11

12 Manuscript IDJAGS-0369-SA-Mar-24

21 • Older adults have been under-represented in clinical trials of medications for disorders that are
22 prevalent but not unique to older adults despite efforts to enroll representative patient
23 populations.

24 • Recent legislation mandates “representative” enrollment in clinical trials and that
25 representativeness be defined by prevalences of the treatment indication in clinical populations

26 • To achieve the goal of representative clinical trial enrollment, current and continually updated
27 data on disease prevalences are needed and expansion of resources for clinical trial conduct will
28 be required.

29 **Why does this matter?**

30 Without the enrollment of older adults that are representative of clinical populations in clinical trials,
31 clinicians will continue to be faced with uncertainty as to the safety and efficacy of new drugs for older
32 adults.

34 **ABSTRACT**

35 Under-representation of subgroups of the population in clinical trials has been and continues to be a
36 problem despite goals of academia, industry, and government. Older adults are among the groups that
37 are under-represented in trials of medications that they are likely to receive once marketing approval has
38 been received. Recent legislation that mandates that clinical trial participants be representative of
39 patient population has been passed and creates hope that greater numbers of older adults will be enrolled
40 in clinical trials and that they will be representative of “typical” geriatric patients. However, there is the
41 need for collection of current data on disease prevalences with granularity as to age, gender, and race as
42 well as geriatric co-morbidities to assess the representativeness of clinical trial participants relative to
43 patient populations. Consensus on definitions and collection of data relevant to geriatric patient
44 populations are needed to evaluate effects of comorbidities, frailty, cognitive and physical function.
45 There will also be a need for expansion of the geriatric research workforce, facilities for research both in
46 academic centers but also in the community and long-term care facilities, and for engagement with and
47 involvement of communities that have been traditionally under-represented to conduct clinical trials that
48 enroll truly representative patient populations.

24 Manuscript IDJAGS-0369-SA-Mar-24

51 **Background**

52 The first “Guideline for the study of drugs likely to be used in the elderly” was published in 1989.¹ It
53 clearly stated that “Drugs should be studied in all age groups, including the geriatric, for which they will
54 have significant utility”. This concept was universally endorsed in 1994 with the International
55 Conference on Harmonization(ICH) E7 that stated a “meaningful number” of geriatric patients in the
56 age groups 65 and older and 75 and older is important. ² These documents stated the importance of
57 clinical testing programs adhere to harmonized guidelines based on ethical and scientific principles
58 so that the international development of valuable innovative drugs is achieved with maximum efficiency.
59 Harmonization in relation to medicines for geriatric populations was considered important because of
60 the increasing population of elderly in Europe, Japan, and the USA and the frequent occurrence of
61 underlying diseases, concomitant drug therapy and the consequent risk of drug interactions in the
62 elderly. In 2010 and 2012, the ICH7 guidelines were supplemented with questions and answers that
63 repeated the need for enrollment of representative numbers of older adult patients and that 100 older
64 patients were unlikely to be sufficient to determine older age-related differences in responses. The
65 document also suggested presenting data for four age subgroups to assess consistency of treatment
66 efficacy and safety with non-older adult patients. These 4 older age subgroups were: adults below 65
67 years of age, adults 65-74 years of age, adults 75-84 years of age and those 85 years and older. ^{3 4} These
68 guidances emphasized studying patients ≥ 75 years of age, avoiding arbitrary upper age limits in

28

29

30 Manuscript IDJAGS-0369-SA-Mar-24

69 clinical trials, encouraging inclusion of patients with concomitant illnesses, inclusion of older adult

70 patients in pivotal Phase 3 trials rather than separate trials, studying the pharmacokinetics (PK) of older

71 adult patients that could be done with sparse sampling population PK analyses if enough patients in

72 different age ranges were included in the trials, and studying the entire spectrum of the older adult

73 patient population to identify age-related differences not explained by other factors (renal and weight).

