of *de novo* Gln synthesis, only ectoderm generates sufficient Gln to sustain cell viability and differentiation, clarifying lineage fate restrictions under Gln withdrawal. Furthermore, Gln acts as a signaling molecule for ectoderm that supersedes lineage-specifying cytokine induction. In contrast, Gln in mesoderm and endoderm is the preferred precursor of  $\alpha$ -ketoglutarate without a direct signaling role. Our work raises a question about whether the nutrient environment functions directly in cell differentiation during development. Interestingly, transcriptome analysis of a gastrulation stage human embryo shows unique Gln enzyme-encoding gene expression patterns may also distinguish germ lineages *in vivo*. Together, our study suggests that intracellular Gln may help coordinate differentiation of the three germ layers.

## Graphical Abstract

## eTOC Blurp

Lu et al. report that cell type specific Gln requirements distinguish the three embryonic germ lineages upon pluripotency exit. They further uncover Gln acts as a signaling molecule to activate mTORC1 and enable downstream ectoderm, but not mesoderm nor endoderm, differentiation.

## INTRODUCTION

Human pluripotent stem cells (hPSCs) self-renew indefinitely or can be induced to differentiate into the three embryonic germ lineages, mesoderm, definitive endoderm (endoderm), and ectoderm (Takahashi et al., 2007; Thomson et al., 1998). Multiple studies show that specific nutrients can supply specific metabolic pathways to generate enzyme cofactors or substrates that enable or amplify PSC self-renewal or differentiation signals (Carey et al., 2015; Chantranupong et al., 2015; Moussaieff et al., 2015; Reid et al., 2017; Shiraki et al., 2014; TeSlaa et al., 2016; Voza et al., 2014; Wellen et al., 2010). We recently reported that mesoderm, endoderm, and ectoderm all consume Gln supplied in cell culture media, yet exogenous Gln deprivation suppressed mesoderm and endoderm lineages and promoted the ectoderm lineage upon spontaneous non-directed differentiation without affecting cell growth or proliferation. This result indicated that the lack of environmental Gln skewed cell fate specification (Lu et al., 2019), with a mechanism for Gln control of stem cell plasticity and lineage differentiation potential unknown.

Multiple case studies have shown the importance of Gln availability in fetal development. For example, inborn glutamine synthetase (GS) enzyme deficiency resulted in severe abnormalities in ectoderm-derived brain development and infant death in two unrelated newborns (Haberle et al., 2005; Haberle et al., 2006). Although the role of Gln as a metabolic precursor and anaplerotic fuel is well known, whether Gln itself has a direct role in stem cell fate determination remains unknown. A recent study reported non-metabolized glucose controlled lineage specification of totipotent stem cells in cleavage stage mouse embryos. Glucose as a nutrient, independent of glycolysis, initiated signaling and transcription to induce trophectoderm, which formed the extraembryonic structures of the placenta but not the embryonic inner cell mass (Chi et al., 2020). Accordingly, our finding that Gln withdrawal induced one cell lineage over others led to a more general question of whether nutrients, without conversion to their metabolic derivatives, can regulate embryonic cell fates.

Here, we report that Gln functions as a signaling molecule that enables the acquisition of ectoderm fate. The requirement for a Gln signal in ectoderm induction supersedes differentiation cues from lineage-inducing cytokines present in the media environment. In contrast, Gln has no direct signaling role and is mainly converted to  $\alpha$ -KG to drive mesoderm and endoderm specification. Gln also cannot be substituted by another nutrient, carbon source, or amino acid in tri-lineage differentiation, reinforcing its specificity in germ layer development. Additionally, we uncover that gene expression signatures of Gln utilization are differentially regulated in each germ lineage *in vivo*. Transcriptome signature analysis of a rare gastrulation stage human embryo resembles enzyme-encoding gene expression patterns found in our *in vitro* studies, generating the hypothesis that distinct Gln utilization may characterize germ lineages *in vivo*. Thus, our study suggests that nutrient signaling, particularly Gln signaling, may coordinate and facilitate germ layer fate determination.

## RESULTS

### Germ lineages have different Gln dependencies

We investigated Gln processing in hPSCs and the three embryonic germ lineages. hPSCs were directed to differentiate into mesoderm, endoderm, and ectoderm cells using nutrient-equivalent base media and lineage-inducing cytokines (Fig. 1A). We previously confirmed that this differentiation method generates homogenous, lineage-specific cell populations by RNA-Seq and transcription factor biomarker expression analyses (Lu et al., 2019), and also cross-referenced transcript profiles with an independent study to verify the reproducibility of this chemically defined differentiation system (Cliff et al., 2017).

To begin, we examined how each lineage handles Gln from the culture media. Two genes, *GLS* (herein *GLS1*) and *GLS2*, encode the first enzyme in Gln metabolism, glutaminase (GLS) and its isoenzymes, GLS1 (low  $K_m$ ) and GLS2 (high  $K_m$ ) (Fig. 1B). GLS amidohydrolase activity converts Gln into ammonia and glutamate (Glu), which can be processed into  $\alpha$ -KG for tricarboxylic acid (TCA) cycle anaplerosis or other uses (Katt et al., 2017). We used RNA-Seq to identify differential expression of glutaminolysis-related and Gln metabolism genes between hPSCs and lineage-induced progeny cells (Fig. 1C). hPSC differentiation repressed *GLS2* expression in all lineages, whereas induction of *GLS1* occurred in mesoderm and endoderm compared to slight repression in ectoderm during differentiation (Figs. 1C, 1D). This lineage-specific isoenzyme switching suggested that increased *GLS1* expression in mesoderm and endoderm could favor exogenous Gln processing, whereas ectoderm may depend less upon Gln from the external environment, consistent with our prior results (Lu et al., 2019).

To study whether ectoderm depends on external Gln, hPSCs were induced to differentiate in Gln-supplemented culture media (Ctr), Gln-free media ( $-$ Gln, except for trace/negligible amounts in Matrigel), or Gln-supplemented culture media with added GLS1 inhibitor, CB-839 (+GLS1i). Mesoderm perished in Gln-free and glutaminolysis-inhibited conditions (Figs. 1E, S1A, S1B) and endoderm had a similar but less drastic response to Gln perturbations (Figs. 1E, S1A). In contrast, ectoderm viability was unaffected by Gln-free and glutaminolysis-inhibited conditions (Figs. 1E, S1A, S1B). Our prior  $^{13}\text{C}$ -isotopologue tracing studies showed that Gln supplied the TCA cycle, with significant Gln-derived carbons and negligible glucose-derived carbons incorporated into  $\alpha$ -KG in all three germ lineages (Lu et al., 2019). To clarify whether mesoderm and endoderm cell death is from a dependence on Gln fueling the TCA cycle, the culture media was supplemented with cell permeable dimethyl  $\alpha$ -KG (dm- $\alpha$ -KG) or pyruvate. Addition of dm- $\alpha$ -KG or pyruvate, but not dichloroacetate (DCA; Fig. 1B) alone, to Gln-free media fully rescued endoderm viability (Figs. 1F, S1C). To quantify differentiation efficacy, differentiated cells were gated by lineage-defining transcription factor positive versus negative populations, which was set by hPSC expression levels. Only dm- $\alpha$ -KG addition to Gln-free conditions resulted in recovery of endoderm differentiation, as measured by the population of SOX17<sup>+</sup> cells, whereas added pyruvate restored viability but not endoderm differentiation (Fig. 1F). Similarly, only dm- $\alpha$ -KG, but not pyruvate, supplementation in Gln-free media completely restored both viability and biomarker validated mesoderm differentiation, as measured by

populations of CD34<sup>+</sup> and SNAI2/SLUG<sup>+</sup> cells (Figs. 1G, S1C). These data indicate that the Gln carbon backbone, retained through glutaminolysis conversion to Glu and then to  $\alpha$ -KG, is necessary for mesoderm and endoderm viability and differentiation. This substrate preference indicates that endoderm and mesoderm, but not ectoderm, favor  $\alpha$ -KG derivation from Gln specifically since glucose/pyruvate-derived carbons cannot substitute for Gln-derived carbons, at least as an alternative TCA cycle fuel or for other metabolic processes.

To study the observed exogenous Gln independence of ectoderm viability, we examined steady-state metabolite patterns in Gln-free and glutaminolysis-inhibited conditions using ultra-high performance liquid chromatography-mass spectrometry (UHPLC-MS) and quantified a panel of 153 central carbon metabolites. Metabolite set variation analysis (MSVA) showed that TCA cycle, amino acid, and pyruvate metabolic pathway activities were elevated in Gln-free compared to Gln-supplemented media (Figs. 1H, S1D), possibly through re-routing of glucose-derived carbons to maintain TCA metabolite levels. In contrast, glutaminolysis inhibition did not show significant metabolic pathway changes compared to no treatment (Figs. 1H, S1E), except for increased purine and pyrimidine metabolism. This suggested that Gln blocked from GLS1 enzymatic conversion to Glu is shunted toward enhanced nucleotide biosynthesis, possibly supporting proliferation (Figs. 1H, S1E). Notably, the Gln-free and glutaminolysis-inhibited metabolomes are distinct; a Gln-free environment results in decreased nucleotide biosynthesis and increased TCA cycle metabolites compared to GLS1 inhibition (Figs. 1H, S1F). Together, these findings indicate that exogenous Gln withdrawal results in widespread metabolic rewiring and that Gln oxidation in the TCA cycle is not required for ectoderm viability.

### Sufficient Gln synthesis distinguishes ectoderm from mesoderm and endoderm

Compensatory metabolic adaptations and sustained ectoderm viability in Gln-free media strongly suggested that ectoderm obtains Gln by *de novo* synthesis from GS conversion of Glu and ammonia to Gln (Fig. 1B) (Bott et al., 2015; Fu et al., 2019; Issaq et al., 2019; Kung et al., 2011; Stadtman, 2004; Tardito et al., 2015). Consistent with this assessment, GS enzyme is highly expressed in Gln-free, but not in Gln-supplemented, media during ectoderm differentiation (Figs. 2A, S2A). Equivalent lineage-specifying PAX6, and suppression of pluripotent OCT4 and NANOG, transcription factor expression also indicated that downstream ectoderm differentiation was unaffected by Gln-free conditions (Figs. 2A, S2A). Prior to widespread cell death, mesoderm and endoderm cells also upregulate GS in response to exogenous Gln withdrawal, an unexpected finding because of the dependence of mesoderm and endoderm cells on exogenous Gln for survival (Fig. S2B). However, heavy isotopologue tracing showed low levels of <sup>13</sup>C<sub>5</sub>-Gln derived from <sup>13</sup>C<sub>5</sub>-glutamic acid at steady state in mesoderm and endoderm cells in Gln-free media (Figs. 2B, S2C). Additionally, there is minimal derivation of <sup>13</sup>C<sub>5</sub>- $\alpha$ -KG from <sup>13</sup>C<sub>5</sub>-glutamic acid in mesoderm and endoderm cells, indicating that even though these lineage cell types are capable of *de novo* Gln synthesis, insufficient levels of Gln and/or  $\alpha$ -KG are generated, resulting in cell death upon exogenous Gln withdrawal (Figs. 1F-G, 2B, S2C). Combined, the data suggests that ectoderm uniquely responds to exogenous Gln withdrawal

by synthesizing sufficient endogenous Gln, in contrast to an insufficient Gln synthesis adaptation that occurs during mesoderm and endoderm differentiation.

