VOLUME DISTORTION IN HOMOTOPY GROUPS

FEDOR MANIN

Abstract. Given a finite metric CW complex $X$ and an element $\alpha \in \pi_n(X)$, what are the properties of a geometrically optimal representative of $\alpha$? We study the optimal volume of $k\alpha$ as a function of $k$. Asymptotically, this function, whose inverse, for reasons of tradition, we call the volume distortion, turns out to be an invariant with respect to the rational homotopy of $X$. We provide a number of examples and techniques for studying this invariant, with a special focus on spaces with few rational homotopy groups. Our main theorem characterizes those $X$ in which all non-torsion homotopy classes are undistorted, that is, their distortion functions are linear.

The object of quantitative topology is to make more concrete various notions coming from the existential results of algebraic topology. Thus, while classical rational homotopy theory gives an exhaustive family of algebraic correlates to rational homotopy classes of simply-connected spaces, a quantitative homotopy theory seeks to give geometric examples or descriptions linked to the algebraic properties of these objects.

The term “quantitative homotopy theory” seems to have first been used by Gromov in the conference paper [Gro99] and in Chapter 7 of the near-simultaneous book [Gro98], although the ideas date back as far as [Gro78]. Construed broadly, however, this program fits into a tradition of extracting metric information from topological data which includes problems from systolic geometry, geometric group theory, and other areas. In particular, geometric group theorists, as specialists in fundamental groups, have explored a host of asymptotic invariants whose higher-dimensional analogues may also be of interest. These include the Dehn function, growth of groups, and distortion of group elements and subgroups.

Higher-dimensional isoperimetric functions of groups, that is, of their Eilenberg–MacLane spaces, have been studied in some detail, notably by Gromov [Gro99], Alonso–Wang–Pride [AWP], Brady–Bridson–Forester–Shankar [BBFS], and Young [Young]. A common theme of this body of literature is the plurality of possible definitions, many of which are equivalent in the one-dimensional case. The subject of growth of higher homotopy groups was broached in chapters 2 and 7 of [Gro98] with a number of examples and a conjecture for simply-connected spaces.

Here we analyze a higher-dimensional analogue of distortion. Heuristically, the distortion of a group element $\alpha \in G$ is given by

$$\delta_{\alpha}(k) = \max\{m \mid \text{size}(\alpha^m) \leq k\}.$$ 

If $G$ is the fundamental group of a space, word length is a natural measure of size. On the other hand, if $G = \pi_n(X)$ for a space $X$, we can choose inequivalent measures of size by taking advantage of different features of a metric structure on $X$, leading once again to a plurality of definitions. For example, suppose that $X$ is a CW complex with a piecewise Riemannian metric. Then we can choose to minimize the Lipschitz constant of a representative, its volume, or more generally the $m$-dilation for some $1 \leq m \leq n$, that is, how much the map $f : S^n \to X$ distorts $m$-dimensional tangent subspaces. Moreover, the asymptotics of each such function are preserved by Lipschitz homeomorphisms. This means that, as long as $X$ is compact, each of these definitions gives a topological invariant.

In all of these situations, it is natural to consider an element undistorted if the best asymptotics are attained by composing $\alpha$ with a degree $k$ map $S^n \to S^n$. Thus an element is Lipschitz undistorted if its Lipschitz distortion is $\sim Ck^n$, and volume undistorted if its volume distortion is $\sim Ck$.

In [Gro99], Gromov states a conjecture about the Lipschitz distortion of homotopy groups.

Conjecture (Gromov). A class $\alpha \in \pi_n X$ of a simply-connected finite metric CW complex $X$ is Lipschitz undistorted if and only if $\alpha$ has nonzero image under the rational Hurewicz map. If $\alpha$ is distorted, then the growth of its Lipschitz norm is polynomial with rational exponent, and at most $Ck^{n+1}$; in the terminology above, the Lipschitz distortion of such an $\alpha$ is at least $\sim Ck^{n+1}$. 

1
Gromov points out that Sullivan’s model of rational homotopy can be used to demonstrate that Lipschitz distortion in this situation is at worst polynomial. Lower bounds on distortion can be obtained in various cases using constructions such as generalized Whitehead products. However, a full proof of the conjecture remains elusive. In this paper, we instead focus on volume distortion, which has not been previously studied.

In contrast with the Lipschitz case, volume distortion is trivial for simply connected spaces: every homotopy class is either undistorted or has a multiple with zero volume, as shown in Theorem 3.11. But for non-simply-connected finite complexes, it’s an interesting invariant: we construct examples in which the volume distortion of an element is $k^r$ for various rational $r$ and where it is $\exp(\sqrt{k})$. One feature that makes volume distortion convenient for non-simply-connected spaces is its invariance up to rational homotopy. More precisely:

**Theorem A.** Suppose two compact connected CW-complexes $X$ and $Y$ are rationally equivalent, that is, there is a space $Z$ and maps $X \to Z \leftarrow Y$ which induce isomorphisms on $\pi_1$ and $\pi_n \otimes \mathbb{Q}$ for every $n$. If $\alpha \in \pi_n(X)$ and $\beta \in \pi_n(Y)$ have the same image in $\pi_n(Z)$, then they have asymptotically equivalent volume distortion functions.

In order to show this, we develop some results in the rational homotopy theory of non-simply-connected spaces. As discussed in Example 2.7, the equivalent statement in the Lipschitz setting appears to be false.

Our main theorem characterizes those spaces which have no distortion in their homotopy groups. It turns out, however, that a natural definition of volume distortion in this context includes not only individual elements but finite-dimensional subspaces. While the definition extends easily, this is a significantly different concept: in Example 3.11(1), we see that a subspace might be distorted even if no element is. This phenomenon can be thought of as distortion in an irrational direction in $\pi_n(X) \otimes \mathbb{R}$, induced by an irrational eigenvector of the action of $\pi_1(X)$ on $\pi_n(X)$.

In order to state the theorem precisely, we need two invariants which together classify rational homotopy fibrations $(S^{2n+1})^r \to X \to B$ up to rational equivalence. The first of these is the monodromy representation $\rho : \pi_1 X \to GL(r_1, \mathbb{Q})$. The second is the obstruction to extending a section from the $(2n+1)$-skeleton to the $(2n+2)$-skeleton, a generalization of the Euler class for sphere bundles. This class, which is defined more thoroughly in section 6, lies in the twisted cohomology group $H^{2n+2}(B; M_\rho)$, where $M_\rho$ is the $\mathbb{Q}[\pi_1 B]$-module corresponding to $\rho$. In turn, the universal covering $\tilde{B} \to B$ pulls this Euler class back to the $L_\infty$ cohomology $H^{2n+2}(\tilde{B}; \mathbb{Q}^{r_1})$. While the definition of $L_\infty$ cohomology relies on a metric on $\tilde{B}$, it is insensitive to small-scale geometry, and so only depends on the topology of $B$.

**Theorem B.** A finite CW complex $X$ has no volume distortion in $\pi_n(X)$ for any $n \geq 2$ if and only if the following conditions hold:

1. $X$ is rationally equivalent to the total space of a fibration over $B\pi_1 X$ with fiber $\prod_{i=1}^s (S^{2n_i+1})^{r_i}$, which further decomposes as a tower of fibrations

   \[ X = X_m \to X_{m-1} \to \cdots \to X_0 = B\pi_1 X \]

   with fibers of the form $(S^{2n_i+1})^{r_i}$, $1 \leq i \leq m$;

2. for each $i$, the monodromy representation $\rho : \pi_1 X \to GL(r_i, \mathbb{Q})$ is elliptic, i.e. its image is contained in a conjugate of $O(r_i, \mathbb{R})$;

3. and for each $i$, the Euler class $eu \in H^{2n_i+2}(X_{i-1}; M_\rho)$ vanishes when considered in the $L_\infty$ cohomology $H^{2n_i+2}(\tilde{X}_{i-1}; \mathbb{Q}^{r_i})$ of the universal cover.

One way of interpreting this result intuitively is as follows: spaces with no distortion must have universal covers which are *coarsely trivial* fibrations, that is they are in some sense finite distance from being a metric product $\prod S^{2n_i+1} \times B\pi_1 X$. In certain cases, this assertion may be interpreted literally—there is a bilipschitz map from $\tilde{X}$ to this product space. In general, however, the author has not been able to turn this intuition into a compelling piece of mathematics.

We say volume distortion is *infinite* if there is a finite-dimensional subspace of $\pi_n(X) \otimes \mathbb{Q}$ in which arbitrarily large vectors have representatives of bounded volume. Our second complete characterization, however, is of when a complex has *weakly infinite* volume distortion. Here we take the minimum volume functional on $\pi_n(X)$ to be a restriction of that on $H_n(X)$; this is natural because for simply connected spaces, least volume functionals are the same for homology and homotopy, at least for $n \geq 3$ (see Lemma 3.6). We
say that (a finite-dimensional subspace of) \( \pi_n(X) \otimes \mathbb{Q} \) is weakly infinitely distorted in (a finite-dimensional subspace of) \( H_n(X; \mathbb{Q}) \) if arbitrarily large vectors in the latter at a bounded distance from the former are represented by integral chains of bounded volume.

**Theorem C.** A finite CW complex \( X \) has no weakly infinite volume distortion in \( \pi_n(X) \) for any \( n \geq 2 \) if and only if the following conditions hold:

1. \( X \) is rationally equivalent to the total space of a fibration over \( B\pi_1X \) with fiber \( \Pi_i=1(S^{2n_i+1})^r_i \);
2. the monodromy representation \( \pi_1X \rightarrow GL(\pi_1(X) \otimes \mathbb{Q}) \) is elliptic;
3. and for every \( n \geq 2 \), the group \( H_n(X; \mathbb{Q}) \) splits as a \( \mathbb{Q}\pi_1X \)-module into the image of the Hurewicz map and its complement.

Which weakly infinitely distorted classes are in fact infinitely distorted remains largely open, although it is certainly not all of them, as evidenced by Theorem \[ \text{[7,3]} \].

**Examples and methods.** In this section, we give an overview of the proof of Theorem \[ \text{[3]} \]. In essence, each of the three conditions is aimed at eliminating a particular potential source of volume distortion; we give examples of each of these three types in this section. The proof works by showing that if a space has no volume distortion of these three types, then it must have no volume distortion at all. Note that this does not preclude the existence of other, yet undiscovered sources of volume distortion in spaces that do have volume distortion.

Certain homotopy classes in \( \pi_n(X) \) have representatives which retract to the \((n-1)\)-skeleton of the space \( X \); this is the simplest possibility, since all such maps have zero volume. This case is exemplified by the Hopf map \( S^3 \rightarrow S^2 \); indeed, in a simply-connected space, all homotopy classes which are zero homologically are distorted in this way. Thus to eliminate this effect, our space \( X \) must have the property that the Hurewicz homomorphism \( \pi_1(X) \otimes \mathbb{Q} \rightarrow H_*(X; \mathbb{Q}) \) on its universal cover is injective. This is equivalent to condition (1).

Distortion may also be caused by the action of the fundamental group on \( \pi_n(X) \). Thus, suppose \( X \) is the mapping torus of a degree 2 map \( f : S^n \rightarrow S^n \). Then for every \( k \), \( 2^k \) times the generator [id\_S\_n] \( \in \pi_n(X) \) has a representative with volume 1, to be thought of as a balloon on a string of length \( k \). The key observation here is that this is because the action of \( \pi_1(X) \) on \( \pi_n(X) \otimes \mathbb{Q} \) sends the generator to an unbounded set. Condition (2) serves to eliminate sources of distortion of this type.

Finally and most subtly, distortion can be induced by the Euler class of a sphere bundle. For example, \( S^3 \rightarrow X \xrightarrow{\text{Hopf}} T^4 \) is a bundle with Euler class \([T^4]\), so that the obstruction to extending a section \( s : (T^4)^{(3)} \rightarrow X \) to the 4-cell is the generator \( \alpha \in \pi_4(X) \). In other words, the attaching map of the 4-cell along this section to a map homotopic to the inclusion of the fiber \( S^3 \hookrightarrow X \). From the perspective of the universal cover \( \tilde{X} \rightarrow \mathbb{R}^4 \), this gives us a Lipschitz section of the 3-dimensional grid which does not extend to all of \( \mathbb{R}^4 \). Consider the map \( f_k : S^3 \rightarrow \tilde{X} \) which is the lift along this section of the boundary of \([0,k]\)^4. This map has volume \( O(k^3) \), but is homotopic to the sum of \( k^3 \) boundaries of cubes of side length 1, each of which is in turn homotopic to the inclusion of the fiber. In other words, \([f_k] = k^3 \alpha\), and so the volume distortion of \( \alpha \) is at least \( Ck^{4/3} \).

Indeed, one can see that this is the only possible source of distortion in this space. Suppose now that \( f : S^n \rightarrow X \) is a map of volume \( V \). At the expense of a multiplicative constant increase in volume, we can assume that its image is in \( \tilde{s}^{-1} \left( (T^4)^{(3)} \right) \). It turns out that \( f \) differs from \( s \circ p \circ f \) by an amount of twisting around the fiber which must be linear in \( V \). Thus the element \([f] \in \pi_3(X) \) has the form

\[
[f] = \text{Fill}(p \circ f) + O(V),
\]

where \( \text{Fill}(p \circ f) \) is the volume of a 4-chain in \( \mathbb{R}^4 \) filling \( p \circ f \). The isoperimetric inequality in \( \mathbb{R}^4 \) leads us to conclude that \([f] = O(V^{4/3}) \).

This key geometric idea can easily be extended to other bundles of the form \( S^n \rightarrow X \rightarrow M^{n+1} \). For example, if \( M \) is hyperbolic, the linearity of its isoperimetric inequality means that there is no distortion in \( X \). Condition (3) of Theorem \[ \text{[3]} \] which turns out to be equivalent to the linearity of a certain isoperimetric inequality, is aimed at eliminating this source of distortion. To prove the theorem in full generality one needs not only to prove this correspondence, but also to provide an argument of the type we gave for the bundle.
over $T^4$—that distortion in the total space of a rational homotopy fibration corresponds to an isoperimetric function in the base—for a larger class of delicate spaces, that is, those that satisfy conditions (1) and (2). However, because fibrations are hard to construct in the world of finite complexes, this argument relies instead on cofibrations with the same homotopy-theoretic properties.

**Results in specific dimensions.** Theorems B and C lay out conditions that are necessary and sufficient for $\pi_n(X)$ to be undistorted and not weakly infinitely distorted, respectively, for every $n$. What can we say about whether a specific $\pi_n(X)$ is distorted?

Here is an alternate sketch of the proof of Theorem B which highlights those aspects which are most relevant for this question. Let $X$ be a finite complex. If for some $n$, $\pi_n(X) \otimes \mathbb{Q}$ is an infinite-dimensional vector space, then, as we will show in Corollary 3.2, there is a distorted element in $\pi_N(X)$ for some $N$; but beyond this, such a situation is hard to analyze. We can say much more when $\pi_n(X) \otimes \mathbb{Q}$ is finite-dimensional. Indeed, more generally, we will give a criterion for whether a finite-dimensional $\mathbb{Q}\pi_1(X)$-submodule $V \subseteq \pi_n(X) \otimes \mathbb{Q}$, that is, a vector subspace invariant under monodromy, is distorted.

Given such a submodule $V$, we can add a finite number of $(n+1)$-cells to get an inclusion $p : X \to B$ with $V = \ker(p_n : \pi_n(X) \to \pi_n(B)) \otimes \mathbb{Q}$. In addition, $p$ is rationally $n$-connected; for our purposes, this makes $p$ close enough to one step in a Postnikov tower and we call the resulting system an almost Postnikov pair. In fact, in this situation, if $\rho : \pi_1(X) \to GL(V)$ is the monodromy representation on $V$, the Euler class $eu \in H^{n+1}(B; M\rho)$ simply sends all $(n+1)$-cells of $X$ to 0 and each of the extra $(n+1)$-cells to the element of $V$ it kills. We can now state our criterion.

**Theorem D.** Fix a finite complex $X$ and an $n \geq 3$, and let $V \subseteq \pi_n(X) \otimes \mathbb{Q}$ be a submodule which is finite-dimensional as a vector space. Then $V$ has no volume distortion if and only if the following conditions hold:

1. the monodromy representation $\rho : \pi_1(X) \to GL(V)$ is elliptic;
2. for some (or any) almost Postnikov pair $X \to B$ with $V = \ker(\pi_n(X) \to \pi_n(B)) \otimes \mathbb{Q}$, the Euler class $eu \in H^{n+1}(B; M\rho)$ vanishes when considered in the $L\infty$ cohomology $H^{n+1}(\tilde{B}; V)$ of the universal cover.

This is the closest we can easily get to isolating individual elements of $\pi_n(X)$ and testing whether they are distorted. It’s hard to say anything about the distortion of individual elements of $\pi_nX$ on which $\rho$ acts nontrivially; even when $V$ is distorted, its elements may not be. This distinction is explored at some length in Section 3.

This theorem gives considerable information on top of Theorem B. Nevertheless, the condition that $V$ be finite-dimensional excludes many natural situations. For example, all higher homotopy groups of $S^1 \vee S^2$ are infinite-dimensional with $\mathbb{Z}$ acting freely. So suppose the $\pi_1$-orbit of $\alpha \in \pi_n(X) \otimes \mathbb{Q}$ is infinite-dimensional. What can we say about the distortion of $\alpha$? If the Hurewicz homomorphism on the universal cover $\tilde{X}$ sends $\alpha \mapsto 0$, then $\alpha$ is certainly volume-distorted. If instead its Hurewicz image in $\tilde{X}$ is detected by an $L\infty$ cocycle, then it is certainly not. These conditions, however, are by no means exhaustive, and the latter can also be difficult to determine, as Example 3.5 demonstrates. Infinite-dimensional homotopy groups, then, remain somewhat of a mystery.

**Corollaries and other results.** The isoperimetric inequality mentioned above turns out, in the case of aspherical spaces, to define a new kind of higher-dimensional filling function for groups. Any cohomology class $\omega \in H^{n+1}(X; \mathbb{Q})$ gives a directed isoperimetric function $FV^\omega_{X,\langle\omega,\cdot\rangle}$. Groups with interesting directed isoperimetric functions then give rise to spaces with interesting distortion functions. For example, we construct a sequence of groups $\mathbb{Q}n$, related to the Baumslag-Solitar group $BS(1, 2)$, which have finite classifying spaces and for which $FV^\omega_{\mathbb{Q}n,\langle\omega,\cdot\rangle}(k) \equiv 2^{\sqrt{k}}$ for any nonzero $\omega \in H^{n+1}(\mathbb{Q}n; \mathbb{Q})$; indeed, for these groups, this coincides with the usual higher-dimensional Dehn function. This implies that nontrivial fibrations $S^n \to X \to B\mathbb{Q}n$ have volume distortion of the form $\exp(\sqrt{k})$ as well.

This correspondence between distortion and filling functions provides more general connections between this subject and geometric group theory. Thus one corollary of Theorem B is that if $X$ is the unit tangent bundle of a closed $n$-manifold which is aspherical or has non-amenable fundamental group, then the class in $\pi_n(X)$ corresponding to the fiber is never distorted. Conversely, for amenable groups such filling functions are never linear for any nonzero cohomology class.
Related work and further directions. Because many of our bounds rely on cellular maps, the results are inherently asymptotic—we do not aspire to minimize volume of specified maps in specified geometries. Others, however, have worked in this direction. [DCS] and [Wen] have found that well-known maps uniquely minimize the Lipschitz constant of maps between round spheres and from products of spheres to spheres, respectively. Larry Guth in [Gut08b] and [Gut08a] provides bounds, depending on the metric in the domain and range, on Lipschitz constants of Hopf-like maps of spheres, as well as on their \(k\)-dilation for various \(k\), a more general measure of the size of a map that includes both volume and Lipschitz constant.

Asking about asymptotic growth only makes sense for rational homotopy classes. For torsion homotopy classes, however, one can also ask a homotopy invariant question: are certain geometric quantities positive or are they zero? In a recent work in this vein [Gut13], Guth addresses the minimal \(k\)-dilation of certain torsion homotopy classes of spheres.

One can ask whether results similar to ours hold for Lipschitz distortion or more generally for distortion with respect to \(k\)-dilation. Since Lipschitz distortion is never infinite, this precludes a result of the genre of Theorem [C]. On the other hand, there is some promise for a result similar to Theorem [B] The reduction to delicate spaces works just as well for Lipschitz distortion, as does a result similar to Theorem [6.3] relating distortion in a sphere bundle to a certain filling function in the base space. However, as far as we know this only holds for actual sphere bundles, not up to rational homotopy. Example [2.7] gives pause to attempts to extend this approach to delicate spaces in general, and so the problem seems less tractable. Still, there are a number of rich phenomena related to Lipschitz distortion which have yet to be explored.

Outline of the paper. Here we describe the main methods and results of each section of the paper.

Section 1 concerns the development of a rational homotopy theory of non-simply-connected CW complexes. We show a rational version of Wall’s result on finiteness properties for CW complexes [Wall] and several other finiteness results which become useful later for applying results from algebraic topology in the context of finite complexes.

In section 2, we discuss metric structures on compact spaces and give detailed definitions for the various types of distortion. We also prove Theorem [A].

In section 3, we discuss distortion in simply-connected spaces as well as distortion from monodromy, and show that spaces with no infinite distortion must satisfy conditions (1) and (2) of Theorems [B] and [C]. We also discuss the applicability of our methods to infinite-dimensional spaces of finite type.

Section 4 reviews previous results surrounding higher-dimensional filling functions of groups and spaces and introduces a new type of filling function. We give examples in which this kind of filling function demonstrates various behaviors, most notably the sequence \(\diamond_n\) described above, whose \(n\)-dimensional filling functions are asymptotically equivalent to \(2^{\sqrt{n}}\).

In section 5, we show that the filling functions defined in section 4 are equivalent to certain cohomological isoperimetric inequalities which may be thought of as dual. This turns out to generalize several known instances of this type of duality.

Finally, in section 6 we tackle the class of delicate spaces. This means first defining almost Postnikov pairs and their Euler classes. We then use the results of sections 4 and 5 to relate distortion in one of the spaces in the pair to a filling function in the other. As a special case of this relationship we complete the proofs of Theorems [B] and [D] and discuss various examples and applications.

Section 7 provides a different, more algebraic look at delicate spaces, yielding a proof of Theorem [C].

Acknowledgements. I would like to thank my advisor, Shmuel Weinberger, for introducing me to this area of research and guiding me throughout the work. Many thanks also to Katie Mann, Jenny Wilson, Chris Beck, Bena Tshishiku, Kevin Whyte, Daniel Studenmund, and others for their support and fruitful conversations. Special thanks to Jeremy Rickard on MathOverflow for suggesting the counterexample [3.8] and to Zeb Brady for walking me through some basic algebraic number theory. Many thanks also to the anonymous referee for a multitude of corrections and suggestions.

This paper is based on a portion of the author’s PhD thesis [M].

1. Algebraic preliminaries 6
1. Algebraic preliminaries

We start this section by proving two simple propositions that will find their uses in later sections, before moving on to a more self-contained discussion developing the rational homotopy theory of finite non-simply-connected complexes. We will tacitly assume all spaces to be connected, and we will frequently and tacitly make use of the natural $\mathbb{Q}\pi_1 X$-module structure on the group $\pi_n(X) \otimes \mathbb{Q}$. As a matter of notation, we write $h_n : \pi_n(X) \otimes \mathbb{Q} \to H_n(X; \mathbb{Q})$ to mean the rational Hurewicz homomorphism. We also write $X^{(k)}$ to refer to the $k$-skeleton of a CW complex $X$.

**Proposition 1.1.** Suppose $X$ is a simply connected complex and $[\alpha] \in \pi_n(X)$ is zero under the Hurewicz map. Then $[\alpha]$ has a representative $f : S^n \to X^{(n-1)}$. More generally, if $h_n([\alpha]) = 0$, then there is some $k > 0$ so that $k[\alpha]$ has a representative $f : S^n \to X^{(n-1)}$.

