively). In contrast,  $\alpha$ 7HMZ-upregulated genes were more evenly split between adult and fetal liver (Figure 1G). Interestingly, alpha-fetoprotein (*Afp*) and other fetal liver genes were expressed at a lower level in  $\alpha$ 7HMZ (Supplementary Figure 1B), suggesting that the  $\alpha$ 7HMZ “program” is not simply a fetal one. Furthermore, while  $\alpha$ 7HMZ mice have a significantly ( $p < 0.01$ ) higher liver-to-body weight ratio than WT or  $\alpha$ 1HMZ (exon 1A swapped for exon 1D in the P2 promoter) at postnatal day 14, the reverse ( $\alpha$ 1HMZ >  $\alpha$ 7HMZ) is observed at

See Supplementary Tables 1, 2 for full lists of genes and Supplementary Figure 1 for additional comparisons.

livers at 10:30 AM (ZT3.5), including several cytochrome P450 (*Cyp*) genes and the NR gene CAR (*Nr1i3*) (Figure 2B).

To examine the impact of P2-HNF4 $\alpha$  on other NR genes, we compared the FPKM values of all NR genes across all three time points. HNF4 $\alpha$  was the most highly expressed NR in both WT and  $\alpha$ 7HMZ; the next most abundant NR, *Rxra*, was expressed at roughly 25% the level of *Hnf4a* (Supplementary Figure 2A). While most NRs displayed similar circadian oscillations in WT and  $\alpha$ 7HMZ livers, there were some notable exceptions: CAR (*Nr1i3*) was significantly downregulated in  $\alpha$ 7HMZ at all three time points (Supplementary Figure 2A, arrow). Rev-Erb $\beta$  (*Nr1d2*), ROR $\gamma$  (*Rorc*) and PPAR $\alpha$  (*Ppara*), all involved in the transcriptional feedback loop that drives circadian expression in the liver (28), exhibited significantly reduced expression in  $\alpha$ 7HMZ livers at one time point (Supplementary Figures 2B), again suggesting a decreased responsiveness to the clock.

## HNF4 $\alpha$ is one of the most highly expressed TFs in the liver

Consistent with the relative abundance of HNF4 $\alpha$  protein in the adult liver (1, 32), HNF4 $\alpha$  had one of the highest transcript levels of any TF, higher even than subunits of RNA polymerase II (e.g., *Polr2m*, *Polr2b*) (Figure 2C). The other liver-enriched TFs (LETFS, *Cebpa*, *Onecut2*, *Foxa1*, *Hnf1a*, *HNF1b*) had transcript levels at least 10-fold lower than *Hnf4a* (Figure 2C, inset, arrows), consistent with HNF4 $\alpha$  being a major regulator of liver-specific gene expression. Several TFs showed statistically significant differences between WT and  $\alpha$ 7HMZ (Figure 2C, asterisk), including those known to play a role in sexual dimorphic gene expression (*Stat5a*, *Stat5b*, *Ahr*, *Nr0b2*) (Figure 2D and Supplementary Figure 2B) (33, 34). Interestingly, *Esr1* (estrogen receptor alpha, ER $\alpha$ ) expression was significantly upregulated in  $\alpha$ 7HMZ while *Ar* (androgen receptor, AR) was downregulated (Figure 2E), suggesting a potential “feminization” of the  $\alpha$ 7HMZ liver.

## P2-HNF4 $\alpha$ dysregulates the expression of genes involved in fatty acid, steroid and xenobiotic/drug metabolism

HNF4 $\alpha$  is a known regulator of Phase I and Phase II enzymes involved in the detoxification of drugs and xenobiotics (35) and has been computationally linked to sexually dimorphic and circadian expression of those genes (36). Therefore, we examined the level of expression of all cytochrome P450 (*Cyp*) genes (Phase I) as well as glutathione S-transferases (*Gst*) and UDP glucuronosyltransferases (*Ugt*) (Phase II). While the diurnal pattern of expression was generally the same in WT and  $\alpha$ 7HMZ, the absolute level of expression was often altered (Figure 3A). For example, the expression of *Cyp2c50* and *Cyp2c54*, which encode enzymes that metabolize linoleic acid, the endogenous HNF4 $\alpha$  ligand (37), was much lower in  $\alpha$ 7HMZ livers (Figures 1E, 3A). Several *Ugt* genes were dysregulated and metabolomic analysis revealed a significant (padj <0.01) decrease in UDP glucuronic

acid in  $\alpha$ 7HMZ livers (Figure 3A, bottom). Since glucose is needed to make UDP glucuronic acid, this decrease could be linked to carbohydrate metabolism.

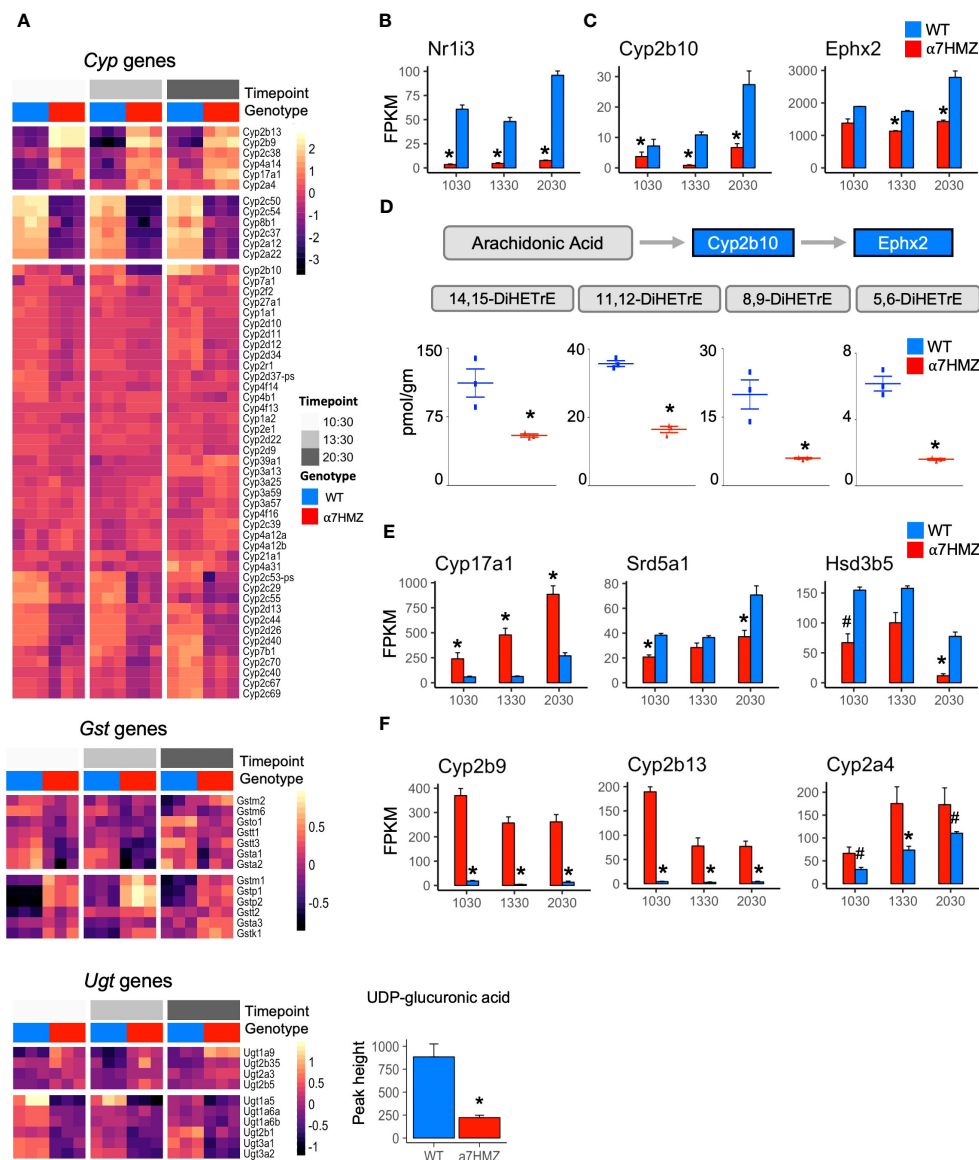

The NR CAR (*Nr1i3*) is downregulated 10- to 18-fold in  $\alpha$ 7HMZ mice (Figure 3B), as reported previously (23), and could explain some of the changes in *Cyp* gene expression observed in  $\alpha$ 7HMZ livers (38). In contrast, the expression of PXR (*Nr1i2*), which is known to co-regulate many Phase I and II genes with CAR and to be upregulated by HNF4 $\alpha$  in fetal liver (38, 39), was not altered (Supplementary Figure 2C), suggesting that the primary role of P2-HNF4 $\alpha$  in the adult liver may not be to regulate xenobiotic metabolism.