74 In 2012, the Food and Drug Administration Safety and Innovation Act (FDASIA) law mandated that

75 within one year, the FDA report publicly on the extent to which clinical trial participation and the

76 inclusion of safety and effectiveness data by demographic subgroups including sex, age, race, and

77 ethnicity is included in new drug applications submitted to the FDA.⁵ In response, the FDA established

78 the Drug Trials Snapshots that originally presented data on approved new drug applications for each

79 year with age breakdowns by multiple older age groups, by sex, and by race. The 2015 report provided

80 data on patients >65, ≥75 and ≥ 80 years of age, but only data aggregated for patients ≥65 years of age

81 have been reported since 2015.⁶

82 Yet, under-representation of subgroups of the population in clinical trials has continued and is present in

83 NIH trials as well as in pharmaceutical industry trials. The NIH has noted under-representation of

84 women and racial minorities, as well as older adults in clinical trials that are not specific to disorders in

85 those groups.⁷ An analysis of NIH-funded clinical trials in 2016 comparing the mean age of trial

86 participants to the mean age of manifestation of the conditions found that only trials on prostate cancer

31 **Submission Confirmation [Print](#)**

32
33 **Thank you for your submission**

34
35
36 Manuscript IDJAGS-0369-SA-Mar-24

87 came close to matching the age of the affected population.⁷ The analysis also found that older adults
88 were often excluded from trials altogether with 27 percent of the studies having arbitrary upper age caps,
89 and many studies had exclusion criteria that would indirectly exclude many older adults. A workshop
90 titled “Inclusion Across the Lifespan” was convened in June 2017 and a new NIH policy issued in
91 December 2017 that requires clinical study applications submitted to NIH to include a plan for enrolling
92 individuals across the lifespan.⁸ However, in a follow-up analysis presented at a workshop in 2020, it
93 was stated that NIH-funded investigators were still “not meaningfully including older adults and
94 children.”⁹

95 The continued inequity in clinical trial participants led to FDA guidance on enhancing clinical trial
96 diversity in 2020 with suggestions for further changes in eligibility criteria, enrollment practices, and
97 trial design to achieve greater clinical trial diversity.¹⁰ The lack of enrollment of older adults in cancer
98 trials received special attention in academia, professional organization, the scientific and lay literature
99 leading to draft guidance for industry on inclusion of older adults in cancer trials in 2020.¹¹ The NIA
100 has begun collecting individual level data on participants in clinical research but analyses have yet to be
101 published. A recent statement from the NIA Directors stated in a blog post on November 1, 2023 that
102 moving forward: “NIA will prioritize funding requests with proposed planned enrollment that are 1)
103 representative of the population affected by the disease, condition, or health experience; and 2)
104 appropriately inclusive of racial and ethnic groups; participants across the lifespan; as well as other

41

42 Manuscript IDJAGS-0369-SA-Mar-24

105 populations experiencing health disparities, including sexual and gender minority, persons with

106 disabilities, or socioeconomically disadvantaged and geographically underrepresented populations.”¹²

107 In parallel to the recognition of the failure to enroll representative older adults into pivotal clinical trials,

108 has come the recognition of the under-representation of other populations—especially racial minorities

109 and women. ⁶ The National Academies of Science, Education, and Medicine reported in 2021 that

110 pregnant and lactating individuals, sexual- and gender-minority populations, and racial and ethnic

111 subgroups of women remain underrepresented in clinical trials. ¹³ And perhaps most importantly, that

112 the racial and ethnic diversity of clinical trials has had little change in diversity over time. ¹³

113

114 **Where are the Biggest Gaps with regards to participation of Older Adults in Clinical Trials?**

115 The Roadmap to 2030 for New Drug Evaluation in Older Adults Workshop was held by the FDA in

116 2021.¹⁴ The objectives included reviewing current data on the inclusion of older adults in clinical trials

117 in select key therapeutic areas, identifying gaps in drug evaluation in older adults, and exploring

118 approaches to closing existing gaps. As part of the preparation for this workshop the enrollment of older

119 adults in clinical trials of new drug applications and biologics license applications approved by the FDA

120 for marketing from 2010 through 2019 was analyzed.¹⁵ The age distribution of clinical trial participants

121 enrolled in registration trials for heart failure, insomnia, non–small cell lung cancer (NSCLC),