### Requirement of intracellular Gln for all germ lineages

We next asked whether ectoderm required Gln at all. Cells were differentiated in the presence of 6-Diazo-5-oxo-L-norleucine (DON), a Gln mimetic that alkylates Gln utilizing enzymes, resulting in >95% death of mesoderm, endoderm, and ectoderm cells (Figs. 2C, 2D). Pharmacological inhibition of GS with MSO in Gln-free media also compromised mesoderm, endoderm, and ectoderm cell viability (Figs. 2C, 2D). This hinted that Gln, and/or the by-products of Gln metabolism, is still required for ectoderm, similar to mesoderm and endoderm. The small percentage (< 2%) of residual viable cells at the end of differentiation grown with either Gln mimetic (Ctr+DON) or Gln-starvation (-G+M) showed significantly decreased populations of respective lineage-specifying transcription factors SNAI2/SLUG (mesoderm), SOX17 (endoderm), and PAX6 (ectoderm) (Figs. 2D, S2D). This indicated that intracellular Gln supports germ lineage cell survival and differentiation potential. Mesoderm and endoderm require exogenous Gln as metabolic fuel for glutaminolysis-derived  $\alpha$ -KG (Figs. 1F-1G), whereas ectoderm synthesizes Gln for role(s) other than glutaminolysis and its reaction products (Figs. 1E, 2A-B, S2A, S2C).

We performed steady-state metabolite profiling by UHPLC-MS following acute Gln-starvation (-G+M) to identify altered Gln-derived metabolites in ectoderm at the initiation of the differentiation process. Aside from Gln, the largest decrease in metabolites occurred for  $\alpha$ -KG, hexosamine biosynthesis pathway (HBP) intermediates, purine nucleosides, and glutathione redox status (GSH/GSSG) (Figs. 2E). Metabolite rescue was attempted by supplementing Gln-starved ectoderm with cell-permeable forms of these Gln-derived metabolites (Fig. 2F) (Qie et al., 2019). Verification of uptake and conversion to related metabolites was confirmed for all supplementations, with the exception of GSH, which did not significantly alter intracellular GSH and GSSG levels (Fig. S2E). The addition of HBP metabolite glucosamine-6-phosphate (GlcN6P) yielded the largest rescue of ectoderm cell viability with a single agent at ~57% (Figs. 2F, S2F), and the combination of GlcN6P and nucleosides resulted in the highest ectoderm cell survival at ~69% compared to control conditions (Figs. 2G, S2F), although full rescue was not achieved with any metabolite or binary combination (Figs. 2F-2G, S2F). Despite partial viability rescue with GlcN6P supplementation, pluripotency is not completely repressed by D5 of differentiation in live-gated Gln-starved (-G+M) ectoderm cells under this metabolite rescue condition, as measured by a residual OCT4<sup>+</sup> cell population (Figs. 2G). Furthermore, supplementation with combined GlcN6P and nucleosides showed significantly decreased populations of PAX6<sup>+</sup>MAP2B<sup>+</sup> and PAX6<sup>+</sup>SOX1<sup>+</sup> ectoderm cells compared to Gln-supplemented (Ctr) and Gln-free (-Gln) conditions by D5 of differentiation (Figs. 2G, S2F). Together, the data show that replenishment of HBP and nucleosides partially restored Gln-starved ectoderm cell viability, but did not restore differentiation, suggesting that Gln has a role in ectoderm generation in addition to a role as a precursor for metabolites.

## Initial Gln absence impairs ectoderm differentiation

Impaired ectoderm differentiation could be a consequence of reduced cell viability due to chronic Gln-starvation. Alternatively, Gln absence could directly impact the ectoderm specification program(s). To examine these possibilities, we measured differentiation status while cell viability and cell cycle progression were progressively altered as Gln-starvation time increased (Figs. 3A, S3A). We quantified ectoderm differentiation status after 24h of Gln-starvation (–G+M), a time point with equivalent viable ectoderm cells relative to control conditions (Fig. 3A). Flow cytometry of live-gated cells showed decreased ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>, PAX6<sup>+</sup>SOX1<sup>+</sup>) cells, and qRT-PCR showed decreased expression of *MAP2B*, *PAX6*, and *OTX2* transcripts in Gln-starvation compared to Gln-supplemented and Gln-free conditions (Figs. 3A, S3B). This differentiation impairment increased with starvation time, and pluripotency biomarkers (OCT4<sup>+</sup>NANOG<sup>+</sup>, OCT4<sup>+</sup>TRA1-81<sup>+</sup>) were suppressed with differentiation regardless of Gln availability (Figs. 3A). Combined, these findings showed that reduced ectoderm differentiation and cell cycle drop out occurred within 24h of Gln-starvation.

To assess a temporal requirement for Gln in implementing ectoderm fate, we replenished Gln after pulsed Gln-starvation while retaining inducing cytokines throughout this differentiation condition (Gln-repletion) (Fig. 3B). After 24h of initial Gln-starvation, Gln-repletion (–G+M→Ctr) completely rescued the viability and cell cycle of ectoderm cells by D5 (Figs. 3B, S3C). However, ectoderm differentiation was not rescued at D5 following Gln-repletion, as indicated by significantly decreased ectoderm specifying biomarkers (PAX6, MAP2B, SOX1, SOX2) quantified by flow cytometry and immunofluorescence imaging (Figs. 3C, 3D, S3D). Pluripotency exit occurred regardless of initial Gln availability during initial ectoderm differentiation as indicated by suppressed pluripotency biomarkers (OCT4, NANOG, TRA-81, SOX2) relative to hPSC progenitors, although Gln-repletion resulted in slight residual pluripotency biomarker expression compared to Gln-supplemented and Gln-free conditions (Figs. 3C, 3D, S3E). Additionally, impaired ectoderm differentiation does not compensate with alternative lineage-specific biomarker (SOX17, endoderm; CD34, mesoderm) expression, confirming the specific failure for an ectoderm fate (Fig. S3E). To exclude off-target effects of MSO treatment in Gln-starved conditions, H9 hPSCs containing short hairpin RNA (shRNA) knockdown of *GLUL*, encoding for GS, were differentiated for 5 days in Gln-free media, and equally led to ectoderm cell death (Figs. 3E, S3F, S3G). We found that a shorter, initial Gln-starvation period of 14h followed by Gln-repletion (–Gln→Ctr) was sufficient to impair ectoderm differentiation, as quantified by a decreased population of PAX6<sup>+</sup>MAP2B<sup>+</sup> cells (Fig. 3E). Additionally, supplementation with Gln-derived metabolites during the initial 14h Gln-starvation period (–G+M+GlcN–6P+nuc→Ctr) equally resulted in impaired ectoderm differentiation (Fig. S3H). Impaired ectoderm differentiation was independent of cell proliferation, nascent protein synthesis, and ATP levels, which were all unaffected immediately after 14h of Gln-starvation and at later time points after Gln-repletion (Figs. 3F-H, S3I-S3J). These results suggest that Gln is required within the first 14h of directed ectoderm differentiation to activate the ectoderm program, a fate that could not be rescued by Gln restoration following this window of time.

To study the ectoderm specificity of this temporal Gln requirement in the larger context of germ layer differentiation, mesoderm and endoderm were grown in initial 14h Gln-free (–Gln) and Gln-starvation (–G+M) media conditions followed by Gln-repletion (→Ctr). Strikingly, initial Gln absence did not affect subsequent mesoderm nor endoderm specification (Figs. 3I-3J). This demonstrates that a temporal Gln requirement is specific to ectoderm differentiation and highlights distinct signatures of Gln dependency for each respective germ lineage cell fate (Fig. 3K).

### Ectoderm differentiation requires Gln-dependent mTORC1 signaling

Because addition of Gln-derived metabolites and delayed Gln add-back failed to restore ectoderm fate specification, we considered an alternative possibility that Gln could signal to activate a nutrient-sensing pathway, similar to glucose signaling in trophectoderm (Chi et al., 2020). Recent work showed that Gln is a substrate that activates the mammalian target of rapamycin complex 1 (mTORC1). mTORC1 activation by Gln occurs through Rag GTPase-dependent activation by Gln exchange for exogenous leucine and arginine, or by Rag GTPase-independent activation directly from a Gln interaction with Arf1 GTPase (Jewell et al., 2015; Meng et al., 2018; Saxton and Sabatini, 2017). We observed that phosphorylation of the canonical mTORC1 substrate, ribosomal protein S6 kinase 1 (S6K1-Thr389), in 24h Gln-starved ectoderm is significantly reduced, indicating mTORC1 inhibition (Figs. 4A, S4A). Pulsed addition of mTORC1 inhibitor rapamycin during initial 14h of tri-lineage differentiation replicated initial Gln-starvation (–G+M→Ctr), with impaired ectoderm and unaffected mesoderm and endoderm differentiation (Figs. 3C-3E, 3I-3K, S3D-S3E, 4B). This result suggested that initial mTORC1 activation, like intracellular Gln presence, is critical for and specific to ectoderm differentiation.

To investigate whether Gln-dependent mTORC1 activation is essential for ectoderm differentiation, we transduced two separate hPSC lines, H9 and UCLA1, with a constitutively active mTORC1 expression vector, *Raptor-Rheb15*, and a control, wild-type (WT) *Raptor* {Sancak et al., 2010}. Construct expression was verified by puromycin selection and DYKDDDDK (FLAG) tag detection (Fig. S4B), and hPSCs were directed toward ectoderm differentiation with an initial 14h Gln-starvation. As anticipated, mTORC1 activation was sustained in Raptor-Rheb15 but not in WT-Raptor transduced hPSCs differentiated into ectoderm with Gln-starvation (Fig. 4C, S4C). After an initial 14h Gln-starvation, Gln-repletion (–G+M→Ctr) completely rescued the viability and cell cycle of ectoderm cells at D5 (Figs. S4D-S4E). Gln-repletion in WT-Raptor ectoderm cells resulted in significantly reduced lineage-specifying biomarkers (PAX6, MAP2B, SOX1, SOX2, OTX2) at D5, whereas Raptor-Rheb15 ectoderm cells grown under the same experimental conditions showed minimal, non-significant changes in ectoderm specification compared to Gln-supplemented and Gln-free conditions at D5 (Figs. 4D-4E, S4F). These results indicated that, in addition to nascent protein synthesis being unaffected within an acute 14h Gln-starvation period (Figs. 3G, S3J), the lack of Gln incorporation into polypeptides was not the cause of impaired ectoderm differentiation because successful ectoderm specification occurred in Raptor-Rheb15 hPSCs following transient Gln absence.

To evaluate the concentration of Gln that impacts differentiation, we performed Gln add-back titrations. Reports suggest that the primary source of Gln in the embryo and fetus is derived from placental conversion of Glu to Gln, with maternal and fetal Gln concentrations ranging from 0.8-1.0 mM (Cruzat et al., 2018; Holm et al., 2017; McIntyre et al., 2020; Neu, 2001). This concentration range is consistent with the amount of Gln required to restore differentiation in transient 14h Gln-starved ectoderm cells at D5, with full recovery of PAX6<sup>+</sup>MAP2B<sup>+</sup> and SOX2<sup>+</sup>OCT4<sup>-</sup> cells starting at 0.8 mM Gln (Figs. 4F, S4G-S4H).

We tested whether only the first hours of ectoderm specification depend on intracellular Gln by performing Gln-starvation studies in the intermediate and late stages of differentiation. Results indicate that only early transient (-G+M→Ctr), but not intermediate (Ctr→-G+M→Ctr) nor late stage (Ctr→-G+M), Gln absence impaired ectoderm differentiation (Figs. 4G, S4I). This suggests that Gln-dependent mTORC1 activation is an early requirement for downstream functional ectoderm specification.