**Proof.** The relative Hurewicz theorem and exact sequences for pairs give us the diagram

$$
\begin{array}{ccc}
\pi_n(X^{(n-1)}) & \longrightarrow & \pi_n(X) \\
\downarrow & & \downarrow \\
0 & \longrightarrow & H_n(X).
\end{array}
$$

Thus the sequence

$$
\pi_n(X^{(n-1)}) \to \pi_n(X) \to H_n(X)
$$

is exact. This gives us the integral result. The rational version follows. $\square$

**Proposition 1.2.** Suppose $(X, A)$ is a CW pair of finite $n$-complexes such that the inclusion $i : A \to X$ induces isomorphisms on $\pi_1$ and on $\pi_i \otimes \mathbb{Q}$ for $2 \leq i \leq n - 1$. Then the induced map $i_* : \pi_n(A) \otimes \mathbb{Q} \to \pi_n(X) \otimes \mathbb{Q}$ is injective.

**Proof.** For any simply connected CW complex $Y$, consider the Serre spectral sequence applied to the fibration

$$
K(\pi_k(Y), k) \to Y^{(k)} \to Y^{(k-1)}
$$

within the Postnikov tower of $Y$. The entry $E^2_{k,0} = H_k(Y^{(k-1)})$ has all differentials going to zero groups and thus survives to the $E^\infty$ page. This implies that the map

$$
H_k(Y; \mathbb{Q}) = H_k(Y^{(k)}; \mathbb{Q}) \to H_k(Y^{(k-1)}; \mathbb{Q})
$$

is a surjection.

By the rational relative Hurewicz theorem, $i_* : H_i(\tilde{A}; \mathbb{Q}) \to H_i(\tilde{X}; \mathbb{Q})$ is also an isomorphism for $i \leq n - 1$. Moreover, since $H_{n+1}(\tilde{X}, A) = 0$, $i_* : H_n(A) \to H_n(\tilde{X})$ is injective. Consider now the Serre spectral sequence for the fibration

$$
K(\pi_n(X), n) \to \tilde{X}^{(n)} \to \tilde{X}^{(n-1)}.
$$

In the $E^2$ page, rows 1 through $n - 1$ are zero, which allows us to construct the Gysin-like exact sequence illustrated below. Here, the boxed groups are assembled from the terms of the $E^\infty$ page of the spectral
sequence, giving rise to the arrows going to and from them.

\[
\begin{array}{cccccccc}
 n & \pi_n(X) \otimes \mathbb{Q} & \partial_{n+1} & H_{n+1}(\tilde{X}_{(n)}; \mathbb{Q}) \\
n - 1 & 0 & & & \\
\vdots & \vdots & & & \\
1 & 0 & \partial_n & H_{n}(\tilde{X}_{(n)}; \mathbb{Q}) \\
0 & H_0(\tilde{X}_{(n-1)}; \mathbb{Q}) & \cdots & H_n(\tilde{X}_{(n-1)}; \mathbb{Q}) & H_{n+1}(\tilde{X}_{(n-1)}; \mathbb{Q}) \\
\end{array}
\]

Moreover, the observation that the map (1.1) is surjective for \( k = n + 1 \) implies that \( H_{n+1}(\tilde{X}_{(n)}; \mathbb{Q}) = 0 \), reducing the sequence to four nonzero terms.

The same analysis holds replacing \( X \) with \( A \). The whole picture is functorial, and so we get a homomorphism of exact sequences

\[
\begin{array}{cccccccc}
 0 & H_{n+1}(\tilde{A}_{(n-1)}; \mathbb{Q}) & \partial_{n+1} \otimes \mathbb{Q} & \pi_n(A) \otimes \mathbb{Q} & H_n(\tilde{A}_{(n)}; \mathbb{Q}) & H_n(\tilde{A}_{(n-1)}; \mathbb{Q}) & 0 \\
0 & H_{n+1}(\tilde{X}_{(n-1)}; \mathbb{Q}) & \partial_{n+1} \otimes \mathbb{Q} & \pi_n(X) \otimes \mathbb{Q} & H_n(\tilde{X}_{(n)}; \mathbb{Q}) & H_n(\tilde{X}_{(n-1)}; \mathbb{Q}) & 0.
\end{array}
\]

Now a diagram chase shows that \( \ker(\iota_*) = 0 \). \( \square \)

**Finiteness conditions and rational homotopy.** In his seminal paper [Wall], Wall proves the following theorem, stated here in abridged form:

**Theorem.** The following conditions on a CW complex \( X \) are equivalent:

1. \( X \) is homotopy equivalent to a complex with finite \( n \)-skeleton.
2. The group \( \Gamma := \pi_1(X) \) is finitely presented, and for every \( k \leq n \), the condition \( F_k \) holds: for every finite complex \( K^{k-1} \) and \( (k-1) \)-connected map \( \varphi : K \to X \), \( \pi_k(\varphi) \otimes \mathbb{Q} \) is a finitely generated \( \mathbb{Z}\Gamma \)-module.

Intuitively, one can understand this as follows. The homotopy of finite complexes, including their rational homotopy, can be very complicated. At the very least, there are many such spaces with complicated fundamental groups \( \Gamma \) for which higher homotopy groups are infinitely generated as modules over \( \mathbb{Z}\Gamma \). This complexity, however, is not mere anarchy, but in some sense is dictated by the fundamental group, give or take a few cells, i.e. a finite number of extra generators or relations.

In this section, we develop a similar theory in a rational setting. Moreover, we show that the rational isomorphisms produced are effective, in the sense that the torsion in the difference has bounded exponent, despite perhaps being vastly infinitely generated. Our main technical tools are a generalized Hurewicz theorem introduced by Serre and an invertibility result for rational equivalences on the level of chain homotopy.

First, we define the appropriate notions of equivalence.

**Definition.** For two CW complexes \( X \) and \( Y \), we say a map \( f : X \to Y \) is **rationally \( n \)-connected** if it induces an isomorphism on \( \pi_1 \) and \( \pi_k(f) \otimes \mathbb{Q} := \pi_k(M_f, X) \otimes \mathbb{Q} = 0 \), where \( M_f \) is the mapping cylinder, for \( 2 \leq k \leq n \). If this is true for every \( k \), we say \( f : X \to Y \) is a **rational equivalence**.

We say that \( X \) is **rationally equivalent** to \( Y \) (\( X \simeq_r Y \)) if there is a CW complex \( Z \) with rational equivalences \( X \to Z \) and \( Y \to Z \). \( X \) is **rationally \( n \)-equivalent** to \( Y \) if there is a CW complex \( Z \) and maps \( X \to Z \) and \( Y \to Z \) which induce isomorphisms on \( \pi_1 \) and \( \pi_k \otimes \mathbb{Q} \) for \( 2 \leq k \leq n \).
Note that a map inducing a rational $n$-equivalence is rationally $n$-connected, and a rationally $n$-connected map induces a rational $(n - 1)$-equivalence, but the converses of these statements are false.

It is not obvious that rational equivalence and $n$-equivalence as we have defined them are in fact equivalence relations. In other words, we have yet to show that any zigzagging sequence of equivalences

$$
\begin{array}{cccccc}
X & \rightarrow & Z_2 & \rightarrow & Z_4 & \rightarrow & \cdots & \rightarrow & Z_M & \rightarrow & Y \\
\downarrow & & \downarrow & & \downarrow & & \cdots & & \downarrow & & \downarrow \\
Z_1 & & Z_3 & & \cdots & & \cdots & & Z_{M-1} & & \downarrow \\
\end{array}
$$

collapses into one with just two maps, $X \rightarrow Z \leftarrow Y$. To show this, it is enough to prove the following lemma.

**Lemma 1.3.** Suppose that $W$, $X$, and $Y$ are CW complexes with rational $(n\text{-})$equivalences $X \xrightarrow{f} W \xrightarrow{g} Y$. Then there is a complex $Z$ with rational $(n\text{-})$equivalences $X \xrightarrow{f'} W \xrightarrow{g'} Y$.

**Proof.** By perhaps replacing $X$ and $Y$ with the mapping cylinders of $f$ and $g$ respectively, we can assume that $W$ is a subcomplex of both $X$ and $Y$. Then let $Z = X \cup_W Y$, with $f' : X \rightarrow Z$ and $g' : Y \rightarrow Z$ the corresponding injections. Consider now the universal covers of all these spaces. By excision, $H_k(\tilde{Z}, \tilde{X}) \cong H_k(\tilde{Y}, \tilde{W})$ for all $k$. The rational relative Hurewicz theorem then implies that if the pair $(Y, W)$ is rationally $n$-connected, then so is the pair $(Z, X)$, and that moreover

$$\pi_{n+1}(Z, X) \otimes \mathbb{Q} \cong H_{n+1}(\tilde{Z}, \tilde{X}; \mathbb{Q}) \cong H_{n+1}(\tilde{Y}, \tilde{W}; \mathbb{Q}) \cong \pi_{n+1}(Y, W) \otimes \mathbb{Q}.$$  

This argument is symmetric with respect to $X$ and $Y$, so in the case of rational equivalence we are done. In the case that $f$ and $g$ are rational $n$-equivalences, this gives us a homomorphism of exact sequences

$$
\begin{array}{cccccc}
\pi_{n+1}(X, W) \otimes \mathbb{Q} & \xrightarrow{f} & \pi_{n}(W) & \xrightarrow{g} & \pi_{n}(X) \otimes \mathbb{Q} \\
\downarrow & & \downarrow & & \downarrow \\
\pi_{n+1}(Z, Y) \otimes \mathbb{Q} & \xrightarrow{f'} & \pi_{n}(Y) & \xrightarrow{g'} & \pi_{n}(Z) \otimes \mathbb{Q} \\
\end{array}
$$

This allows us to conclude that $f'$ and $g'$ are indeed rational $n$-equivalences. \hfill \Box

An important technical tool we will use is a wide-ranging generalization of the Hurewicz theorem introduced by Serre. Our reference for this is section 9.6 of Spanier’s algebraic topology textbook [Spa]. First, we need to introduce some terminology.

**Definition.** A class $\mathcal{C}$ of abelian groups is an *acyclic Serre ideal* if

1. it is closed under subquotients and extensions;
2. if $A \in \mathcal{C}$ and $B$ is any abelian group, then $A \otimes B, \text{Tor}_1(A, B) \in \mathcal{C}$;
3. if $A \in \mathcal{C}$, then $H_n(A) \in \mathcal{C}$ for every $n > 0$.

We say that two groups $G$ and $H$ are *isomorphic modulo $\mathcal{C}$* if there is a homomorphism $G \rightarrow H$ whose kernel and cokernel are in $\mathcal{C}$.

**Theorem** (generalized relative Hurewicz theorem, 9.6.21 in [Spa]). Let $\mathcal{C}$ be an acyclic Serre ideal of abelian groups and $(X, A)$ be a pair of simply connected CW complexes. Then the following are equivalent:

1. $\pi_k(X, A) \in \mathcal{C}$ for $2 \leq k \leq n$.
2. $H_k(X, A) \in \mathcal{C}$ for $2 \leq k \leq n$.

Moreover, each of these implies that the Hurewicz homomorphism $\pi_{n+1}(X, A) \rightarrow H_{n+1}(X, A)$ is an isomorphism modulo $\mathcal{C}$.

The most obvious examples of acyclic Serre ideals are the class containing only the group 0 and the class of torsion groups. However, there is another such class that we would like to use. Suppose that $(X, K)$ is a rationally highly connected CW pair. This means that for each element $\alpha \in \pi_n(X)$, there is some $p > 0$ such that $p\alpha$ can be homotoped into $K$. However, a priori this $p$ can grow without bound depending on the $\alpha$ we select. On the other hand, for a comparison between the metric behavior of $\pi_n(X)$ and $\pi_n(K)$ to be meaningful, we would prefer to find a universal such $p$, and indeed this turns out to be possible for finite complexes. To this end, we define the class of groups of bounded exponent.
**Definition.** An abelian group $A$ has bounded exponent if $pA = 0$ for some $p \in \mathbb{N}$. We call the smallest such $p$ the period of the group.

**Proposition 1.4.** The class $\mathcal{BE}$ of abelian groups of bounded exponent is an acyclic Serre ideal.

**Proof.** Closure under subquotients, extensions, and tensor products is immediate.

Suppose $A$ has period $p$. Since $\text{Tor}_1(\mathbb{Z}/k\mathbb{Z}, B) = \{x \in B : kx = 0\}$, it has period $k$. Now, the Tor functor commutes with filtered colimits and direct sums; in particular,

$$\text{Tor}_1(A, B) = \bigcup_{G \subseteq A \text{ finite}} \text{Tor}_1(G, B) = \bigcup_{G \subseteq A \text{ finite}} \bigoplus_{G = \oplus \mathbb{Z}/k\mathbb{Z}} \text{Tor}_1(\mathbb{Z}/k\mathbb{Z}, B)$$

has period $p$.

Since $H_n(\mathbb{Z}/k\mathbb{Z}) = 0$ for even $n$ and $\mathbb{Z}/k\mathbb{Z}$ for odd $n$, the K"{u}nneth formula tells us that for finite $G$, the period of $H_n(G)$ is at most that of $G$. According to Theorem 9.5.9 of [Spa], for any group $A$, $H_*(A) \cong \varprojlim \{H_*(G) : G \subset A \text{ finite}\}$. Hence if $A$ has period $p$ then $H_n(A)$ has period at most $p$. □

For the future, we need one more property of groups of bounded exponent.

**Proposition 1.5.** Let $\Gamma$ be a group and $M$ a finitely generated torsion $\Gamma$-module. Then $M$ is of bounded exponent as a group.

**Proof.** Let $M = \langle a_1, \ldots, a_m \rangle$. Then $k_ia_i = 0$ for some $k_i > 0$. Let $r = \text{lcm}\{k_i : 1 \leq i \leq n\}$. A general element $a \in M$ is given by $a = \sum t_jg_ja_j$, where $t_j \in \mathbb{Z}$ and $g_j \in \Gamma$. Thus $ra = 0$. □

Now we come to our second technical tool. From an algebraic-topological perspective, any map can be replaced by the inclusion into its mapping cylinder. Thus the next proposition may be thought of as a very weak invertibility result for rational $n$-equivalences: they have homotopy inverses in the category of chain complexes with rational coefficients. In fact, this will be our main tool for proving rational invariance both in this section and in the rest of the paper. Furthermore, a map is rationally $n$-connected if and only if its rational homotopy fiber is $(n−1)$-connected; thus this proposition also turns out to be an important tool for analyzing rational homotopy fibrations.

**Proposition 1.6.** Let $(X, K)$ be a rationally $n$-connected CW pair. Then the inclusion of cellular chain complexes $i_k : C_k(\tilde{K}; \mathbb{Q}) \rightarrow C_k(\tilde{X}; \mathbb{Q})$ is a chain homotopy equivalence through dimension $n$. In particular, for $0 \leq k \leq n$, there is a $\pi_1$-equivariant homotopy inverse $j_k : C_k(\tilde{X}; \mathbb{Q}) \rightarrow C_k(\tilde{K}; \mathbb{Q})$ such that $j_k \circ i_k = \text{id}$ and $i_k \circ j_k$ is homotopic to the identity via a $\pi_1$-equivariant chain homotopy $u_k : C_k(\tilde{X}; \mathbb{Q}) \rightarrow C_{k+1}(\tilde{X}; \mathbb{Q})$ which is zero on the image of $i$. We call $j_k$ a lifting homomorphism.

**Proof.** We produce $j_k$ and $u_k$ by induction on $k$. For $0$-cells $e$ of $\tilde{X}$ outside $\tilde{K}$, we can set $j_0(e)$ to be any $0$-cell of $\tilde{K}$ in an equivariant way, and $u_0(e)$ to be a path between $e$ and $j_0(e)$. Now suppose that we have constructed $j_{k−1}$ and $u_{k−1}$. Let $e$ be a $k$-cell of $\tilde{X}$. Then $e + u_{k−1}(\delta e)$ represents an element of $H_k(\tilde{X}, \tilde{K}; \mathbb{Q})$ and so there’s a chain $j_e \in C_k(\tilde{K}; \mathbb{Q})$ such that $i_k(j_e) − e − u_{k−1}(\delta e) = \partial u_e$ for some $u_e \in C_{k+1}(\tilde{X}; \mathbb{Q})$. We set $j_k(e) = j_e$ and $u_k(e) = u_e$. We then extend equivariantly over the equivalence class of $e$. If $e$ is a cell of $\tilde{K}$, we can take $j_e = e$ and $u_e = 0$ by induction. □

With the two main tools in place, we can show that rationally highly connected finite CW pairs have homotopy groups with bounded exponent.

**Corollary 1.7.** Suppose $n \geq 2$ and $(X, K)$ is a rationally $n$-connected finite CW pair. Then for $i \leq n$, $H_i(\tilde{X}, \tilde{K})$ and $\pi_i(\tilde{X}, \tilde{K}) \cong \pi_{i+1}(\tilde{X}, \tilde{K})$ have bounded exponent. Moreover, $H_{n+1}(\tilde{X}, \tilde{K}) \cong \pi_{n+1}(X, K)$ mod $\mathcal{BE}$.

**Proof.** Let $j_k : C_k(\tilde{X}; \mathbb{Q}) \rightarrow C_k(\tilde{K}; \mathbb{Q})$ and $u_k : C_k(\tilde{X}; \mathbb{Q}) \rightarrow C_{k+1}(\tilde{X}; \mathbb{Q})$ be a lifting homomorphism and the corresponding chain homotopy. There are a finite number of equivalence classes of $k$-cells $e$ in $\tilde{X}$, and for each such cell, there are elements $\alpha_e \in C_k(\tilde{K}; \mathbb{Z})$ and $\beta_e \in C_{k+1}(\tilde{X}; \mathbb{Z})$ and integers $q_e$ and $q_e'$ such that

$$j_k(e) = \frac{1}{q_e} \alpha_e \text{ and } u_k(e) = \frac{1}{q_e'} \beta_e.$$
Taking the least common denominator $q_k$ of all the $q_c$’s and $q_e$’s, we get that for any $k$-chain $c$ with boundary in $\tilde{K}$, $q_k c$ is integrally homologous to a $k$-chain in $\tilde{K}$. This proves that $H_i(\tilde{X}, \tilde{K})$ have bounded exponent. The rest of the conclusion follows by the generalized relative Hurewicz theorem. \hfill \Box

We can also now prove a rational version of Wall’s theorem. We will use it to prove two corollaries on the finiteness of certain complexes which will in turn be applied later in the paper. Corollary 1.9 shows that rationally equivalences can be kept within the category of complexes with finite skeleta, while Theorem 1.10 relates the finiteness properties of the three spaces in a rational homotopy fibration.

**Theorem 1.8 (rational Wall theorem).** Let $X$ be a CW complex and $n \geq 2$. Then the following are equivalent:

1. $X$ is rationally equivalent to a CW complex $Y$ with finite $n$-skeleton.
2. There is a CW complex $Y$ with finite $n$-skeleton and a rational equivalence $Y \to X$. (Equivalently, there is an $n$-complex with an $n$-connected map to $X$.)
3. The group $\Gamma := \pi_1(X)$ is finitely presented, and for every $k \leq n$, the condition $F_k(\mathbb{Q})$ holds: for every finite complex $K^{k-1}$ and rationally $(k-1)$-connected map $\varphi : K \to X$, $\pi_k(\varphi) \otimes \mathbb{Q}$ is a finitely generated $\mathbb{Q}\Gamma$-module.

**Proof.** (2) clearly implies (1).

Suppose (1) is true. That is, there are a finite complex $Y$ and a complex $Z$ such that $f : X \to Z$ and $g : Y \to Z$ are rational equivalences. Since $\Gamma = \pi_1(Y)$, it must be finitely presented. Now suppose that $K$ is a $(k-1)$-complex and $\varphi : K \to X$ is a rationally $(k-1)$-connected map. Then $\psi := f \circ \varphi$ is as well, so that, by Hurewicz,

$$\pi_k(\psi) \otimes \mathbb{Q} = \pi_k(Z, K) \otimes \mathbb{Q} \cong \pi_k(\tilde{Z}, \tilde{K}; \mathbb{Q}) \cong H_k(\tilde{Z}, \tilde{K}; \mathbb{Q}).$$

Moreover, we can assume by taking mapping cylinders that $K$ and $Y$ are subcomplexes of $Z$. Let $j_\bullet : C_\bullet(\tilde{Z}; \mathbb{Q}) \to C_\bullet(\tilde{K}; \mathbb{Q})$ and $u_\bullet : C_\bullet(\tilde{Z}; \mathbb{Q}) \to C_{\bullet+1}(\tilde{Z}; \mathbb{Q})$ be the lifting homomorphism and associated chain homotopy for the pair $(\tilde{Z}, \tilde{K})$, and let $j'_\bullet$ and $u'_\bullet$ be the lifting homomorphism and chain homotopy for the pair $(\tilde{Z}, \tilde{Y})$. Then there is a homomorphism

$$F : C_k(\tilde{Y}; \mathbb{Q}) \oplus C_{k-1}(\tilde{K}; \mathbb{Q}) \to H_k(\tilde{Z}, \tilde{K}; \mathbb{Q}),$$

given on cells by

$$F(e', e) = [e' + u_{k-1}(\partial e') - u'_{k-1}(e) - u_{k-1}(\partial u'_{k-1}(e))].$$

The boundary of this chain is

$$j_{k-1}(\partial e') - j_{k-1}(\partial u'_{k-1}(e)) \in C_{k-1}(\tilde{K}; \mathbb{Q}),$$

Figure 1. A schematic illustrating $F(e', e)$ for an arbitrary pair of chains $e' \in C_k(\tilde{Y}; \mathbb{Q})$ and $e \in C_{k-1}(\tilde{K}; \mathbb{Q})$. 

so it is in fact a cycle in \((\tilde{Z}, \tilde{K})\). Moreover, if \(c\) is a chain in \(\tilde{Z}\) with boundary in \(\tilde{K}\), then
\[
F(j^*_k(c), \partial c) = [(j^*_k(c) - u'_{k-1}(\partial c)) + u_{k-1}(\partial j^*_k(c)) - u_{k-1}(\partial u'_{k-1}(\partial c))] \\
= [(c + \partial u_k(c)) + u_{k-1}(\partial j^*_k(c)) + (-u_{k-1}(j^*_k(\partial c)) + u_{k-1}(\partial c))] \\
= [c + \partial u_k(c)] = [c] \in H_k(\tilde{Z}, \tilde{K}; \mathbb{Q}),
\]
showing that \(F\) is onto. Since the domain of \(F\) is a finitely generated free \(\mathbb{Q}\Gamma\)-module, this means that \(H_k(\tilde{Z}, \tilde{K}; \mathbb{Q})\) is finitely generated, proving (3).

On the other hand, suppose (3) is true. We will inductively construct a \(Y\) with finite \(n\)-skeleton with a rational equivalence \(Y \to X\). Since \(\Gamma\) is finitely presented, we can construct a finite 2-complex \(A\) with \(\pi_1(A) = \Gamma\). This gives a 1-connected map \(\varphi: A \to X\), so \(\pi_2(\varphi) \otimes \mathbb{Q}\) is finitely generated. We can add a finite number of 2-cells to kill it, building \(Y^{(2)}\) and extending \(\varphi\). By induction, we can build a finite complex \(Y^{(n)}\) and extend \(\varphi\) to it. Finally, we can add cells to build the rest of \(Y\).

**Corollary 1.9.** Suppose, for some \(n \geq 2\), that \(K\) and \(L\) are CW-complexes with finite \(n\)-skeleta and \(K \xrightarrow{f} Y \xleftarrow{g} L\) are rational equivalences. Then indeed there are rational equivalences \(K \xrightarrow{f} Z \xleftarrow{g} L\) where \(Z\) has finite \(n\)-skeleton.

**Proof.** As usual, let \(\Gamma\) refer to \(\pi_1 K = \pi_1 L = \pi_1 Y\).

By taking a double mapping cylinder, we can assume that \(f\) and \(g\) are both inclusions. By inducting on dimension, we will build a complex \(Z\) with maps

\[
\begin{array}{ccc}
K & \xrightarrow{f} & Z \\
\downarrow & & \downarrow \\
Y & \xrightarrow{g} & L
\end{array}
\]

where \(h\) is a rational equivalence, and hence so are the inclusions into \(Z\). For the base case, let \(\varphi: L^{(1)} \times [0,1] \to Y\) be a homotopy taking \(g|_{L^{(1)}}\) into \(K^{(1)}\), and let \(Z^{(2)} = K^{(2)} \cup \varphi|_{L^{(1)} \times [0,1]} L^{(1)} \times [0,1] \cup \varphi|_{L^{(1)} \times \{0\}} L^{(2)}\).