In addition to *Cyp2c50/54*, transcript levels of other fatty acid metabolic enzymes were also decreased in  $\alpha$ 7HMZ livers. *Cyp2b10* and *Ephx2* (Figure 3C), which convert arachidonic acid to oxylipins via a two-step process (40), were significantly downregulated, as were all four DiHETrE products of arachidonic acid in the CYP2B10-EPHX2 pathway (Figure 3D), confirming a phenotypic effect on fatty acid metabolism. Changes in gene expression in the steroid metabolism pathway were also observed in  $\alpha$ 7HMZ livers with an increase in *Cyp17a1* and a decrease in *Srd5a1* and *Hsd3b5* (Figure 3E). CYP17A1 plays a predominant role in steroid hormone biosynthesis, while steroid 5-alpha-reductase (*Srd5a1*) metabolizes the conversion of testosterone into the more potent dihydrotestosterone (DHT) and 3 beta-hydroxysteroid dehydrogenase type 5 (*Hsd3b5*) is typically lower in female livers (41). Tellingly, several of the most significantly increased transcripts in  $\alpha$ 7HMZ livers, including *Cyp2b9*, *Cyp2b13* and *Cyp2a4* (Figure 3F), are female-specific, have testosterone hydroxylase activity and are known to be regulated by HNF4 $\alpha$  (42). Furthermore, *Ephx2* expression and activity is downregulated by estrogen (43), which could explain the observed decrease in DiHETrEs in  $\alpha$ 7HMZ livers. All told, these results are consistent with the “feminization” of the  $\alpha$ 7HMZ livers suggested by the increase in ER $\alpha$  and decrease in AR expression (Figure 2E).

## P1- and P2-HNF4 $\alpha$ isoforms have similar but non-identical DNA binding profiles both *in vivo* and *in vitro*

To determine whether the P2-HNF4 $\alpha$  transcriptional program is due to alterations in chromatin binding, ChIP-seq analysis was performed at 10:30 AM (ZT3.5) using an antibody ( $\alpha$ 445) that recognizes both isoforms (Figure 1A). Consistent with the high level of expression of the *Hnf4a* gene, there was a large number of HNF4 $\alpha$  binding events in both WT and  $\alpha$ 7HMZ livers (~40,000 peaks). While the vast majority of peaks were similar in the two sets of mice, ~1.4 to 2.6% of the peaks were enriched for a particular isoform (WT unique: 572 peaks;  $\alpha$ 7HMZ unique: 1067 peaks) (Figure 4A). Analysis of the feature distribution of the ChIP peaks shows that both WT- and  $\alpha$ 7HMZ-unique peaks were less frequently located in the promoter region ( $\leq$  2kb from +1) than the common peaks and the  $\alpha$ 7HMZ-unique peaks were enriched in intronic regions (Figure 4B).

Motif mining showed that the most common motif in both the WT and  $\alpha$ 7HMZ unique peaks was an HNF4 $\alpha$  motif (xxxxCAAAGTCCA).

**FIGURE 3** P2-HNF4 $\alpha$  dysregulates the expression of genes involved in fatty acid, steroid and xenobiotic/drug metabolism. **(A)** Heatmap of row-normalized read counts from RNA-seq for Phase I and II genes ( $p_{adj} \leq 0.01$ ) between WT and  $\alpha 7$ HMZ at any time point. *Bottom*, level of UDP-glucuronic acid in WT and  $\alpha 7$ HMZ livers, \*  $p \leq 0.01$  by Mann-Whitney. **(B, C, E, F)** Average FPKM values. \*  $p_{adj} \leq 0.01$  and #  $p_{adj} \leq 0.05$  between WT and  $\alpha 7$ HMZ at a given time point. **(D)** diHETrE oxylipins (or DHETs, dihydroxytrienoic acid) levels in WT and  $\alpha 7$ HMZ livers ( $n=3$ , 12-13 weeks old), generated from arachidonic acid by CYP2B10 and EPHX2. \*  $p \leq 0.01$  by Student's T-test.

To determine whether there might be additional TFs bound in those peaks, we analyzed the DNA sequence of the uniquely bound peaks with an HNF4 $\alpha$ -trained support vector machine (SVM) algorithm and categorized the peaks into one of four categories ( $>2$ , 2 to 1.75, 1.75 to 1.5 and 1.5 to 1.25 SVM score) based on the single highest-scoring SVM motif within the peak. All but a few peaks fell into one of these categories suggesting that the isoform-specific peaks are likely due to direct binding to the DNA. Nonetheless, *de novo* motif calling with MEME-ChIP revealed different TF motifs in some of the isoform-specific peaks. CEBPA and FOX were the only motifs significantly enriched in WT-unique peaks, but several motifs were found in

$\alpha 7$ HMZ-unique peaks, including SOX, GATA5, SMAD2, ETS, CEBPB, FOX and PAR bZIP (Figure 4C).

To investigate the innate DNA binding specificity of the HNF4 $\alpha$  isoforms, we designed PBMs with variations on HNF4 $\alpha$  consensus motifs (a direct repeat with a spacing of 1, DR1, AGGTCAXAGGTCA, or DR2, AGGTCAXXAGGTCA), as well as genomic sequences mined from HNF4 $\alpha$  ChIP-seq peaks (Figure 4D, top middle). In total, ~44,000 test sequences were spotted in quadruplicate on a glass slide and probed with human HNF4 $\alpha 2$  or HNF4 $\alpha 8$  ectopically expressed in COS-7 cells or with liver nuclear extracts (NEs) from WT and  $\alpha 7$ HMZ mice (HNF4 $\alpha 2$ /