We next asked whether the initial absence of other mTORC1 sensed amino acids impacted ectoderm differentiation. Since leucine (Leu) and/or arginine (Arg) signaling to activate mTORC1 is well-characterized (Wolfson and Sabatini, 2017), H9 and UCLA1 hPSCs were differentiated in Leu- or Arg-free media for the first 14h, followed by repletion until D5. We observed that from these mTORC1 sensed amino acids, only the initial absence of Gln, and not Leu nor Arg, impaired initial mTORC1 activation and downstream ectoderm differentiation, indicating specificity for the Gln requirement (Figs. 4H, S4J-S4K).

Finally, we confirmed that constitutively active mTORC1 is not compatible with mesoderm nor endoderm directed-differentiation, as indicated by significantly decreased levels of cell viability in Raptor-Rheb15 compared to WT-Raptor transduced cells. At the differentiation endpoint, the remaining ~20% live Raptor-Rheb15 mesoderm cells did not exhibit significantly decreased lineage nor pluripotency biomarker expression, whereas the ~60% live endoderm cells showed decreased lineage and pluripotency biomarker expression (Figs. 4I, S4L). This result supports a working model in which early mTORC1 activity is critical for ectoderm differentiation but is detrimental to mesoderm and endoderm differentiation (Figs. 4A, S4A, S4M), highlighting distinct requirements for germ lineage cell fates. The data showed that a Gln signal activates mTORC1 within the initial hours of differentiation induction to produce ectoderm (Fig. 4J). Gln itself, but not the by-products of Gln metabolism, were required for ectoderm differentiation.

### Transcriptome signatures suggest unique, lineage-specific Gln utilization *in vivo*

Our experimental model of Gln withdrawal and add-back is a useful tool to identify nutrient specificities *in vitro*, similar to gain and loss of function genetic studies, and provided predictions for potential differences in Gln dependency for each germ layer *in vivo*. Although hPSC differentiation is a reproducible method for studying human gastrulation (Taniguchi et al., 2019), cross-referencing hPSC results to available *in vivo* data would add further support for lineage-specific Gln utilization. To generate hypotheses for potential translation of these hPSC study results, we compared hPSC findings with human embryo development at approximately the same post-implantation stage (Mascetti and Pedersen, 2016; Taniguchi et al., 2019). To do this, we queried the single cell RNA-Seq transcriptome

of a gastrulating human embryo ~16-19 days post fertilization (Tyser et al., 2020). Since hPSC derived mesoderm and endoderm depend on exogenous Gln, and ectoderm can synthesize sufficient Gln *de novo*, we used these distinguishing features as a proxy for Gln utilization patterns. We calculated the ratio of Gln degradation [averaged (*GLS1* + *GLS2*) transcripts] to endogenous Gln synthesis [*GLUL* transcripts] to correlate the tendencies for Gln auxotrophy versus prototrophy in each lineage. In both *in vitro* (Fig. 5A) and queried *in vivo* (Fig. 5B) transcriptome datasets, we found that Gln degradation transcripts were much lower than Gln synthesis transcripts in ectoderm, but not in mesoderm nor endoderm related lineages, as quantified by the [averaged (*GLS1* + *GLS2*)]/*GLUL* ratio. A comparison of our *in vitro* hPSC-derived germ lineage model versus the *in vivo* human gastrula sample showed similar clustering of Gln degradation to synthesis ratios in corresponding lineages. Thus, relative lineage-specific Gln consumption and synthesis transcript patterns identified in the *in vitro* model and *in vivo* sample may be maintained in the human embryo (Fig. 5C), and presents an enticing hypothesis for future studies.

## DISCUSSION

Our current understanding of how metabolism permits cell state transitions between pluripotency and differentiation is fragmented and limited. A particular knowledge gap is that previous studies focused largely on the metabolic roles of Gln and its by-products in maintaining pluripotency (Carey et al., 2015; Marsboom et al., 2016; Tohyama et al., 2016; Vardhana et al., 2019) or regulating multipotent cell lineages (Johnson et al., 2018; Oburoglu et al., 2014; Yu et al., 2019). Here, we report that Gln itself is a required signaling molecule in ectoderm differentiation. We demonstrate that Gln synthesis and consumption is differentially regulated between lineages *in vitro*, and possibly *in vivo*, and that Gln has an irreversible temporal requirement in ectoderm, but not mesoderm nor endoderm, lineage differentiation (Fig. 5D).

*In vivo* evidence for the developmental significance of Gln and mTORC1 has recently been reported, in which dysregulated Gln-Glu cycling and mTORC1 signaling contributed to placental dysfunction and fetal growth restriction (McIntyre et al., 2020). Additionally, prior studies showed that mTORC1 inhibition favors PSC differentiation to mesoderm and endoderm lineages, yet a mechanism has never been reported (Jung et al., 2016; Nazareth et al., 2016; Zhou et al., 2009). Our results show that a Gln activating signal for mTORC1 enables ectoderm, whereas this nutrient-signaling activation is detrimental for mesoderm and endoderm fates, as an attempt to direct differentiation of constitutively active mTORC1 Raptor-Rheb15 hPSCs into mesoderm and endoderm lineages led to widespread cell death. Gln is essential for mTORC1 activation within the first hours of ectoderm induction, because a transient absence of Gln in this initial period, but not in later time periods, caused slight residual pluripotency biomarker retention and diminished ectoderm-specifying biomarker expression. In contrast to this strict ectoderm time requirement for Gln, mesoderm and endoderm cells achieve full differentiation even with an initial Gln absence (Figs. 4J, 5D, S5A-S5E, S6A).

Gln is a non-essential amino acid not previously implicated in germ lineage differentiation, but here we reveal it is conditionally essential and depends upon cell fate context. A

divergence in Gln essentiality depending on germ lineage was unexpected since all three lineages initiate from a common pluripotent progenitor cell. We speculate on the possibility of a Gln-specific symbiotic relationship amongst the three germ lineages during early *in vivo* development. Specifically, ectoderm may generate *de novo* Gln to support nearby mesoderm and endoderm cells dependent on exogenous Gln, which could influence tissue patterning. This hypothesis is supported by our previous media footprint profiling data showing high secretion of Gln in ectoderm and high consumption of Gln in mesoderm (Lu et al., 2019). Patterns of Gln metabolism during blastocyst development may be one of multiple input signals for embryos experiencing nutrient gradients and discontinuities. This tempting possibility is also suggested, but not yet proven, by human embryo transcriptome data showing the Gln synthesis to consumption expression signature is higher in ectoderm compared to mesoderm and endoderm lineages, which is at least consistent with our *in vitro* model system (Figs. 5A-C). Thus, our data begin building a framework for how temporal and/or spatial fluctuations in Gln could potentially impact normal development.

In conclusion, our findings uncover a new testable model in which a nutrient acts as a signaling molecule that could differentially coordinate the development of the three embryonic germ lineages. Our study provides several testable hypotheses for nutrient-specific signaling cues as contributors to organizational structure and fidelity in early mammalian development. These include targeting key Gln gatekeeping enzymes in *in vivo* development models, and future investigations of additional nutrient specificities implicated in cell fate decisions. These findings could also provide more logical manipulations of the metabolite environment and pathway fluxes *in vitro* to produce higher quality hPSC derivatives for disease modeling, tissue engineering, and eventual therapeutic usage.

## LIMITATIONS

Here, we report that specific Gln requirements define the three embryonic germ lineages upon *in vitro* pluripotency exit. We further uncover Gln acts as a signaling molecule to activate mTORC1 and enable downstream ectoderm differentiation. However, two main limitations temper our study conclusions. First, to the best of our knowledge, transient Gln removal does not occur during *in vivo* development. Thus, this experimental perturbation does not reflect endogenous regulation, but was a useful tool to identify nutrient specificities of different cell types. Second, we present correlative evidence linking *GLS1*, *GLS2*, *GLUL* RNA expressions to potential functional *in vivo* trilineage Gln dependency. This is a study limitation since transcript levels do not necessarily equate to protein abundance/activity. We note that this comparison of relative gene expression made between embryo tissue and hPSC-derived cells may inspire future work regarding *in vivo* tissue-specific regulation of Gln metabolism.

## STAR METHODS

### RESOURCE AVAILABILITY

**Lead contact**—Further information and requests for reagents will be addressed by the corresponding author, Michael A. Teitell (MTeitell@mednet.ucla.edu).

**Materials availability**—This study did not generate new unique reagents.

**Data and code availability**—Raw RNA-Seq data for nutrient balanced hPSC and tri-lineage differentiation to ectoderm, mesoderm, and endoderm were deposited in the NCBI Gene Expression Omnibus (GEO) under accession number GSE127270. All raw and processed UHPLC-MS metabolomics data from this study are in Excel spreadsheet format as Supplemental Table 1. All data were analyzed with standard programs and packages, as detailed above. All R Jupyter notebooks and supplemental files used to process RNA-Seq and UHPLC-MS data will be uploaded upon manuscript press to Github at <https://github.com/fahsan/GlnFateGatekeeper>. All raw images, immunoblots, and values for quantification are available from the corresponding author and lead contact on request.

## EXPERIMENTAL MODEL AND SUBJECT DETAILS

**Cell culture**—Human embryonic stem cell (hESCs) lines H9 (WA09 – Female, RRID:CVCL\_9773) and UCLA1 (Female, RRID:CVCL\_9951) were grown in six-well tissue culture-treated polystyrene microplates (Falcon, 08-772-1B). Polystyrene plates were coated with feeder-free Matrigel basement membrane matrix (Corning, CB-40234A) diluted at 1:60 in DMEM/F-12 w/o glutamine (Gibco, 21331020), and incubated for 30 m at 37°C. hESCs were cultured in mTeSR Plus (Stemcell Technologies, 05825), with media changes every 48h, to 80% confluency at 5% CO<sub>2</sub> in a 37°C incubator. For passaging, hESCs were washed with DPBS 1x w/o calcium & magnesium (Corning, 21031CV) and removed from culture plates using Gentle Cell Dissociation Reagent (Stemcell Technologies, 07174) at 37°C for 5 m. Cells were passaged onto Matrigel-coated plates in mTeSR Plus as described above. Cells were tested for mycoplasma (Lonza, LT07-418) every two weeks.

**Tri-lineage directed differentiation**—Twelve-well tissue culture-treated polystyrene microplates (Falcon, 08-772-29) were coated in Matrigel basement membrane matrix. hESCs at 75%-85% confluency were removed from culture plates and dissociated into single cells using Gentle Cell Dissociation Reagent at 37°C for 10 min. Gentle Cell Dissociation Reagent was diluted in an equal volume of DMEM/F-12 (Gibco, 11320033). hESCs were scraped and centrifuged at 450 x g for 5 m, and cell number was quantified with a hemocytometer. Cells were reseeded at 125,000 cells/cm<sup>2</sup> onto Matrigel-coated plates in mTeSR Plus with 10 μM ROCK inhibitor (Y-27632; Stemcell Technologies, 72304).