Then the inclusion \(Z^{(2)} \hookrightarrow Y\) induces an isomorphism on \(\pi_1\). Moreover, any element in \(\pi_2(K)\) has a representative which maps to \(Z^{(2)}\), so \(\pi_2(Z) \otimes \mathbb{Q}\) surjects onto \(\pi_2(Y) \otimes \mathbb{Q}\). In particular, \(Z^{(2)} \hookrightarrow Y\) is rationally 2-connected.

Now suppose we have constructed \(Z^{(k)}\) with rationally \(k\)-connected \(h_k: Z^{(k)} \to Y\). Then since \(Y\) has the rational homotopy type of \(K\), the rational Wall theorem tells us that \(\pi_{k+1}(h_k) \otimes \mathbb{Q}\) is a finitely generated \(\mathbb{Q}\Gamma\)-module, and so we can add in a finite number of \((k+1)\)-cells to kill it, in such a way that the map \(h_k\) extends to an \(h_{k+1}\) which is then rationally \((k+1)\)-connected. To ensure that \(K\) and \(L\) are included in our final \(Z\), we make sure that all their \((k+1)\)-cells are on the list.

By induction, \(h\) is a rational equivalence, and hence so are the inclusions \(K \hookrightarrow Z \hookrightarrow L\). □

**Theorem 1.10.** Let \(n \geq 2\), and suppose \(f: X \to Y\) is a \(\pi_1\)-isomorphic map of CW complexes such that \(\pi_k(f) \otimes \mathbb{Q}\) is finite-dimensional for \(2 \leq k \leq n+1\) and \(\pi_2(f) \otimes \mathbb{Q} = 0\). Then \(Y\) is rationally equivalent to a complex with finite \(n\)-skeleton if and only if \(X\) is.

**Proof.** Suppose first that \(Y\) is rationally equivalent to a complex with finite \(n\)-skeleton. We will show that the homotopy fiber of \(f\) is also rationally equivalent to a complex with finite \(n\)-skeleton, and use this to construct an \(n\)-complex with an \(n\)-connected map to \(X\).

By adding cells in dimensions 3 and 4 to \(Y\), we can kill the torsion subgroup of \(\pi_2 Y\) without affecting its rational homotopy type. Thus we can assume that \(\pi_2(f) = 0\). Using the standard path space construction, we can assume that \(f\) is a fibration; let \(F\) be its fiber, which is simply connected. By assumption, \(\pi_k(F) \otimes \mathbb{Q}\) is finite-dimensional for \(k \leq n\), so by the generalized Hurewicz theorem, so is \(H_k(F; \mathbb{Q})\). This means that \(F\) is rationally equivalent to a complex with finite \(n\)-skeleton, for example by Theorem 9.11 of [FHT]; by the rational Wall theorem we can find a finite complex \(F'\) such that the map \(F' \to F\) is rationally \(n\)-connected.
Let $B \to Y$ be a rationally $n$-connected map from a finite complex with one 0-cell to $Y$. We will construct finite rational approximations $A_k$ to $E_k := f^{-1}(B^{(k)})$ by induction on $k$. We write $\tilde{B}$ for the universal and let $\tilde{E}$, etc., be the corresponding covers of our other spaces mapping to $\tilde{B}$; note that these are not always universal covers.

Clearly, $F' \to E_0 \cong F$ is a rationally $n$-connected map, so we can set $A_0 = F'$. Moreover, we can construct $A_1$ as follows. For each 1-cell $c : [0, 1] \to B$, we have two rationally $n$-connected maps $F' \to c^*X$ corresponding to the two endpoints of the interval. We can use the proof of Corollary 1.14 to find a complex which includes them both and which maps to $c^*X$ via a rationally $n$-connected map. To construct $A_1$ as desired, we construct such a complex for each 1-cell and glue them together along all the copies of $F'$. Then the map $A_1 \to E_1$ is rationally $n$-connected since the universal covers $A_1$ and $\tilde{E}_1$ live in a commutative square

$$
\begin{array}{ccc}
F' & \longrightarrow & \tilde{A}_1 \\
\downarrow & & \downarrow \\
F & \longrightarrow & \tilde{E}_1
\end{array}
$$

where the other three maps are rationally $n$-connected.

Now let $k \geq 2$, and suppose we have constructed a rationally $n$-connected map $A_{k-1} \to E_{k-1}$. We will add cells to $A_{k-1}$, again by induction on dimension, in order to build $A_k$. We will use the following fact, which is a standard step in deriving the Serre spectral sequence, as for example in [Hat]:

$$(1.2) \quad H_i(\tilde{E}_k, \tilde{E}_{k-1}) \cong H_k(\tilde{B}^{(k)}, \tilde{B}^{(k-1)}) \otimes H_{i-k}(F).$$

We start with the base case, which is slightly different for $k = 2$ and $k > 2$. For $k > 2$, the map $A_{k-1} \to E_k$ is already rationally $(k-1)$-connected, and so by the generalized relative Hurewicz theorem,

$$\pi_k(E_k, A_{k-1}) \otimes \mathbb{Q} \cong H_k(\tilde{E}_k, \tilde{A}_{k-1}; \mathbb{Q}) \cong H_k(\tilde{E}_k, \tilde{E}_{k-1}; \mathbb{Q}).$$

By (1.2), this is a finitely generated module, so it can be killed by adding a finite number of $k$-cells. This gives us a finite complex $A_k(0)$ with a rationally $k$-connected map $A_k(0) \to E_k$.

In the case $k = 2$, we instead have that $A_1 \to E_2$ is an (integrally) 1-connected map, and we can use another form of the Hurewicz theorem (Theorem 4.37 in [Hat]) to show in a similar way that $\pi_2(E_2, A_1)$ is finitely generated over $\mathbb{Z}[\pi_1 E_1]$.

Now let $0 < i \leq n - k$, and suppose we have constructed a finite complex $A_k(i - 1)$ with a rationally $(k + i - 1)$-connected map $A_k(i - 1) \to E_k$. Consider the exact sequence

$$H_{k+i}(\tilde{E}_k, \tilde{A}_{k-1}; \mathbb{Q}) \to H_{k+i}(\tilde{E}_k, \tilde{A}_{k-1}; \mathbb{Q}) \to H_{k+i-1}(\tilde{A}_{k-1}; \mathbb{Q}).$$

The last module is finitely generated because $A_k(i - 1)$ and $A_{k-1}$ are finite complexes; the first, by (1.2). Therefore $H_{k+i}(\tilde{E}_k, \tilde{A}_{k-1}; \mathbb{Q}) \cong \pi_{k+i}(\tilde{E}_k, \tilde{A}_{k-1}) \otimes \mathbb{Q}$ is finitely generated. Killing it gives us $A_k(i)$ as desired.

In the end, we obtain a rationally $n$-connected map $A_n \to X$. We can complete $A_n$ to a complex rationally equivalent to $X$ by adding cells in dimensions $n + 1$ and higher. This completes one direction of the proof.

Now we tackle the other direction. Suppose that $X$ is rationally equivalent to a complex with finite $n$-skeleton, and suppose that $Y$ is not. Let $3 \leq k \leq n$ be the first dimension in which a complex rationally equivalent to $Y$ necessarily has infinitely many cells, and so $\pi_k(Y, Y^{(k-1)}) \otimes \mathbb{Q}$ is infinitely generated. Consider the homotopy pullback $g : Z \to Y^{(k-1)}$ of the homotopy fibration $f : X \to Y$; in particular, $\pi_i(g) = \pi_i(f)$ for every $i$ and the map $Z \to X$ is rationally $(k-1)$-connected. By the $Y \Rightarrow X$ direction, $Z$ is rationally equivalent to a complex $K$ with finite skeleton and indeed there is a rational equivalence $K \to Z$. Let $\varphi : K^{(k-1)} \to X$ and $\psi : K^{(k-1)} \to Y^{(k-1)}$ be the maps which factor through $Z$, so that $\pi_k(\varphi) \otimes \mathbb{Q}$ is finitely generated by Theorem 1.8 whereas $\pi_k(\psi) \otimes \mathbb{Q}$ is finitely generated by the exact sequence of triples

$$\pi_k(K, K^{(k-1)}) \otimes \mathbb{Q} \to \pi_k(\psi) \otimes \mathbb{Q} \to \pi_k(f) \otimes \mathbb{Q} \to 0.$$
shows that $\pi_k(Y,K^{(k-1)}) \otimes \mathbb{Q}$ is finitely generated, while the exact sequence of triples

$$
\pi_k(\psi) \otimes \mathbb{Q} \rightarrow \pi_k(Y,K^{(k-1)}) \otimes \mathbb{Q} \rightarrow \pi_k(Y,Y^{(k-1)}) \otimes \mathbb{Q} \rightarrow \pi_{k-1}(\psi) \otimes \mathbb{Q}
$$

shows that $\pi_k(Y,K^{(k-1)}) \otimes \mathbb{Q}$ is infinitely generated, since $\pi_{k-1}(\psi) \otimes \mathbb{Q} \cong \pi_{k-1}(f) \otimes \mathbb{Q}$. Thus we have a contradiction. \qed

2. Basic properties

In this section, we define distortion functions and discuss relationships between different definitions. As mentioned in the introduction, what we mean by “distortion” can be defined for any measure of “size” in a group, that is, for any subadditive functional on that group. We will start with this purely formal definition before specifying it to Lipschitz and volume distortion in higher homotopy and homology groups.

The Lipschitz and volume functionals we use are only defined up to additive and multiplicative constants, forcing us to discuss distortion functions only up to asymptotic equivalence. That is, when comparing functions $N \rightarrow \mathbb{R} \cup \{\infty\}$, we will use the relations

$$f \lesssim g \iff \text{for some } A,B,C,D, \ f(n) \leq Ag(Bn + C) + D$$

$$f \sim g \iff f \lesssim g \text{ and } f \gtrsim g.$$

We now give a number of formal definitions relating to distortion functions.

**Definition.** Let $G$ be an abelian group, let $\varphi : G \rightarrow G \otimes \mathbb{Q}$ be the rationalization homomorphism, and $F : G \rightarrow \mathbb{R}^+$ a subadditive functional. Define the $F$-distortion function of $\alpha \in G$ to be the function $\delta_{\alpha,F} : \mathbb{N} \rightarrow \mathbb{R}^+ \cup \{\infty\}$ given by

$$\delta_{\alpha,F}(k) = \sup\{m \mid F(\alpha m) \leq k\}.$$

We say $\alpha$ is distorted if $F(k\alpha)/k \rightarrow 0$ as $k \rightarrow \infty$, and that $\alpha$ is infinitely distorted if there is a $k$ such that $\delta_{\alpha,F}(k) = \infty$.

Similarly, given a norm $\| \cdot \|$ on a finite-dimensional vector subspace $V \subseteq G \otimes \mathbb{Q}$, we can define the $F$-distortion function of $V$ to be

$$\delta_{V,F}(k) = \sup\{\|\varphi(\alpha)\| \mid \alpha \in G \text{ with } \varphi(\alpha) \in V \text{ and } F(\alpha) \leq k\}.$$

Note that the asymptotics of $\delta_V$ do not depend on the norm. We say that $V$ is distorted if $k/\delta_{V,F}(k) \rightarrow 0$ as $k \rightarrow \infty$, and infinitely distorted if there is a $k$ such that $\delta_{V,F}(k) = \infty$.

Finally, we will say that $V$ is weakly distorted in another finite-dimensional subspace $U$ if for some constant $C$,

$$\sup\{\|\varphi(\alpha)\| \mid \text{dist}(\varphi(\alpha),V) < C \text{ and } F(\alpha) \leq k\} \gtrsim k.$$

Similarly, $V$ is weakly infinitely distorted in $U$ if there are constants $C$ and $k$ such that

$$\sup\{\|\varphi(\alpha)\| \mid \text{dist}(\varphi(\alpha),V) < C \text{ and } F(\alpha) \leq k\} = \infty.$$

These conditions also clearly do not depend on $\| \cdot \|$.

That is, a subspace is weakly distorted if there are vectors which close to it, but not necessarily in it, on which $F$ is small. It turns out, as we show below, that for purely formal reasons weak distortion always implies distortion, at least when distortion in $V$ is a meaningful idea at all. This contrasts with the infinite version; as we will show in Example 3.11.3, weak infinite distortion does not imply infinite distortion. An identical argument shows that if the one-dimensional subspace $Q\varphi(\alpha)$ is F-distorted, then so is the element $\alpha$. However, here again the distortion functions may be different; such a case will be demonstrated in Example 3.11.1.

**Lemma 2.1.** Let $G$ be an abelian group and $F$ a subadditive functional, and let $V \subseteq U \subseteq G \otimes \mathbb{Q}$ be finite-dimensional subspaces. If $\varphi(G)$ contains a basis of $V$ and $V$ is weakly $F$-distorted in $U$, then $V$ is $F$-distorted.

**Proof.** Fix a finite set $\{\alpha_i\} \subseteq G$ such that $\{\varphi(\alpha_i)\}$ generates $\varphi^{-1}(U)$, and let $C' = \max_i F(\alpha_i)/\|\varphi(\alpha_i)\|$. Then for every $\gamma \in G$ with $\varphi(\gamma) \in U$, there is a sufficiently large $M$ that $M\gamma$ is in the subgroup of $G$ generated by the $\{\alpha_i\}$ and therefore $F(\gamma) \leq C'M\|\Gamma\|$.
The assumptions guarantee that $\varphi(G) \cap V$ is “coarsely dense” in $V$: that is, there is a constant $K$ such that every point in $V$ is at most distance $K$ from $\varphi(G)$. Since $V$ is weakly $F$-distorted, there is a $C$ such that for every $\varepsilon > 0$ and $N > 0$ there is a $\alpha \in G$ such that $\text{dist}(\alpha, V) < C$ and $N < F(\alpha) \leq \varepsilon \|\varphi(\alpha)\|$. We can then write $\alpha = \beta + \gamma$ where $\varphi(\beta) \in V$ and $\|\varphi(\gamma)\| \leq K + C$. Let $M$ be such that $M\gamma$ is in the subgroup generated by $\{\alpha_i\}$. Then

$$F(M\beta) \leq \varepsilon M\|\varphi(\alpha)\| + C'M(K + C) \leq M(\varepsilon\|\varphi(\alpha)\| + \text{const}).$$

Supposing that for a given $\varepsilon > 0$ we choose $N = C'(K + C)/\varepsilon$, this gives us

$$F(M\beta) \leq \text{const} \cdot \varepsilon M\|\varphi(\beta)\| = \text{const} \cdot \varepsilon\|\varphi(M\beta)\|.$$ 

Since we can satisfy this inequality for every $\varepsilon > 0$, $V$ is $F$-distorted. 

Note that this proof is utterly ineffective: the fact that $V$ is weakly distorted means only that it has some superlinear distortion function, but its divergence from linearity could be arbitrarily slow.

In these definitions, $G$ may be rather complicated even when $G \otimes \mathbb{Q}$ is a finitely generated vector space. For example, $G = \mathbb{Z}\left[\frac{1}{2} + \frac{i}{2}\right] \subset \mathbb{Q}[i] \cong \mathbb{Q}^2$ is infinitely generated as a group; if we see it as generated by $\{(\frac{1}{2} + \frac{i}{2})^n : n \in \mathbb{N}\}$, then each generator has the same 2-norm in $\mathbb{Q}^2$. Thus the universe of conceivable behaviors of the functional $F$ is very large indeed.

It is worth giving a little bit of flavor as to the kind of functionals $F$ that we will deploy. A basic example is as follows: let $G = \mathbb{Z}$, and let $F(z)$ denote the least number of powers of 2 one needs to add or subtract to get to $z$. Thus for example $F(1023) = F(2^{10} - 2^9) = 2$. Then $F$ is unbounded, but so is $\{z \in \mathbb{Z} : F(z) = 1\}$; therefore $\delta_{1,F}(n) = \infty$ for every $n \geq 1$. In other words, the element 1 is infinitely distorted, even though some of its multiples have large minimal representations.

More generally, to any group $G$ and any generating set $\{g_i\}_{i\in I}$ we may associate the functional $F$ which, for any $g \in G$, gives the minimal sum of the coefficients of a way of representing $g$ as $\sum_i C_i g_i$. In Examples 3.11 and the later parts of section 3 we discuss several examples of this type; the complexity revealed there is as much a consequence of the linear algebra in the definitions we have given thus far as it is of the geometry of the relevant spaces.

We now specify these ideas to the study of homotopy groups and their metric properties. Let $X$ be a compact Riemannian manifold with boundary or a finite CW-complex with a piecewise Riemannian metric. Rademacher’s theorem, applied to some piecewise smooth local embedding of $X$ into $\mathbb{R}^N$, tells us that a Lipschitz map $f : S^n \to X$ is almost everywhere differentiable. In particular, one can define its volume:

$$\text{vol } f := \int_{S^n} \|\text{Jac}(f)\|dvol.$$

**Definition.** Given $\alpha \in \pi_n(X)$, write

$$|\alpha|_{\text{Lip}} := \sup\{\text{Lip } f \mid f : S^n \to X \text{ is a Lipschitz representative of } \alpha\}.$$ 

The **Lipschitz distortion** of $\alpha$, written $L\delta_\alpha(k)$, is the distortion of $\alpha$ with respect to the functional $F(\alpha) = |\alpha|_{\text{Lip}}$. Similarly, write

$$|\alpha|_{\text{vol}} := \min\{\text{vol } f \mid f : S^n \to X \text{ is a Lipschitz representative of } \alpha\}.$$ 

The **volume distortion** of $\alpha$, written $V\delta_\alpha(k)$, is the distortion of $\alpha$ with respect to the volume functional.

Given a finite-dimensional vector subspace $V \subseteq \pi_n(X) \otimes \mathbb{Q}$ together with a norm $\|\cdot\|$, we define the distortion functions

$$L\delta_V(k) = \sup \{\|v\| \mid \exists \alpha \in \pi_n(X) \text{ such that } \alpha \overset{\mathbb{Q}}{\to} v \in V \text{ with } |\alpha|_{\text{Lip}} \leq k\},$$

$$V\delta_V(k) = \sup \{\|v\| \mid \exists \alpha \in \pi_n(X) \text{ such that } \alpha \overset{\mathbb{Q}}{\to} v \in V \text{ with } |\alpha|_{\text{vol}} \leq k\}.$$ 

If $\alpha$ is torsion, then $|k\alpha|_{\text{Lip}}$ and $|k\alpha|_{\text{vol}}$ are bounded, and so the corresponding distortion functions are eventually infinite. In all cases, $|k\alpha|_{\text{Lip}} \lesssim k^{1/n}\alpha$ because we can get a representative of $k\alpha$ by precomposing a map $f \in \alpha$ with a map $S^n \to S^n$ of degree $k$ and Lipschitz constant $k^{1/n}$. Thus for any $\alpha$, $L\delta_\alpha(k) \gtrsim k^n$. Moreover, a $k$-Lipschitz map has volume at most $k^n$, so for any $\alpha$, $V\delta_\alpha(k) \leq L\delta_\alpha(k)^{1/n}$. In particular, $V\delta_\alpha(k)$ is at least linear. This motivates another definition:
Definition. A class $\alpha$ or subspace $V$ in $\pi_n(X) \otimes \mathbb{Q}$ is Lipschitz undistorted if $L\delta_\alpha(k) \sim k^n$ (respectively $\delta_V(k) \sim k^n$), and undistorted if in addition its volume distortion is linear.

Clearly, for any subspace $V$ and any $0 \neq \alpha \in V$, $L\delta_V(k) \gtrsim \delta_\alpha(k)$ and $V\delta_V(k) \gtrsim V\delta_\alpha(k)$. On the other hand, we will later see an example of an $X$ such that $\pi_n(X) \otimes \mathbb{Q}$ is distorted although none of its elements are. This provides extra motivation for the definitions of $L\delta_V$ and $V\delta_V$.

A Lipschitz homotopy equivalence $X \stackrel{f}{\to} Y$ induces an asymptotic equivalence on distortion functions, since

$$|\alpha|_{\text{Lip}} \leq \text{Lip}_f|f_*\alpha|_{\text{Lip}} \leq \text{Lip}_f \text{Lip}_g|\alpha|_{\text{Lip}}$$

and

$$|\alpha|_{\text{vol}} \leq (\text{Lip}_g)^n|f_*\alpha|_{\text{vol}} \leq (\text{Lip}_f^n(\text{Lip}_g)^n)|\alpha|_{\text{vol}}.$$  

In particular, we can speak of distortion functions of finite CW complexes and compact manifolds without specifying a metric. Another way of simplifying our object of study is to restrict to a more combinatorial class of functions $S^n \to X$.

Definition (BBFS). Given a CW-complex $X$ and an $n$-manifold $M$, call a map $f : M \to X$ admissible if $f(M) \subseteq X^{(n)}$ and for every interior $U$ of an $n$-cell of $X$, $f^{-1}(U)$ is a disjoint union of balls which map homeomorphically to $U$. If $M$ is compact, define the cellular volume $\text{vol}_C(f)$ to be the total number of these balls.

If $X$ has a piecewise Riemannian metric and a finite $n$-skeleton, then for any admissible map $f$,

$$c \text{vol}(f) \leq \text{vol}_C(f) \leq C \text{vol}(f),$$

where $c$ and $C$ are the least and greatest volume of a cell, respectively. Thus asymptotically speaking, it doesn’t matter which notion of volume we consider. Before we can use this fact, however, we need to make sure that the asymptotics of distortion functions remain the same if we only consider admissible maps. For this, we use a theorem originally from geometric measure theory.

Theorem 2.2 (Federer–Fleming deformation theorem [EPC⁺]). For any finite-dimensional simplicial complex $Y$, for example for a triangulated manifold, there is a $c > 0$ with the following property. Any Lipschitz $k$-cycle $T$ can be decomposed as $T = Q + \partial R$, where $R$ is a Lipschitz $(k+1)$-chain and $Q$ is a smooth $k$-cycle whose simplices are cellular, such that mass$_{k+1}R \leq c \text{mass}_k Q \leq c^2 \text{mass}_k T$ and $Q$ and $R$ are contained in the smallest subcomplex of $Y$ containing $T$.

Indeed, if $N$ is a triangulated manifold, then a Lipschitz map $f : N \to Y$ is Lipschitz homotopic, via a homotopy of mass bounded by $c^2 \text{vol}_f$, to an admissible map $g$ with $\text{vol}_C(g) \leq c \text{vol}_f$.

The second statement, though not stated as such by [EPC⁺], falls out of the proof they give. Every CW complex $X$ has a simplicial approximation $Y$ with a homotopy equivalence $Y \to X$ that sends each $k$-simplex either homeomorphically to a cell or to $X^{(k-1)}$, and when $X$ is compact this can be made Lipschitz. Therefore, the same statement holds for CW complexes. Thus we have the following consequences.

Corollary 2.3. The minimal volume of a representative of $\alpha \in \pi_n(X)$ is approximated to within a multiplicative constant, depending on $n$ and $X$, by an admissible representative. To find the asymptotic behavior of the distortion function of an element of $\pi_n(X)$, it is enough to consider admissible representatives. In particular, the asymptotic behavior of the volume distortion functions of $\pi_n(X)$ depends only on the topology of the $(n+1)$-skeleton of $X$.

These homotopy invariance results are also true for Lipschitz constants, using a Lipschitz version of the deformation theorem which is beyond the scope of this paper. But the following lemma gives a stronger independence result which only seems to work for volume distortion. Namely, it shows that all multiples have maps that pull back through rational equivalences in a volume-preserving way.