47

48 Manuscript IDJAGS-0369-SA-Mar-24

122 nonvalvular atrial fibrillation (NVAF) stroke prevention, osteoporosis, and type 2 diabetes or adults was
123 compared with the age distribution of the U.S. population with the disease or disorder (prevalent
124 population). The participation to prevalence ratio (PPR) was calculated as the Percentage of Patients by
125 Age (Sub)Group Among Trial Participants/Percentage of Patients by Age (sub)Group Among US
126 Prevalent Population with a PPR of 0.8-1.2 considered adequate representation. These trials enrolled
127 almost 230,000 participants and all had under-representation of the oldest age groups. Trials for heart
128 failure, NVAF stroke prevention, osteoporosis, and sleep disorders had PPRs below 0.8 for ages 80
129 years and above. Heart failure trials had a PPR of about 0.2 for patients 80 years and older. Trials for
130 type 2 diabetes had PPRs below 0.8 for ages 65-74 years of age and was about 0.2 for ages 75 and older.
131 For all but the diabetes trials, the inclusion of older patients from 60 to 75 years of age was reasonably
132 close to the corresponding prevalence of the treatment indication in older adults. Illustrative prevalence
133 and PPR data for the NVAF stroke prevention and heart failure trials are shown in Fig 1. Other major
134 gaps identified at the workshop were the under-representation of older adults with frailty, multimorbidity
135 or polypharmacy in clinical trials, the lack of accepted criteria for benchmark “representative”
136 populations for clinical trial enrollment, the unknown effect of aging on pharmacodynamics and of
137 chronic conditions on pharmacokinetics and pharmacodynamics, efficacy, and safety in older adults, and
138 absence of patient-centered endpoints important to older adults. ¹⁶

54 Manuscript IDJAGS-0369-SA-Mar-24

140 **The upcoming paradigm shift to *representative patient population enrollment into Clinical Trials***

141 Despite guidances over the past few decades and universal endorsement of the principle of enrolling
142 representative populations into clinical trials of new therapeutic agents, this goal has not been achieved.
143 Many have hypothesized that only requirements and not ideals would accomplish this goal. The COVID
144 pandemic brought a focus on the disproportional burden and death rates of minoritized groups and older
145 adults. A glaring lack of inclusion of minorities and older adults in trials of COVID vaccines and
146 therapies was widely publicized.^{13,17} This created an environment ready for legislation to improve
147 clinical trial conduct and diversity. On December 29, 2022, President Biden signed into law “The
148 Consolidated Appropriations Act of 2023”.¹⁸ Included in the omnibus bill is the Food and Drug
149 Omnibus Reform Act of 2022 (“FDORA”), with provisions to promote diversity in clinical trial
150 enrollment, encourage the growth of decentralized clinical trials, and streamline clinical trials. This
151 finally provides a legal mandate for clinical trial participants to be representative of clinical populations.
152 Sections related to clinical trial participation are summarized in Figure 2. Implementation will require
153 achieving consensus and actions on several key issues for all populations and for geriatrics in particular.
154 These include:

155 1) How to Define and Evaluate Representativeness

156 2) Consensus on definitions for medical and health-related conditions and co-morbidities

157 a. Standardizing definitions and measurement for key geriatric conditions (such as frailty)

55 Submission Confirmation [Print](#)

56

57 **Thank you for your submission**

58

59

60 Manuscript IDJAGS-0369-SA-Mar-24

158 3) Addressing patient-level barriers and motivators to clinical trial participation

159 **1) Defining Representativeness: Age-stratified prevalence data.** The legislation suggests basing the
160 diversity plan on the “Estimated prevalence or incidence in the U.S. of the disease or condition for which
161 the drug or device is being investigated *if such estimated prevalence or incidence is known or can be*
162 *determined based on available data*”. The prevalence ratio (PPR) defined above as the percentage of
163 patients by age group among clinical trial participants to the percentage of patients by age group among
164 U.S. prevalent population is a logical approach. Advantages of this approach is that it would meet the
165 overall goal of providing the information on safety and efficacy in a representative population before a
166 drug or new chemical entity comes to market. In contrast to requiring blanket inclusion of older patients
167 (or pediatric patients), it would not mandate enrollment of older patients in trials of agents that are
168 unlikely to be used in this age group and expose them to unnecessary risks. Additionally, age is
169 universally measured the same way. Disadvantages of this approach is that numbers in subgroups
170 enrolled may be insufficient for comparative analyses, only the “healthiest in the age group” may be
171 enrolled, or those hypothesized to be at greatest risk may not be enrolled in sufficient numbers for
172 subgroup analyses. However, if multimorbidity is present in 2/3 to 3/4 of older adults this is likely to be
173 present in age-representative enrolled participants. Depending on whether the definition of frailty is
174 based on phenotype or accumulation of disorders, 25-50% of older adults 75 years of age and above will
175 have this condition and the likelihood of representation may be somewhat lower. Therefore, the

61 Submission Confirmation [Print](#)

62
63 **Thank you for your submission**

64
65
66 Manuscript IDJAGS-0369-SA-Mar-24

176 possibility of specific sample size targets for subgroups of interest may also need to be incorporated in
177 evaluations of enrollment plans.