**Ectoderm differentiation**—To generate ectoderm, seeded cells were changed to a chemically-defined nutrient-balanced differentiation media 48 h after seeding. Cells were differentiated over a five-day period, cultured in DMEM/F12 supplemented with 450 μM 1-Thioglycerol (Millipore Sigma, M6145), 1 mg/mL BSA (Gibco, 15260037), 0.11 μM 2-mercaptoethanol (Gibco, 21985023), 1% Glutamax (Gibco, 35050061), 1% N-2 supplement (Gibco, 17502048), 2% B-27 supplement (Gibco, 17504044), 10 μM SB43154 (Stemgent, 04-0010), and 0.2 μM Dorsomorphin (Stemgent, 04-0024). Media was sterilized through a 0.22 μm filter (Denville, 1210N26), and changed every 24 h until D5 differentiation.

**Mesoderm differentiation**—To generate mesoderm, seeded cells were changed to a chemically-defined nutrient-balanced differentiation media 48 h after seeding. Cells were

differentiated over a five-day period, cultured in DMEM/F12 supplemented with 450  $\mu$ M 1-Thioglycerol, 1 mg/mL BSA, 0.11  $\mu$ M 2-mercaptoethanol, 1% Glutamax, 0.7  $\mu$ g/mL insulin (Millipore Sigma, 11376497001), 15  $\mu$ g/mL transferrin (Millipore Sigma, 10652202001), 1 mL/100 mL chemically-defined lipid concentrate (Gibco, 11905031), 100 ng/mL VEGF-165 (Stemcell Technologies, 78073.1), 100 ng/mL BMP4 (Peprotech, 120-05ET), and 20 ng/mL FGF2 (Peprotech, 78003). During the first 24 h of differentiation, media was supplemented with 100 ng/mL Activin A (Stemcell Technologies, 78001). Media was sterilized through a 0.22  $\mu$ m filter (Denville, 1210N26), and changed every 24 h until D5 differentiation.

**Endoderm differentiation**—To generate endoderm, seeded cells were changed to a chemically-defined nutrient-balanced differentiation media 48 h after seeding. Cells were differentiated over a three-day period, cultured in DMEM/F12 supplemented with 450  $\mu$ M 1-Thioglycerol, 1 mg/mL BSA, 0.11  $\mu$ M 2-mercaptoethanol, 1% Glutamax, 0.7  $\mu$ g/mL insulin (Millipore Sigma, 11376497001), 15  $\mu$ g/mL transferrin (Millipore Sigma, 10652202001), 1 mL/100 mL chemically-defined lipid concentrate (Gibco, 11905031). During the first 24 h of differentiation, media was supplemented with 100 ng/mL Activin A, 2  $\mu$ M CHIR99021 (Stemcell Technologies, 72052), and 50 nM PI-103 (Fisher Scientific, 29-301). After 24 h of differentiation, media was supplemented with 100 ng/mL Activin A and 250 nM LDN 1931189 (Stemgent, 04-0074). Media was sterilized through a 0.22  $\mu$ m filter (Denville, 1210N26), changed every 24 h until D3 differentiation.

## METHOD DETAILS

**Glutamine perturbations**—For all glutamine-free conditions, differentiation media (as described above) was made with DMEM/F-12 w/o glutamine and in the absence of 1% Glutamax (note: trace/negligible amounts of glutamine may be present in Matrigel). To achieve glutamine-starvation conditions, glutamine-free media was supplemented with 1 mM L-methionine sulfoximine (Millipore Sigma, 91016). Metabolite rescue experiments were performed under glutamine-starvation media in the presence of 8 mM dimethyl 2-oxoglutarate (Millipore Sigma, 349631), 60  $\mu$ L/mL Embryomax nucleosides (Millipore Sigma, ES-008), 10 mM D-glucosamine 6-phosphate (Millipore Sigma, G5509), 2 mM D-(+)-glucosamine hydrochloride (Sigma-Aldrich, G1514), or 1 mM L-glutathione reduced (Millipore Sigma, G6529). Gln utilization was blocked by addition of 50  $\mu$ M 6-diazo-5-oxo-L-norleucine (Millipore Sigma, D2141) or 1  $\mu$ M CB-839 (Selleckchem, S7655) to either Gln-supplemented or Gln-free media. Gln, Arg, or Leu starvation/deprivation timed pulse experiments were performed by culturing cells in respective deprivation conditions for an initial 14 h or 24 h, washed with PBS, and then grown in Gln, Arg, or Leu replete conditions until D5 of differentiation.

**Intracellular flow cytometry**—Cells were dissociated using Gentle Cell Dissociation Reagent for 10 m, diluted in sterile dPBS, and pelleted at 450 x g for 5 m. Supernatant was aspirated off, and cells were re-suspended in 250  $\mu$ L of Fixation/Permeabilization solution (BD Biosciences, 554714) and incubated at 4°C for 30 m. Following fixation, cells were washed with 1x BD Perm/Wash Buffer (BD Biosciences, 554714) and pelleted at 450 x g for 5 m. Cells were re-suspended in 100  $\mu$ L of 1x BD Perm/Wash Buffer. Conjugated antibodies were incubated with fixed cells for 45 m at 4°C in the dark. Samples were

processed on a LSRFortessa flow cytometer (BD Biosciences) and analyzed using FlowJo software (FlowJo, Inc.). For cell viability quantifications, values were generated from EF780 Fixable Viability Dye negative (EF780-) cell populations or from Annexin A5 and 7AAD double negative (%AV- 7AAD- dn) cell populations. For cell cycle quantifications, values were determined based on 7AAD-stained DNA content and histone H3 (phospho-S28). Experiments were performed at least three independent times. The following conjugated antibodies were used: Alexa Fluor 647 Rat anti-histone H3 (pS28) (BD Biosciences, 558217), APC anti-DYKDDDDK tag (Biolegend, 637308), PE Mouse anti-SNAI2/Slug (BD Biosciences, 564615), Alexa Fluor 488 Mouse anti-human Sox17 (BD Biosciences, 562205), PerCPCy5.5 Mouse anti-human PAX6 (BD Biosciences, 562388), human Pax6 PE-conjugated antibody (R&D Systems, IC8150P-100), Alexa Fluor 488 mouse anti-MAP2B (BD Biosciences, 560399), PE Mouse anti-human Sox1 (BD Biosciences, 561592), Alexa Fluor 488 mouse anti-Oct3/4 (BD Biosciences, 560253), V450 mouse anti-Sox2 (BD Biosciences, 561610), PerCP-Cy5.5 mouse IgG2a,  $\kappa$  isotype control (BD Biosciences, 558020), Alexa Fluor 700 mouse IgG1,  $\kappa$  isotype control (BD Biosciences, 557882), Alexa Fluor 488 mouse IgG1  $\kappa$  isotype control (BD Biosciences, 557782), PE mouse IgG1  $\kappa$  isotype control (BD Biosciences, 556680), V450 mouse IgG1, and  $\kappa$  isotype control (BD Biosciences, 560373). For flow cytometry quantification of phosphorylated mTORC1 substrates, the following antibodies were used: rabbit anti-phospho-p70 S6 kinase (Thr389) (108D2) (Cell Signaling, 9234) and Alexa Fluor 568 goat anti-rabbit IgG (H+L) (Invitrogen, A11036, 1/1000).

**Immunofluorescence**—Cells were differentiated in 35 mm  $\mu$ -Dish on No. 1.5 ibitreat polymer coverslips (ibidi GmbH, 81156, 80416) coated with Matrigel (Corning, CB-40234A). Cells were fixed in 4% methanol-free formaldehyde (Thermo Scientific, 28906) for 10-15 min at RT. Cells were washed with PBS, permeabilized with 0.3% Triton X-100 in PBS for 10 min at RT, washed again with PBS, and incubated in blocking buffer (5% normal donkey serum in PBS) for 1hr at RT. Cells were incubated with primary antibodies diluted in blocking buffer overnight at 4C, washed with PBS, then incubated with secondary antibodies diluted in blocking buffer for 1hr at RT. Cells were counterstained and mounted with ibidi Mounting Medium with DAPI (ibidi GmbH, 50011, nD 1.42–1.44). The following antibodies were used: rabbit anti-OCT-4 (Cell Signaling, 610517, 1/200), mouse anti-OCT-4 (Cell Signaling, 2750, 1/200), goat anti-human NANOG (R&D Systems, AF1997, 5  $\mu$ g/mL), mouse anti-SOX2 (Cell Signaling, 4900, 1/400), rabbit anti-PAX6 (Cell Signaling, 60433, 1/200), mouse anti-MAP2 (Invitrogen, MA5-12826, 1/500), rabbit anti-OTX2 (Abcam, ab114138, 4  $\mu$ g/mL), goat anti-Brachyury/TBXT (R&D Systems, AF2085, 15  $\mu$ g/mL), rabbit anti-SLUG/SNAI2 (Cell Signaling, 9585, 1/400), rabbit anti-SLUG/SNAI2 (Cell Signaling, 9585, 1/400), mouse anti-SOX17 (Invitrogen, MA5-24891, 1/100), rabbit anti-FoxA2/HNF3 $\beta$  (Cell Signaling, 8186, 1/400), mouse anti-DYKDDDDK Tag (Cell Signaling, 8146, 1/200), rabbit anti-phospho-p70 S6 kinase (Thr389) (Cell Signaling, 9234). Actin counterstain was done following ActinRed™ 555 ReadyProbes® Reagent Protocol (Rhodamine phalloidin) (Invitrogen, R37112). All secondary antibodies were from sourced from donkey host of the Alexa Flour series (Life technologies, A-31573, A-21202, A-21432, A-11055, A-31570).

**Confocal microscopy image acquisition and processing**—Imaging was performed on Leica TCS SP8 DLS (Digital LightSheet) confocal microscope, equipped with a Galvo X resonant scanner and sCMOS camera controlled by the Leica Application Suite (LAS) X software, using a HC PL APO CS2 63x/1.40 OIL lens and a TD 488/552/638 main beamsplitter. Pinhole size was set to 1AU with an 8,000 Hz scan speed. 2048 x 2048 8- or 16-bit images at 1.25 zoom were acquired using HyD (410nm - 527nm, 655nm - 685nm) and PMT (567nm - 607nm) detectors. All samples with the same immunolabeling and/or compared to each other were acquired with the same settings. DAPI was excited with Diode 405 nm laser line and emission collected with HyD detector (455±45nm). Alexa Fluor 488 was excited with OPSL 488 nm laser line and emission collected with HyD detector (518±13nm) or PMT (518±21nm). Alexa Fluor 555 was excited with OPSL 552 nm laser line and emission collected with HyD detector (584±23nm) or PMT (569±10nm). Alexa Fluor 647 was excited with Diode 638 nm laser line and emission collected with HyD detector (670±15nm).

All compared image sets had identical processing in shift phase (arithmetic mean), denoising (median filtering with radius of 2-6 pixels), and histogram normalization (brightness and contrast) using the Leica Application Suite (LAS) X software according to field standards (Aaron and Chew, 2021; Schmied and Jambor, 2020). All experiment interpretations and data analysis were done on raw image files. False color LUTs and image merges were done on the Leica Application Suite (LAS) X software.