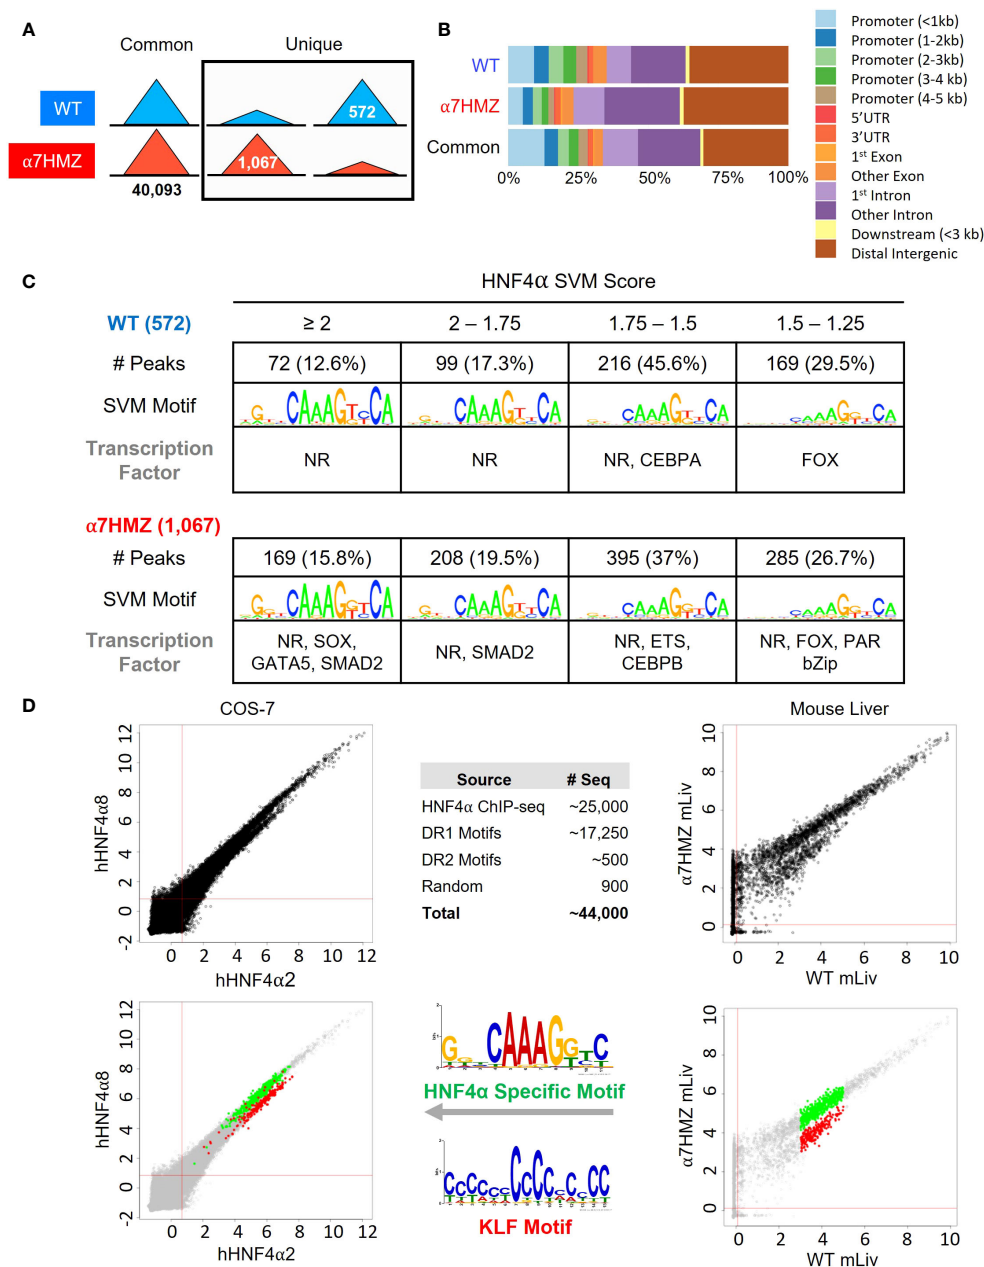

FIGURE 4

HNF4 $\alpha$  isoforms exhibit similar but non identical chromatin binding profiles *in vivo* and *in vitro*. (A) Number of common, WT- and  $\alpha$ 7HMZ-unique HNF4 $\alpha$  ChIP-seq peaks. (B) Feature distribution plots from ChIPseeker. (C) WT- and  $\alpha$ 7HMZ-unique ChIP peaks grouped by HNF4 $\alpha$  SVM motif score. TFs corresponding to the top DNA motifs from *de novo* MEME-ChIP analysis are given. NRs, HNF4 $\alpha$  DR1-like motif. See also [Supplementary Figures 3, 4](#). (D) Log<sub>2</sub> average binding intensities from PBMs with ectopically expressed human HNF4 $\alpha$ 8 versus HNF4 $\alpha$ 2 in COS-7 cells, and mouse liver NEs from  $\alpha$ 7HMZ versus WT; test sequences shown are from HNF4 $\alpha$  ChIPseq peaks in Caco-2 cells. *Middle top*, test sequences used in entire PBM design. *Middle bottom*, PWMs for red (KLF Motif, boottom spur) and green (HNF4 $\alpha$  Specific Motif, top spur) spots in mouse liver scatterplot, which are mapped back onto COS-7 plots. See [Supplementary Table 5](#) for data plotted in these graphs.

$\alpha$ 8 have a 10-amino acid insertion in the F domain of HNF4 $\alpha$ 1/ $\alpha$ 7, respectively). Scatter plot analysis of the PBM scores verified that the two HNF4 $\alpha$  isoforms exhibited nearly identical DNA binding affinity and specificity across all test sequences in the COS-7 extracts; shown are the results from ~25,000 sequences derived from the ChIP-seq (Figure 4D, top left). Liver NEs from WT and  $\alpha$ 7HMZ mice were also nearly identical except for a subset of

sequences that differed between WT and  $\alpha$ 7HMZ (Figure 4D, top right). Motif analysis of the two groups of sequences, shown in green (top spur, HNF4 $\alpha$  specific motif) and red (bottom spur, KLF motif), revealed a preference for HNF4 $\alpha$  in WT livers for GC-rich sequences recognized by SP1/KLF proteins (Figure 4D, bottom right, middle). A similar, albeit less pronounced, preference was noted in the COS-7 extracts (Figure 4D, bottom left). Consistently,

HNF4α1 has been found to interact with SP1 both on and off chromatin, an interaction that involves the N-terminal domain of HNF4α1 (44–46).

### HNF4α isoforms have unique interactomes

To assess the contribution of differential chromatin binding to changes in gene expression, we cross-referenced the ChIP-seq and RNA-seq datasets at the 10:30 AM time point and found that ~22% of WT-specific (62 out of 294) and α7HMZ-specific genes (41 out of 181) have one or more unique ChIP peaks within 50 kb of the transcription start site (TSS, +1) (Figure 5A). WT-specific genes matching these criteria include *Nr1i3*, *Cyp2c50*, *Cyp2c54*, *Rarres1*, *Fmn1*, *Cdhr5*, and *Camk1d*, while α7HMZ-specific genes include

*Cyp2b9*, *Fgfr1*, *Wnk4*, *Cyp4a14*, *Ppl*, *Vnn1*, *Acot1*, and *Cyp17a1* (Supplementary Table 2). Many of the most dysregulated genes contained differentially bound peaks within ~5 kb of +1 – *Nr1i3*, *Apoa4*, *Cyp2c50*, *Cyp2c54*, *Cyp2b9*, *Cyp4a14*, *Acot1*, *Cyp17a1*, *Ucp2*, *Cyp2d26* and *Treh* (Figures 5B, C and Supplementary Figure 4A, B). While the differential peaks were typically not the only nor the largest peak in the gene, they could reflect rapid cycling on and off the DNA with functional consequences.

Since the majority of dysregulated genes had no nearby HNF4α isoform-specific ChIP peak, we examined HNF4α protein-protein interactions in WT and α7HMZ livers by RIME at 10:30 (ZT3.5) and 20:30 (ZT13.5). Both time points yielded a considerable number of interacting proteins at least eight-fold above the background, including many proteins that bound a single isoform (10:30: 167 WT-specific, 108 α7HMZ-specific; 20:30: 357 WT-

FIGURE 5

HNF4α isoforms have unique protein-protein interactions. (A) Number of genes with one or more WT- or α7HMZ-unique ChIP-peaks within a 50-kb of +1 of differentially expressed genes in WT and α7HMZ livers (padj < 0.01). (B, C) UCSC Genome Browser view of dysregulated genes with a unique ChIP-signal and RNA-seq from 10:30 AM. Axes for WT and α7HMZ signals are set to the same scale but may differ between genes. (D) Top, number of proteins bound to HNF4α in WT vs. α7HMZ livers at 10:30 (ZT3.5 left), at 20:30 (ZT13.5 right) and in both WT and α7HMZ at 10:30 vs. 20:30 (middle). Bottom, select proteins involved in transcription regulation bound only in WT, α7HMZ or both genotypes. See Supplementary Figure 4D for interactions with signaling proteins and Supplementary Table 3 for all interacting proteins.

specific, 256  $\alpha$ 7HMZ-specific) (Figure 5D, top). There was considerable overlap between the common groups for the two time points (96 proteins bound HNF4 $\alpha$  in both WT and  $\alpha$ 7HMZ livers at both time points), underscoring the robustness of the method. There were also many proteins that bound both isoforms but only at a single time point (10:30: 141; 20:30: 401). Notably, core circadian regulator CRY1 bound HNF4 $\alpha$  in both WT and  $\alpha$ 7HMZ livers but only at 10:30 AM (Figure 5D, bottom). In contrast, BHLHE40 bound both isoforms at both 10:30 and 20:30, while NFIL3 uniquely bound in WT livers and ARNTL (BMAL1) and CLOCK in  $\alpha$ 7HMZ but only at 10:30 (Figure 5D, bottom). These findings are consistent with recent reports of HNF4 $\alpha$  interacting with the clock machinery and playing a role in maintaining circadian oscillations in the liver (29).

Several LETFs interacted with both isoforms but only at one time point (10:30 only: CEBPA, CEBPB, HNF1B, ONECUT2; 20:30 only: FOXO1, ONECUT1); only HNF1A interacted at both time points (Figure 5D, bottom, middle). Many NRs interacted with HNF4 $\alpha$  in both WT and  $\alpha$ 7HMZ livers, including NR3C1(GR) and NR0B2 (SHP), both of which have been shown previously to functionally interact with HNF4 $\alpha$ , further validating the RIME results (47, 48). There were also isoform-specific interactions, mostly with WT at 10:30 (NR1H2, NR2C1, NR2C2, PPARA). Interestingly, xenobiotic receptor PXR (NR1I2) interacted with HNF4 $\alpha$  but only in  $\alpha$ 7HMZ livers at 10:30 (Figure 5D, bottom left and right). While the expression of *Nr1i2* was not changed in  $\alpha$ 7HMZ livers (Supplementary Figure 2C), an environmental estrogen that activates PXR has been shown to increase the expression of two female-specific Cyp genes (*Cyp2b9* and *Cyp2a4*) in male mice: both are significantly upregulated in  $\alpha$ 7HMZ livers and bound by HNF4 $\alpha$  (Figure 5C and Supplementary Table 2) (49). HNF4 $\alpha$  in  $\alpha$ 7HMZ livers also uniquely interacted with ESRRG (ERR $\gamma$ , *Nr3b3*) but only at 20:30: ERRs play important roles in mitochondrial biogenesis and function, including fatty acid oxidation (50). Interestingly, ERR DNA binding motifs were found in  $\alpha$ 7HMZ ChIP peaks but not WT (Supplementary Figure 3B).