To demonstrate some of the intuition behind this, here is a warmup problem. Consider the rational equivalence $Z \to T^3$, where $Z$ is defined as follows. The 3-cell of $T^3$ has an attaching map $\alpha : S^2 \to (T^3)^{(2)}$; define $Z = (T^3)^{(2)} \cup_{\text{onu}} D^3$, where $u : S^2 \to S^2$ is a map of degree 2. Then an extension of $u$ to the interior
of \( D^3 \) defines a map \( \varphi : Z \to T^3 \); since \( \tilde{T}^3 \) is contractible and \( \tilde{Z} \) has torsion homology in all dimensions \( n > 0 \), this is a rational equivalence. Let \( f : (D^3, S^2) \to \tilde{T}^3 \) be the composition
\[
D^3 \xrightarrow{\text{degree } 2} [0, k]^3 \hookrightarrow \mathbb{R}^3.
\]
We know this map is homotopic rel boundary to \( \varphi \circ g \) for some map \( g : (D^3, S^2) \to Z \). But how do we construct such a map? The two preimages of each 3-cell are quite far away from each other, but we need to join their boundaries into a single map of degree 2.

It turns out that one way to do this is to take a path from one preimage to the other and nullhomotope its image through \((\tilde{T}^3)^{\{2\}}\), which is simply connected. Although this forces the map to become very distorted, the cellular volume is not affected. An observation of this sort was originally made by Brian White in [White].

In this example, our job is made easier by the fact that the 2-skeletons of the two complexes happen to coincide. When that is not the case, forcing the map to behave correctly on lower skeleta takes some rather intuition-free wrangling.

**Lemma 2.4.** Let \( (X, K) \) be a CW pair, and \( n \geq 2 \), such that the inclusion \( K \hookrightarrow X \) is rationally \( n \)-connected. Then there are constants \( p_n(X, K) > 0 \) and \( \kappa_n(X, K) \) such that for any map \( f : S^n \to X \) of volume \( k \) there is an admissible map \( g : S^n \to K \) for which \( p_n f \simeq g \) and \( g \) has volume \( \kappa_n k + \kappa_n \). If \( f \) is admissible, then as cellular chains, \( g_*([S^n]) = p_n j_* f_*([S^n]) \), where \( j_* : C_n(X) \to C_n(K) \) is a lifting homomorphism.

**Proof.** By passing to a homotopy equivalent situation, we assume that \( X \) and \( K \) have the same 1-skeleton and that all boundary maps are admissible. At the cost of increasing \( \kappa_n \), we assume \( f \) is admissible.

First, fix some notation. For every \( i \) and \( r \), fix degree \( r \) maps \( d_r : (D^i, S^{i-1}) \to (D^i, S^{i-1}) \) and \( d_r : S^i \to S^i \). In an abuse of notation, we distinguish these only by context. Given maps \( a : i \times S^{i-1} \to X \) and \( b : D^i \to X \) such that \( a|_{\{0\} \times S^{i-1}} = b|_{\partial D^i} \), define the map \( a \vee b : D^i \to X \) to be “a on the outside and \( b \) on the inside.” Finally, let \( q_n \) be the period of the group \( H_n(X, \hat{K}) \), which has bounded exponent by Corollary 1.7.

Suppose first that \( n = 2 \). Let \( f : S^2 \to X^{(2)} \) be an admissible map. Since \( \pi_1(X) \cong \pi_1(K) \), given a 2-cell \( e \) with attaching map \( \gamma_e : S^1 \to X^{(1)} \), we can extend \( \gamma_e \) to a map \( h_e : (D^2, S^1) \to (K, K^{(1)}) \). Define a map \( f' : S^2 \to K^{(2)} \subset X \) which agrees with \( f \) on \( f^{-1}(X^{(1)}) \) and where every homeomorphic preimage of a cell \( e \) is replaced with \( h_e \). Then \( f' \) differs from \( f \) by a torsion element of \( \pi_2(X) \). Therefore \( f \circ d_{q_2} \) is homotopic to \( f' \circ d_{q_2} \). This shows the lemma for \( n = 2 \), with \( p_2 = q_2 \).

The proof for \( n \geq 3 \) is much more complicated and the homotopy we construct involves several steps. On the interval \([0, 1/3] \), we homotope \( f \circ d_{q_n} \) to an admissible map which has degree zero on all \( n \)-cells of \( X \setminus \hat{K} \). On the interval \([1/3, 2/3] \), we cancel out preimages with opposite orientations; this leaves us with a map \( S^n \to X^{(n-1)} \cup K \). Finally, we show that a particular multiple of this map can be homotoped into \( K \) without changing the volume. This last homotopy is itself quite involved and involves several intermediate maps, whose relationships to each other are sketched in Figure 2.

We take \( f : S^n \to \tilde{X} \) to be a lift of the original map to the universal cover. To begin the first step, let \( \alpha \in C_n(\tilde{X}) \) be the cellular cycle \( f_*([S^n]) \). Fix a lifting homomorphism \( j_n : C_n(\tilde{X}; \mathbb{Q}) \to C_n(K; \mathbb{Q}) \) and a corresponding chain homotopy \( u_n : C_n(\tilde{X}; \mathbb{Q}) \to C_{n+1}(\tilde{X}; \mathbb{Q}) \), and choose a listing \( \{ e_r \}_{1 \leq r \leq V} \) of the cells of \( q_n u_n(\alpha) \), with multiplicity. We build a homotopy \( h : [0, 1/3] \times S^n \to \tilde{X} \) starting with \( h_0 = f \circ d_{q_n} \). As \( t \) increases, we homotope through each cell \( e_r \), so that
\[
h_*([\{t \times S^n\}] = h_*([\{t_{r-1} \times S^n\}] + \partial e_r.
\]
Thus \( h_*([\{1/3 \times S^n\}] = q_n j_n(\alpha) \). We can also ensure that \( h \) is admissible by leaving it constant for a time \( \varepsilon \) between homotoping through cells. Moreover, we can assume that in \( h_{1/3} \), the closures of preimages of open cells in \( \tilde{X} \) are disjoint closed disks; in other words, \( h_{1/3}^{-1}(X^{(n-1)}) \) is a path-connected compact manifold.

On the interval \([1/3, 2/3] \), we cancel out all preimages of cells with opposite orientations; this way, the cellular volume of \( h_{2/3} \) will be \( \|q_n j_n(\alpha)\|_1 \). Choose two preimages of an \( n \)-cell under \( h_{1/3} \) which have opposite orientation; call these \( a_1, a_2 : B^n \to S^n \) and the interior of the cell \( C \subset \tilde{X} \). We can find a simple smooth path \( \gamma \) through the interior of \( h_{1/3}^{-1}(X^{(n-1)}) \) whose endpoints are a point \( b_1 \) on the boundary of \( a_1(B^n) \) and a point \( b_2 \) on the boundary of \( a_2(B^n) \) with \( f(b_1) = f(b_2) \). Moreover, \( X^{(n-1)} \) is simply connected, so \( h_{1/3} \circ \gamma \) is a nullhomotopic loop in \( X^{(n-1)} \). Let \( N \) be a tubular neighborhood of \( \gamma \) containing a smaller tubular
There is an homotopy $\Phi : \partial \mapsto \mapsto \tilde{A}$ which maps to $\tilde{A}$.

By Proposition 1.2, the inclusion $\tilde{A}$ is in $\tilde{A}$, and consider the diagram

\[
\begin{array}{ccc}
Z\Gamma\#(n\text{-cells of } K) & \xrightarrow{\theta} & \pi_{n-1}(\tilde{K}) \\
\downarrow{t_*} & & \downarrow{\iota} \\
Z\Gamma\#(n\text{-cells of } X) & \xrightarrow{\pi_{n-1}(\tilde{X})} & \pi_{n-1}(\tilde{A})
\end{array}
\]

induced by the inclusions $K(n-1) \hookrightarrow K$ and $X(n-1) \hookrightarrow X$. From a diagram chase, we get that $\ker t_*$ is an extension of a bounded exponent group by $A := Z\Gamma\#(n\text{-cells of } K) / \ker \theta$; since $\ker t_*$ is known to be torsion, $A$ must be torsion, and thus by Proposition 1.3 it has bounded exponent. Therefore $\ker t_*$ itself has bounded exponent, and there is an $r_2(X, K, n)$ such that $h_{2/3}|_{\partial B} \circ d_{r_2}$ is nullhomotopic in $\tilde{K}(n-1)$ via a nullhomotopy $\psi$.

Together, $\psi \circ d_{r_1}$ and $\varphi \circ d_{r_2}$ give us a map

$$
\chi := \psi \circ d_{r_1} \lor \varphi \circ d_{r_2} : S^n \to \tilde{K}
$$

which is homotopic in $\tilde{X}$ to

$$
\psi \circ d_{r_1} \lor h_{2/3}|_{\partial B} \circ d_{r_1} \circ d_{r_2} : S^n \to \tilde{X}(n-1).
$$
Now, we have the diagram (with decorations mod $BE$)

$$
\begin{array}{ccc}
\pi_{n+1}(\tilde{X}, \tilde{K}) & \longrightarrow & \pi_n(\tilde{K}) \\
\downarrow & & \downarrow \\
H_{n+1}(\tilde{X}, \tilde{K}) & \longrightarrow & H_n(\tilde{K}),
\end{array}
$$

where the rows are exact. We know that $h_X(\iota_*[\chi]) = 0$; on the other hand, a diagram chase confirms that for some $r_3(X, K, n)$, there is an $\alpha \in \pi_n(\tilde{K})$ with $\iota_*\alpha = 0$ and $h_K(\alpha) = r_3h_K[\chi]$. By Prop.1.11 $r_3[\chi] - \alpha$ has a representative $\tilde{\chi}$ whose image is in $\tilde{K}^{(n-1)}$. In particular, $\tilde{\chi} \simeq \chi \circ d_{r_3}$ in $\tilde{X}$.

Set $r = r_1r_2r_3$ and let $\Phi$ be a homotopy that takes $h_{2/3}B \circ d_r$ to $\psi \circ d_{r_1} \circ d_{r_3} \cup \chi \circ d_{r_3}$ and then deforms $\chi \circ d_{r_3}$ to $\tilde{\chi}$. 

By precomposing with $d_r$ on the interval $[0, 2/3]$, we then get a homotopy $H : [0, 1] \times S^{n-1} \to \tilde{X}$ with

$$H(t, x) = \begin{cases} h_{1/2}(d_{r}(x)) & \text{if } t \in [0, \frac{2}{3}] \\ h_{2/3}(d_{r}(x)) & \text{if } t \in \left[\frac{2}{3}, 1\right] \text{ and } x \in S^{n-1} \setminus B \\ \Phi(x) & \text{if } t \in \left[\frac{2}{3}, 1\right] \text{ and } x \in B \end{cases}$$

and $H_1$ lands in $\tilde{K}$ with $H_1([S^n]) = r_qn_{j,n}(\alpha)$, is admissible and has no cells of opposite orientations. In particular, if we let $t_n = \max\{|j_n(e)| : e \text{ is an n-cell of } X\}$, $\text{vol} g \leq r_qn_{t_n} \text{vol} f$. Thus we can set $p_n = r_qn_{t_n}$, and in our homotopy equivalent setup $\kappa_n = r_qn_{t_n}$ and $g = H_1$. The homotopy equivalence may impose a penalty on the constant. 

More generally, if a map $\varphi : Y \to X$ obeys the same conditions on homotopy, then using the mapping cylinder, we can prove that for any $f : S^n \to X$, $rf$ lifts to a map of volume $C_k$ for constants $C(\varphi, n)$ and $r(\varphi, n)$. As a corollary, we have Theorem A.

**Theorem 2.6 (Rational invariance of volume distortion).** Let $X$ and $Y$ be rationally $n$-equivalent finite complexes, with $n$-equivalences $X \xrightarrow{f} Z \xleftarrow{g} Y$. Then for any $\alpha \in \pi_n(X)$ and $\beta \in \pi_n(Y)$ such that $f_*\alpha = g_*\beta$, $\text{Vol}_\alpha \sim \text{Vol}_\beta$. Similarly, for any finite-dimensional $V \subseteq \pi_n(X) \otimes \mathbb{Q}$ and $W \subseteq \pi_n(Y) \otimes \mathbb{Q}$ which are sent to the same subspace of $\pi_n(Z) \otimes \mathbb{Q}$, $\text{Vol}_V \sim \text{Vol}_W$.

**Proof.** By Corollary 1.9 we can assume that $Z$ is also finite; it is not necessarily the case then that $f_*\alpha = g_*\beta$, but certainly this is true for some multiple of $\alpha$ and $\beta$.

For any $k$,

$$|kf_*\alpha|_{\text{vol}} \leq (\text{Lip } f)^k|k\alpha|_{\text{vol}}.$$

Conversely, by Lemma 2.4 there are a $p_n(X, Z)$ and a $\kappa_n(X, Z)$ such that

$$|p_nk\alpha|_{\text{vol}} \leq \kappa_n|k\alpha|_{\text{vol}} + \kappa_n.$$

Therefore the distortion functions of $\alpha$ and $f_*\alpha$ are asymptotically equivalent. The same holds for $\beta$ and $g_*\beta$. The proof of the subspace case follows. 

This fact allows us to ignore torsion information when studying volume distortion functions. Indeed, in our subsequent discussion, we will often speak of spaces and maps “up to rational equivalence”. However, we conjecture that such an approach is not sufficient for studying Lipschitz distortion.

**Example 2.7.** Let $X$ be the total space of a fibration $S^3 \to X \to T^4$ with Euler class equal to the fundamental class $[T^4]$. Define a map $f_k : S^3 \to T^4$ which sends $S^3$ to the sides of a 4-cube with side length $k$. This map is $C_k$-lipschitz, for $C$ independent of $k$, and as will be discussed it lifts to a $C_k$-lipschitz map $g_k : S^3 \to X$ which is a representative of $k\beta$, where $\beta$ is a generator of $\pi_3(X)$. Thus $\beta$ is lipschitz distorted in $X$ with $L\delta_k(\beta) \gtrsim k^4$.

On the other hand, let $Z = (T^3) \cup_{\text{ad-m}} D^3$ be the space mentioned above which has a rational equivalence $i : Z \to T^3$. Then the map $\text{id} \times i : S^1 \times Z \to T^3$ is also a rational equivalence. Thus we can define a pullback fibration with total space $Y = (\text{id} \times i)^*X$, and $Y \to X$ is also a rational equivalence. On the other hand, suppose that $L\delta_k(\beta) \gtrsim k^4$. It is possible to show that this is equivalent to the existence of admissible maps $f_k : (D^4, S^3) \to \hat{Z}$ of volume $k^4$ with admissible boundary such that $\text{Lip}(f_k|_{S^3}) \lesssim k$. By composing $f_k|_{S^3}$
with a projection onto \( \tilde{Z} \), we get a sequence of \( Ck \)-Lipschitz admissible maps \( D^3 \to \tilde{Z} \) with area \( C'k^3 \). Although we don’t know a proof, we suspect that such maps do not exist.

This would mean that \( Y \) and \( X \) have asymptotically different Lipschitz distortion functions. In other words, torsion matters for Lipschitz distortion, at least for spaces with a nontrivial fundamental group.

### 3. Sources of volume distortion

In this section, we discuss two ways volume distortion can be induced in finite complexes: homological triviality and actions by the fundamental group. The ultimate goal of this is to show that conditions (1) and (2) of Theorem 3.1 are necessary, but we will allow ourselves various detours along the way to explore these phenomena in greater detail.

Both of these phenomena induce a particularly coarse kind of distortion. Throughout the section, let \( X \) be a finite CW complex with universal cover \( \tilde{X} \) and fundamental group \( \Gamma \). Restating the previous section’s definition, a class \( \alpha \) or finite-dimensional subspace \( V \) in \( \pi_n(X) \otimes \mathbb{Q} \) is infinitely distorted if there is some constant \( C \) such that there are arbitrarily large \( k \) (respectively, arbitrarily large vectors \( \vec{v} \in V \)) such that \( |k\alpha|_{\text{vol}} \leq C \) (respectively, \( |\vec{v}|_{\text{vol}} \leq C \)). As discussed in the previous section, this does not necessarily mean that the volume of all multiples of \( \alpha \) is uniformly bounded. Thus, by defining distortion the way we do rather than simply studying the function \( f(k) = |k\alpha|_{\text{vol}} \), we are obscuring a certain amount of complexity.

Lipschitz distortion in simply connected spaces is fairly subtle. It has been previously studied by Gromov in [Gro78, Gro99, and Gro98]. On the other hand, volume distortion is trivial in the simply connected case: all elements either have all multiples with uniformly bounded volume, or are undistorted, depending on whether they are homologically trivial.

Recall that we use the notation \( h_n : \pi_n(X) \otimes \mathbb{Q} \to H_n(X; \mathbb{Q}) \) to refer to the rational Hurewicz homomorphism.

**Theorem 3.1.** Suppose \( X \) is a simply connected complex and \( \alpha \in \pi_n(X) \otimes \mathbb{Q} \). Then \( k\alpha \) has a representative of zero volume for some \( k \) if and only if \( h_n(\alpha) = 0 \); otherwise \( \alpha \) is undistorted.

**Proof.** If \( h_n(\alpha) \neq 0 \), then there is a cohomology class \( \omega \in H^n(X; \mathbb{Q}) \) which pairs nontrivially with any representative of \( k\alpha \), giving some \( kC \). Thus \( k\alpha \) cannot have zero volume and in fact the cellular volume

\[
\text{vol}_C(k\alpha) \geq kC/\min_{n\text{-cells} c \in X} \omega(c).
\]

In particular, \( \alpha \) is undistorted.

On the other hand, if \( h_n(\alpha) = 0 \) then some \( k\alpha \) has a representative of zero volume by Proposition 1.1. \( \square \)

We can make the same observation for piecewise Riemannian complexes using differential forms and the metric definition of volume. Indeed, we can apply it even to non-compact spaces by requiring our differential forms to be bounded. This prefigures the use of \( L_\infty \) cohomology later in the paper. For the moment, however, we restrict ourselves to exploring how this relates distortion to the homology of covering spaces.

**Definition.** Given a \( k \)-form \( \omega \) on a piecewise Riemannian space \((X, g)\), let \( \|\omega\|_\infty = \sup (\omega(v_1, \ldots, v_k)) \), where the supremum ranges over all orthonormal frames \((v_1, \ldots, v_k)\). We say \( \omega \) is bounded if \( \|\omega\|_\infty < \infty \). It is clear that a form on a compact space is bounded, and that the boundedness of a form on \( \tilde{X} \) with respect to a Riemannian metric lifted from a compact \( X \) is independent of the metric. We may therefore speak of bounded forms on \( X \) and \( \tilde{X} \) without specifying a metric.

**Lemma 3.2.** If \( \alpha \in \pi_n(X) \) and there is a bounded closed form \( \omega \in \Omega^n(\tilde{X}) \) such that \( \langle \omega, \alpha \rangle = c \neq 0 \), then \( \alpha \) is volume-undistorted.

**Proof.** If \( f : S^n \to X \) is a map representing \( k\alpha \), then \( \langle \omega, f \rangle = ck \), and so \( \text{vol} f \geq ck/\|\omega\|_\infty \sim k \). \( \square \)

In particular, if a class is has a nonzero image under the Hurewicz homomorphism in some finite cover of \( X \), then this condition is satisfied. One might even hope—as it turns out in Example 3.3 incorrectly—that this is the only way such bounded cocycles can be generated.

**Corollary 3.3.** Let \( \alpha \in \pi_n(X) \). If for some finite cover \( \varphi : Y \to X \) and lift \( \tilde{\alpha} \in \pi_n(Y) \) of \( \alpha \), \( 0 \neq h_n(\tilde{\alpha}) \in H_n(Y) \), then \( \alpha \) is volume-undistorted.
Proof. Let \( \pi : \tilde{X} \to X \) be the universal cover. It is enough to show that there is a bounded form \( \omega \) on \( \tilde{X} \) and lift \( \tilde{\alpha} \) of \( \alpha \) to \( \tilde{X} \) such that \( \langle \omega, h_n(\tilde{\alpha}) \rangle \neq 0 \). We can define a form on \( Y \) which integrates on cells to the cellular cochain which is cell-wise dual to \( h_n(\tilde{\alpha}) \). The pullback of this form to \( \tilde{X} \) is the form we are looking for. \( \square \)

We have an example in which this applies nontrivially:

Example 3.4. Let \( A = S^2 \vee S^1 \vee S^1 \), with \( x, a, \) and \( b \) denoting the identity maps on the three spheres and \( \cdot \) denoting the action of \( \pi_1 A \) on \( \pi_2 A \). For some function \( f \simeq x + a \cdot x + b \cdot x \), set \( X = A \cup f D^3 \). Then in \( H_2(X) \), \( x \) represents an element of order 3, and so \( h_3(x) = 0 \).

On the other hand, let \( Y \) be the threefold cover of \( X \) corresponding to the normal subgroup \( \langle (a^3, ab) \rangle \); this has three 2-cells which we may call \( x_1, x_2, \) and \( x_3 \). In the cellular homology of \( Y \), the relation induced by each lift of the 3-cell is \( x_1 + x_2 + x_3 = 0 \); therefore the \( x_i \) are homologically nontrivial, and \( x \) is undistorted by Corollary 3.3.

But also an example demonstrating that it is not a necessary condition:

Example 3.5. According to \( \text{McG} \), the Baumschlager-Solitar group \( BS(2, 3) = \langle a, b | ab^2a^{-1}b^{-3} \rangle \) is not residually finite; in particular every surjection onto a finite group sends \( g := [a^b, a] \to 1 \). Moreover, \( g \) and \( b \) generate a free subgroup of \( BS(2, 3) \). Let \( X \) be a 2-complex with \( \pi_1 X = BS(2, 3) \), and let \( \tilde{Y} = X \vee (Y \setminus X) \), for some \( f \) such that \( \langle f \rangle = y + g \cdot y + b \cdot y \), where \( y \) is the generator of \( \pi_2 Y \). To show that \( y \) is undistorted in \( Y \), we need to find a cellular cocycle in \( H^2(Y; \mathbb{Q}) \) which is nonzero on some lift \( \tilde{y} \) of \( y \). By the argument in the previous example, such a cocycle can be defined on the cells \( (g, b) \cdot \tilde{y} \); we can extend it to the other cosets of \( (g, b) \) by defining it to be zero there.

On the other hand, in any finite cover, \( y \) does not have any nontrivial lifts from the point of view of rational homology. Indeed, suppose \( \varphi : Z \to Y \) is a finite cover and \( \tilde{y} \) any lift of \( y \) to \( Z \). Then the disk attached via \( f \) induces the relation \( (2 + b)h_2(\tilde{y}) = 0 \). Moreover, there’s an \( r \) for which \( b^r \) acts trivially on \( H_2(Z) \), so that

\[
0 = (2^r - (b^r))h_2(\tilde{y}) = (2^r + (-1)^{r-1})h_2(\tilde{y}).
\]

Thus \( \tilde{y} \) is sent via the Hurewicz map to a torsion element of \( H_2(Z) \).

Spaces with injective Hurewicz homomorphisms. For the time being, we will expand our discussion to possibly infinite spaces with finite skeleta. Although these are not compact, distortion is still well-defined if we stick to admissible maps, independent of the definition of volume used, or indeed maps \( S^n \to X(N) \) for any fixed \( N(n) \). In all these situations, it is still the case that if \( \alpha \in \pi_n(X) \) goes to 0 under the Hurewicz homomorphism, then its volume is zero. Therefore, in order for a space to have no distortion, its rational Hurewicz homomorphisms must all be injective. Here we classify spaces with this property.

Proposition 3.6. Let \( X \) be any simply-connected CW complex. Then the rational Hurewicz homomorphism \( h_n : \pi_n(X) \otimes \mathbb{Q} \to H_n(X; \mathbb{Q}) \) is injective for all \( n \geq 2 \) if and only if \( X \) is rationally equivalent to a product of Eilenberg–MacLane spaces.

Proof. If \( X \) is a K(G, n), then \( \pi_n(X) \to H_n(X) \) is an isomorphism and all other homotopy groups vanish. This injectivity is preserved under arbitrary products, so the backwards implication is true.

For the converse, we note that every simply-connected complex can be rationalized; that is, it has a rational equivalence to a complex whose reduced homotopy and homology groups are rational vector spaces. One may for example see Chapter 7 of \( \text{GM} \). Thus it is enough to prove this for rational spaces.