**qRT-PCR**—Cells were grown to between 70% and 80% confluence and harvested as described above. RNA was isolated using the RNeasy Mini Kit (Qiagen, 74104) and RNase-free DNase (Qiagen, 79254) following the manufacturer's protocols. RNA was quantified using a Nanodrop spectrophotometer (Thermo Scientific). cDNA was synthesized with 2 µg of RNA using the iScript cDNA synthesis kit (Bio-Rad, 1708841). qRT-PCR was performed on a LightCycler480 (Roche) using SYBR green (Roche, 04887352001). Experiments were performed at least three independent times. Primers were used as follows: *RPLPO*, forward, 5'-CAGATTGGCTACCCAACTGTT-3', reverse, 5'-GGAAGGTGTAATCCGTCTCCAC-3'; *OCT4*, forward, 5'-CAAAGCAGAAACCCTCGTGC-3', reverse, 5'-TCTCACTCGGTTCTCGATACTG-3'; *NANOG*, forward, 5'-CCCCAGCCTTTACTCTTCCTA-3', reverse, 5'-CCAGGTTGAATTGTTCCAGGTC-3'; *SOX2*, forward, 5'-TACAGCATGTCCTACTCGCAG-3', reverse, 5'-GAGGAAGAGGTAACCACAGGG-3'; *MAP2*, forward, 5'-CTCAGGACCGCTAACAGAGG-3', reverse, 5'-CATTGGCGCTTCGGACAA-3'; *OTX2*, forward, 5'-CAAAGTGAGACCTGCCAAAAGA-3', reverse, 5'-TGGACAAGGGATCTGACAGTG-3'; *PAX6*, forward, 5'-TGGGCAGGTATTACGAGACTG-3', reverse, 5'-ACTCCCGCTTATACTGGGCTA-3'; *GLS1*, forward, 5'-TGGTGGCCTCAGGTGAAAAT-3', reverse, 5'-CCAAGCTAGGTAACAGACCCTGTTT-3'; *GLS2*, forward, 5'-AACGAATCCCTATCCACAAGTTCA-3', reverse, 5'-GCAGTCCAGTGGCCTTTAGTG-3'; *GLUL*, forward, 5'-AAGAGTTGCCTGAGTGGAATTC-3', reverse, 5'-AGCTTGTTAGGGTCCTTACGG-3'.

**Immunoblot**—Cells were grown to between 70% and 80% confluence and harvested as described above. Cells were lysed in SDS buffer (40 mM Tris-HCl pH 6.8, 3% glycerol, 1% SDS), 1x protease inhibitor (Sigma, P8340) and 1x phosphatase inhibitor (Sigma, P5726 and Sigma, P0044). Protein concentrations were quantified using a BCA assay (Pierce). 50  $\mu$ g aliquots were supplemented with 5% 2-mercaptoethanol and loaded onto gels at 90 V for 20 m followed by 120 V for 75 m. Protein was transferred to a nitrocellulose membrane at 250 mA for 2 h. Membranes were blocked with Odyssey Blocking Buffer TBS (Li-Cor, 927-50010) for 30 m and incubated in primary antibodies overnight at 4°C. Following incubation, membranes were washed in TBST for 20 m. IRDye-conjugated secondary antibodies IRDye 680RD donkey anti-rabbit IgG (H + L) (LiCor, 926-68703, 1/10,000) and IRDye® 800CW goat anti-mouse IgG (H + L) (LiCor, 925-32210, 1/10,000) were added to membranes, incubated for 1 h at RT, and washed in TBST for 20 m. All images were captured with an Odyssey Fc (Licor). Experiments were performed at least three independent times. The following antibodies were used: rabbit anti-pyruvate dehydrogenase E1-alpha subunit (phospho S293) (ab177461, 1/500), rabbit anti-pyruvate dehydrogenase E1-alpha subunit (ab168379, 1/500), mouse anti-glutamine synthetase (BD Biosciences, 610517, 1/500), rabbit anti-PAX6 (Cell Signaling, 60433, 1/500), mouse anti- $\beta$ -tubulin (Millipore Sigma, T4026, 1/10,000), rabbit anti-phospho-p70 S6 kinase (Thr389) (108D2) (Cell Signaling, 9234, 1/500), rabbit anti-p70 S6 kinase (49D7) (Cell Signaling, 2708, 1/500).

### Click chemistry reactions

**EdU labeling:** Samples were cultured for 4 h with fresh media supplemented with 5  $\mu$ M EdU (Invitrogen, A10044), harvested and fixed in 100  $\mu$ L 4% phosphate-buffered paraformaldehyde for 15 m at RT, permeabilized in 100  $\mu$ L of saponin-based permeabilization wash for 15 m at RT, and proceeded to Click-iT reaction labeling.

**L-Azidohomoalanine (AHA) labeling:** Samples were pulsed for 15 m with DMEM/F-12 w/o L-methionine (US Biological Life Sciences, D9807-05A) differentiation media for optimized AHA labeling. Then, samples were cultured in DMEM/F-12 w/o L-methionine differentiation media with 1 mM AHA (Sigma-Aldrich, 900892; labeling condition) or 0.1 mM L-methionine (Sigma-Aldrich, M5308; control condition) for 1 h. As a negative control, nascent protein synthesis was blocked by addition of 1  $\mu$ M Blasticidin S HCL (Gibco, A1113903) to AHA-supplemented media. As with EdU labeling, samples were harvested and fixed in 100  $\mu$ L 4% phosphate-buffered paraformaldehyde for 15 m at RT, permeabilized in 100  $\mu$ L of saponin-based permeabilization wash for 15 m at RT, and proceeded to Click-iT reaction labeling.

**Click chemistry reaction:** For EdU labeling, Alexa Fluor 488 azide (Invitrogen, A10266) was used. For AHA labeling, Alexa Fluor 488 Alkyne (Invitrogen, A10267) was used. Freshly prepared Click-iT reagent mix was made with saponin-based wash reagent, 100 mM copper(II) sulfate (Sigma-Aldrich, C1297), Click-iT buffer additive (Invitrogen, C10269), and 1  $\mu$ M Alexa Fluor 488 azide or Alexa Fluor 488 Alkyne. Following permeabilization, samples were incubated with 500  $\mu$ L reagent for 30 m at RT in the dark, then washed twice

with saponin-based wash reagent. Samples were then stored in saponin-based wash reagent at 4°C in the dark for flow cytometry and/or further intracellular antibody labeling.

**shRNA knockdown**—pLKO.1 vectors containing shRNA targeting *GLUL* RNA transcripts were purchased from Sigma-Aldrich (Sigma, SHCLNG-NM\_002065 TRCN0000343991 and SHCLNG-NM\_002065, TRCN0000343992). pLKO.5 vectors containing shRNA control targeting non-mammalian turboGFP were also purchased from Addgene (Sigma, SHC 202). Vectors were packaged along with pCMV-dR8.2 dvpr (Addgene, 8455) and pCMV-VSV-G (Addgene, 8454) into HEK293FT cells. HEK293FT cells were seeded into 100 mm dishes and grown to 65% - 80% confluence in DMEM with L-Glutamine and Sodium Pyruvate (Corning, MT10013CV) supplemented with 10% Fetal Bovine Serum (Omega Scientific, FB-11), 1% Glutamax, and 1% non-essential amino acids (Gibco, 1140). HEK293FT cells were transfected with 829  $\mu$ L of .020  $\mu$ g/ $\mu$ L plasmid solution (8  $\mu$ g shRNA plasmids, 8  $\mu$ g pCMV-dR8.9, 2  $\mu$ g pCMV-VSVG) in OptiMEM (Gibco, 11058021) and Fugene HD (Promega, E2312). Media was collected 48 h and 60 h after transfection and concentrated using Lenti-X Concentrator (Clontech, 631231). hESC lines grown until 80% confluency were transduced with 5 – 10 x 10<sup>5</sup> lentiviral particles and 6  $\mu$ g/mL polybrene for 8 h on D1. Transduction was repeated on D2 and D3, doubling viral concentration each successive day. Transduced cell lines were selected with 1  $\mu$ g/mL puromycin on D5 – 8.

**cDNA transfection**—pLJM1 vectors FLAG Raptor Rheb 15, FLAG Raptor, and Empty were purchased from Addgene (26634, 26633, 91980). Vectors were a gift from the laboratories of David Sabatini and Joshua Mendell. Vectors were packaged along with pCMV-dR8.2 dvpr (Addgene, 8455) and pCMV-VSV-G (Addgene, 8454) into HEK293FT cells. HEK293FT cells were seeded into 100 mm dishes and grown to 65% - 80% confluence in DMEM with L-Glutamine and Sodium Pyruvate (Corning, MT10013CV) supplemented with 10% Fetal Bovine Serum (Omega Scientific, FB-11), 1% Glutamax, and 1% non-essential amino acids (Gibco, 1140). HEK293FT cells were transfected with 829  $\mu$ L of .020  $\mu$ g/ $\mu$ L plasmid solution (8  $\mu$ g shRNA plasmids, 8  $\mu$ g pCMV-dR8.9, 2  $\mu$ g pCMV-VSVG) in OptiMEM (Gibco, 11058021) and Fugene HD (Promega, E2312). Media was collected 48 h and 60 h after transfection and concentrated using Lenti-X Concentrator (Clontech, 631231). hESC lines grown until 80% confluency were transduced with 5 – 10 x 10<sup>5</sup> lentiviral particles and 6  $\mu$ g/mL polybrene for 8h on D1. Transduction was repeated on D2 and D3, doubling viral concentration each successive day. Transduced cell lines were selected with 1  $\mu$ g/mL puromycin on D5 – 8.

**Media preparation for metabolite extraction and UHPLC-MS processing**—For Gln-free conditions, ectoderm differentiation media (as described above) was made with DMEM/F-12 w/o glutamine and in the absence of 1% Glutamax. For glutaminolysis-inhibited conditions, ectoderm differentiation media (as described above) was made with DMEM/F-12 supplemented with 1  $\mu$ M CB-839. To achieve Gln-starvation conditions, Gln depleted media was additionally supplemented with 1 mM L-methionine sulfoximine (Millipore Sigma, 91016). For Gln-replete conditions, ectoderm differentiation media was made with DMEM/F-12 w/o glutamine and .01% Glutamax. For Glu conversion to Gln

isotopologue tracing, cells were labeled with 0.5mM  $^{13}\text{C}_5$ -Glu for 1 h under defined Gln perturbation conditions.

**Metabolite extraction and UHPLC-MS processing**—Ultra-high performance liquid chromatography and mass spectrometry was performed as previously described (Lu et al., 2019). To extract intracellular metabolites, cells were washed with warm PBS for less than 10 s, rinsed with ice-cold 150 mM ammonium acetate (pH 7.3), and quenched with 1 mL/well of cold 80% MeOH in water. Wells were scraped and contents transferred to Eppendorf tubes and vortexed for 10 s. 5 nmol D/L-norvaline was added to each cell suspension as an internal control, and tubes were centrifuged at 16,000 x g for 15 m at 4°C. The supernatant was transferred into glass vials and dried under a vacuum. Dried metabolites were re-suspended in 50% ACN:water and one-tenth was loaded onto a Luna 3um NH2 100A (150 x 2.0 mm) column (Phenomenex). The chromatographic separation was performed on an Ultimate 3000RSLC or a Vanquish Flex (Thermo Scientific) with mobile phases A (5 mM NH<sub>4</sub>AcO pH 9.9) and B (ACN) and a flow rate of 200 µl/min. A linear gradient from 15% A to 95% A over 18 m was followed by 9 m isocratic flow at 95% A and re-equilibration to 15% A. Metabolites were detection with a Thermo Scientific Q Exactive mass spectrometer run with polarity switching (+3.5 kV/- 3.5 kV) in full scan mode with an m/z range of 65-975. TraceFinder 4.1 (Thermo Scientific) was used to quantify the targeted metabolites by area under the curve using expected retention time and accurate mass measurements (< 5 ppm). Experiments were performed with three biological replicates.