There were many other TFs and co-regulators that interacted with a single HNF4 $\alpha$  isoform, often in a circadian fashion (Figure 5D, bottom), which could explain the observed differential gene expression between WT and  $\alpha$ 7HMZ. Several of these proteins were previously confirmed by more conventional means (31, 51–53). Finally, there were several signaling molecules that interacted uniquely with the isoforms and at distinct time points – one or more of these could also contribute to isoform-specific gene expression, independent of ChIP peaks (Supplementary Figure 4D).

## HNF4 $\alpha$ isoforms differentially impact circadian gene expression

Interactions with circadian TFs suggest that HNF4 $\alpha$  may play a role in the hepatic clock. Analysis of all DEGs between any two time points (10:30, 13:30 or 20:30;  $p < 0.01$  and  $\log_2FC > 2$ ) for either WT or  $\alpha$ 7HMZ yielded 53 genes, including commonly known

circadian genes (*Cry1*, *Rorc*, *Dbp*, *Bhlhe41*, *Usp2*, *Per2*, *Per3*, *Arntl*, and *Nr1d1*) as well as many metabolism-related genes (*Fmo3*, *Lpl*, *Car3*, *Corin*, *Npas2*, *Hmgcs1*, *Mme*, *Slc45a3*, *Hsd3b4*, *Hsd3b5*, *Slc10a2*) (Figure 6A top). While most of these circadian-regulated genes showed the same general profile in WT and  $\alpha$ 7HMZ livers, there were some differences in the magnitude of the circadian effect between the genotypes. For example, *Fmo3*, a drug metabolizing gene whose expression varies greatly between individuals, had a much higher expression in  $\alpha$ 7HMZ livers at 20:30. In contrast, *Aqp8*, a water channel protein important for mitochondrial respiratory function (54), had much lower levels of expression in  $\alpha$ 7HMZ at all time points (Figure 6A, arrows).

While the majority of the clock machinery maintained cyclic expression in both genotypes (Figure 6A bottom), there were significant differences in expression between WT and  $\alpha$ 7HMZ in core clock components *Arntl*, *Clock*, *Cry1*, *Nfil3*, *Npas2* and *Per3* at one or more time points (Figure 6B), as well as *Rorc* and *Ppara* (Supplementary Figure 2B). The fact that other core components of the clock machinery did not show differences between the two genotypes (e.g., *Per1*, *Per2*, *Rora*, *Bhlhe40*) (Supplementary Figure 5A) suggests that the effect of P2-HNF4 $\alpha$  on the clock is a specific one.

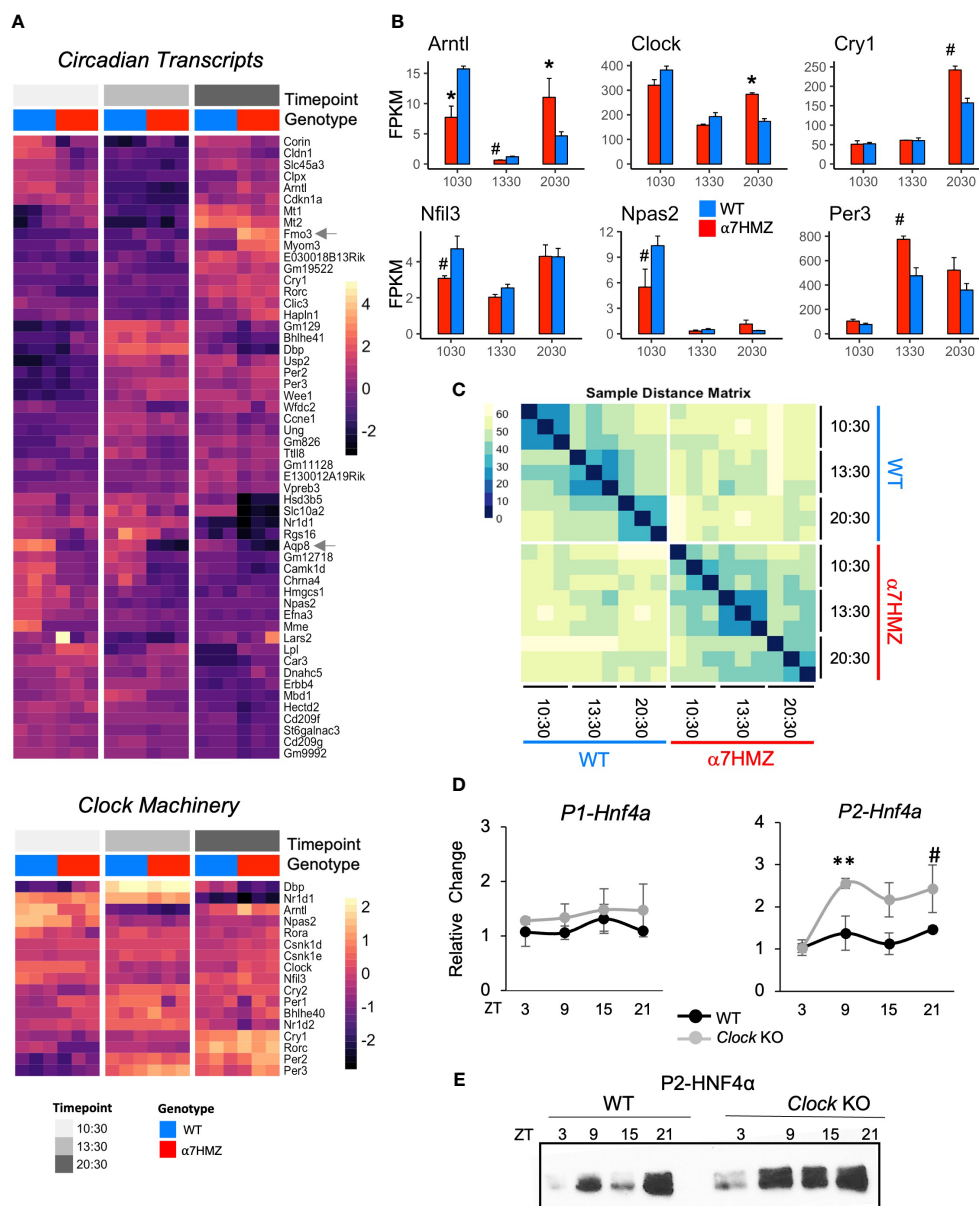

A sample distance matrix further confirmed a subtle yet real effect of P2-HNF4 $\alpha$  on the hepatic clock. While the WT replicates at a given time point are much more similar to each other than they are to other time points,  $\alpha$ 7HMZ replicates show strong self-identity only in the 13:30 samples (Figure 6C). This is despite the fact that a principal component analysis (PCA) showed a good separation and categorization of each sample group (Supplementary Figure 7A).

## P2-HNF4 $\alpha$ is expressed at discrete times in the normal adult liver

While expression of P2-HNF4 $\alpha$  protein in the normal adult liver has not been previously reported, this could be due to the time of day that livers are typically harvested (before midday). Since the current results show links between P2-HNF4 $\alpha$  in  $\alpha$ 7HMZ livers and the circadian clock, we harvested livers from WT mice at four time points (ZT3, ZT9, ZT15, ZT21) and looked for P2-HNF4 $\alpha$  mRNA by RT-qPCR and protein by immunoblot (IB). The results show expression of P2-HNF4 $\alpha$  at ZT9 (4 PM) and ZT21 (4 AM) and a further increase in *Clock* KO livers. In contrast, P1-HNF4 $\alpha$  RNA and protein levels did not oscillate in either WT or *CLOCK* KO mice (Figure 6E, Supplementary Figures 5B, C).