So let \( X \) be a rational space, and consider a step of its Postnikov tower, \( K(\pi, n) \to X(n) \to X(n-1) \); \( X(n) \) and \( X(n-1) \) are also rational spaces. If this fibration is not a product, then there is a nonzero \( k \)-invariant \( k \in H^{n+1}(X(n-1) ; \pi) \) giving the obstruction to extending a section \( (X(n-1))^{(n)} \to X(n) \). Choose a cellular cycle \( c \in C_{n+1}(X(n-1)) \) which pairs nontrivially with \( k \), and let \( f : S^n \to X(n-1) \) be the sum of the boundary maps of the cells in \( c \). Then in our partial section, \( f \) lifts to a representative \( \tilde{f} : S^n \to (X(n))^{(n)} \) of \( (k,c) \in \pi_n(X) \). Since \( c \) is a cycle, \( f \) has degree 0 on each \( n \)-cell; thus \( [\tilde{f}] \) is also homologically trivial.

Therefore, if the Hurewicz homomorphism is injective, every stage of the Postnikov tower of \( X \) must be a product. \( \square \)
Now, for even \( n \), \( K(\mathbb{Q}, n) \) has an infinite number of nonzero cohomology groups; for odd \( n \), \( K(\mathbb{Q}, n) \cong_{\mathbb{Q}} S^n \).
Moreover, an infinite product or a \( K(V, n) \) where \( V \) is an infinite-dimensional rational vector space will always have infinitely many nonzero cohomology groups. This gives us

**Corollary 3.7.** If \( X \) is a finite complex with no distortion in its homotopy groups, then \( \tilde{X} \) is rationally equivalent to a finite product of odd-dimensional spheres.

We will show later that this condition is equivalent to condition (1) of Theorems [3] and [4].

One could hope that with a result as powerful as Proposition 3.6, we could proceed through a classification like that of Theorem [3] for spaces with finite skeleta. However, the rest of our analysis relies heavily on the fact that the rational homotopy groups of our spaces are finite-dimensional; dealing with larger homotopy groups would require radically new techniques. How could one hope to carry this analysis through to infinite complexes with finite skeleta? Consider the following restatement of Corollary [2]: if \( X \) is finite, then if one of its rational homotopy groups is infinite-dimensional, some higher homotopy group has homologically trivial rational elements. One approach would be to try to demonstrate that this still holds for complexes with finite skeleta. The following example demonstrates that such an approach cannot work: there is an undistorted space with finite skeleta whose universal cover is homotopy equivalent to \( (S^3)^\infty \). This means that condition (1) of Theorem [3] cannot hold true in the same form for such complexes.

**Example 3.8.** Consider Thompson’s group \( F \). Brown and Geoghegan [BrG] give a \( K(F, 1) \) with two cells in each dimension; call this space \( X \). The group \( F \) acts transitively on the set \( A \) of dyadic rationals strictly between 0 and 1, as a subgroup of \( \text{Homeo}_+(0, 1) \): the stabilizer \( S \) of a point \( a \in A \) under this action is isomorphic to \( F \times F \), corresponding to homeomorphisms that fix \( [a, 1] \) and those that fix \( [0, a] \). These two copies of \( F \) are generated by four elements; call these \( g_1, g_2, g_3, g_4 \). Then as a module,

\[
\mathbb{Q}[A] = \mathbb{Q}F/(g_i - 1 : i = 1, 2, 3, 4).
\]

Thus we can attach four 4-cells to \( X \) along \( g_i \circ \text{id}_{S^3} - \text{id}_{S^3} \), to get a space \( Y_4 \) with finite skeleta and with \( \pi_3(Y) \cong \mathbb{Q}[A] \). One may think of \( Y_4 \) as

\[
X \cup_{K(S, 1)^{(3)}} (K(S, 1)^{(1)} \times S^3).
\]

Continuing to add four cells in every dimension gives us a space \( Y = X \cup_{K(S, 1)^{(n)}} (K(S, 1) \times S^3) \), whose universal cover is homotopy equivalent to \( \bigvee_{a \in A} S^3 \).

We now require a second induction to embed \( Y \) in a space whose universal cover is homotopy equivalent to \( \prod_{a \in A} S^3 \). In general, \( F \) acts transitively on unordered \( n \)-element subsets of \( A \) with stabilizer \( F_{n+1} \). Suppose, then, that we have constructed a space \( Z_{n-1} \) such that \( \tilde{Z}_{n-1} \) is homotopy equivalent to \( K^{(3(n-1))} \), where \( K \cong \prod_{a \in A} S^3 \) is a complex with one 3k-cell corresponding to each \( k \)-tuple of elements in \( A \). To construct \( Z_n \), we add a single 3n-cell corresponding to an \( n \)-tuple of elements of \( A \); then proceed as in the construction of \( Y \), using \( 2(n+1) (3n+1) \)-cells to identify those of its translates which correspond to the same \( n \)-tuple, and so on with \( 2(n + 1) \) cells in each subsequent dimension.

At the end of this induction, we have a complex \( Z \) with \( O(n^2) \) cells in dimension \( n \) whose universal cover is homotopy equivalent to \( \prod_{a \in A} S^3 \). Moreover, the \( S^3 \) we attached originally is homologically nontrivial in \( Z \); therefore \( \pi_3(Z) \) is undistorted.

**Distortion via monodromy.** Another potential source of infinite distortion is the action by the fundamental group on \( \pi_n(X) \): volume is preserved under this action, but a norm on a finite-dimensional subspace of \( \pi_n(X) \otimes \mathbb{Q} \) need not be. The most basic example is when \( X \) is the mapping torus of a degree 2 map on \( S^2 \); here \( \pi_2(X) \cong \mathbb{Z}[\frac{1}{2}] \), and so \( \pi_2(X) \otimes \mathbb{Q} \cong \mathbb{Q} \). Let \( \alpha = [\text{id}_{S^2}] \in \pi_2(X) \); then \( 2^k \alpha \) has a cellular representative of volume 1 for every integer \( k \), and indeed any integer multiple \( k\alpha \) has a representative of volume \( \leq \log_2 k \).

More generally, let \( \alpha \in \pi_n(X) \), \( \gamma \in \Gamma \), and suppose that the \( \mathbb{Q}[\mathbb{Z}] \)-module generated by \( \gamma^i \cdot \alpha \) is an \( m \)-dimensional \( \mathbb{Q} \)-vector space \( V \) for some finite \( m \). Then \( \gamma \) acts on \( V \) via a linear transformation \( T \in GL(V) \). Then either \( T \) is conjugate to an element of \( O(m, \mathbb{R}) \), or there is some vector \( \vec{v} \) such that \( T^k(\vec{v}) \) increases without bound and thus \( V \) is infinitely distorted. A similar dichotomy holds if \( \mathbb{Q}^\Gamma \cdot \alpha \) is a finite-dimensional submodule of \( \pi_n(X) \otimes \mathbb{Q} \): either \( \gamma \cdot \alpha \) gets arbitrarily large, or the entire submodule conjugates into \( O(m, \mathbb{R}) \).

**Definition.** We say a transformation \( T \in GL(m, \mathbb{Q}) \), or more generally a representation \( \rho : \Gamma \to GL(m, \mathbb{Q}) \), is **elliptic** if it preserves a norm on \( \mathbb{Q}^m \), or equivalently if as a representation over \( \mathbb{R} \) it conjugates into \( O(m, \mathbb{R}) \).
Proposition 3.9. Any representation $\rho : \Gamma \to GL(m, \mathbb{Q})$ which is bounded in operator norm is elliptic.

Proof. Let $K \subset GL(m, \mathbb{R})$ be the closure of $\rho(\Gamma)$; this is a closed subgroup and hence a compact Lie group. Averaging any norm over $K$ gives us a $\rho$-invariant norm on $\mathbb{Q}^m$. \hfill \Box

Corollary 3.10. For any finite complex $X$ such that $\pi_n X \otimes \mathbb{Q}$ is finite-dimensional, either $\pi_n X \otimes \mathbb{Q}$ is infinitely distorted, or the monodromy representation $\rho : \pi_1 X \to GL(\pi_n X \otimes \mathbb{Q})$ is elliptic.

In other words, we have just shown the necessity of condition (2) of Theorems 13 and 14. The reader who is impatient to see the proofs of these theorems is invited to skip forward to Section 4. In the rest of this section, we take a closer look at how the monodromy action of an individual element of $\Gamma$ affects the distortion function of individual elements of finite-dimensional subspaces of $\pi_n(X) \otimes \mathbb{Q}$; in particular, we will show that such distortion functions need not be infinite. We also demonstrate distinctions between distortion functions of elements and subspaces, and between weakly infinite and infinite distortion.

This case is relatively easy to analyze because we can use the fact that $\mathbb{Q}[z]$ is a PID. Thus, given a general $X$ with $\pi_1X = \Gamma$ and a $\gamma \in \Gamma$, consider an finite-dimensional $\mathbb{Q}[\gamma, \gamma^{-1}]$-submodule $V \subseteq \pi_n(X) \otimes \mathbb{Q}$. Then $V$ decomposes as

$$V = \oplus_{i=1}^r \mathbb{Q}[\gamma, \gamma^{-1}] / p_i(\gamma)^{q_i} =: \oplus_{i=1}^r V_i,$$

where the $p_i$ are irreducible factors of the characteristic polynomial of the action $T \in GL(V)$ of $\gamma$ on $V$. The distortion we have described depends on finding ways of writing vectors in $V$ as $\sum_{i=-r}^r T^i \bar{v}_i$, where the $\bar{v}_i$ are in the lattice generated by some generating set whose precise nature is irrelevant. Thus we can assume that generating set contains a basis for each $V_i$, and we can classify the possible distortion effects by looking at irreducible actions.

Of course, in a completely general setting, we can only talk of the contribution of monodromy to the distortion of an element. But there is a simple way of constructing examples of spaces $X$ for which all distortion in $\pi_nX$ is caused by monodromy by a single element. Given an integer $m \times m$ matrix $A$, we can construct the mapping torus $X_{A,n}$ of a map $\bigcup_m S^n \to \bigcup_m S^n$ which is modeled on it. If $A$ has non-zero determinant, then it corresponds to the monodromy action of the generator of $\pi_1X_{A,n} \cong \mathbb{Z}$ on $\pi_nX_{A,n} \otimes \mathbb{Q} \cong \mathbb{Q}^m$. What’s more, since all admissible maps $S^n \to X_{A,n}$ are combinations of translates of the generators, the monodromy is the only source of distortion for elements of $\pi_nX_{A,n}$.

More generally, given an element $B = \frac{1}{q} A \in GL(m, \mathbb{Q})$, where $A$ is again an integer matrix, we can construct a similar “mapping torus” $X_{B,n}$, with one cell added to $\bigcup_m S^n \vee S^1$ for each column of $A$ which homotopes $q$ times the corresponding sphere to a map corresponding to this column. For example, in the simplest case when $m = 1$, we can construct a space $X_{(5/3),n}$ by gluing both sides of $S^n \times I$ to a copy of $S^n$, the left side with degree 3 and the right side with degree 5. Here again, the monodromy determines the distortion.

First, we consider some examples of the form suggested above and see that the distortion of a subspace need not correspond to that of any of its elements.

Examples 3.11. (1) Consider the space $X_{A,n}$ where $A$ is the companion matrix of the polynomial $x^4 - 2x^3 - 2x + 1$. This polynomial is irreducible over $\mathbb{Q}$ and has four distinct complex roots, two of which are on the unit circle and two of which are real. Call these roots $\xi, \overline{\xi}, \eta, \eta^{-1}$, and let $ar{u}_\xi \in \mathbb{C}^4$, etc., be the corresponding eigenbasis. Fix $0 \neq \bar{v} \in \pi_n(X) \otimes \mathbb{Q}$; then the coordinates of $\bar{v}$ in each of these basis vectors are nonzero. On the other hand, for any admissible map $f : S^n \to X$ of volume 1, the element $[f] = T^k e_i \in \pi_n(X) \otimes \mathbb{Q}$ has $\bar{u}_\xi$- and $\bar{u}_\overline{\xi}$-coordinates at most 1. Therefore, any admissible map representing $k\bar{v}$ has to have volume proportional to $k$. The deformation theorem then implies that $\bar{v}$ admits neither volume nor Lipschitz distortion in $X$.

(2) Consider the space $X_{(5/3),3}$ constructed above. One can think of this as the “mapping torus” of multiplication by $5/3$. Note that $\pi_n(X) \otimes \mathbb{Q} \cong \mathbb{Q}$ is infinitely distorted, since $(5/3)^k$ can be represented with volume 1. However, any given element in $\pi_n(X)$ is not infinitely distorted, since for any $N$ there is a finite number of integers that can be expressed as the sum of $V$ powers of $5/3$. So a one-dimensional subspace need not have the same distortion function as one of its elements!

(3) This example demonstrates that a subspace which is weakly infinitely distorted is not necessarily infinitely distorted. Consider the space $X_{B,n}$ for $B = \begin{pmatrix} A & 0 \\ I & A \end{pmatrix}$, where $A = \begin{pmatrix} 3/5 & -4/5 \\ 4/5 & 3/5 \end{pmatrix}$. Then
for \( \vec{v}, \vec{w} \in \mathbb{R}^2 \) the vector corresponding to \((\vec{v}, \vec{w})\) shifted by \(k\) is

\[
B^k \left( \begin{array}{c} \vec{v} \\ \vec{w} \end{array} \right) = \left( \begin{array}{c} A^k \vec{v} \\ kA^{k-1} \vec{v} + A^k \vec{w} \end{array} \right).
\]

This indicates in particular that the subspace generated by the first two basis vectors is undistorted. On the other hand, letting \(\alpha\) be the irrational angle of rotation of \(A\), we get

\[
(B^k - B^{-k}) \left( \begin{array}{c} \vec{v} \\ 0 \end{array} \right) = \left( \begin{array}{c} 2 \cos(k\alpha) \vec{v} \\ 2k \sin((k-1)\alpha) A^{-1} \vec{v} \end{array} \right).
\]

In two-thirds of cases, \(\sin(k-1)\alpha > 1/2\), and so \(\|B^k - B^{-k}\| \geq k\|\vec{v}\|\). Thus \(\pi_n(X)\) is infinitely distorted, and indeed any individual rational vector in \(\langle \vec{e}_3, \vec{e}_4 \rangle\) is weakly infinitely distorted. In contrast,

**Lemma 3.12.** For any \(k\), elements of \(\langle \vec{e}_3, \vec{e}_4 \rangle\) with cellular volume at most \(k\) have length bounded by some \(L(k)\).

To prove this, we need a purely algebraic lemma whose precise statement and proof are relegated to an appendix, but which generalizes the following observation. Images of integer lattice points under \(A\) are only themselves lattice points \(1/5\) of the time; \(\vec{v}\) and \(A\vec{v}\) are both integer lattice points if and only if \(\vec{v}\) is in the lattice generated by \(\left( \begin{array}{c} -2 \\ 1 \end{array} \right) \) and \(\left( \begin{array}{c} 1 \\ 2 \end{array} \right)\), so the length of such a vector is \(\sqrt{5z}\) for some integer \(z\). More generally, if \(A^t \vec{v}\) and \(A^t \vec{v}\) are both integer points, then \(\|\vec{v}\|^2 \in 5^{i-j} \mathbb{Z}\). Similarly, if \(A^t \vec{u} = A^t \vec{v}\) and \(\vec{u}\) and \(\vec{v}\) are both integer vectors, then they must be zero or exponentially large in \(|i-j|\). For this proof, we require a stronger statement involving linear combinations of \(A^t\) for various \(j\).

**Proof.** To see this, we induct on \(k\). For \(k = 1\), the options are \(B^j \vec{e}_j\) for \(i \in \mathbb{Z}\) and \(j = 3, 4\), which all have length 1.

Now fix a \(V > 1\), and take a particular linear combination

\[
\vec{u} = B^{t_0} \vec{u}_0 + B^{t_1} \vec{u}_1 + \ldots + B^{t_r} \vec{u}_r
\]

with \(\sum_i |\vec{u}_i| \leq V\) and the \(u_i = \left( \begin{array}{c} \vec{v}_i \\ \vec{w}_i \end{array} \right)\) are integer vectors. If \(\vec{u} \in \langle \vec{e}_3, \vec{e}_4 \rangle\), then \(\sum_i A^{t_i} \vec{v}_i = \vec{0}\). We can assume that the \(t_i\) are increasing and \(t_0 = 0\) since multiplying by \(B^n\) doesn’t change the length of a vector in \(\langle \vec{e}_3, \vec{e}_4 \rangle\). Moreover, we can assume that all the \(\vec{w}_i\) are zero, since they contribute at most a linear amount of total length.

Now, either (1) \(\sum_{i=0}^{t} A^{t_i} \vec{v}_i \neq \vec{0}\) for any \(\ell < r\), or (2) we know that \(\|\vec{u}\| \leq L(k_1) + L(k_2)\) for some \(k_1 + k_2 = k\). In case (1), by Lemma \([\text{A.1}]\), \(t_k \leq kf(k)\) for some \(f(k) \sim \log k\). Therefore there is a finite number of choices of \(\vec{u}\) satisfying (1), and their lengths are bounded by some number \(L'(k)\). We can thus set

\[
L(k) = \max\{L'(k), L(k-1) + L(1), L(k-2) + L(2), \ldots\},
\]

completing the proof. \(\square\)

The logarithmic bound given in Lemma \([\text{A.1}]\) implies that a map of volume \(k\) represents a vector of length \(O((k \log k)^2)\). With some more painstaking accounting, it should be possible to bring this bound done to a quadratic one.

Since, e.g., \(\vec{e}_3\) is weakly infinitely distorted, it is in particular distorted. To find an estimate from below, we construct a sequence of maps of volume \(O(k)\) representing \(5k^2 \vec{e}_3\). This will be given as a sum of powers of \(B\) applied to a certain sequence of length \(k\) vectors; a cancellation trick will ensure that at each step we add \(O(k)\) times \(\vec{e}_3\) but only \(O(1)\) volume. Specifically, let \(\vec{v}_0 = \left( \begin{array}{c} 5k \\ 0 \end{array} \right)\), and for \(1 \leq i \leq k\) let \(\vec{v}_i\) be a point such that \(\vec{v}_i\) and \(A^{-1} \vec{v}_i\) are both lattice points and such that
\[ \left\| \sum_{j=1}^{k-1} \hat{A}^{i}v_j - i\vec{v}_0 \right\| < \sqrt{5}. \]

Then
\[ \vec{u} = \sum_{i=0}^{k-1} B^{i+1} \begin{pmatrix} \vec{v}_i \\ \vec{0} \end{pmatrix} - B^i \begin{pmatrix} \hat{A} \vec{v}_i \\ \vec{0} \end{pmatrix} = \sum_{i=0}^{k-1} \begin{pmatrix} \vec{0} \\ \hat{A}^i \vec{v}_i \end{pmatrix} \]

can be represented by a map \( S^n \to X \) of volume \( O(k) \), since \( \| \vec{v}_i - \hat{A} \vec{v}_{i+1} \| \leq 2\sqrt{5} \); on the other hand, since the distance between \( \vec{u} \) and \( 5k^2 \vec{e}_3 \) is at most \( \sqrt{5} \), we can convert the one into the other by adding correction terms of the form \( B^i(\vec{v}_i + q \vec{e}_3) \) and length at most \( 2\sqrt{5} \) for each \( 0 \leq i \leq k - 1 \). Thus \( 5k^2 \vec{e}_3 \) can be represented with volume \( O(k) \). This gives us our lower bound on distortion, and so \( k^2 \lesssim V \delta_{\vec{e}_3}(k) \lesssim (k \log k)^2 \).

However, all of the examples of undistorted elements depend on the characteristic polynomial \( p_i \) having roots on the unit circle. If all the roots of \( p_i \) are off the unit circle, then in fact all elements of \( V \) are at least exponentially distorted.

**Lemma 3.13.** Suppose that \( \gamma \in \pi_n(X) \) and that \( V \subseteq \pi_n(X) \otimes \mathbb{Q} \) is a finite-dimensional irreducible \( \mathbb{Q}[\gamma, \gamma^{-1}] \)-submodule \( V \cong \mathbb{Q}[\mathbb{Z}]/(p_i) \), and all complex roots \( \lambda_j \) of \( p_i \) have \( |\lambda_j| \neq 1 \). Then any \( \alpha \in V \) has distortion function \( \delta_\alpha(k) \gtrsim \exp k \).

**Proof.** Let \( T : V \to V \) be the transformation induced by the action of \( \gamma \). Our general strategy will be to express vectors as a sum of logarithmically many terms of the form \( T^i v_i \), where all the \( v_i \) are lattice points within a fixed ball. To do this, we first need to find an appropriate lattice.

Let \( \lambda_1, \ldots, \lambda_r \) be the eigenvalues of \( T \) with multiplicity, with \( |\lambda_1|, \ldots, |\lambda_n| < 1 \) and \( |\lambda_{n+1}|, \ldots, |\lambda_r| > 1 \). Let \( v_1, \ldots, v_r \) be a corresponding real Jordan basis for \( V \otimes \mathbb{R} \) with respect to \( T \), and \( V \otimes \mathbb{R} = V_- \oplus V_+ \), where \( V_- \) is spanned by \( v_1, \ldots, v_s \) and \( V_+ \) by \( v_{s+1}, \ldots, v_r \).

On the other hand, let \( u_1, \ldots, u_n \) be a (rational) basis for \( V \) consisting of elements of \( \pi_n(X) \), and \( \| \cdot \| \) the Euclidean norm with respect to this basis, with the property that \( T \) is \( \| \cdot \| \)-increasing on \( V_+ \) and \( \| \cdot \| \)-decreasing on \( V_- \). Note that this is a nontrivial condition: for example, the matrix \( \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \) does not increase the standard Euclidean norm of every vector. This can be remedied, however, by scaling one of the coordinates in order to decrease the off-diagonal term. In general, one can, for example, choose sufficiently large multiples of a close rational approximation to a basis consisting of scalings of the \( v_i \) in which the off-diagonal entries of \( T \) are very small.

We let \( \Lambda \) be the lattice generated by the \( u_i \). Finally, we fix the following constants:
- \( Q \) such that the matrices of \( T \) and \( T^{-1} \) with respect to the basis \( \{ u_i \} \) are both in \( \mathbb{Q}[\mathbb{Z}] \);
- \( L = \min \{ \min_{u \in V_+} \| Tu \|, \min_{u \in V_-} \| Tu \| \} \};
- \( U = \max \{ \max_{u \in V_+} \| Tu \|, \max_{u \in V_-} \| Tu \| \} \} \}

In particular, every vector in \( Q \Lambda \) has a preimage in \( \Lambda \) under both \( T \) and \( T^{-1} \). Take an element \( \alpha \in V \subseteq \pi_n(X) \otimes \mathbb{Q} \). It has a multiple which is a lattice point \( p \in \Lambda \), which decomposes over \( \mathbb{R} \) as \( p = p_- + p_+ \), with \( p_- \in V_- \) and \( p_+ \in V_+ \). Fix \( M \) such that \( \| Mp \| \geq Q\sqrt{T} \).

Suppose first that \( V_- = 0 \), i.e. \( T \) only has large eigenvalues. Then for any \( M > Q\sqrt{T} \), take \( q = Tp' \) to be the nearest point in \( Q \Lambda \) whose coordinates are smaller than those of \( Mp \). Then \( Mp = p_0 + Tp' \), where \( p_0 \) and \( p' \) are lattice points, \( \| p_0 \| \leq Q\sqrt{T} \) and \( \| p' \| \leq M \| p \| / L \). Continuing this construction inductively gives us
\[ Mp = \sum_{i=0}^{\ell} T^i p_i, \]
with \( \| p_i \| \leq Q\sqrt{T} \) for every \( i \) and \( \ell \leq \log_\ell(M \| p \|) \). Thus
\[ |M \alpha|_{\text{vol}} \leq \ell Q\sqrt{T} \in O(\log \| p \|). \]

If \( V_+ = 0 \), the same computation holds substituting \( T^{-1} \) for \( T \).

Now suppose \( T \) has both small and large eigenvalues. In other words, multiplying by a power of \( T \) shrinks a vector in certain irrational directions and stretches it in others. If these directions were rational, then by the above we could distort a vector going in just one of them. Our strategy will be to express our chosen vector as a sum of shrinking and expanding components as precisely as possible.
To this end, we write \( Mp = a + b + p_0 \), where \( a \) and \( b \) are in \( QA \), \( \|p_0\| < Q\sqrt{r} \), \( \|a - p_\| < Q\sqrt{r} \) and \( \|b - p_+\| < Q\sqrt{r} \). Applying \( T^{-1} \) to this sort of decomposition, we get the following lemma.