## QUANTIFICATION AND STATISTICAL ANALYSIS

**Metabolomics data analysis**—Metabolomics analysis was performed as previously described (Waters et al., 2019). Data analysis was performed using the statistical language R v3.6.3 and Bioconductor v3.6.1 packages (Huber et al., 2015; R Core Team, 2017). Metabolite abundance was normalized per µg of protein content per metabolite extraction, and metabolites not detected were set to zero.

Pathway-level relative amounts metabolite set variation analysis (MSVA) was performed using R Bioconductor package GSVA v1.26.0 (Hanzelmann et al., 2013). Metabolite normalized relative abundances were standardized using a  $\log_2(\text{normalized amounts} + 1)$  transformation, and metabolites per sample were converted to a pathways per sample matrix using function `gsva()` with parameters “method = gsva, rnaSeq = FALSE, abs.ranking = FALSE, min.sz = 5, max.sz = 500”. GSVA pathway enrichment scores were then extracted and significance testing between conditions was calculated using R Bioconductor package `limma` v3.34.9, fitting a linear model to each metabolite and assessing differences in normalized abundance using an empirical Bayes moderated F-statistic with an adjusted *P* value threshold of 0.05, using the Benjamini-Hochberg false discovery rate of 0.05 (Benjamini and Hochberg, 1995; Ritchie et al., 2015). Pathway metabolite sets were constructed using the KEGG Compound Database and derived from the existing Metabolite Pathway Enrichment Analysis (MPEA) toolbox (Kanehisa et al., 2012; Kankainen et al., 2011).

**RNA-Seq analysis**—RNA-Seq data analysis was performed as previously described (Lu et al., 2019). TPM values were extracted from GEO:GSE127270 for genes that were determined to be differentially expressed via statistical testing using R Bioconductor package DESeq2 v1.18.1 (Love et al., 2014). Differentially expressed genes were identified using Wald significance testing, with an adjusted P value threshold below 0.05 for one or more comparisons. A *variance stabilized transform* matrix (*VST*) was generated using DESeq2, and subset for the differentially expressed genes (DEGs) identified above. *VST* values were row scaled by subtracting the average mean per gene row between samples, and then averaged per condition. Heatmaps were generated using R Bioconductor package pheatmap v1.0.8 (Kolde, 2015).

**Comparison of Gln synthesis to Gln consumption:** RNA-Seq data from a previous publication (Lu et al., 2019) and single cell RNA-Seq data from Tyser et al. 2020 (Tyser et al., 2020) were used to query the ratio of Gln consumption transcripts [average(*GLS1* + *GLS2*)] to Gln synthesis transcripts [*GLUL*]. For the single cell RNA-Seq data, the ratio was calculated for each individual cell and then normalized to the average Epiblast value. For bulk RNA-Seq, each replicate was normalized to the average hPSC value.

**Statistical testing**—Statistical testing for all data except for RNA-Seq and UHPLC-MS metabolomics was performed using Prism 7 and 8 (Graphpad). Details for statistical testing of RNA-Seq and UHPLC-MS metabolomics data are included in the section above. Unless otherwise noted, each experiment is n=3, where n represents the number of independent biological replicates. Statistical details can be found in each figure legend. Parametric data were analyzed using Student's t tests or one-/two-way ANOVA with multiple comparisons correction. Metabolite pathway enrichment values were quantified using empirical Bayes linear modelling with multiple hypothesis correction. P values < 0.05 were considered significant for all data assayed. \*P < 0.05, \*\*P < 0.01, \*\*\*P < 0.001, \*\*\*\*P < 0.0001.

**HIGHLIGHTS**

1. All three lineages make *de novo* Gln, but only ectoderm can survive in Gln-free media.
2. Intracellular Gln is more crucial than cytokines for enabling ectoderm specification.
3. Exogenous Gln is the preferred precursor for  $\alpha$ -KG in mesoderm and endoderm.
4. Transcriptome of a human embryo shows unique Gln enzyme-encoding expression patterns.

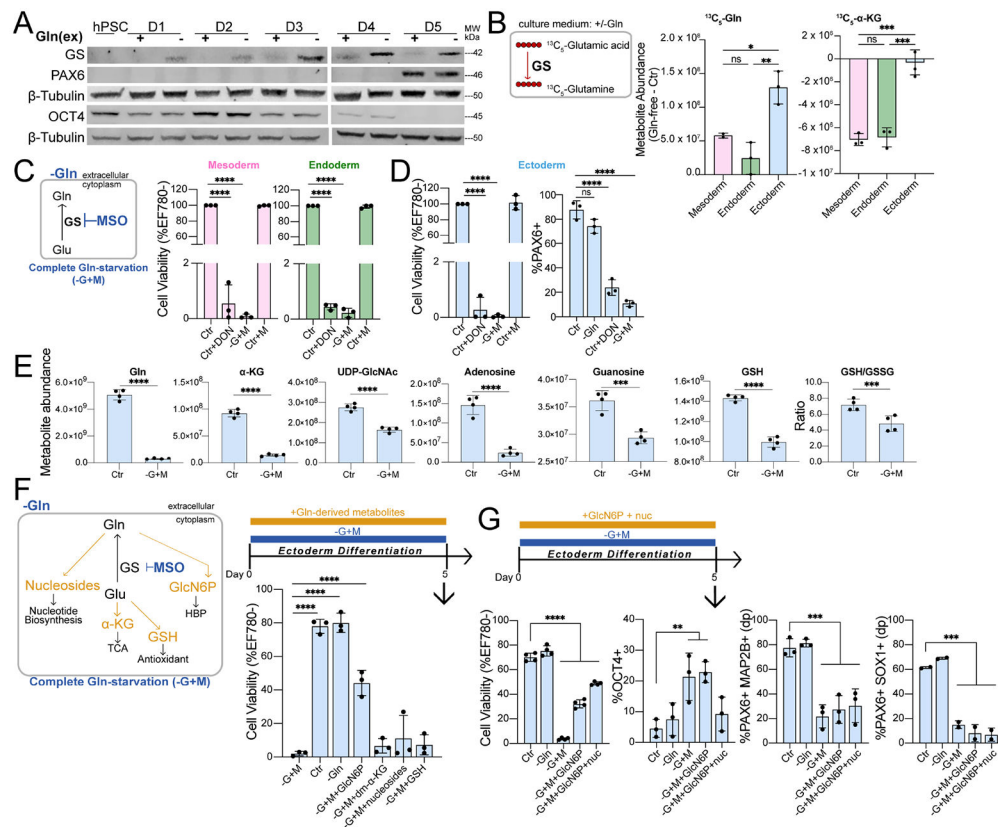

**Figure 1. The germ lineages have distinct dependencies on exogenous Gln and catabolism**  
**(A)** hPSC differentiation into three embryonic germ lineages mesoderm, endoderm, and ectoderm in nutrient-equivalent culture media.  
**(B)** Schematic of Glc and Gln entry into the TCA cycle. Gln catabolism and anabolism pathways highlighted in grey box. Dichloroacetate (DCA) increases pyruvate flux into the TCA cycle.  
**(C)** Heatmap of differentially expressed glutaminolysis enzyme transcripts. Values represent the Z-score of variance stabilizing transformation (VST) normalized RNA-Seq counts across each gene listed (n=6). Genes shown are significantly altered between pairwise combinations of hPSC, mesoderm, endoderm, and mesoderm ( $p < 0.05$ ).  
**(D)** qRT-PCR analysis of *GLS1* and *GLS2* isoenzymes in mesoderm, endoderm, and ectoderm throughout differentiation.  
**(E)** Cell viability of D5 mesoderm, D3 endoderm, and D5 ectoderm cells grown in Gln-free (-Gln) or Gln-supplemented with added 1 μM CB-839 glutaminase inhibitor (+GLS1i) culture media relative to Gln-supplemented (Ctr).  
**(F)** Cell viability of D3 endoderm cells grown in Gln-free (-Gln) or Gln-supplemented with added 1 μM CB-839 glutaminase inhibitor (+GLS1i) culture media relative to Gln-supplemented (Ctr).  
**(G)** Cell viability of D5 mesoderm cells grown in Gln-free (-Gln) or Gln-supplemented with added 1 μM CB-839 glutaminase inhibitor (+GLS1i) culture media relative to Gln-supplemented (Ctr).  
**(H)** AGSVA Score (relative to Ctr) for various metabolic pathways.

**(F-G)** Cell viability and differentiation quantifications of H9-derived **(F)** endoderm (SOX17<sup>+</sup>) and **(G)** mesoderm (CD34<sup>+</sup>, SNAI2/SLUG<sup>+</sup>) cells in Gln-free and metabolic rescue conditions.

**(H)** Metabolite set variation analysis of ectoderm cells in Gln-free (-Gln) or added CB-389 (+GLSi) conditions. Scores represent pathway enrichment difference between the given treatment to baseline vehicle (Ctr) (n = 3). Pathways displayed are significantly enriched either with -Gln or +GLSi treatment relative to Ctr (p < 0.05).

Data represent mean ± SD of n = 3 biological replicates. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001; \*\*\*\*p < 0.0001. The p values were determined by **(C)** Wald test with Benjamini-Hochberg FDR correction, **(D)** two-way ANOVA, **(E-G)** one-way ANOVA with correction for multiple comparisons, or **(H)** moderated t-statistics determined using empirical Bayes linear modelling.

**Figure 2. Sufficient Gln synthesis distinguishes ectoderm from other germ lineages**

(A) Immunoblot of GS, PAX6, and OCT4 expression during H9-derived ectoderm differentiation in Gln-free conditions.

(B) Difference in  $^{13}\text{C}_5$ -Gln and  $^{13}\text{C}_5$ - $\alpha$ -KG amounts derived from  $^{13}\text{C}_5$ -glutamic acid in Gln-free ( $-$ Gln) relative to supplemented (Ctr) conditions.