## Metabolomic profiling indicates a role for P2-HNF4 $\alpha$ in ketogenesis

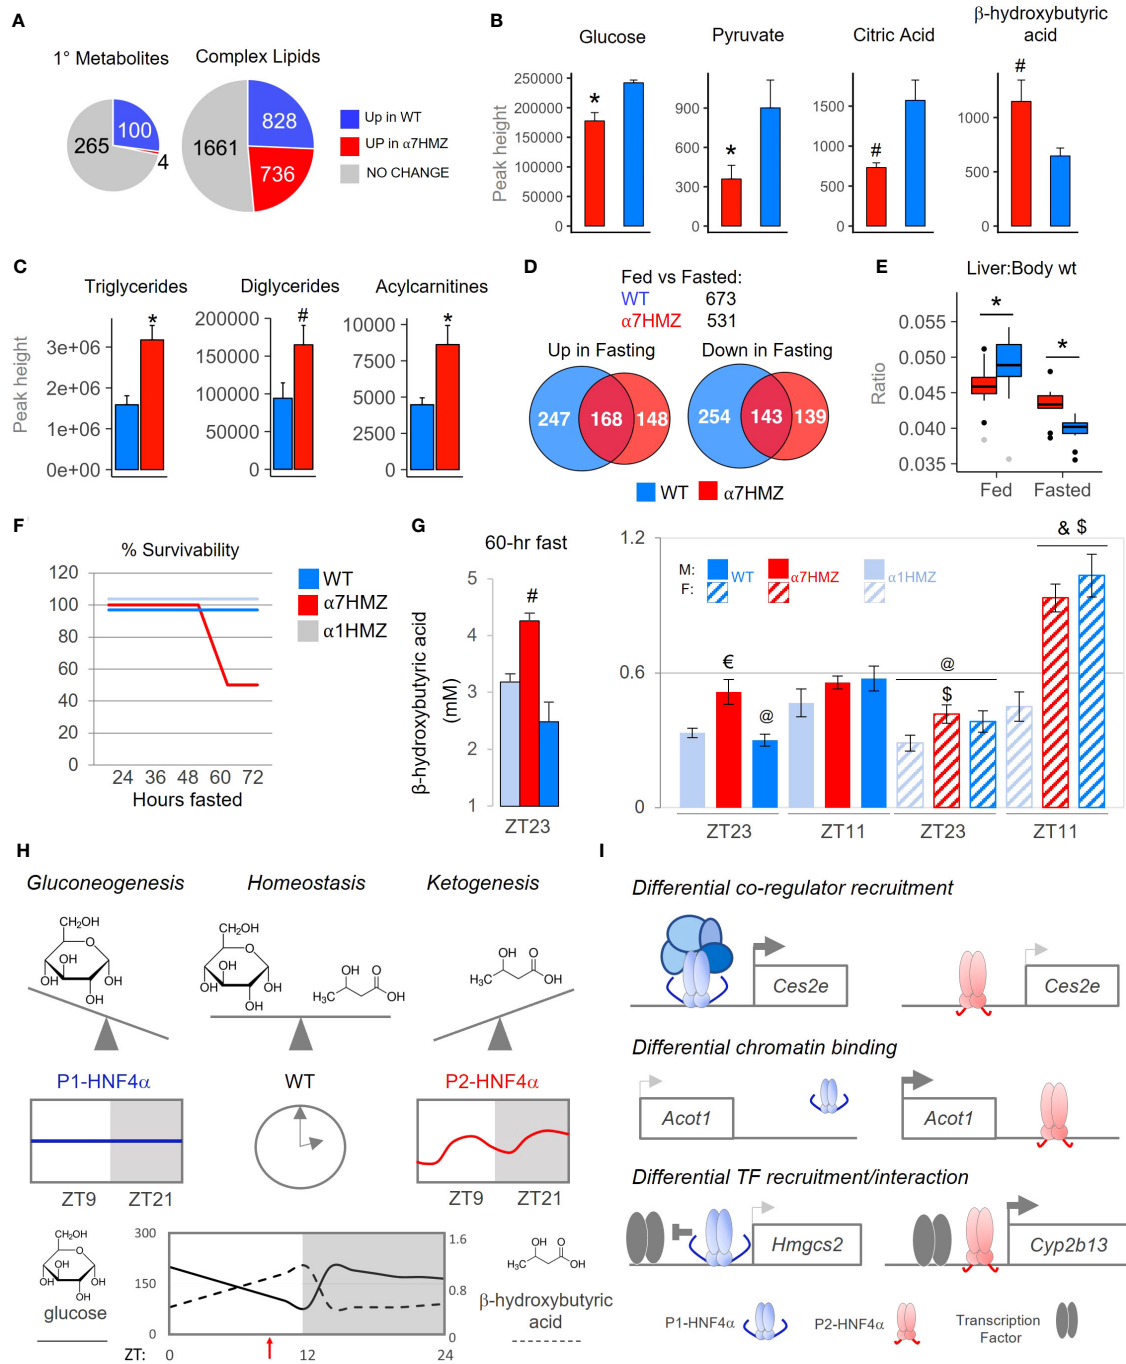

Since metabolism is tightly linked to the clock in the liver (55–57), we performed metabolomic analysis of primary metabolites and complex lipids on WT and  $\alpha$ 7HMZ livers at 10:30 AM (ZT3.5). Nearly one-quarter of the primary metabolites (100 out of 369 total)

**FIGURE 6**  
HNF4 $\alpha$  isoforms differentially impact diurnal gene expression. **(A)** Heatmap of log read counts for all circadian-regulated and core clock genes with  $\text{padj} \leq 0.01$  and  $\log_2\text{FC} \geq 2$  between any pair of time points. 10:30, ZT3.5; 13:30, ZT6.5; 20:30 ZT13.5 **(B)** Average FPKM of select circadian clock genes. #  $\text{padj} \leq 0.05$ ; \*  $\text{padj} \leq 0.01$ . **(C)** Sample distance matrix for each RNA-seq replicate, calculated across the full transcriptome. Error bars, SEM ( $n=3-4$ ). **(E)** Representative IB of diurnal expression of P2-HNF4 $\alpha$  protein in WCE from WT and *Clock* KO livers using P2-specific antibodies ( $n=3-4$ ). See also [Supplementary Figure 5](#).

were significantly down-regulated ( $p < 0.05$ ) in  $\alpha 7\text{HMZ}$  livers (Figure 7A, up in WT). Metabolite Set Enrichment Analysis showed that the top four enriched categories in WT are involved in carbohydrate metabolism and protein biosynthesis (Supplementary Figure 6A). Glucose and pyruvate were both significantly down in  $\alpha 7\text{HMZ}$  livers (Figure 7B), as was PEPCK (*Pck1*), an important enzyme in gluconeogenesis (Supplementary Figure 6B). Genes in pathways downstream of pyruvate were also significantly decreased in  $\alpha 7\text{HMZ}$ , including lactate dehydrogenase

(*Ldha*, *Ldhb*), pyruvate carboxylase (*Pcx*) and citrate synthase (*Cs*) in the Krebs's cycle (Supplementary Figure 6C), as was citric acid, a key intermediate in the cycle (Figure 7B). Krebs's intermediates oxalic and succinic acid were also reduced although they did not reach significance (Supplementary Figure 6D). In contrast, genes involved in the formation of ketone bodies were upregulated in  $\alpha 7\text{HMZ}$  (*Hmgcs2*, *Hmgcl*) (Supplementary Figure 6E), as was the ketone body  $\beta$ -hydroxybutyric acid (Figure 7B), as previously reported (23). Levels of hundreds of complex lipids were altered

**FIGURE 7**  
 P1-HNF4 $\alpha$  drives gluconeogenesis while P2-HNF4 $\alpha$  drives ketogenesis; both are required for homeostasis in carbohydrate and lipid metabolism. **(A)** Number of primary metabolites and complex lipids in WT and  $\alpha$ 7HMZ livers of fed mice at 10:30 AM (n=8 per group). Uniqueness identified by Mann-Whitney U-test ( $p \leq 0.05$ ). **(B, C)** Primary metabolites related to Krebs cycle and ketogenesis [a single mouse outlier was omitted for both the WT and  $\alpha$ 7HMZ datasets for a final n=7 per group, **(B)**] and known complex lipids [n=8 per group, **(C)**]. Student's T-test: #  $p \leq 0.05$ ; \*  $p \leq 0.01$ . **(D)** Number of genes dysregulated (padj  $\leq 0.01$ ) in fed vs. fasted (12 hr) WT and  $\alpha$ 7HMZ livers (10:30 AM). **(E)** Liver-to-body weight ratios in fed and fasted WT and  $\alpha$ 7HMZ mice (n = 9-14). \*  $p \leq 0.01$  by Student's T-test, excluding outliers (gray dots). **(F)** Percent survival of WT,  $\alpha$ 1HMZ and  $\alpha$ 7HMZ male mice (~20 wks) during a prolonged fast (n=5-6). **(G)**  $\beta$ -hydroxybutyric acid levels in blood of WT,  $\alpha$ 7HMZ and  $\alpha$ 1HMZ during a 60-hr fast (left) (n=3-5) and at ZT23 and ZT11 after 1 week of restricted feeding (food removed between ZT0 and ZT12) (right) (n = 6-8). Student's T-test: #  $p < 0.05$  vs. other two genotypes; \$  $p < 0.05$  vs.  $\alpha$ 1HMZ females at the same time point; &  $p < 0.05$  vs. males of same genotype at ZT11; @  $p < 0.05$  vs. females of the same genotype at ZT11; €  $p < 0.05$  vs. WT and  $\alpha$ 1HMZ males at ZT23. **(H, I)** Models discussed in text; see also [Supplementary Figures 6, 7](#). See [Supplementary Table 4](#) for complete metabolomics data.

(up or down) in  $\alpha 7$ HMZ livers, including a notable increase in total triglycerides, diacylglycerides and acylcarnitines in the  $\alpha 7$ HMZ liver and a decrease in phospholipid species (Figures 7A, C and Supplementary Figure 6F).