178 A major hindrance to this approach is that currently published data on disease prevalences often
179 do not contain the detailed age information need to allow comparisons across the older age span and
180 publicly available sources may not be regularly updated. National health data are collected at varying
181 intervals but are often reported for broader age groupings and merge all data for older adults. In contrast,
182 the standards for reporting of U.S. ethnicity and race are standardized across government agencies
183 (specifically at minimum: ethnicity: Hispanic or Latino or not-Hispanic or Latino; race: American
184 Indian or Alaska Native, Asian, Black or African American, Native Hawaiian or Other Pacific Islander,
185 or White¹⁹).

- 186 • *Data Needs: Collection, Warehouse and Access to granular U.S. age and disease prevalence*
187 *data (Fig 3)*

188
189 **2) Consensus for Definitions of medical and health-related conditions and co-morbidities.**

190 Currently most clinical trials collect data and report on individual medical conditions and may analyze
191 data for effects on subgroups with the individual co-morbid condition. Co-morbid conditions are not
192 reported at an individual participant or age group level. Definitions for medical conditions may not be
193 uniform in clinical care records or survey data and may not be comprehensively collected or reported.

67 Submission Confirmation [Print](#)

68

69 **Thank you for your submission**

70

71

72 Manuscript IDJAGS-0369-SA-Mar-24

194 The legislation states that non-demographic factors, “including co-morbidities” are important to

195 consider. Co-morbid conditions are present in the majority of older adults but multiple approaches to

196 defining medical co-morbidities exist and consensus is needed for which are most informative for older

197 age groups or therapies for specific conditions.

198 • *Implementation Need: Standardized disease/condition and multiple co-morbid condition*

199 *definitions and nationally representative prevalence data stratified by age*

200 a) Defining Representativeness based on Function. Disease-specific functional status and outcomes

201 are used routinely for many clinical trials as are medical quality of life measures. However,

202 functional assessment of daily activities or independent daily activities have yet to be

203 incorporated into U.S. guidances, either for baseline assessment or for assessment of

204 drug/therapeutic effects. Alterations in these functions may be highly important to people and

205 may be especially affected by drugs with effects on the central nervous system.

206 • *Implementation Need: Collection and analysis of standardized functional status data*

207 **3) Addressing patient-level barriers and motivators to clinical trial participation.**

208 Recommendations to alter trial design and conduct to address the lack of “typical” older patients with

209 multiple chronic conditions in evaluations of new therapies have been made by academicians, journals,

210 politicians, professional societies and the government.^{7,16,20-27} Many suggestions focus on

73 Submission Confirmation [Print](#)

74

75 **Thank you for your submission**

76

77

78 Manuscript IDJAGS-0369-SA-Mar-24

211 decentralization of clinical trials with use of internet recruitment, consent, and virtual visits as well as

212 less frequent research encounters to relieve transportation challenges, as well as community-based trials

213 and engagement efforts to achieve broader racial participation. ^{7,16,20,21,28}

214 Age is one of the most-cited barriers to the use of telemedicine as well as with inability to access

215 internet-enabled devices or broadband internet in homes. ²⁹ Older adults may also have hearing and

216 vision disorders, as well as financial constraints that may present challenges for virtual clinical trial

217 enrollment and conduct.³⁰ Thus, it is not clear that a move to decentralization and virtual platforms

218 would enhance enrollment of representative older adults without provisions for internet access, training

219 on virtual and video platforms, provision of real-time support, closed captioning, and low vision

220 interfaces. Even if such provisions were made, our recent national survey found that 2/3 of adults with

221 multimorbidity would prefer clinical trials that included in-person visits and about 1/2 would not join a

222 clinical trial that had video or telephone only visits.³¹ Suggestions for changes in clinical trial design

223 and conduct are unlikely to have the desired outcome unless they align with the preferences of currently