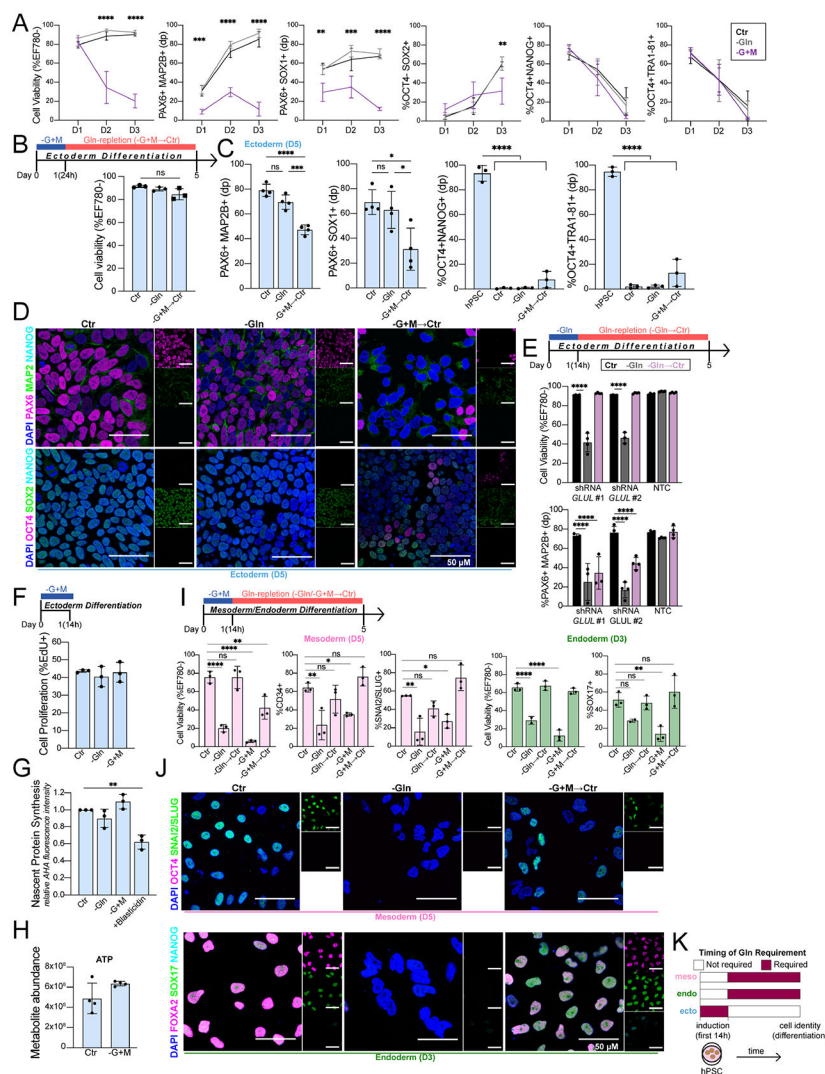

(C-D) (Left) Complete Gln-starvation ( $-$ G+M) is attained by culturing cells in Gln-free media and inhibiting *de novo* Gln synthesis with 1 mM MSO. (Right) Cell viability of (C) mesoderm, endoderm and (D) differentiation of ectoderm cells grown in Gln-free ( $-$ Gln) conditions with 50  $\mu\text{M}$  DON or 1 mM MSO relative to Gln-supplemented (Ctr) media.

(E) Metabolite abundance quantified by UHPLC-MS in differentiated ectoderm cells treated in Gln-supplemented (Ctr) or 1h Gln-starvation ( $-$ G+M) conditions.

(F) (Top) Schematic of Gln-starvation ( $-$ G+M) supplemented with individual cell-permeable Gln-derived metabolites. (Bottom) Cell viability of H9-derived D5 ectoderm cells differentiated in Gln-starvation and supplemented with GlcN6P, dm- $\alpha$ -KG, nucleosides, or GSH.

(G) Cell viability and percentage of ectoderm (PAX6 $^+$ MAP2B $^+$  double positive (dp), PAX6 $^+$ SOX1 $^+$  (n=2)) and pluripotent (OCT4 $^+$ ) biomarkers in H9-derived D5 ectoderm cells grown in Gln-starvation with added GlcN6P or both GlcN6P and nucleosides.

Data represent mean  $\pm$  SD of n = 3 biological replicates unless indicated otherwise. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001; \*\*\*\*p < 0.0001. The p values were determined by (B-D, F, G) one-way ANOVA, or (E) unpaired two-tailed Student's t test with correction for multiple comparisons.

**Figure 3. Gln is required at the initiation of ectoderm, but not mesoderm and endoderm**  
**(A)** Cell viability and percentage of ectoderm (PAX6+MAP2B+, PAX6+SOX1+, OCT4+SOX2-) and pluripotent (OCT4+NANOG+, OCT4+TRA1-81+) biomarkers in H9-derived ectoderm cells grown continuously in Gln-starvation for D1 (24h), D2 (48h), and D3 (72h).  
**(B)** (Top) Schematic of pulsed Gln-starvation experiments. Ectoderm cells were Gln-starved for the first 24h of differentiation then switched to Gln-supplemented media (Gln-repletion, -G+M→Ctr) until D5. (Bottom) Cell viability of H9-derived D5 ectoderm cells after initial 24h Gln-starvation.  
**(C)** Percentage of ectoderm (PAX6+MAP2B+, PAX6+SOX1+) and pluripotent (OCT4+NANOG+, OCT4+TRA1-81+) biomarkers in H9-derived D5 ectoderm cells after initial 24h Gln-starvation (-G+M→Ctr).  
**(D)** Representative immunofluorescence images of ectoderm and pluripotent biomarkers in H9-derived D5 ectoderm cells grown in Gln-supplemented (Ctr), Gln-free (-Gln), or Gln-repletion after initial 24h Gln-starvation (-G+M→Ctr). (Top) PAX6 (magenta, ectoderm); MAP2B (green, ectoderm); NANOG (cyan, pluripotent). (Bottom) OCT4

(magenta, pluripotent); SOX2 (green, ectoderm/pluripotent); NANOG (cyan, pluripotent).

Scale bar indicates 50  $\mu\text{m}$ .

**(E)** H9-derived ectoderm expressing shRNA targeting *GLUL* (shRNA *GLUL* #1; shRNA *GLUL* #2) or a non-targeting control (NTC). Cell viability and percentage of PAX6<sup>+</sup>MAP2B<sup>+</sup> D5 ectoderm cells in Gln-supplemented (Ctr), Gln-free (-Gln), or Gln-repletion after initial 14h Gln-free treatment (Gln→Ctr).

**(F)** Percentage of proliferating H9-derived ectoderm cells (EdU<sup>+</sup> staining) immediately after 14h Gln-free or Gln-starvation treatment.

**(G)** Nascent protein synthesis in H9-derived ectoderm cells immediately after 14h Gln-free, Gln-starvation, or blasticidin treatment relative to Ctr.

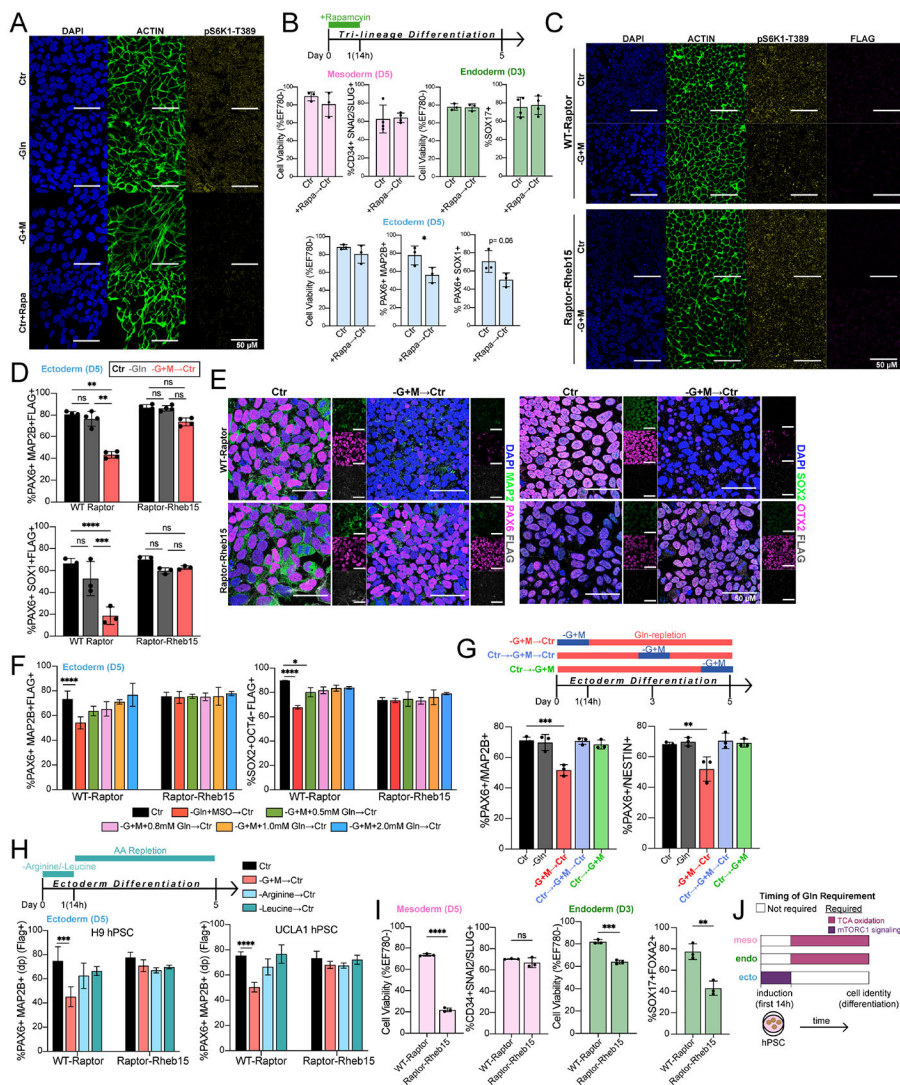

**(H)** ATP levels, quantified by UHPLC-MS, in ectoderm cells after Gln-starvation.

**(I)** Cell viability and percentage of H9-derived D5 mesoderm (CD34<sup>+</sup>, SNAI2/SLUG<sup>+</sup>) and D3 endoderm (SOX17<sup>+</sup>) cells after initial 14h Gln-free (-Gln→Ctr) or Gln-starvation (-G+M→Ctr) treatment.

**(J)** Representative immunofluorescence images of pluripotent and lineage-specific biomarkers in H9-derived (Top) D5 mesoderm and (Bottom) D3 endoderm cells grown in Gln-supplemented (Ctr), Gln-free (-Gln), or Gln-repletion follow initial 14h Gln-starvation (-G+M→Ctr). (Top) OCT4 (magenta, pluripotent); SNAI2/SLUG (green, mesoderm). (Bottom) FOXA2 (magenta, endoderm); SOX17 (green, endoderm); NANOG (cyan, pluripotent). Scale bar indicates 50  $\mu\text{m}$ .

