This case describes and depicts cardiac standstill with thrombosed blood within the chambers of the heart. This was likely due to stasis of blood from a prolonged no-flow state. After viewing this ultrasound finding, the decision was made to halt resuscitative efforts in this case of a patient in cardiac arrest. [Clin Pract Cases Emerg Med. 2019;3(4):430–431.]

CASE PRESENTATION
An 88-year-old female with gastric cancer presented to the emergency department (ED) in cardiac arrest. She was at an outpatient clinic when she lost pulses. Cardiopulmonary resuscitation (CPR) was initiated by emergency medical services upon their arrival after a downtime of several minutes without chest compressions. Upon arrival in the ED, CPR was in progress. During a rhythm and pulse check, transthoracic echocardiography was performed demonstrating cardiac standstill, as well as a collection of echogenic material within the ventricles. This finding represented thrombosed blood (Image 1-2 and Video). After visualizing cardiac standstill with intracardiac clots, the decision was made to stop resuscitation.

DISCUSSION
Cardiac standstill is defined as the lack of movement of the valves and free wall of the heart. When visualized on ultrasound during cardiac arrest assessment it has been discussed as a potential endpoint to CPR. Cohort studies have shown that cardiac standstill was associated with a very low rate of survival from 0-0.6%. In contrast, cardiac activity on ultrasound during cardiac arrest is strongly associated with return of spontaneous circulation and survival, and therefore provides prognostic information that may guide resuscitation efforts. This case also demonstrates clot formation within the heart, which is hypothesized to be from stasis of blood after a prolonged downtime prior to initiating CPR. Due to the initial lack of chest compressions, it is possible that there was a period without blood flow through the heart causing coagulation. This patient’s history of cancer also may have contributed to a hypercoagulable state. There are no case reports discussing intracardiac clots in cardiac arrest, but this type of echocardiography pattern has been described to be fine, speckled, and with a uniform appearance. Perhaps with further investigation, this echocardiography pattern...
Cardiac Standstill With Intracardiac Clot Formation

**CPC-EM Capsule**

What do we already know about this clinical entity?

*Increased clot burden can be caused by a low-flow state, create an even lower flow state, and can increase strain on the myocardium.*

What is the major impact of the image(s)?

*Rarely do you see this amount of clot burden inside both ventricles of a patient with a witnessed arrest and cardiopulmonary resuscitation. It provides a clear illustration.*

How might this improve emergency medicine practice?

*The presence of significant clot burden in both ventricles could give the physician an indication of prolonged downtime.*

**Video.** Transthoracic echocardiography: parasternal long view of the heart demonstrating echogenic (thrombosed) blood within the left and right ventricles.

**Image 2.** Transthoracic echocardiography: parasternal short view of the heart demonstrating thrombosed blood within the left and right ventricles.

Documented patient informed consent and/or Institutional Review Board approval has been obtained and filed for publication of this case report.