Since ketone bodies are elevated upon fasting, we performed RNA-seq on livers from 12-hr fasted WT and  $\alpha 7$ HMZ mice. The transcriptomes for both WT and  $\alpha 7$ HMZ fasted livers were quite distinct from the fed time points as well as from each other (Supplementary Figures 7A, B): WT mice had more genes altered upon fasting (673 versus 531 in  $\alpha 7$ HMZ) as well as more WT-specific genes either up- or downregulated (Figure 7D). Liver-to-body weight ratios were significantly lower in  $\alpha 7$ HMZ versus WT fed mice; in contrast, in fasted livers the ratio was lower in WT (Figure 7E). Since WT mammals are known to store fat in their liver during periods of fasting and since fasted  $\alpha 7$ HMZ livers accumulate more fat than WT mice (Figure 7C) (23), these results suggest that P2-HNF4 $\alpha$  might promote a “fasting-response” program, consistent with the expression of P2-HNF4 $\alpha$  at ZT9, near the end of the daily fasting period.

However, when the mice were subjected to a prolonged fast, unexpectedly, 50% of the  $\alpha 7$ HMZ mice died after ~60 hrs; in contrast,  $\alpha 1$ HMZ and WT mice survived a full 72 hrs without food (Figure 7F). Mortality was not due to hypoglycemia as blood glucose levels did not drop below 65 mg/dL; in fact, they increased after 48 hrs of fasting at ZT11, especially in  $\alpha 1$ HMZ (Supplementary Figure 7C). In contrast, circulating ketone bodies were highly elevated in the  $\alpha 7$ HMZ mice that survived the 60-hr fast (4.25 mM) (Figure 7G), and suggested that the  $\alpha 7$ HMZ mice undergoing a prolonged fast might have died of ketoacidosis.

Since the  $\alpha 7$ HMZ transcriptome showed signs of “feminization” and since females tend to have higher levels of ketone bodies than males (24, 58), we examined whether the elevated levels of ketone bodies in WT females is due to the ability to express P2-HNF4 $\alpha$ . As anticipated, in WT mice ketone bodies were higher near the end of the daily fast (ZT11, 7 PM) than at the end of the feeding period (ZT23, 7 AM), in both males and females (Figure 7G). In contrast,  $\alpha 7$ HMZ males had ketone bodies at ZT23 nearly as high as at ZT11. Importantly,  $\alpha 7$ HMZ and WT females had much higher levels of ketone bodies at ZT11 than their male counterparts, whereas the  $\alpha 1$ HMZ females had levels similar to  $\alpha 1$ HMZ males and much lower than either WT or  $\alpha 7$ HMZ females (Figures 7G). This suggests that P2-HNF4 $\alpha$  is required for the elevated levels of ketone bodies in females.

## Discussion

While many mammalian genes have multiple promoters that drive expression of proteins with alternative N-termini, the physiological relevance of those different isoforms is seldom known. Using exon-swap mice and omics approaches, we show for the first time that the alternative isoform of the *Hnf4a* gene (P2-HNF4 $\alpha$ ), previously thought to be expressed only in fetal liver and liver cancer, plays an important metabolic role in the adult liver and is implicated in both the circadian clock and sex-specific gene expression.

## Both P1- and P2-HNF4 $\alpha$ are required for metabolic homeostasis in males and females

The “P2-HNF4 $\alpha$  program” is characterized by a decrease in carbohydrate metabolism and an increase in hepatic fat storage, as well as ketogenesis, which typically occur during periods of fasting (59). Altered expression of genes involved in fatty acid oxidation or oxidative phosphorylation in the mitochondria are consistent with a shift from carbohydrates to fatty acids as an energy source (e.g., *Hmgcs2*, *Acot1*, *Ucp2*, Figure 1F and Supplementary Table 2). In contrast, it appears that P1-HNF4 $\alpha$  drives gluconeogenesis and is required to temper the P2-HNF4 $\alpha$  response to avoid ketoacidosis under conditions of stress, such as fasting. Only WT mice, which express both HNF4 $\alpha$  isoforms in the liver, achieve homeostatic balance between carbohydrate and lipid metabolism (Figure 7H). We propose that this balance is achieved on a daily basis by upregulating P2-HNF4 $\alpha$  at the end of the fasting period (~ZT9) (Figure 7), resulting in the well characterized elevation of ketone bodies right before feeding (60). Intriguingly, P2-HNF4 $\alpha$  is also required for the elevated levels of ketone bodies in female mice (Figure 7G), consistent with a “feminization” of the  $\alpha 7$ HMZ livers and previous results showing that KO of HNF4 $\alpha$  in the adult liver leads to a loss of male-specific genes and an increase of female-specific genes (61). Finally, P2- but not P1-HNF4 $\alpha$  interacts with the NAD-dependent deacetylase SIRT1, which is activated upon fasting and is associated with fatty acid oxidation, ketogenesis and fatty liver (Figure 5D) (62).

## Multiple mechanisms are responsible for HNF4 $\alpha$ isoform-specific gene regulation

Our results indicate that P2-HNF4 $\alpha$  drives its unique transcriptional program via multiple mechanisms. Differential recruitment of co-regulators to target gene promoters (Figure 5D) could explain altered expression of genes such as *Ces2e*, which encodes carboxylesterase 2, an enzyme that hydrolyzes triacylglycerols (Figure 7I top). Both P1- and P2-HNF4 $\alpha$  bind the *Ces2e* promoter in a similar fashion but *Ces2e* is expressed at much lower levels in  $\alpha 7$ HMZ livers compared to WT, which could explain the elevated levels of triglycerides in  $\alpha 7$ HMZ livers (Figures 1E, 7C, Supplementary 4C). A second potential mechanism is differential binding to regulatory regions. An enriched ChIP-seq peak in  $\alpha 7$ HMZ livers, for example, could explain the upregulation of a key enzyme in  $\beta$ -oxidation of fatty acids, *Acot1* (Figures 7I middle and Supplementary Figure 4A). Similarly, a reduction in ChIP peaks could explain the decrease in expression of *Apoa4* and *Nr1i3* (CAR) in  $\alpha 7$ HMZ livers (Figures 5B, C). A third mechanism involves differential recruitment and/or interaction of TFs with a given HNF4 $\alpha$  isoform (Figure 7I bottom). For example, PPAR $\alpha$  is known to be a major player in ketogenesis, activating the expression of the mitochondrial enzyme HMGCS2 which catalyzes the first step in ketogenesis (59). P1-HNF4 $\alpha$  has been shown to decrease *Hmgcs2* expression by repressing PPAR $\alpha$ -dependent activation (63). This repression could be facilitated by

a unique protein-protein interaction between P1-HNF4 $\alpha$  and PPAR $\alpha$  (Figure 5D). In contrast, in  $\alpha$ 7HMZ livers *Hmgcs2* expression is elevated and HNF4 $\alpha$  ChIP-seq peaks in  $\alpha$ 7HMZ livers are similar to those in WT (Supplementary Figures 4C, 6E). Similarly, specific interactions between P2-HNF4 $\alpha$  and TFs involved in sex-specific gene expression (e.g., NR1I2, SP1 family/KLF) could contribute to increased expression of female-specific genes such as *Cyp2b13* (Figures 3F, 5D, Supplementary Figure 4C) (49). Additional mechanisms driving the P2-HNF4 $\alpha$  program include differential interaction with signaling molecules, altered expression of other TFs, such as those that play a role in sex-specific gene expression (*Stat5b*, *Stat5a*, estrogen and androgen receptors) (33, 36), and elevated levels of ketone bodies which can impact histone deacetylase activity, as well as the circadian clock (64) (Figures 2, 7G, Supplementary Figure 4D).

## Physiological and pathological triggers of the P2-HNF4 $\alpha$ program

There are now three known physiological conditions in which P2-HNF4 $\alpha$  is expressed in the liver – fetal liver and ZT9 and ZT21 in adult liver (Figure 6). Increased expression of P2-HNF4 $\alpha$  expression right before birth (E17.5), followed by a sharp decline after birth (5, 6), could explain why the  $\alpha$ 7HMZ transcriptome is not more similar to that of the E14.5 fetal liver: rather than promoting early liver development, the role of P2-HNF4 $\alpha$  appears to be a metabolic one, perhaps preparing the fetus to survive the birthing process and immediate postnatal period by increasing fat in the liver. The subsequent decrease in P2-HNF4 $\alpha$  expression after birth could be mediated by GR which is induced by stress hormones released during parturition (65): GR preferentially increases the expression of P1-HNF4 $\alpha$  (7, 66) which would in turn repress the P2 promoter (6).