224 under-represented older people with multiple medical conditions. A recent viewpoint concluded that “At

225 present, evidence for the advantages of decentralized clinical trials, including health equity–related

226 benefits, consists primarily of anecdotal reports, uncontrolled studies, and expert opinion.”³²

79 **Submission Confirmation [Print](#)**

80

81 **Thank you for your submission**

82

83

84 Manuscript IDJAGS-0369-SA-Mar-24

227 • *Implementation Need: Determine and Adopt Clinical Trial conduct preferences of*

228 *“representative” older adults*

229 **Other missing Pieces—Infrastructure: the clinical research workforce and networks. (Fig 4)**

230 Most of this paper has dealt with issues related to under-representation of older adults in clinical trials

231 but a lack of racial and ethnic diversity in clinical trial populations also exists. The barriers to overcome

232 inadequate recruitment of diverse patient groups may differ somewhat from older patients. Lack of

233 knowledge about clinical trials, trust, and opportunity/accessibility, differing language requirements,

234 lack of research personnel diversity may need to be addressed, and community engagement may need to

235 play a larger role.^{28 13 33}

236 Irrespective of diversity issues, the infrastructure for clinical trials and research needs to be expanded.

237 The numbers of sites and investigators and staff able to conduct clinical trials of high quality needs to be

238 increased if transportation and access issues are to be minimized. Networks may need to be created in

239 order to include potential participant pools not present in any one geographic area or to allow

240 participation across the continuum of care in the community, hospital, and long-term care sites.

241 Simplified institutional requirements and inter-institutional agreements are needed to facilitate

242 collaboration. Time for clinician participation and rewards for involvement in clinical trials need to be

243 created. Clinical research and trial participation needs to be promoted at all levels within the health care

85 **Submission Confirmation Print**

86

88

89

90 Manuscript IDJAGS-0369-SA-Mar-24

244 system but also in the community. Facilities must also be welcoming and able to accommodate all

245 populations of patients with differing physical and medical challenges.

246 **SUMMARY**

247 There is universal agreement that clinical trials should be representative of the clinical population that

248 will be treated with the tested therapies and that this goal has not been met with adequate representation

249 of older adults, or for racial or ethnic people. The 2023 Omnibus Bill now provides the legal impetus to

250 conduct trials that are representative of clinical populations but will require efforts and investment of

251 everyone involved in clinical research to implement changes to achieve this goal.

252 Acknowledgments. Dr. Schwartz credits her involvement in NASEM panels, an Oakridge fellowship at

253 the FDA, and participation in the AGS national meeting in 2023 as well as interactions with many

254 colleagues in AGS, UCSF and the FDA as contributing to the concepts presented in this paper.

352 **Figure Legends**

353 **Figure 1.** Recent enrollment by age subgroups in clinical trials of medications for heart failure (upper
354 left panel) and stroke prevention in patients with non-valvular atrial fibrillation (lower left panel) are
355 shown in orange and the prevalence of these conditions in the U.S. by age group in green as visual
356 examples to assess age representation. On the right, these same data are presented quantitatively with
357 the solid horizontal bars indicating the (clinical trial) participant to (U.S. patient) prevalence ratio (PPR).
358 The shaded green area indicates PPR's of 0.8-1.2 that are usually considered adequate representation.
359 Data from Reference ¹⁵

360 **Figure 2.** Summary of older-age relevant sections of the Consolidated Appropriations Act, 2023,
361 Chapter 1 Clinical Trial Diversity

362 **Figure 3.** Data needs to achieve representative patient enrollment in clinical trials includes initial and
363 continually updated disease prevalence and clinical trial enrollment data and analysis.

364 **Figure 4.** Infrastructure needs to achieve representative patient enrollment in clinical trials includes
365 expansion of the workforce with administrative support and community collaborators, places to conduct
366 the work, programmatic support with uniform platforms and protocols, and promotion at all levels of
367 society.

Encouraging clinical study participation that reflects the prevalence of the disease or condition among demographic subgroups, where appropriate, and other topics, including...

- how and when to collect and present the prevalence or incidence data on a disease or condition by demographic subgroup, including possible sources for such data and methodologies for assessing such data...
- the establishment of goals for enrollment in clinical trials, including the relevance of the estimated prevalence or incidence, as applicable, in the United States of the disease or condition for which the drug or device is being developed..