**Lemma 3.14.** For any lattice point \( q \in V_+ \oplus V_- \), we can write \( q = a + Tb \), with \( a \) and \( b \) lattice points, \( \|a_+\| < Q\sqrt{r} \) and \( \|b_-\| < UQ\sqrt{r} \); \( \|a_-\| \leq \|q_-\| + Q\sqrt{r} \) and \( \|b_+\| \leq \frac{\|q_+\|}{L} \). The same thing holds switching \( V_+ \) and \( V_- \) components if we substitute \( T^{-1} \) for \( T \).

Applying Lemma 3.14 to \( Mp \), we get \( Mp = a + p_0 + Tp_1 \) with the appropriate bounds. Applying the lemma inductively to \( p_i \) gives

\[
Mp = a + \sum_{i=0}^{\ell} T^i p_i,
\]

where \( \|p_i\| \leq (U + 1)Q\sqrt{r} \) and \( \ell \leq \log_L(M\|p\|) \). We can now also apply the \( T^{-1} \) case of Lemma 3.14 to \( a \) to get

\[
Mp = \sum_{i=-\ell}^{\ell} T^i p_i,
\]

and the same bounds on \( p_i \) and \( \ell \) hold. Hence

\[
|M_{\alpha}|_{\text{vol}} \leq 2\ell(U + 1)Q\sqrt{r} \in O(\log M\|p\|).
\]

Thus for any \( \alpha \), volume distortion is at least exponential. \( \square \)

Conversely, generalizing Example 3.11(1), one sees that if \( T \) is diagonalizable and has at least one eigenvalue on the unit circle, then the action of \( \gamma \) does not induce any distortion on \( V \).

The situation is more complex when \( T \) has eigenvalues on the unit circle but is non-diagonalizable. If it is quasiumipotent, i.e. the eigenvalues are roots of unity, then we can take a power of it which is in fact unipotent. For an irreducible unipotent \( T \), there is an eigenvector \( \vec{v} \) and a \( \vec{u} \) for which \( T\vec{u} = \vec{u} + \vec{v} \). Then \( k\vec{v} = T^k\vec{u} - \vec{u} \) and so \( \vec{v} \) is infinitely distorted. For all but one of the other generalized eigenvectors, one can find similar polynomials, showing that they are infinitely distorted as well. The remaining generalized eigenvector is undistorted. If \( T \) has eigenvalues with irrational angles, then certain individual vectors are distorted because they are weakly infinitely distorted, as one sees in Example 3.11(3). The precise distortion functions are harder to ascertain, though it seems reasonable to suppose that, as in Example 3.11(3), they are polynomial.

**Summary.** In this section, we saw that if \( X \) is a finite complex and no subspace of \( \pi_*(X) \) is infinitely distorted, then:

- \( \pi_*(X) \otimes \mathbb{Q} \) is finite dimensional;
- the universal cover \( \tilde{X} \) is rationally equivalent to a product of odd-dimensional spheres;
- and the action of \( \Gamma \) on \( \pi_*(X) \otimes \mathbb{Q} \) is elliptic.

We will refer to spaces that satisfy these conditions as **delicate spaces**.

### 4. Filling functions

In this section, we study various notions of isoperimetry in higher dimensions, aiming to build a library of general results and examples which we can deploy later. Section 3 will relate these to a dual cohomological notion, and we will apply this duality to the study of distortion in Section 6.

The template for most study of isoperimetry in higher dimensions is the one-dimensional example of Dehn functions. The Dehn function of a group \( \Gamma \) describes the difficulty of solving the word problem in that group; specifically, \( \delta_1(k) \) is the minimal number of conjugates of relations required to trivialize a trivial word of length \( k \). This has a geometric interpretation as the cellular volume of fillings of cellular loops in the Cayley 2-complex of \( \Gamma \).

There are several different ways to generalize this notion to higher dimensions. Higher-dimensional Dehn functions were first defined by \cite{AWP}, and filling volume functions by Gromov in \cite{Gro}; later, other equivalent and non-equivalent definitions of filling functions in groups and spaces have been given by \cite{BBFS}, \cite{Young}, and \cite{Groft}.  

25
Robert Young [Young] formalizes the distinction between homotopical Dehn functions, which measure the difficulty of extending maps from spheres to disks, or more generally, maps from $\partial M$ to $M$ for a manifold $M$, and homological isoperimetric functions, which measure the difficulty of filling chains by cycles. We will additionally introduce directed isoperimetric functions, which measure pairings of fillings with cohomology classes and which have not been discussed before in this guise. Except in dimension 2, homotopical filling functions bound homological filling functions from above. These, in turn, bound directed isoperimetric functions, creating a kind of hierarchy of “coarseness.”

Certain of these functions are harder or easier to compute in certain situations. To take advantage of the ability to make comparisons between them, we give definitions of all three types.

We start with the most obvious Dehn function for fillings of spheres with disks.

**Definition.** Let $X$ be a compact space with fundamental group $\Gamma$ and $n$-connected fundamental cover $\tilde{X}$. Given a Lipschitz map $f : S^n \to \tilde{X}$, define the filling volume of $f$ to be the minimal volume of an extension of $f$ to $D^{n+1}$:

$$\delta^\ast_X(f) = \inf\{\text{vol}(g) \mid g : D^{n+1} \to \tilde{X} \text{ s.t. } g|_{\partial D^{n+1}} = f\}.$$  

The $n$-dimensional Dehn function of $X$ is

$$\delta_X^n(k) = \sup\{\delta^\ast_X(f) \mid f : S^n \to \tilde{X} \text{ s.t. } \text{vol} f \leq k\}.$$  

One can also ask, for another $(n+1)$-manifold with boundary $(M, \partial M)$, how hard it is to fill a map $\partial M \to X$ with a map $M \to X$:

**Definition.** Given a Lipschitz map $f : \partial M \to \tilde{X}$, define the filling volume of $f$ to be

$$\delta^\ast_X(M, \partial M)(f) = \inf\{\text{vol}(g) \mid g : M \to \tilde{X} \text{ s.t. } g|_{\partial M} = f\}$$

and we can define the corresponding Dehn function

$$\delta_X(M, \partial M)(k) = \sup\{\delta^\ast_X(M, \partial M)(f) \mid f : \partial M \to \tilde{X} \text{ s.t. } \text{vol} f \leq k\}.$$  

Next, we define the filling volume or homological isoperimetric functions.

**Definition.** Let $X$ be a compact space with fundamental group $\Gamma$ and $n$-connected fundamental cover $\tilde{X}$.

Given a Lipschitz boundary $\beta \in C_n(\tilde{X})$, define the filling volume of $\beta$ to be

$$\text{FVol}^\ast_X(\beta) = \inf\{\text{vol}(\alpha) \mid \alpha \in C_{n+1}(\tilde{X}) \text{ s.t. } \partial \alpha = \beta\}$$

and the filling volume function

$$\text{FVol}^\ast_X(k) = \sup\{\text{FVol}^\ast_X(\beta) \mid \beta \in C_n(\tilde{X}) \text{ s.t. } \text{vol} \beta \leq k\}.$$  

One can also restrict to boundaries that look like a specific $n$-manifold $N$ to get

$$\text{FVol}^N_X(k) = \sup\{\text{FVol}^\ast_X(\beta) \mid \beta \in C_n(\tilde{X}) \text{ s.t. } \text{vol} \beta \leq k \text{ and } \beta = f_\ast[N] \text{ for some } f : N \to \tilde{X}\}.$$  

By restricting chains to be cellular and maps to be admissible, one can get similar cellular definitions. Note, however, that cellular and Lipschitz filling functions of $X$ might not be asymptotically equivalent as defined earlier; e.g. one may be linear and the other sublinear. Instead, we need a slightly weaker notion of coarse equivalence,

$$f \lesssim_C g \iff f(k) \leq A g(Bk + C) + Dk + E$$

$$f \sim_C g \iff f \lesssim_C g \text{ and } f \gtrsim_C g,$$

for arbitrary constants $A, B, C, D,$ and $E$. It is easy to apply the deformation theorem to see that these functions are indeed coarsely equivalent. One also then sees that the cellular versions depend only on the $(n+1)$-skeleton of $X$, and that a homotopy equivalence up to dimension $n$ between $X$ and $Y$ induces a coarse equivalence of filling functions. This gives a well-defined notion of $\text{FVol}^n_\Gamma$ and $\text{FVol}^N_\Gamma$ for any group $\Gamma$ of type $\mathcal{F}_{n+1}$, that is, which has a $K(\Gamma, 1)$ with finite $(n+1)$-skeleton.

We will now refine the notion of filling volume to define filling homology classes and directed isoperimetric functions.
Definition. Assume that $X$ is constructed via Lipschitz attaching maps and that $\tilde{X}$ is $(n+1)$-connected. Let $p: \tilde{X} \to X$ be the universal covering map. Given an $n$-manifold $M$ and an admissible map $f: M \to \tilde{X}$, define the chain evaluation $[f] \in C_n(X)$ to be the cellular chain whose value on a cell $c$ is the degree of the map $p \circ f$ in $H_n(X, X \setminus c)$. Suppose $[f] = 0$. Then for any homological filling $\Gamma = C_{n+1}(\tilde{X})$ of $f$, its image $p \# G \in C_{n+1}(X)$ is a cycle, and we can define the filling class $\text{Fill}(\Gamma) \in H_{n+1}(X)$ to be its homology class. This is well-defined since two such fillings differ by an $(n+1)$-boundary in $X$.

Now, given a seminorm $\| \cdot \|$ on $H_{n+1}(X; \mathbb{Q}) = H_{n+1}(\Gamma; \mathbb{Q})$, define the directed isoperimetric function of $\Gamma$ with respect to $\| \cdot \|$ to be

$$\text{FV}_{\Gamma,\| \cdot \|}^M(k) = \sup \{ \| \text{Fill}(\Gamma) \| : f: M \to \tilde{X} \text{ admissible s.t. } [f] = 0 \text{ and } \text{vol } f \leq k \}.$$ 

If $b \in C_n(\tilde{X})$ is a cellular boundary with $p \# b = 0$, then we can similarly define a filling class $\text{Fill}(b) \in H_{n+1}(X)$, and filling functions

$$\text{FV}_{\Gamma,\| \cdot \|}^n(k) = \sup \{ \| \text{Fill}(b) \| : b \in C_n(\tilde{X}) \text{ cellular s.t. } p \# b = 0 \text{ and } \text{vol } b \leq k^{1/n} \}.$$ 

More generally, suppose $X$ is any finite complex with Lipschitz attaching maps, $p: \tilde{X} \to X$ is the universal covering map, and $\| \cdot \|$ is a seminorm on $H_{n+1}(X; \mathbb{Q})/p_*H_{n+1}(\tilde{X}; \mathbb{Q})$. Then a map $f: M \to \tilde{X}$ with $[f] = 0$, or a boundary $b \in C_n(\tilde{X})$ with $p \# b = 0$, has a filling class

$$\text{Fill} f \in H_{n+1}(X; \mathbb{Q})/p_*H_{n+1}(\tilde{X}; \mathbb{Q}),$$

and we can define the filling functions $\text{FV}_{\Gamma,\| \cdot \|}^M$ and $\text{FV}_{\Gamma,\| \cdot \|}^n$ as above.

It is clear from the definitions that for any $X$, $n$, and seminorm $\| \cdot \|$, $\text{FV}_{\Gamma,\| \cdot \|}^n(k) \sim \text{FV}_{\Gamma}^n(k)$. We now try to understand directed isoperimetric inequalities in their own right.

Examples 4.1. Here are two examples of seminorms with respect to which we may take directed isoperimetric inequalities:

1. Define the cellular norm of $h \in H_{n+1}(X)$ by

$$\| h \|_{\text{cell}} = \min \left\{ \sum a_i \sum c_i : a_i c_i \text{ is a cellular representative of } h \right\}.$$ 

Then $\text{FV}_{\Gamma,\| \cdot \|}^M$ is defined whenever $H_{n+1}(\tilde{X}) = 0$. The cellular norm is maximal among the seminorms we might consider: for any other seminorm $\| \cdot \|$ on $H_{n+1}(X)$, $\| \cdot \| \leq C\| \cdot \|_{\text{cell}}$ for some $C$.

2. Suppose that $e \in H^n(X; \mathbb{Q})$ is a cohomology class such that $p^* e = 0$. Then $\langle e, \cdot \rangle$ defines a seminorm on $H_{n+1}(X; \mathbb{Q})/p_*H_{n+1}(\tilde{X}; \mathbb{Q})$. The directed isoperimetric functions we will use most often are with respect to this seminorm.

Example 4.2. For the most obvious examples, that is $\Gamma = \mathbb{Z}^2$ and other surface groups, $\text{FV}_{\Gamma,\| \cdot \|}^1(k) \sim \text{FV}_{\Gamma}^1(k)$ for any nonzero seminorm $\| \cdot \|$; in any case all such choices of seminorm differ by a constant.

In order to get a sense of the difference between homological and directed isoperimetric functions, consider the famous Baumslag-Solitar group $B = BS(1, 2) = \langle a, b \mid bab^{-1} = a^2 \rangle$. The Dehn function of this group is exponential: the word $b^k a b^{-k} a b^{-k} a b^{-k} a^{-1}$ of length $4k + 4$ represents the trivial element but takes $O(2^k)$ cells to fill. By the same token, $\text{FV}_{\Gamma}^1(k)$ is also exponential in $k$.

On the other hand, the filling class of this word in $H_2(B)$ is zero, because in the usual filling, for every cell of positive orientation, there is a cell of negative orientation. Indeed, it is easy to see that $H_2(B) = 0$, since the Cayley complex only has one 2-cell and its boundary is nonzero. Thus this kind of cancellation must happen for every word whose chain evaluation is zero. In particular, $\text{FV}_{\Gamma,\| \cdot \|}^1(k) \not\sim 0$ for any norm $\| \cdot \|$.

Looking at this example, one may wonder if we have been too restrictive in defining directed isoperimetric functions. We know that every map is close enough to an admissible map, so there is no harm done in restricting to such maps. We would like to show in addition that every map or chain is close in the same sense to a map or chain whose chain evaluation is zero. Then we have better reason to believe that directed isoperimetric inequalities tell us something about all maps or chains.

Lemma 4.3. Let $X$ be a finite complex with admissible boundary maps an universal covering map $p: \tilde{X} \to X$, and $n \geq 1$. Then there is a constant $C$ depending on $n$ and $X$ such that the following holds.
(1) Let $f : S^n \to \tilde{X}$ be an admissible map of cellular $n$-volume $k$ such that $|\partial f|$ is a boundary. Then $f$ can be deformed via a homotopy with $(n + 1)$-volume $Ck$ to an admissible map $g$ of volume $Ck$ with $|\partial g| = 0$.

(2) Let $b \in C_n(\tilde{X})$ be a boundary of volume $k$. Then $b$ is homologous via an $(n + 1)$-chain of volume $Ck$ to a boundary $c$ of volume $Ck$ with $p_{\#}c = 0$.

Proof. We only prove (1); the proof of (2) is similar.

We work in $X$, since all the maps we are considering lift to $\tilde{X}$. We know $|||f|||_{\text{cell}} \leq \text{vol} f = k$. Since $X$ is finite, the boundaries $B_n(X)$ form a finitely generated group. Thus there is a constant $A$ such that we can always find an $(n + 1)$-chain $c$ with $\partial c = ||f||$ and $||c||_{\text{cell}} \leq Ak$.

Let $B$ be the maximal volume of an attaching map $f_i$ of an $(n + 1)$-cell $c_i$. Then a map $D^n \to X$ which takes the disk to a balloon starting at a basepoint and with head $f_i$ has volume at most $B$. By mapping the upper hemisphere of $S^n$ to $X$ via $Ak$ balloons corresponding to the cells of $-c$ and the lower hemisphere via $f$, we create a map $g$ of volume $(AB + 1)k$ with $|\partial g| = 0$. Since each $f_i$ can be nullhomotoped through $c_i$, this map is homotopic to $f$ via a homotopy with volume $||c||_{\text{cell}} = Ak$. Thus we have proven the lemma with $C = AB + 1$.

To further promote the admission of directed functions to the filling function pantheon, we would like to prove that they are well-defined for groups with appropriate finiteness properties.

Proposition 4.4. Suppose $\Gamma$ is a group of type $F_{n+1}$. Then given a norm $\|\cdot\|$ on $H_{n+1}(\Gamma; \mathbb{Q})$, $\text{FV}_{\Gamma} \|\cdot\|$ depends up to coarse equivalence only on $\Gamma$, justifying the notation.

Proof. Suppose $X$ and $Y$ are two complexes with fundamental group $\Gamma$ and $n$-connected universal cover such that $H_{n+1}(X) = H_{n+1}(Y) = H_{n+1}(\Gamma)$. The last condition can always be satisfied given a complex which satisfies the first two by adding a finite number of $(n + 2)$-cells.

In particular, we can find a cellular map $h : X^{(n+2)} \to Y$ which induces an isomorphism on $H_{n+1}$. Now suppose $f : S^n \to X$ is an admissible map of volume $k$ with $|\partial f| = 0$. Then $h \circ f$ is a cellular map of volume $Ck$. Although it may not be admissible, it has well-defined degrees on $n$-cells and is homotopic in $Y^{(n+1)}$ to a map $g$ with the same bound on the same degrees and the same degrees on $n$-cells; in particular, $|\partial g| = 0$. Moreover, an admissible filling of $f$ gives a corresponding cellular filling of $g$. Since $h_* : H_{n+1}(X) \to H_{n+1}(Y)$ is induced by the corresponding map of chain complexes, $h_* \text{Fill}(g) = \text{Fill}(f)$.

These are the only general results for directed isoperimetric functions that we will show at this time. Before we move on to some more interesting examples, we prove some comparison results about filling volumes and Dehn functions.

First, we show that in dimensions other than $2$, every cellular boundary is induced by a map $f : S^n \to X$; we say that every boundary is spherical. This means that isoperimetric functions are equivalent whether or not we require boundaries to be spherical.

Lemma 4.5. Let $X$ be a finite complex with universal cover $\tilde{X}$ and $n \geq 3$. Then for every integral boundary $c \in C_n(\tilde{X})$, there is an admissible $f : S^n \to X$ with $f_\#(S^n) = c$ and no cells of opposite orientations. In particular, $\text{FV}_X^{S^n} \sim \text{FV}_{\tilde{X}}^{S^n}$ and for every norm $\|\cdot\|$ on $H^{n+1}(X)$, $\text{FV}_X^{S^n} \|\cdot\| \sim \text{FV}_{\tilde{X}}^{S^n} \|\cdot\|$.

Proof. This proof generalizes Remark 2.6(4) in [BBFS]. Let $c$ be a boundary in $C_n(\tilde{X})$, and take an admissible map $g : (D^n, S^{n-1}) \to (\tilde{X}, \tilde{X}^{(n-1)})$ such that $g(D^n) = c$ and with no cells of opposite orientations, for example by mapping the boundary to a sum of attaching maps. Then

$$g_\#(D^n, S^{n-1}) = 0 \in H_n \left(\tilde{X}, \tilde{X}^{(n-1)}\right),$$

and thus, by the relative Hurewicz theorem, $|g| = 0 \in \pi_n(\tilde{X}, \tilde{X}^{(n-1)})$. This means $|g|_{\partial D^n} = 0 \in \pi_{n-1}(\tilde{X}^{(n-1)})$, that is, it is nullhomotopic within the $(n - 1)$-skeleton. Using such a nullhomotopy, and including $D^n \subset S^n$ as the upper hemisphere, we can extend $g$ to a map $f : S^n \to X$ with the desired properties.

Finally, it’s worth remarking that for groups, homological filling functions are always finite. This is not the case for all spaces. For example, if we set $X = S^2 \times S^1$, then a 2-boundary in $\tilde{X}$ of volume 2 can have arbitrarily large filling volume: just take two copies of $S^2$ arbitrarily far apart with opposite signs.
Lemma 4.6. Let $\Gamma$ be a group of type $F_n$. Then for every $1 \leq m \leq n$, $\text{FV}_m^\Gamma(k) < \infty$.

Proof. Fix a CW complex $X$ with $\pi_1 X = \Gamma$ and $n$-connected universal cover $\tilde{X}$. Theorem 1 of [AWP] states among other things that $\delta^\pi_m(k) = \delta^\Gamma_m(k) < \infty$ for $1 \leq m \leq n$. By Lemma 4.3 for $m \geq 3$, $\text{FV}_m^\Gamma(k) < \delta_m^\pi(k)$, which completes the proof in that case. The same inequality is true for $m = 1$, since every 1-cycle is a union of circles. The only case in which we have something to prove is $m = 2$; here it may be harder to fill a surface of positive genus than a sphere.

We will now show that $\text{FV}_2^\Gamma(k)$ is finite for every $k$. We may assume that $X^{(2)}$ is a simplicial complex and use simplicial volume as our measure of 2-volume. Then given a cocycle, and hence coboundary, $\alpha \in C_2(\tilde{X})$ of volume $k$, we can glue the cells of $\alpha$ into a simplicial map $f : \Sigma := \bigcup_{i=1}^r \Sigma_i \to \tilde{X}$, with each surface $\Sigma_i$ glued out of triangles. Note that $r \leq k$ and the Euler characteristic of $\Sigma$ is bounded in terms of $k$:

$$\chi \left( \bigcup_{i=1}^r \Sigma_i \right) = \sum_{i=1}^r (2 - 2g_i) \geq -\frac{k}{2}$$

since the difference between these two quantities is the number of vertices of $\Sigma$. Thus $G(\Sigma) = \sum_{i=1}^r g_i$ is also bounded in terms of $k$.

From here, we will show by induction on $G$ that $\text{FV}_2^\Sigma(k)$ is finite. Since $\delta_2^\Sigma(k)$ is finite, this is true when $G = r$, that is, when $g_i = 0$ for all $i$. Now, by Gromov’s systolic inequality for surfaces (Theorem 11.3.1 in [Katz]), for any Riemannian surface $V = \Sigma$, there is a nonseparating loop $\gamma : S^1 \to \Sigma_0$, of length at most $C \log g \sqrt{\text{vol} V}$. A simplicial version of this inequality is shown, for example, in [CHM]. Thus we can find a simple, nonseparating simplicial loop $\gamma : S^1 \to \Sigma$, of length $k' \leq C \log g \sqrt{\text{vol} V}$. Define a surface $\Sigma'$ and a map $f' : \Sigma' \to X$ by cutting $\Sigma_i$, at $\gamma$ and gluing in two copies of a minimal disk filling $\gamma$. Then $G(\Sigma') = G(\Sigma) - 1$ and

$$\text{vol} \Sigma' \leq k' := k + 2\delta_2^\Sigma(C \log g \sqrt{\text{vol} V}).$$

Moreover, any filling of $f'$ is also a filling of $f$. Thus $\text{FV}_2^\Sigma(k) \leq \text{FV}_2^\Sigma(k')$ is finite.

Since for each $k$, there is a maximal possible $G$, this gives us an overall bound on $\text{FV}_2^\Gamma(k)$.

Examples 4.7. To conclude the section, we give some examples of directed isoperimetric functions.

(1) Suppose $\Gamma$ is a group of type $F_{n+1}$ with homological Dehn function $\text{FV}_1^\Gamma = f(k)$. By a theorem of [Young] for $n \geq 2$, $\text{FV}_n^\Gamma(k) \geq f(k)$ because if $\gamma$ is hard to fill in $\Gamma$, then $\gamma \times \cdots \times \gamma$ is hard to fill in $\Gamma^n$. However this doesn’t tell us anything about directed isoperimetric functions, because if $D$ is a chain filling some 1-chain $\gamma$ in $\Gamma$ whose chain evaluation is zero, then

$$D \times \gamma \times \cdots \times \gamma$$

is a filling of $\gamma \times \cdots \times \gamma$ whose chain evaluation is also zero.