Factors responsible for increased expression of P2-HNF4 $\alpha$  at ZT9 have not been identified, but its expression seems to be required for the increased expression of ketogenic genes and ketone bodies in response to the daily fast (Figures 7B, G, Supplementary Figure 6E). The role of P2-HNF4 $\alpha$  at ZT21 is more difficult to explain as ketone bodies are low at that time (Figure 7G) (60). Total protein synthesis is increased at  $\sim$ ZT22 (67), as well as both P2- and P1-HNF4 $\alpha$ -specific targets (Supplementary Figure 7D), so expression of P2- (and P1-)HNF4 $\alpha$  at ZT21 could be the result of a global effect on protein synthesis.

In addition to physiological triggers, there are now four pathological conditions in which P2-HNF4 $\alpha$  is known to be elevated in the adult liver – cancer (11, 12, 68), high fat diet (12, 20), disrupted clock (Figures 6D, E) and alcoholic hepatitis (68). In terms of cancer, our results indicate that P2-HNF4 $\alpha$  is not oncogenic per se – the P2-HNF4 $\alpha$  transcriptome shows only a partial overlap with HCC, key proliferation markers (Ki67 and PCNA) are not upregulated in  $\alpha$ 7HMZ livers and there is no evidence of hepatomegaly (Figures 1H, 7E, Supplementary Figures 1D,E). Furthermore, no increase in spontaneous, macroscopic tumors has been observed in  $\alpha$ 7HMZ livers, even in older mice (unpublished observation). While HCC patients with

increased P2-HNF4 $\alpha$  have a poor prognosis (13), rather than acting as an oncogene per se, P2-HNF4 $\alpha$  may be upregulated simply due to a decrease in the expression of the tumor suppressor P1-HNF4 $\alpha$  (7, 66) and inadvertently promote liver cancer progression via metabolic effects. For example, acylcarnitines are elevated in  $\alpha$ 7HMZ livers (Figure 7C, Supplementary Figure 6F) and have been identified as potential diagnostic and prognostic biomarkers for HCC (69, 70). Given the renewed interest in cancer metabolism, including in HCC, it will be of interest to determine exactly how a metabolism altered by unopposed P2-HNF4 $\alpha$  might contribute to cancer progression and/or treatment (71). This is particularly true considering that elevated ketone bodies may trigger a protective mechanism against oxidative stress (72), which would suggest that elevated levels of P2-HNF4 $\alpha$  in HCC may actually play a protective role. Finally, several matrix metalloproteinases (*Mmp14*, *Mmp15*, *Mmp19*), which are linked to poor prognosis of liver or colorectal cancer patients (73–75), are also upregulated by P2-HNF4 $\alpha$  (Supplementary Table 1) and dysregulation of genes involved in drug metabolism could impact treatment of liver cancer (Figure 3).

The second condition that leads to expression of P2-HNF4 $\alpha$  in the adult liver – high fat diet (HFD) – could be related to both cancer and the third condition, disrupted clock. We recently reported that P2-HNF4 $\alpha$  expression is increased in the livers of mice fed a HFD and that the circadian regulator BMAL1 represses P2-HNF4 $\alpha$  expression in HCC (12). Consistently, P2- but not P1-HNF4 $\alpha$  interacts with BMAL1 (ARNTL) and CLOCK and the *Clock* KO increases P2- but not P1-HNF4 $\alpha$  expression (Figures 6D, 7D, E). Dysregulation of the clock, such as during jet lag, could potentially contribute to liver cancer by upregulating P2-HNF4 $\alpha$  (Figures 6D, E) (21). While HNF4 $\alpha$ , including exon 1A and exon 1D, is highly conserved between mouse and human (96% identity on the protein level in BLAST) (2), given the genetic variation in regulatory regions between species, it will be of interest to determine whether P2-HNF4 $\alpha$  expression impacts the expression of genes involved in the human hepatic metabolome (and hepatic circadian clock) in the same fashion as the mouse (76).

The fourth pathological condition where P2-HNF4 $\alpha$  is expressed in the liver – human alcoholic steatohepatitis (68) – is consistent with increased fat in  $\alpha$ 7HMZ livers and an enrichment of genes associated with alcoholism in  $\alpha$ 7HMZ mice (Figures 1F, 7C). The TGF $\beta$  pathway is implicated in P2-HNF4 $\alpha$  expression under this scenario; SMAD binding motifs were found in  $\alpha$ 7HMZ ChIP-seq peaks but not WT peaks (Supplementary Figure 3B).

In summary, the results presented here strongly suggest that the function of P2-HNF4 $\alpha$  is to modulate the hepatic metabolic response in general, rather than to solely promote proliferation during fetal development and liver cancer. While the elevated levels of circulating ketone bodies in  $\alpha$ 7HMZ mice suggest that P2-HNF4 $\alpha$  may be a player in the fasting response, other results suggest that the role of the alternative isoform of HNF4 $\alpha$  may be more complex. For example, expression of CAR (*Nr1i3*) is significantly decreased in  $\alpha$ 7HMZ livers and yet CAR is known to be increased during fasting, due to the action of PPAR $\alpha$  and PGC1 $\alpha$ , along with HNF4 $\alpha$ , on the *Nr1i3* promoter (77). Additionally, while expression of PEPCK (*Pck1*), a major driver of gluconeogenesis, did not increase after a 12-hour fast in  $\alpha$ 7HMZ livers as it does in WT animals, others have shown that P2-HNF4 $\alpha$  can

activate the *Pck1* promoter more effectively than P1-HNF4 $\alpha$ , at least in the presence of PGC1 $\alpha$  (20). Taken together, the findings presented here indicate that P2-HNF4 $\alpha$  plays an important physiological role in the normal adult liver and intersects with the circadian clock in a complex fashion that merits further investigation.

## Materials and methods

(See [Supplemental Methods](#) for additional methods and details).

### Animal models

Young adult (16 to 20 weeks) male WT and  $\alpha$ 7HMZ mice in a mixed 129/Sv plus C57BL/6 background (23) were fed a standard lab chow (LabDiet, #5001:13.6% fat from pork lard; 28.9% protein; 57.5% carbohydrates) and used for RNA-seq, CHIP-seq, RIME analysis (all samples from the same set of mice), and oxylipin analysis. The  $\alpha$ 7HMZ male mice used for primary metabolite and complex lipid metabolomic analysis were backcrossed to C57BL/6N for 10+ generations and used with C57BL/6N WT controls (n=8, 35 weeks of age).  $\alpha$ 7HMZ and  $\alpha$ 1HMZ (backcrossed 10+ generations into C57BL/6N) were compared to scientific C57BL/6N (WT) controls for newborn liver analysis (mixed-sex) and glucose/ketone body analysis (males and females; ~16 to 20 weeks of age). *Clock*-deficient (*Clock* KO) male mice were provided by Dr. David Weaver (78) and fed a standard rodent diet (PicoLab Rodent Diet #5053: 13.1% fat from soybean oil; 24.5% protein; 62.4% carbohydrates). All mice were fed *ad libitum* and kept in 12-hr light/dark conditions in a specific pathogen-free (SPF) facility, unless indicated otherwise, and euthanized by CO<sub>2</sub> asphyxiation followed by tissue harvest at the indicated time points. Care and treatment of the animals were in strict accordance with guidelines from the Institutional Animal Care and Use Committee at the University of California, Riverside (UCR), or the McGovern Medical School, UT Health.

### Expression profiling (RNA-seq) and analysis

Next generation sequencing of RNA (RNA-seq) was carried out as previously described (79). WT and  $\alpha$ 7HMZ male mice were sacrificed (n=3, aged 16-18 weeks) at the indicated time points – 10:30, 13:30, 20:30 (ZT3.5, ZT6.5, and ZT13.5, respectively) – within a 30-min interval. Fasted mice had food removed from 22:30 (ZT15:30) to 10:30 AM (ZT3.5) the following day (12 hr). Libraries were submitted for 75-bp single-end sequencing with Illumina NextSeq 500 at the UCR Institute of Integrated Genome Biology (IIGB) Genomics Core. A total of 24 libraries (3 fed time points, 1 fasted time point, 2 genotypes each, 3 replicates) were multiplexed and sequenced in two separate runs, each of which yielded ~600 M reads, averaging ~50 M reads per sample.

Reads were aligned to the mouse reference genome (mm10) with TopHat v2.1.1 using default parameters except for allowing only 1 unique alignment for a given read. Raw read counts were

calculated at the gene level for each sample using HTSeq v0.6.1. Library normalization was performed with EDASeq (80); within-lane normalization on GC content was performed with the LOESS method and between-lane normalization was performed with non-linear full quantile method. Normalization factors from EDASeq were used for differential expression analysis with DESeq2. Normalized read counts, FPKM (fragments per kilobase per million), and rlog (regularized log transformation) results were generated for downstream analysis.