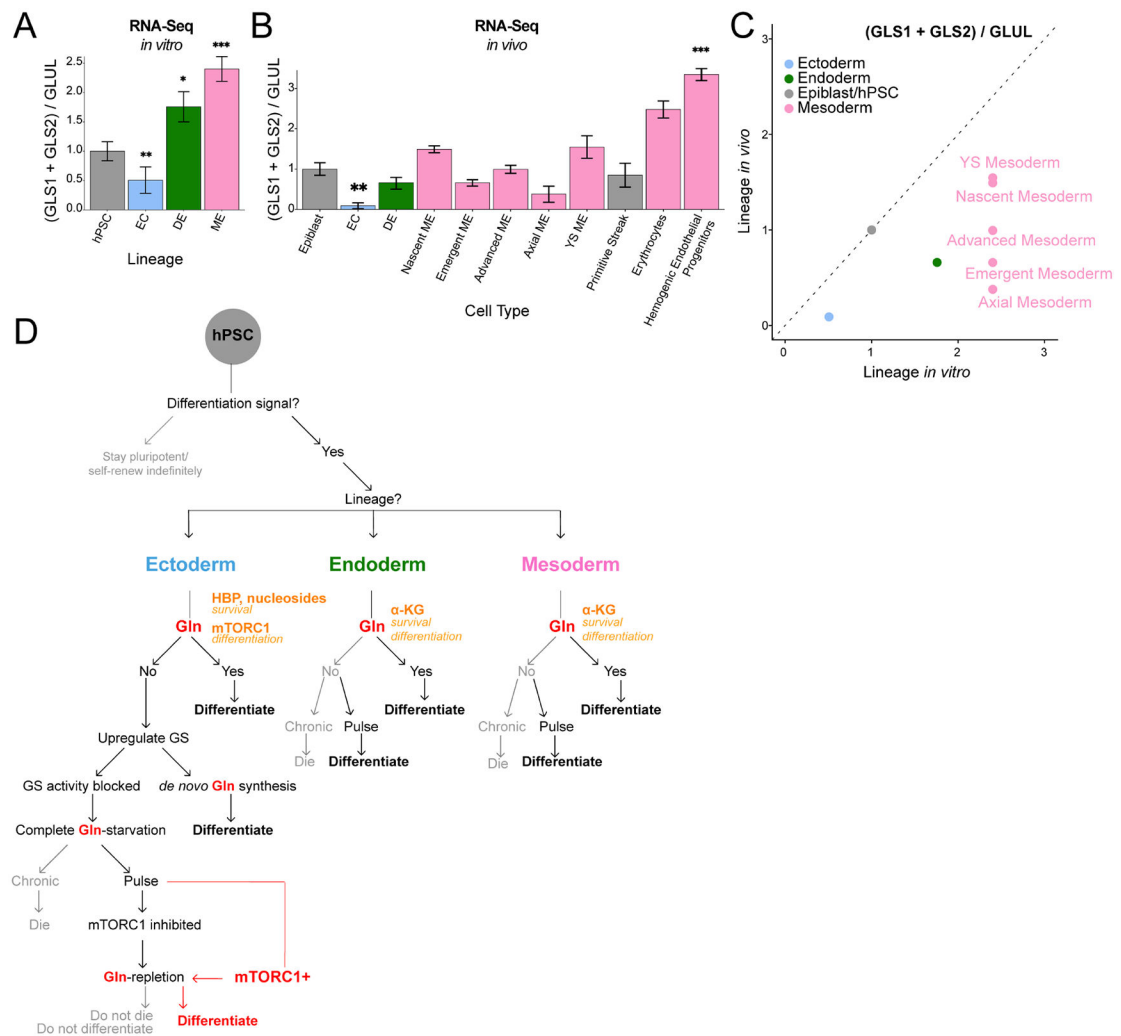

**(K)** Timing of Gln requirement for downstream lineage cell identity.

Data represent mean  $\pm$  SD of n = 3 biological replicates. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001; \*\*\*\*p < 0.0001. The p values were determined by **(A-C, F-G, I)** one-way ANOVA, **(E)** two-way ANOVA with correction for multiple comparisons or **(H)** unpaired two-tailed Student's t test.

**Figure 4. Ectoderm differentiation requires initial Gln-dependent mTORC1 signaling**  
**(A)** Representative immunofluorescence images of mTORC activation in H9-derived ectoderm cells grown for 24h in Gln-supplemented (Ctr), Gln-free (-Gln), Gln-starvation (-G+M), or 200 nM rapamycin treatment (Ctr+Rapa). DAPI (blue, nucleus); ACTIN (green, cytoskeleton); pS6K1-Thr389 (yellow, mTORC1 activation). Scale bar indicates 50  $\mu$ m.  
**(B)** Percentage of H9-derived D5 mesoderm (CD34<sup>+</sup>SNAI2/SLUG<sup>+</sup>), D3 endoderm (SOX17<sup>+</sup>FOXA2<sup>+</sup>), and D5 ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>, PAX6<sup>+</sup>SOX1<sup>+</sup>) cells after initial 14h 200 nM rapamycin treatment.  
**(C)** Representative immunofluorescence images of mTORC activation in H9-derived WT-Raptor or Raptor-Rheb15 ectoderm cells grown for 12h in Gln-supplemented (Ctr) or Gln-starvation (-G+M). DAPI (blue, nucleus); ACTIN (green, cytoskeleton); pS6K1-Thr389 (yellow, mTORC1 activation); FLAG tag (magenta; transduced cell line reporter). Scale bar indicates 50  $\mu$ m.

- (D)** Percentage of H9-derived D5 WT-Raptor or Raptor-Rheb15 ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>FLAG<sup>+</sup>, PAX6<sup>+</sup>SOX1<sup>+</sup>FLAG<sup>+</sup>) cells after initial 14h Gln-starvation (-G+M→Ctr).
- (E)** Representative immunofluorescence images of ectoderm biomarkers in H9-derived D5 (Top) WT-Raptor or (Bottom) Raptor-Rheb15 ectoderm cells grown in Gln-supplemented (Ctr) or Gln-repletion follow initial 14h Gln-starvation (-G+M→Ctr). (Left) MAP2B (green, ectoderm); PAX6 (magenta, ectoderm); FLAG (grey, transduced cell line reporter). (Bottom) SOX2 (green, ectoderm/pluripotent); OTX2 (magenta, ectoderm), FLAG (grey, transduced cell line reporter). Scale bar indicates 50 μm.
- (F)** Percentage of ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>FLAG<sup>+</sup>) and pluripotent (SOX2<sup>-</sup>OCT4<sup>+</sup>FLAG<sup>+</sup>) biomarkers in H9-derived D5 WT-Raptor or Raptor-Rheb15 ectoderm cells after initial 14h Gln-starvation with increasing concentrations of exogenous Gln supplementation.
- (G)** Percentage of H9-derived D5 ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>, PAX6<sup>+</sup>NESTIN<sup>+</sup>) cells after initial (-G+M→Ctr), intermediate (Ctr→-G+M→Ctr), or late (Ctr→-G+M) 14h Gln-starvation.
- (H)** Arginine (Arg) or Leucine (Leu) were removed from culture media for 14h then switched to Arg/Leu-supplemented conditions (AA repletion) until D5. Percentage of (Left) H9 or (Right) UCLA1-derived D5 WT-Raptor or Raptor-Rheb15 ectoderm (PAX6<sup>+</sup>MAP2B<sup>+</sup>FLAG<sup>+</sup>) cells after initial 14h Gln-starvation, Arg deprivation, or Leu deprivation.
- (I)** Cell viability and percentage of H9-derived WT-Raptor or Raptor-Rheb15 D5 mesoderm (CD34<sup>+</sup>SNAI2/SLUG<sup>+</sup>FLAG<sup>+</sup>) and D3 endoderm (SOX17<sup>+</sup>FOXA2<sup>+</sup>FLAG<sup>+</sup>) cells.
- (J)** Timing of Gln requirement for downstream lineage cell identity. Gln is required as a metabolite precursor in mesoderm and endoderm cells and as a mTORC1 signaling activator in ectoderm cells. Related to Figure 3K.
- Data represent mean ± SD of n = 3 biological replicates. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001; \*\*\*\*p < 0.0001. The p values were determined by **(B, I)** unpaired two-tailed Student's t test, **(D, F, H)** two-way ANOVA, or **(G)** one-way ANOVA with correction for multiple comparisons.

**Figure 5. Distinct transcript patterns of Gln utilization characterize germ lineages *in vivo***  
**(A)** Ectoderm but not endoderm and mesoderm cells exhibit increased Gln synthesis (*GLUL* transcripts) relative to Gln consumption (*GLS1 + GLS2* transcripts) *in vitro*. The average *GLS1* and *GLS2* expression was divided by *GLUL* expression for each lineage and values were normalized to hPSC control.

**(B)** Ectoderm cells exhibit increased Gln synthesis (*GLUL* transcripts) relative to Gln consumption (*GLS + GLS2* transcripts) *in vivo*. Single cell RNA-sequencing data from Tyser et al., 2020 were used to calculate the same ratio as in **(A)**. The values were normalized to the average Epiblast ratio. Lineages were taken from Tyser et al., 2020.

**(C)** Ectoderm cells exhibit similar trends in Gln synthesis and Gln consumption in both *in vitro* and *in vivo* contexts. Results from **(A)** and **(B)** are shown with a reference line drawn at  $y = x$ .

**(D)** Working model of germ lineage cell fate dependent on Gln.

Data represent mean  $\pm$  SD. \* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ . The  $p$  values were determined by **(A-B)** unpaired two-tailed Student's  $t$  test.

## KEY RESOURCES TABLE

REAGENT or RESOURCE	SOURCE	IDENTIFIER
<b>Antibodies</b>		
Mouse anti-Glutamine Synthetase; 1/500	BD Biosciences	Cat#610517; RRID:AB_2313837
Rabbit anti-PAX6; 1/500	Cell Signaling Technology	Cat#60433; RRID:AB_2797599
Rabbit anti-Pyruvate Dehydrogenase E1-alpha subunit (phospho S293); 1/500	Abcam	Cat#ab177461; RRID:AB_2756339
Rabbit anti-Phospho-p70 S6 Kinase (Thr389) (108D2); 1/500	Cell Signaling Technology	Cat#9234; RRID:AB_2269803
Rabbit anti-p70 S6 Kinase (49D7); 1/500	Cell Signaling Technology	Cat#2708; RRID:AB_390722
Rabbit anti-OCT-4; 1/200	Cell Signaling Technology	Cat#2750; RRID:AB_823583
Mouse anti-OCT-4 (D7O5Z); 1/200	Cell Signaling Technology	Cat#75463; RRID:AB_2799870
Goat anti-human NANOG; 5 µg/mL	R&D Systems	Cat#AF1997; RRID:AB_355097
Mouse anti-SOX2; 1/400	Cell Signaling Technology	Cat#4900; RRID:AB_10560516
Mouse anti-MAP2; 1/500	Invitrogen	Cat#MA5-12826; RRID:AB_10976831
Rabbit anti-OTX2; 4 µg/mL	Abcam	Cat#ab114138
Goat anti-Brachyury/TBXT; 15 µg/mL	R&D Systems	Cat# AF2085; RRID:AB_2200235
Rabbit anti-SLUG/SNAI2; 1/400	Cell Signaling Technology	Cat#9585; RRID:AB_2239535
Mouse anti-SOX17; 1/100	Invitrogen	Cat#MA5-24891; RRID:AB_2725395
Rabbit anti-FoxA2/HNF3β (D56D6); 1/400	Cell Signaling Technology	Cat#8186; RRID:AB_10891055
Mouse anti-β-tubulin; 1/1000	Millipore Sigma	Cat#T4026; RRID:AB_477577
Alexa Fluor 647 Rat Anti-Histone H3 (pS28)	BD Biosciences	Cat#558217; RRID:AB_397065
APC anti-DYKDDDDK Tag Antibody	Biolegend	Cat#637308; RRID:AB_2561497
PE Mouse Anti-SNAI2/Slug	BD Biosciences	Cat#564615; RRID:AB_2738866
Alexa Fluor 488 Mouse Anti-Human Sox17	BD Biosciences	Cat#562205; RRID:AB_10893402
PerCPCy5.5 Mouse anti-Human PAX6	BD Biosciences	Cat#562388; RRID:AB_11153319
Alexa Fluor 488 Mouse anti-MAP2B	BD Biosciences	Cat#560399; RRID:AB_1645358
PE Mouse anti-Human Sox1	BD Biosciences	Cat#561592; RRID:AB_10714631
Alexa Fluor 488 Mouse anti-Oct3/4	BD Biosciences	Cat#560253; RRID:AB_1645304
V450 Mouse Anti-Sox2	BD Biosciences	Cat#561610; RRID:AB_10712763
PerCP-Cy5.5 Mouse IgG2a, κ Isotype Control	BD Biosciences	Cat#558020; RRID:AB_396989
Alexa Fluor 700 Mouse IgG1, κ Isotype Control	BD Biosciences	Cat#557882; RRID:AB_396920
Alexa Fluor 488 Mouse IgG1 κ Isotype Control	BD Biosciences	Cat#557782; RRID:AB_396870
PE Mouse IgG1 k Isotype Control	BD Biosciences	Cat#554680 RRID:AB_395506
V450 Mouse IgG1, κ Isotype Control	BD Biosciences	Cat#560373; RRID:AB_1645606