(2) Suppose $M^{n+1}$ is a closed oriented smooth manifold with fundamental group $\Gamma$. By dualizing a handle decomposition, we see that filling an $n$-boundary in $M$ is equivalent to finding a 0-cochain cobounding a compactly supported 1-cochain in the Cayley graph of $\Gamma$. Thus any $n$-boundary $b$ has a unique filling; moreover, $b = b_+ + b_-$, where $\text{vol} b = \text{vol} b_+ + \text{vol} b_-$ and $b_+$ has a filling by positively oriented copies of the top cell while $b_-$ has a filling by negatively oriented copies. Thus $\text{FV}_n^M(k)$, $\text{FV}_n^{M,[(M^k)\times]}(k)$, the isoperimetric problem for domains in $M$, and the problem of bounding from below the sizes of boundaries of subsets of $\Gamma$ are all equivalent. In particular, $\text{FV}_n^M(k) \sim \text{FV}_n^{M,[(M^k)\times]}(k)$ is linear if and only if $\Gamma$ is non-amenable.

(3) Define the $n$th diamond group

$$\diamond_n = \left\langle b_1, c_1, \ldots, b_n, c_n, a \left| b_i^{-1} a b_i = c_i^{-1} a c_i = a^2, [b_i, b_j] = [b_i, c_j] = [c_i, c_j] = 0 \text{ for } i \neq j \right. \right\rangle.$$

We can think of $\diamond_n$ as $F_n^2$ with an extra generator $a$ together with some relations involving it. Alternatively, we can define $\diamond_n$ inductively by setting $\diamond_0 = \mathbb{Z}$ and $\diamond_n$ to be a multiple ascending HNN extension of $\diamond_{n-1}$, specifically, the fundamental group of the graph of groups with a single vertex $\diamond_{n-1}$ and two edges each labeled by the injective self-homomorphism $a \to a^2$, $b_i \to b_i$, $c_i \to c_i$. (Indeed, when $n \geq 2$, this is an automorphism.) This last definition gives a construction for
a \((n+1)\)-dimensional classifying complex \(X_n\) for \(\Diamond_n\), starting with an \(S^1\) with one 1-cell and setting \(X_n\) to be the appropriate quotient space of \(X_{n-1} \times ([0,1] \cup [0,1])\) with the product cell structure.

The space \(X_n\) has \(2^n (n+1)\)-cells \(\epsilon_I\) corresponding to elements \(I \in \{b,c\}^n\). It’s easy to see that the only \((n+1)\)-cycles are multiples of

\[
\sigma_n = \sum_{I \in \{b,c\}^n} (-1)^{\text{number of } b\text{'s in } I} \epsilon_I \in C_{n+1}(X_n),
\]

and so \(H_{n+1}(X_n) \cong \mathbb{Z}\).

For now, we show that all the top-dimensional isoperimetric functions of \(\Diamond_n\) have the same superpolynomial growth.

**Theorem 4.8.** Let \(n \geq 1\), and let \(h \neq 0 \in H^{n+1}(\Diamond_n)\). Then

\[
FV^h_{\Diamond_n}(k) \sim FV^h_{\Diamond_n}(k) \sim \delta^h_{\Diamond_n}(k) \sim 2^\sqrt{k}.
\]

**Proof.** We start by setting some notation. Let \(p : \tilde{X} \to X\) be the universal covering and let \(\rho_1 : \Diamond_1 \to \Diamond_1\) be the monodromy homomorphism \(a \mapsto a^2\), \(b_1 \mapsto b_1\), \(c_1 \mapsto c_1\) used in the construction of \(\Diamond_{k+1}\). We write \(I_1\) and \(I_2\) for the two intervals used to construct \(X_n\) from \(X_{n-1}\). Note that the universal cover \(\tilde{X}_{n+1}\) consists of glued-together copies of \(\tilde{X}_n \times [0,1]\) indexed by edges of the Bass-Serre tree corresponding to the graph of groups, which we call layers.

As already discussed, for \(n \neq 2\), it is automatic that

\[
FV^h_{\Diamond_n}(k) \lesssim FV^h_{\Diamond_n}(k) \lesssim \delta^h_{\Diamond_n}(k).
\]

In the case \(n = 2\), the second inequality does not obviously hold, but

\[
FV^2_{\Diamond_2}(k) \lesssim \max \left\{ \delta^{(M,\partial M)}_{\diamond}(k) : (M, \partial M) \text{ 3-manifold with boundary} \right\}.
\]

Thus it is enough to show that \(2^\sqrt{k} \lesssim FV^2_{\Diamond_2}(k)\) and that \(\delta^{(M,\partial M)}_{\diamond}(k) \lesssim 2^\sqrt{k}\) for every \((n+1)\)-manifold with boundary \((M, \partial M)\).

To show the first of these two inequalities, we construct chains with large directed fillings in \(\tilde{X}_n\). Specifically, by induction on \(n\), we construct a chain \(\tau_n(k) \in C_{n+1}(\tilde{X}_n)\) for which \(p_\# \tau_n(k) = K\sigma_n\) for some \(2^k < K < 2^{n+k}\), and whose boundary has volume \(O(k^n)\), if \(n\) is viewed as a constant. Notice that because from a homological point of view all fillings are equivalent, we do not need to show that \(\tau_n(k)\) is the “best” filling of its boundary.

In \(\Diamond_1\), the construction of \(\tau_n(k)\) is similar to the usual demonstration that \(BS(1,2)\) has exponential Dehn function. Namely, we take \(\tau_1(k)\) to be the disk bounded by \(b_1^{-k} a b c_1 b_1^{-k} a^{-1} c_1^{-1}\). Notice for the purpose of the induction that \(\rho_1(\tau_1(k-1))\) gives a disk that differs from \(\tau_1(k)\) by only two cells.

Now suppose by induction that we have constructed \(\tau_{n-1}(k) \in C_n(\tilde{X}_{n-1})\), for each \(k \geq 0\), with the following properties:

\begin{itemize}
  \item \(p_\# \tau_{n-1}(k) = K\sigma_{n-1}\) for some \(2^k \leq K \leq 2^{n+k}\);
  \item \(\tau_{n-1}(0) = 0\);
\end{itemize}
Figure 4. An illustration of the 3-chain $\tau_2(4)$ in the universal cover $\tilde{X}_2$. It is an optimal filling of its boundary, which is a hard-to-fill 2-sphere in the group $\tilde{\Phi}_2$. The highlighted plane is a layer corresponding to $\tau_1(3)$.

- $\text{vol}(\partial \tau_{n-1}(k)) = O(k^{n-1})$;
- for every $k \geq 1$, the $n$-chains $\rho_{n-1} \tau_{n-1}(k-1)$ and $\tau_{n-1}(k)$ differ by $O(k^{n-2})$ cells.

We construct $\tau_n(k)$ from $2k$ layers, that is, certain copies in $\tilde{X}_n$ of $(-1)^\ell \tau_{n-1}(j) \times I_\ell$ for $j = 1, \ldots, k$ and $\ell = 1, 2$. This way, $p_\# \tau_{n-1}(k) = K\sigma_n$ with $K$ in the appropriate range. Specifically, we pick these so that

- the two copies of $\tau_{n-1}(k-1) \times \{1\}$ cancel out;
- for each $2 \leq j \leq k-1$, $\tau_{n-1}(j) \times \{0\}$ cancels out with $\tau_{n-1}(j-1) \times \{1\}$, except for the aforementioned $O(k^{n-2})$ cells.

Then $\partial \tau_n(k)$ is the sum over $j$ and $\ell$ of copies of $(-1)^\ell \partial \tau_{n-1}(j) \times I_\ell$ and $(-1)^\ell [\tau_{n-1}(j) - \rho_{n-1} \tau_{n-1}(j-1)]$. This means that in total,

$$\text{vol}(\partial \tau_n(k)) \leq 2kO(k^{n-1}) + 2kO(k^{n-2}).$$

Moreover, since $\rho_n|_{\partial \Phi_{n-1}} = \rho_{n-1}$, $\rho_n(\tau_{n-1}(j) \times I_\ell)$ differs from $\tau_{n-1}(j+1) \times I_\ell$ by $O(k^{n-2})$ cells. Thus $\rho_n \tau_n(k)$ differs from $\tau_n(k+1)$ by

$$2kO(k^{n-2}) + 2^{n+1} = O(k^{n-1})$$

cells. This completes the inductive step.

To show that $\delta_{n,\Phi_n}(k) \lesssim 2^{n+1}$, we do another induction. It’s clear that $\delta_{n,\Phi_n}(k) \leq 2^k$, and moreover, by Lemma 7.4 of [BBFS], $\delta_{\Phi_n,M}(\partial M) \leq 2\delta_{\Phi_n}(k)$ for any surface with boundary $M$, giving us the base case. For the inductive step when $n \geq 2$, we adapt and strengthen the argument of Theorem 7.2 of [BBFS], which concerns the top-dimensional Dehn functions of multiple ascending HNN extensions.
Theorem (7.2 in [BBFS]). Let $A_{n-1}$ be the $n$-dimensional classifying complex of a group $H$, and suppose that $F$ is a nondecreasing function such that $\delta_H^{(N,\partial N)}(k) \leq F(k)$ for all $n$-manifolds $N$ with boundary. Let $A_{n+1}$ be the complex corresponding to a multiple ascending HNN extension $G$ of $H$. Then for all $(n+1)$-manifolds with boundary $(M, \partial M)$, $\delta_G^{(M,\partial M)}(k) \leq F(k)$.

The idea of their proof is as follows. First of all, since the dimension of the filling is equal to the dimension of the complex, the optimal filling will always be unique. Moreover, for a map $f : (M, \partial M) \to A_{n+1}$, the volume of this filling is the sum of volumes of layers.

Once again the universal cover $\tilde{A}_{n+1}$ consists of glued-together layers $\tilde{A}_n \times [0,1]$, indexed by edges $e$ of the Bass-Serre tree. For each layer, let $Z_e$ be the corresponding copy of $\tilde{A}_n \times \{1/2\}$, and let $Z = \bigsqcup Z_e$ Then given an admissible $f : (M, \partial M) \to \tilde{A}_{n+1}$ which is transverse to $Z$ (in the sense defined in §VII.2 of [BRS]) and setting, for each edge $e$ of the Bass-Serre tree, $N_e := f^{-1}(Z_e)$ and $f_e = f|_{N_e}$, we have

$$\text{vol } f = \sum_e \text{vol}(f|_{N_e}).$$

On the other hand,

$$\text{vol}(f|_{\partial M}) = \sum_e \text{vol}(f|_{\partial N_e}) + h,$$

where $h$ stands for any “horizontal” volume which is the difference between fillings of the various $N_e$ meeting at a given vertex of the Bass-Serre tree. Thus $\partial M$ is as easy to fill in $X_n$ as $\bigsqcup N_e$ is in $X_{n-1}$, and its volume is at least as large.

In our case, however, this decomposition gives additional information. When certain boundaries have fillings which are much larger than $\text{vol}(\partial N)$, this means that there must be adjacent boundaries that have very similar fillings. This allows us to show that there is a large number of layers that have large intersections with $f$. We will use this to prove the stronger statement that if $\delta^{(N,\partial N)}(k) \lesssim 2^{-\sqrt{k/3}}$ for all $(N,\partial N)$, then $\delta^{(M,\partial M)}(k) \lesssim 2^{-\sqrt{k/3}}$.

So suppose $n \geq 2$, and let $M$ be an $(n+1)$-manifold with boundary and $f : (M, \partial M) \to \tilde{X}_n$ be a map of volume $2^k$ which is an optimal filling of its boundary. We would like to show that $\text{vol } f|_{\partial M} \gtrsim k^n$. Our strategy will be to actually assume that $\text{vol } f|_{\partial M} \lesssim k^n$, and then show that under that assumption $\text{vol } f|_{\partial M} \gtrsim k^n$, because there are at least $\gtrsim k$ layers each of which contributes volume at least $\gtrsim k^{n-1}$ to the boundary.

So assume that $\text{vol } f|_{\partial M} \lesssim k^n$, and that

$$k > k_{\min}(n) = \max\{k_{\min}(n-1), 3n \log_2 k + 2\}.$$

(We can choose $k_{\min}(1) = 1$.) Choose an edge $e_0$ for which $\text{vol } (f|_{N_{e_0}})$ is maximal, so that

$$\text{vol } (f|_{N_{e_0}}) \gtrsim \frac{2^k}{k^n} \gtrsim 2^{2k/3+1}.$$

By the inductive assumption, this means that $\text{vol } (f|_{\partial N_{e_0}}) \gtrsim C_{n-1}k^{n-1}$. Now let $v$ be a vertex incident to $e_0$, which has degree 4 in the Bass-Serre tree since $\rho_n$ is an automorphism. Since $\rho$ multiplies areas by at most 2, we know that for one of the edges incident to $v$, which we call $e_1$, we have

$$\text{vol } (f|_{N_{e_1}}) \lesssim \text{vol } (f|_{\partial M}) + \text{vol } (f|_{\partial \partial M}).$$

Continuing in this vein, for $r = \lfloor k/9 \rfloor$, we can pick a path $e_0, e_1, \ldots, e_r$ such that

$$\text{vol } (f|_{N_{e_j}}) \gtrsim \frac{1}{6} \text{vol } (f|_{N_{e_{j-1}}}) - k^n \gtrsim 2^{2k/3+2-3j} \gtrsim 2^{k/3+2}.$$ 

By the inductive assumption, for each $0 \leq j \leq r$, $\text{vol } (f|_{\partial N_{e_j}}) \gtrsim (k/3)^{n-1}$, so

$$\text{vol } (f|_{\partial M}) \gtrsim \frac{k}{9} C_{n-1} (k/3)^{n-1} = 3^{-(n+1)} C_{n-1} k^n.$$ 

By induction, we get that if $k > k_{\min}(n)$ and $\text{vol } f = 2^k$, then $\text{vol } (f|_{\partial M}) \gtrsim C_n k^n$, where $C_n = 3^{-O(n^2)}$. This completes the proof. $\square$
5. $L_\infty$ COHOMOLOGY AND Fillings

Correspondences between isoperimetry and the cohomology theories that turn up in coarse geometric settings have been noted a number of times in the literature, notably by Block and Weinberger [BIW], Attie, Block and Weinberger [ABW], Gersten [Ger96], and Nowak and Špakula [NS]. The main technical theorem of this section generalizes most of these results, as well as the classical max flow–min cut theorem from graph theory, using a technique from the theory of algorithms, the duality theorem for linear programming problems. In effect, a linear programming problem seeks to optimize a linear function subject to a number of linear constraints. In the dual linear program, the role of the constraints and variables is switched. The theorem of linear programming duality states that the optimum solution to the original and dual programs is the same. Our proof proceeds by translating our two conditions into this formal setting and demonstrating that they generate dual linear programs and are therefore equivalent. For a more detailed discussion of these ideas, see a textbook on algorithms, such as [CLRS].

Linear programming duality is widely applicable, including in geometry. For an example of a very differently flavored application to isoperimetric problems, see [KK].

We will use the following form of linear programming duality:

**Theorem (Linear programming duality, standard form; 29.10 in [CLRS]).** For vectors in $\mathbb{R}^q$ for any $q$, use $\leq$ to denote coordinate-wise comparison. Let $A$ be an $m \times n$ matrix, $b \in \mathbb{R}^m$, $c \in \mathbb{R}^n$. Then the maximal value of $c \cdot \bar{x}$, $\bar{x} \in \mathbb{R}^n$, subject to the constraints $Ax \leq b$ and $\bar{x} \geq 0$, is the same as the minimal value of $b \cdot \bar{y}$, $\bar{y} \in \mathbb{R}^m$, subject to the constraints $AT\bar{y} \geq c$ and $\bar{y} \geq 0$.

**Theorem 5.1 (Isoperimetric duality).** Suppose $Y$ is a metric CW complex in which balls intersect a finite number of cells, and write $E_n(Y)$ for the set of $n$-cells of $Y$. For $\mathbb{F} = \mathbb{Q}$ or $\mathbb{R}$, let $\omega \in C^{n+1}(Y; \mathbb{F}^r)$ be any cochain. For each $e \in E_n(Y)$, fix a (perhaps asymmetric) polyhedral norm $N_e$ on $\mathbb{F}^r$, and let $N'_e$ be the dual norm on $(\mathbb{F}^r)^*$. Then the following are equivalent:

1. for all chains $\sigma \in C_{n+1}(Y; (\mathbb{F}^r)^*)$, $\langle \omega, \sigma \rangle \leq \sum_{e \in E_n(Y)} N'_e(\partial \sigma(e))$;
2. $\omega = d\alpha$ for a cochain $\alpha \in C^n(Y; \mathbb{F}^r)$ with $N_e((\alpha, e)) \leq 1$ for every $e \in E_n(Y)$.

Note that (1) is an isoperimetric condition: what may be termed the “$\omega$-content” of any chain $\sigma$ is bounded by the $N$-volume of its boundary. On the other hand, (2) says that $\omega$ is the coboundary of an $N$-bounded cochain.

**Proof.** Fix a radius $R$, let $* \sigma$ be a basepoint in $Y$, and let $\{e_i : i \in I\}$ be an enumeration of the $(n+1)$-cells that intersect the open ball $B_R(*)$, and $\{f_j : j \in J\}$ be an enumeration of the $n$-cells which either intersect $B_R(*)$ or are incident to $e_i$ for some $i$. We denote the coefficient of $f_j$ in $\partial e_i$ by $\partial_j e_i$. For each $j$, we can write the norm $N_{f_j}$ as

$$N_{f_j}(v_1, \ldots, v_r) = \max \left\{ \sum_{k=1}^r c(j, \ell)k v_k : \ell = 1, \ldots, L_j \right\}$$

for constants $L_j$ and constant vectors $c(j, \ell)$. With these notations in place, condition (2) holds restricted to $B_R(*)$ if and only if the linear programming problem

$$\begin{align*}
\text{maximize} & \sum_{i \in I} \sum_{k=1}^r x_{i,k} \\
\text{subject to} & \\
& \text{for } i \in I, 1 \leq k \leq r, \quad 0 \leq x_{i,k} \leq |\langle \omega, e_i \rangle|_k \quad (A_{i,k}) \\
& \text{for } i \in I, 1 \leq k \leq r, \quad x_{i,k} = \text{sign}(\langle \omega, e_i \rangle_k) \sum_{j \in J} \partial_j e_i \alpha_{j,k} \quad (C_{i,k}) \\
& \text{for } j \in J, 1 \leq \ell \leq L_j, \quad \sum_{k=1}^r c(j, \ell)k \alpha_{j,k} \leq 1, \quad (B_{j,\ell})
\end{align*}$$

has the maximal possible solution, $x = \sum_{i \in I} \|\langle \omega, e_i \rangle\|_1$. Here, the vectors

$$(\alpha_{j,1}, \ldots, \alpha_{j,r}) = \langle \alpha, f_j \rangle$$

are the values on $n$-cells of a cochain $\alpha$ which the inequalities $(B_{j,\ell})$ constrain to have $N_{f_j}(\langle \alpha, f_j \rangle) \leq 1$. The equations $(C_{i,k})$ guarantee that

$$(\text{sign}(\langle \omega, e_i \rangle_1)x_{i,1}, \ldots, \text{sign}(\langle \omega, e_i \rangle_r)x_{i,r}) = \langle d\alpha, e_i \rangle$$
are the values on \((n+1)\)-cells of \(d\alpha\), and the equations \((A_{i,k})\) guarantee that these are no greater than and have the same signs as the values of \(\omega\). Thus \(x = \sum_{i \in I} \| (\omega, e_i) \|_1\) is a solution if and only if one can find an appropriate \(\alpha\) with \(d\alpha = \omega\).

Note that this linear programming problem is not quite in the standard form quoted above. To convert it, we can replace the equations \((C_{i,k})\) with two inequalities \((C_{i,k})\) and \((C_{j,k})\) with opposite signs, and replace the variables \(\alpha_{j,k}\) with differences \((\alpha_{j,k} - \alpha_{j,k}^-)\) where both \(\alpha_{j,k}\) and \(\alpha_{j,k}^-\) are nonnegative. When we take the dual of the resulting problem, the mirrored variables become mirrored inequalities and vice versa, and we can turn them back into equalities and perhaps-negative variables, respectively. Thus by linear programming duality, \(x\) is the solution to (5.2) if and only if it is

\[
\text{the minimal value of } \sum_{i \in I} \sum_{k=1}^r |(\omega, e_i)_k| A_{i,k} + \sum_{j \in J} \sum_{\ell=1}^{L_j} B_{j,\ell}
\]

subject to

\[
\begin{align*}
\text{for } i \in I, 1 \leq k \leq r, & \quad A_{i,k} + C_{i,k} \geq 1 \\
\text{for } j \in J, 1 \leq k \leq r, & \quad \sum_{\ell=1}^{L_j} c(j, \ell) B_{j,\ell} = \sum_{i \in I} \text{sign}(\langle \omega, e_i \rangle) \partial_j e_i C_{i,k} \quad (\alpha_{j,k}) \\
\text{for } i \in I, 1 \leq k \leq r, & \quad A_{i,k} \geq 0 \\
\text{for } j \in J, 1 \leq \ell \leq L_j, & \quad B_{j,\ell} \geq 0.
\end{align*}
\]

Set \(\sigma \in C_{n+1}(Y; F^*)\) to be

\[
\sigma = \sum_{i \in I} (\text{sign}(\langle \omega, e_i \rangle)) C_{i,1}, \ldots, \text{sign}(\langle \omega, e_i \rangle) C_{i,r}) e_i
\]

in the dual basis to the standard basis. Then the right side of \((\alpha_{j,k})\) adds up to \(\partial \sigma(f_j)\). So picking the \(B_{j,\ell}\) amounts to adding together nonnegative multiples of the vectors \(\vec{c}(j, \ell)\) for each \(\ell\), and \(\sum B_{j,\ell}\) is the sum of these coefficients, i.e. the dual norm \(N_f'((\partial \sigma(f_j))\). Thus, keeping in mind that \(A_{i,k} \geq 1 - C_{i,k}\), we can bound the quantity \(M\) being minimized in (5.3) as

\[
M \geq \sum_{i \in I} \sum_{k=1}^r |(\omega, e_i)_k| (1 - C_{i,k}) + \sum_{j \in J} \sum_{\ell=1}^{L_j} B_{j,\ell} = x - \langle \omega, \sigma \rangle + \sum_f N_f'((\partial \sigma(f))
\]

If (1) is true, then \(M \geq x\) for every \(R\) and choice of \(\sigma\). On the other hand, if (1) is not true, then for some \(R\), take a counterexample \(\sigma \in B_R(\ast)\) for which \((\omega, \sigma) > \sum_{c \in E_n(Y)} N'_f((\partial \sigma(c))\). We can scale such a \(\sigma\) so that (5.4) is satisfied with \(|C_{i,k}| \leq 1\) for every \(i\) and \(k\), and then set \(A_{i,k} = 1 - C_{i,k}\) and the \(B_{j,\ell}\) accordingly. This gives us a vector which satisfies the constraints and results in \(M < x\); thus condition (1) is equivalent to the dual problem (5.3) satisfying \(M = x\) for every \(R\).

In other words, this demonstrates that (2) implies (1), and that (1) implies that for every \(R\) there is an \(\alpha_R\) which satisfies (2) when restricted to \(B_R(\ast)\). To get an \(\alpha\) as desired on all of \(Y\), we take a weak-* accumulation point of the \(\alpha_R\). \(\square\)

Mutatis mutandis, the same proof shows a version of the theorem with the role of chains and cochains reversed. Both versions have a number of corollaries obtained through specific choices of norms. The one which will be most useful to us refers to \(L_\infty\) cohomology, that is, the cohomology of the complex of cellular cochains whose values on cells are uniformly bounded. (Note that the somewhat similarly defined singular theory known as \textit{bounded cohomology} results in a very different invariant of spaces; see for example [Ger92].)

**Corollary 5.2.** The following are equivalent for a cochain \(\omega \in C^{n+1}(Y; F^*)\):

1. there is a constant \(K\) such that for all chains \(\sigma \in C_{n+1}(Y; F^*), \| (\omega, \sigma) \|_\infty \leq K \text{vol}(\partial \sigma)\);
2. \(\omega\) is an \(L_\infty\) coboundary.