### Chromatin immunoprecipitation sequencing (ChIP-seq) and SVM analysis

ChIP-seq of isolated liver cells from WT and  $\alpha$ 7HMZ males (n=3, aged 16-18 weeks) was performed as previously described (79) using 4.2  $\mu$ g of affinity-purified anti-HNF4 $\alpha$  ( $\alpha$ 445) (1) or rabbit IgG control (Santa Cruz, cat#sc-2027). Libraries were submitted for 50-bp single end sequencing by Illumina HiSeq 2500 at the UCR IIGB Genomics Core. Reads were aligned to the mouse reference genome (mm10) with Bowtie2. Peaks were called with MACS2 for individual samples, as well as a pooled peak dataset using the SPMR (signal per million reads) parameter. Aligned reads and MACS2 peak-sets were analyzed with DiffBind (81) with DESeq2 and library size equal to total aligned reads to identify common and uniquely bound regions of the genome. Default parameters were used unless noted otherwise. ChIP-seq peaks were called with MACS2 and then filtered on  $-\log_{10}(\text{p-value}) \geq 10$ , to approach six-fold enrichment above control. Differentially bound peaks were identified using DiffBind with MACS2 output. Curated peak lists were generated by filtering all results on peaks with “concentration”  $\geq 5$ ; defined by DiffBind as the “mean (log) reads across all samples” in contrast. The kernel-based SVM was trained as previously described using results from independent HNF4 $\alpha$  PBM experiments (82).

### Protein binding microarrays (PBM)

Protein binding microarrays (PBMs) were carried out as previously described (82). Nuclear extracts (NE) were prepared from COS-7 cells transiently transfected via CaPO<sub>4</sub> with HNF4 $\alpha$  expression vectors for human HNF4 $\alpha$ 2 (NM\_00457) and HNF4 $\alpha$ 8 (NM\_175914) essentially as previously described (83). Liver NE from WT and  $\alpha$ 7HMZ mice were prepared as previously described (37). A custom-designed array was ordered from Agilent (SurePrint G3 Custom GE 4x180k), which contained oligonucleotides ~60 nucleotides (nt) in length comprised of: sequences within 100 bp of the center of HNF4 $\alpha$  ChIP-seq peaks from human colon cancer cells (proliferative Caco-2) (84) were taken in 30-nt windows moving 5 nt at each step (~25,000 sequences); 17,250 permutations of canonical HNF4 $\alpha$  DR1 motifs (5'-AGGTCAAA GGTCA -3'); 500 permutations of DR2 motifs with variable spacer (5'-AGGTCNNNNGGTCA -3'); ~900 random control 13-mer DNA sequences and ~170 positive controls. A total of ~44,000 test sequences were spotted in quadruplicate on the slide as single-stranded DNA for a total of ~176,000 spots of DNA. The DNA was made double-stranded

and transiently transfected Cos-7 cells expressing human HNF4 $\alpha$ 2 or human HNF4 $\alpha$ 8 or liver NEs from adult male mice fed a standard rodent diet were applied. HNF4 $\alpha$  binding was imaged with 2- $\mu$ m resolution using Agilent G2565CA Microarray Scanner at the UCLA DNA Microarray Core. Extraction and normalization of the data were as described previously (82) using gProcessedSignal from Agilent software with background correction. PWMs were generated using seqLogo. See [Supplementary Table 5](#) for PBM results from the Caco-2 ChIPseq peaks (~25,000 unique sequences) presented in [Figure 5C](#) and the PBM Project at [Synapse.org](https://synapse.org) for the entire dataset.

## Rapid immunoprecipitation and mass spectrometry of endogenous proteins (RIME)

RIME was performed as previously described (85) with slight modifications. Livers from the same mice used for the RNA-seq and ChIP-seq – WT and  $\alpha$ 7HMZ males  $n=3$ , 16–18 weeks of age sacrificed at 10:30 (ZT 3.5) or 20:30 (ZT13.5) – were crosslinked and IP'd with the P1/P2 antibody. Multidimensional protein identification technology (MudPIT) analysis was performed by the UCR IIGB Proteomics Core. Raw MS1 and MS2 spectra were processed with Proteome Discoverer 2.1 (Thermo Scientific) and submitted to Mascot search engine to match against NCBI non-redundant mouse protein database. Only proteins with 1% FDR cut-off ( $q \leq 0.01$ ) were considered for subsequent analysis. Area under the curve, as reported by Proteome Discoverer, was averaged together for WT and  $\alpha$ 7HMZ samples ( $n=3$ ) at each time point. IgG samples ( $n=3$ ) from both WT and  $\alpha$ 7HMZ were averaged together to create a background sample. Areas were converted to log<sub>2</sub> scale and the fold-change above IgG background was calculated for the WT and  $\alpha$ 7HMZ samples. Proteins with less than 8-fold change above background were omitted. Similarly, a 8-fold difference between WT and  $\alpha$ 7HMZ samples was used to identify unique protein interactions.

## Primary metabolite, complex lipids and oxylipin analysis

All metabolomic analysis was performed at the West Coast Metabolomics Center at the University of California Davis as described previously (86) using liver tissue rinsed in cold PBS, snap frozen and stored in liquid nitrogen. Data (pmol/gm tissue or peak height) are presented as mean  $\pm$  standard error of mean (SEM). Student's T-test was used to determine statistical significance ( $p < 0.05$ ) using GraphPad Prism v6.

Primary metabolite (carbohydrates and sugar phosphates, amino acids, hydroxyl acids, free fatty acids, purines, pyrimidines, etc.) and complex lipid analysis (87) was on WT (C57BL/6N) and  $\alpha$ 7HMZ (backcrossed into C67BL/6N) male mice harvested mid-morning and fed the standard chow ( $n=8$ , aged 38 weeks). Fold-enrichment was performed using MetaboAnalyst (88). One outlier from each group was removed before plotting and statistical analysis. Analysis of non-esterified oxylipins was performed on a

mixed 129/Sv plus C57BL/6 background WT and  $\alpha$ 7HMZ males ( $n=3$  per group, aged 12–13 weeks). Tissue homogenates (100 mg) were extracted by solid phase extraction and analyzed by ultrahigh performance liquid chromatography tandem mass spectrometry (UPLC-MS/MS) (Agilent 1200SL-AB Sciex 4000 QTrap) as previously described (89, 90). Analyst software v.1.4.2 was used to quantify peaks according to corresponding standard curves with their corresponding internal standards.

## Quantification and statistical analysis

Differential gene expression (DEG) was measured using raw read counts with DESeq2: statistical significance was defined as adjusted p-value ( $\text{padj}$ )  $\leq 0.01$ , unless otherwise noted. Legends denote thresholds using log<sub>2</sub> fold change (log<sub>2</sub>FC) cutoffs. R library “gage” was utilized to identify differentially enriched KEGG pathways in [Figure 1](#). Heatmaps were generated with pheatmap package in R; data were row-normalized before plotting, except for NR heatmap in [Supplementary Figure 2](#). Transcription Factor (TF) rankings for Cleveland plots were ordered at the 13:30 (peak HNF4 $\alpha$  expression) then manually curated with the aid of PANTHER (Mi et al., 2017). Venn diagrams were generated by the VennDiagram package in R. Unique and common RIME results were submitted to DAVID for ontology analysis. Statistical significance for primary metabolite and complex lipid data defined as  $p \leq 0.05$  by Mann-Whitney U-test or Benjamini-Hochberg  $\text{padj} < 0.05$ , as indicated. All barplots represent mean  $\pm$  SEM; significant differences are noted between genotypes at a given time point, unless indicated otherwise. For FPKM plots,  $\text{padj}$  values are from DESeq2; in other plots, p-values are from two-way Student's T-test or One/Two-way ANOVA, as indicated. Student's Ttest was used while comparing two groups/conditions. One-way ANOVA was used for analyzing data for more than two groups that were compared for only one factor and two-way ANOVA was used for analyzing data from more than two groups that were compared for two factors. Posthoc analysis was applied for the ANOVAs to account for multiple comparisons. Standard statistical tests/programs were used for analyzing the metabolomics and transcriptomics data. External expression datasets and analysis are described in [Supplemental Methods](#).

## Data availability statement

The raw and processed RNA-seq data have been deposited in GEO under GSE117972 (<https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE117972>).

The raw and processed ChIP-seq data have been deposited in GEO under GSE231538 (<https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE231538>).

The processed PBM data (HNF4 $\alpha$ 8 PBM) have been deposited in Synapse.org under the PBM Project (DOI: <https://doi.org/10.7303/syn52624564>).

The raw metabolomics data (primary metabolites and complex lipids) have been deposited in Metabolomics Workbench ([www.metabolomicsworkbench.org](http://www.metabolomicsworkbench.org)) under Project #PR000461.

## Ethics statement

The animal studies were approved by Institutional Animal Care and Use Committee at the University of California, Riverside (UCR) and the McGovern Medical School, UT Health. The studies were conducted in accordance with the local legislation and institutional requirements.