Proof: The corollary is obtained by applying the theorem separately to each coordinate of \(\omega = (\omega_1, \ldots, \omega_r)\), with \(N_c(\cdot) = |\cdot|\) for every \(c\) and \(\ell = 1, \ldots, r\). \(\square\)

The similar theorem for 0-chains proved in [BIW] is a corollary in the following formulation:

**Corollary 5.3.** The following are equivalent:
(1) the isoperimetric inequality for subsets of \( Y(0) \) is linear;

(2) the chain in \( C_0^{(\infty)}(Y;F) \) which takes the value 1 on every vertex is an \( L^{\infty} \) boundary.

Notably, [35] also prove that this is equivalent to the triviality of the entire zeroth homology group in this \( L^{\infty} \) theory. The Poincaré dual of this result used in [ABW] is another corollary of our theorem.

Similarly, if we take \( r = 1 \), choose a basepoint \( * \in Y \) and define \( N_e(x) = |x/f(d(*, e))| \) for some non-decreasing function \( f : [0, \infty) \to [0, \infty) \), we recover an analogous theorem for the groups \( H_n^F \) introduced by [37], generalizing their Theorem 4.2:

**Corollary 5.4.** The following are equivalent for a chain \( \sigma \in C_{n+1}(Y;*;F) \):

1. there is a constant \( K \) such that for all cochains \( \omega \in C_{n+1}(Y;F) \), \( \inf \|\omega/\sigma\|_{\infty} \leq K \sum e(f(*, e))d\omega(e) \);
2. \( [\sigma] = 0 \in H_n^F(Y;F) \).

### 6. Finite approximations of Postnikov towers

Suppose now that \( X \) is a delicate space, and once again let \( \Gamma = \pi_1 X \). We would like to show that \( X \) is built out of simpler spaces in an easy-to-analyze way; we will then use this decomposition to complete the proofs of Theorems [35] and [37]. First, note that the homotopy fiber of the inclusion \( X \to B\Gamma \) is \( \hat{X} \) and hence rationally equivalent to \( \prod_{i=1}^{r} S^{2n_i+1} \). Next, we see that up to rational homotopy \( B\Gamma \) also has finite skeleta.

**Lemma 6.1.** Suppose \( X \) is a finite complex and \( \hat{X} \) is rationally equivalent to a complex \( F \) with finite skeleta. Then \( \Gamma = \pi_1 X \) is of type \( F_{\infty}(Q) \), i.e. \( B\Gamma \) is rationally equivalent to a complex with finite skeleta.

**Proof.** Let \( f : X \to B\Gamma \) be the canonical map. Since for every \( n \), \( \pi_n(f) \otimes Q = \pi_{n-1}(F) \otimes Q \) is finite-dimensional, by Theorem [10] \( B\Gamma \) is rationally equivalent to a complex with finite skeleta. \( \square \)

Note that \( B\Gamma \) need not itself have finite skeleta. Thus for example, if \( L \) is a flag triangulation of \( S^3 \mathbb{R}P^2 \), then the Bestvina-Brady group \( H_L \) is finitely presented and the fundamental group of a \( Q \)-aspherical 3-complex, but not of an aspherical complex with finite skeleta [35].

When \( X \) is a delicate space, for any \( N \), we get a sequence of compact spaces

\[
\prod_{i=1}^{r} S^{2n_i+1} \to X \to B,
\]

which maps to a fibration \( \prod_{i=1}^{r} K(\mathbb{Q},2n_i + 1) \to \hat{X} \to B\Gamma \) via rational \( N \)-equivalences. We can pick \( N \) sufficiently large that in a desired range, these maps rationally obey the homotopy exact sequence of a fibration and the Serre spectral sequence. Moreover, the fibration splits into a tower of rational homotopy fibrations by products of same-dimensional spheres which is rationally equivalent to a Postnikov tower. In other words,

**Proposition 6.2.** If \( X \) is a delicate space, then it satisfies conditions (1) and (2) of Theorem [37].

More generally, let \( X \) be a finite complex such that \( \pi_n(X) \otimes Q \) is finite-dimensional. By adding a few cells, we can get a finite complex \( B \) such that the pair \( (B,X) \) is rationally \( n \)-connected and \( \pi_n(B) \otimes Q = 0 \). By studying such a map, we can get a handle on the distortion of \( \pi_n(X) \).

**Almost Postnikov pairs and the Euler class.** These last very weak conditions are strong enough to analyze a step of our approximate Postnikov tower. So in the rest of this section, an almost Postnikov pair will denote a system \( X \to B \) of finite complexes where the map \( p \) is rationally \( n \)-connected and the vector space \( V_p := \ker(\pi_n(X) \to \pi_n(B)) \otimes Q \) is finite-dimensional. Note that by adding cells to \( B \), perhaps infinitely many, one obtains a map, well-defined up to rational homotopy, whose rational homotopy fiber is \( K(V_p, n) \). In fact, although this definition is much more general, one loses very little for the purposes of this paper by thinking of all almost Postnikov pairs as \( K(Q^r, n) \)-fibrations for some \( r \).

We will say that an almost Postnikov pair is normal if in addition the Hurewicz map on \( V_p \) is injective in the universal cover \( \hat{X} \) and the action of \( \pi_1(X) \) on \( V_p \) is elliptic. This terminology is motivated by the fact that in this case, the corresponding fibration of universal covers is trivial up to rational homotopy. That is, it behaves as a product.

We would like to define invariants for almost Postnikov pairs. As a warmup, we define the same invariant in a more traditional context.
Definition. Let \( K(\mathbb{Q}, n)^r = F \to X \to B \) be a fiber bundle with monodromy representation \( \rho : \pi_1 B \to GL(\mathbb{H}_n(F; \mathbb{Q})) \), with a corresponding \( \mathbb{Q} \pi_1 B \)-module \( M_p \). This defines a bundle of groups \( \mathcal{H}(\rho) \) over \( B \) with fiber \( H_n(F; \mathbb{Q}) \). Define a class \( e u \in H^{n+1}(B; \mathcal{H}(\rho)) = H^{n+1}(B; M_p) \) as the obstruction to lifting a singular \((n+1)\)-simplex in \( B \) to \( X \), giving a lifting of the singular chain complex through dimension \( n \). By analogy, we refer to this as the Euler class of the bundle, although one could just as well call it its \( k \)-invariant.

We need to show that the Euler class is well-defined, that is,

1. the cochain is a cocycle;
2. the choice of lifts of \((n)\)-simplices determines it up to a coboundary.

We can assume fixed lifts for simplices in \( C_n(B) \) for \( s \leq n - 1 \), since such a lifting is unique up to homotopy. Notice then that two ways to lift \((n)\)-simplices giving representatives \( c_1, c_2 \) of the Euler class give us a cochain \( b \in C^n(B; M_p) \) with \( \delta b = c_1 - c_2 \). This proves (2).

Now we prove (1). Let \( f : \Delta^{n+2} \to B \) be a simplex, and choose a lifting of the singular chain complex through dimension \( n \) which takes \( g : \Delta^n \to B \) to \( \tilde{g} \), which induces an obstruction cochain \( c \). Finally, let \( \Delta_{ij} \) be the \((n)\)-simplex which does not include vertices \( v_i \) and \( v_j \). To show that \( eu(\partial f) = 0 \), we lift the \((n)\)-simplices containing \( v_0 \), and then extend by homotopy lifting to a lift \( \tilde{f} \) of \( f \). Then the restrictions \( \tilde{f}|\Delta_{ij} \) differ from \( f|\Delta_{i0} \), but the sum of the obstructions on the \((n+1)\)-simplices is the same for both.

§VI.5 of [1] gives a more abstract homotopy-theoretic treatment of these invariants. In particular, they show that it is always possible to construct a fiber bundle with the given monodromy representation and \( k \)-invariant, and that conversely, Postnikov towers are determined up to homotopy by their monodromy representations and \( k \)-invariants. Up to rational homotopy, these results restrict to finite complexes: if \( B \) has finite skeleta, then by Theorem 1.30 one can find an \( X \) that does as well. In other words, given a base and a monodromy representation and Euler class, one can always construct a corresponding almost Postnikov pair.

Conversely, suppose that \( X \xrightarrow{p} B \) is an almost Postnikov pair. The map \( p \) may not be a fibration, but there is nevertheless an Euler class associated with the rational homotopy type of the fibration which it is approximating. We would like to come up with a cellular representative of the Euler class in \( C^{n+1}(X; M_p) \) which gives an obstruction to extending lifts through \( \pi \). So let \( Z_p \) be the mapping cylinder of \( p \), and let \( j_n : C_n(Z_p; \mathbb{Q}) \to C_n(X; \mathbb{Q}) \) be a lifting homomorphism with a corresponding chain homotopy \( u_n : C_n(Z_p; \mathbb{Q}) \to C_{n+1}(Z_p; \mathbb{Q}) \). Then taking an \((n+1)\)-cell \( c \) of \( B \) to

\[
c + u_n(\partial c) \in H_{n+1}(Z_p, X; \mathbb{Q}) \cong \pi_{n+1}(Z_p, X) \otimes \mathbb{Q} \to V_p
\]
gives us the cellular representative we want. Moreover, if the almost Postnikov pair is normal, so that \( V_p \) injects into \( H_n(X; \mathbb{Q}) \), we can further identify the image of \( c \) with \( j_n(\partial c) \in H_{n}(X; \mathbb{Q}) \).

Distortion from the Euler class. Already in the introduction we gave an example in which the Euler class relates distortion in the total space of an almost Postnikov pair to isoperimetry in the base space. Now we can translate this example into the language that we will be using. Suppose that instead of a bundle, our almost Postnikov pair is actually an injective cellular map—we can always guarantee this by taking a mapping cylinder.

For the concrete case we are interested in, suppose \((B, X)\) is a CW pair with \( B \simeq T^4 \) such that the homotopy fiber of the inclusion is \( S^3 \) and the Euler class is the fundamental class \([T^4]\). Then any admissible map \( f : S^3 \to X \) represents an element of \( \pi_{3}(X) \) which is, by definition, equal to the pairing of the representative of the Euler class constructed above with a filling of \( f \). Conversely, any boundary in \( C_n(B) \) deforms via a lifting homomorphism to a chain in \( C_n(X) \) whose filling differs by a linear amount. In this formulation, then, the equivalence between the functions \( FV^{S^3}(\alpha, \cdot)(k) \) and \( V\delta_{\alpha}(k) \) for \( \alpha \neq 0 \in \pi_{3}(X) \) is almost tautological. This equivalence extends to other almost Postnikov pairs with one-dimensional fiber.

Theorem 6.3. Let \( X \xrightarrow{B} B \) be a normal almost Postnikov pair in dimension \( n \) with \( V_p \cong \mathbb{Q} \) and Euler class \( e u \neq 0 \). Then any element \( \alpha \in V_p \) has distortion function \( V\delta_{\alpha}(k) \sim_{C} FV^{S_{B}(\alpha, \cdot)}(k) \). In particular, this is true if \( B \cong \mathbb{Q} B^1 \) for some group \( \Gamma \).

Proof. In this case, elliptic monodromy means that every element acts by multiplication by 1 or \(-1\), so by taking a double-cover we can assume that the monodromy is trivial. Suppose that \( V\delta_{\alpha}(k) = M \), so that
there is an admissible \( f : S^n \to X \) with volume \( k \) which represents the class \( M\alpha \in \pi_n(X) \). By Lemma 1.4, we can find a nearby \( g : S^n \to B \) with \( \|g\| = 0 \), and so there are constants \( C \) and \( C' \) such that

\[
\text{FV}^n_{B,\{\text{eu},\cdot\}}(Ck) \geq M - C'k.
\]

Conversely, suppose that \( \text{FV}^n_{B,\{\text{eu},\cdot\}}(k) = M \), so that there is a map \( f : S^n \to B \) with \( \|f\| = 0 \) such that \( \langle \text{eu}, \text{Fill}(f) \rangle = M \). Then by Lemma 2.4, there is a constant \( p \) such that one can find a \( g : S^n \to X \) with \( g_\#(\langle S^n \rangle) = p\text{vol}_n\langle S^n \rangle \), where \( j_n \) is a lifting homomorphism. Therefore, there are constants \( C \) and \( C' \) such that

\[
\text{V} \delta_\alpha(pCk) \geq M - C'k.
\]

This shows the desired equivalence. \( \Box \)

In other words, the fact that even admissible maps to \( X \) and to \( B \) do not match up perfectly can in any case only impose linear differences in the asymptotics of these two functions.

In general, however, in particular for almost Postnikov pairs with nontrivial monodromy, the situation is rather more nebulous. Here it is still the case that small maps \( S^n \to \tilde{B} \) do lift to \( \tilde{X} \) which represent big homotopy classes in \( \pi_n(\tilde{X}) \). However, because of the twisting, different lifts to the universal cover of the same cell in \( B \) correspond to different elements of \( \pi_n(X) \); the homotopy class of a map in \( B \) does not depend solely on its filling homology class in \( B \). This means, for example, that the same sequence of fillings in \( B \) may demonstrate the distortion of many different elements of \( \pi_n(X) \), depending on how we lift it to the universal cover. Moreover, if the homotopy fiber is \( (S^n)^r \) for some \( r \geq 2 \), then not every map represents a multiple of some given \( \alpha \). These two complications prevent us from giving a neat characterization like above, and we are left with a statement which is even more nakedly tautological:

**Theorem 6.4.** Let \( X \overset{p}{\to} B \) be a normal almost Postnikov pair with \( p \) an injective cellular map. Let \( j_\ast : C_{\leq n}(\tilde{B};\mathbb{Q}) \to C_{\leq n}(\tilde{X};\mathbb{Q}) \) be a lifting homomorphism, and \( \omega_j \) be the representative of the Euler class induced by \( j_\ast \). Then there are constants \( 0 < c \leq 1, p_n(j_\ast) \geq 1 \) such that for every \( \alpha \in V_p \),

\[
\frac{c}{p_n} |p_n\alpha|_{\text{vol}} \leq \min\{\text{vol}(f) \mid f : S^n \to \tilde{B} \text{ admissible and } \langle \omega_j, \text{Fill}(f) \rangle = \alpha\} \leq C|\alpha|_{\text{vol}} + C.
\]

**Proof.** The right inequality is true since any map \( f : S^n \to X \) deforms to an admissible one. Conversely, for any \( f : S^n \to B \) we can apply Lemma 2.4 to concoct a map \( g : S^n \to X \) representing \( p\alpha \) with \( g_\#|S^n| = p_n j_n(f_\#|S^n|) \) and \( \text{vol} g \leq C_n \text{vol} f \), where \( p_n \) and \( C_n \) depend only on \( j_n \). \( \Box \)

This fact seems rather unwieldy to use, but it does allow us to analyze certain examples. It also has the useful consequence that homological isoperimetric functions give us a bound on how distorted classes may be, regardless of monodromy.

**Corollary 6.5.** Given a normal almost Postnikov pair \( X \overset{p}{\to} B \), for any \( \alpha \in V_p \), \( \text{V} \delta_\alpha(k) \lesssim \text{FV}^n_B(k) \).

This stands in contrast with almost Postnikov pairs which are not normal, in which volume distortion is always infinite.

In concrete examples, the main principle is as follows: to show a class \( \alpha \in \pi_n(X) \) to be distorted, one needs to find a sequence of boundaries in \( \tilde{B} \) which lift to multiples of \( \alpha \). The exact lift depends on the exact representative of the Euler class chosen, but any pair of representatives gives lifts which diverge from each other linearly. Thus in principle, if \( \alpha \) is distorted, then we can use any representative of the Euler class to demonstrate this.

**Examples 6.6.** In these examples, we assume \( n \) odd, so that \( K(\mathbb{Q}, n) \cong \mathbb{Q} S^n \).

1. Mineyev [Min] shows that hyperbolic groups satisfy linear isoperimetric inequalities for fillings of boundaries with cycles. In particular, if \( \Gamma \) is hyperbolic, \( \text{FV}^n_{\Gamma,\{\text{eu},\cdot\}}(k) \) is linear for all \( n \geq 1 \), and hence so is \( \text{FV}^n_{\Gamma,\{e,\cdot\}}(k) \) for any \( e \in H^{n+1}(\Gamma;\mathbb{Q}) \). Therefore, if \( X \) is the total space of a fibration \( (S^n)^r \to X \to B\Gamma \), then \( \pi_n(X) \) is undistorted.
(2) Conversely, if $\Gamma = \mathbb{Z}^d$ for $d > n$, then the isoperimetric inequality $k^{(n+1)/n}$ is attained by fillings of round spheres in $(n + 1)$-dimensional coordinate hyperplanes, which correspond to the generators of $H^{n+1}(\Gamma)$. Suppose that $X$ is a bundle over $T^r$ with finite monodromy. Given $0 \neq \omega \in H^{n+1}(\Gamma)$, $\langle \omega, x \rangle \neq 0$ for one of these generators $x$, so $FV_{\omega, \Gamma}(k) \sim k^{(n+1)/n}$, and if $X$ has Euler class $\omega$, then $\pi_n(X)$ is distorted with $VD_\alpha(k) \sim k^{(n+1)/n}$.

(3) A somewhat more subtle situation occurs when $\Gamma = \mathbb{Z}$ previously, which has surface area of large elements of to simplify the notation in the rest of this example, we can choose a representative

The notation indicates that the sum runs over all choices of either

$C$ in $a$

Indeed, so is any rational linear combination of such vectors, that is, any

choosing a cellular representative of the Euler class we can choose to lift $\hat{\omega}$ such cochains to any pair of vectors differing by multiplication by

$C$

On the other hand, suppose the Euler class takes $\hat{\omega}$ is the total space of a rational homotopy fibration ($S^3$) fiber ($\rho$) which is zero on the lifts of every cell except for

Moreover, so is $\rho(a)\delta(i\hat{\omega})$, for any $k$, as we can see by taking the relevant parallel flat. Indeed, so is any rational linear combination of such vectors, that is, any $\rho(m)i\hat{\omega}$ for $m \in \mathbb{Q}$.

On the other hand, suppose the Euler class takes $\hat{\omega}$ to a vector $\vec{v}$, and consider the boundaries of cochains in $C^3(B; \rho)$. Of the 3-cells bounding $\hat{\omega}$, the ones perpendicular to $\hat{\omega}$ can be lifted by such cochains to any pair of vectors differing by multiplication by $A$. Since $A - I$ is of rank 2, when choosing a cellular representative of the Euler class we can choose to lift $\hat{\omega}$ to any vector as long as it has the correct first coordinate. If we choose the lift to be $(v_1, 0, 0)$, then this vector is distorted by the argument in the previous example. On the other hand, this does not induce distortion in any vectors in other directions.

Thus vectors with nonzero second and third coordinate can only be distorted as a result of the pairing of the Euler class with $\hat{\omega}$, but any flat may cause distortion of vectors of the form $(v_1, 0, 0)$.

(4) Now take $\Gamma = \phi_n$, the $n$th diamond group defined earlier, and its classifying space $X_n$, and suppose that $Y$ is the total space of a rational homotopy fibration ($S^n$) $\rightarrow Y \rightarrow X_n$. From the earlier discussion we see that if the monodromy of this fibration is trivial and the Euler class is nontrivial, then the volume distortion function of $Y$ will be $\exp(k^{1/n})$. Indeed, we can also demonstrate this for certain other monodromy representations. As before, we let $a, b_1, \ldots, b_n, c_1, \ldots, c_n$ be the generators of $\phi_n$. Suppose that the monodromy representation $\rho : \phi_n \rightarrow GL_r(\mathbb{Q})$ of our fibration takes $a \mapsto 1$ and maps the $b_i$ and $c_i$ via any elliptic representation of $F_2^n$, and that the Euler class $e_{\varphi} \in H^{n+1}(X_n; \rho)$ is nonzero.

Note that $H^{*+1}(X_n; \rho)$ $\cong \mathbb{Q}^r$. To see this, fix a lift $\tilde{e}_I$ of each $(n + 1)$-cell $e_I$ of $X_n$ to $\tilde{X}_n$ so that all of these lifts coincide on the edge $a^{2n}$, as illustrated in Figure 3. In this basis, coboundaries in $C^{n+1}(X_n; \rho)$ are those $\omega$ which satisfy the vector equation

$$A(\omega) := \sum_{\substack{I \in (e_i)^n \subseteq \mathbb{Q} \cup c_i \cup c_i, \#(i^*), b_i}} \prod_{i=1}^n (\rho(\omega_i) - 2I)^{-1}\langle \omega, \tilde{e}_I \rangle = 0.$$

The notation indicates that the sum runs over all choices of either $b_i$ or $c_i$ for each $i$. In particular, to simplify the notation in the rest of this example, we can choose a representative $\omega$ of $e_{\varphi} \in H^{n+1}(X_n; \rho)$ which is zero on the lifts of every cell except for $e_C = e_{(c, \ldots, c)}$.

As an upper bound on the distortion function of $\pi_n(Y)$, we already know that $FV_{\omega, \Gamma}(k) \sim \exp(k^{1/n})$. To show that this bound is sharp, we construct a sequence of small representatives of large elements of $\pi_n(Y)$. Specifically, we pick the embedding $\partial\tau_n(k + 1)$ of $S^n \subset X_n$ described previously, which has surface area $O(k^n)$. Since this has filling $\tau_n(k + 1)$, it lifts to a representative
the volume distortion of elements of \( V \) (\cite{Gro91}).

Now we multiply both sides of this equation by \( \prod_{i=1}^n (\rho(c_i^{-1}) - 2I) \) and notice that the transformation on the right hand side can be thought of as \( \rho(m_{n,k}) \) for a certain element \( m_{n,k} \in \mathbb{Z}^* \wedge_n^* \):

\[
\prod_{i=1}^n (\rho(c_i^{-1}) - 2I) \bar{v}(k+1) = \rho(m_{n,k}) \langle \omega, \tilde{e}_C \rangle.
\]

Then there is an inductive formula

\[
m_{n,k} = (c_n^{-1} - 2) \sum_{j=0}^k c_n^j m_{n-1,k-j}.
\]

By cancelling certain terms at each step of this induction, we find that

\[
\prod_{i=1}^n (c_i^{-1} - 2I) \bar{v}_n(k+1) = [-2^{k+n} + R(\rho(c_1), \ldots, \rho(c_n))] \langle \omega, \tilde{e}_C \rangle \in \pi_n(Y) \otimes \mathbb{Q},
\]

where the remainder term \( R \) is a polynomial in the \( \rho(c_i) \) with \( O(k^n) \) terms, all of which have integer coefficients in \( O(2^n) \). Indeed, since the argument was on the level of elements of \( \mathbb{Z}^* \wedge_n^* \), one can construct a finitely-presented module \( M \), and hence a finite \( Y \), such that the equality holds even before rationalizing:

\[
\prod_{i=1}^n (c_i^{-1} - 2) \cdot \alpha(k+1) = [-2^{k+n} + R(c_1, \ldots, c_n)] \cdot [\partial \tilde{e}_C] \in \pi_n(Y) \cong M,
\]

where \( \alpha(k+1) \in \pi_n(Y) \) is the element represented by the equivariant lift of \( \tau_n(k+1) \) induced by \( \omega \). By Corollary \ref{cor:1.7} for any \( Y \) with the same rational homotopy type, the same equality holds once both sides are multiplied by an integer \( p(Y) \).

Thus we can represent the element \( -2^{k+n} [\partial \tilde{e}_C] \in \pi_n(Y) \) via \( O(3^n) \) copies of the lift of \( \tau_n(k+1) \) summed with \( O(2^n k^n) \) copies of various inclusions of the fiber, hence with volume \( O(k^n) \). This means that \( [\partial \tilde{e}_C] \) is distorted with distortion function \( \exp(\sqrt{3}) \). Moreover, so is any other lift of this cell or linear combination of such lifts; that is, for any \( m \in \mathbb{Z}^* \wedge_n^*, \rho(m)[\partial \tilde{e}_C] \) has the same distortion function. Moreover, we can use other embeddings of \( S^n \), depending on choices of branches in the Bass-Serre tree, to obtain other, perhaps distinct distorted vectors. Thus the one-to-one relationship between homology classes downstairs and homotopy classes upstairs that we see in the case of trivial monodromy, as exemplified by Theorem \ref{thm:6.3} does not have an equivalent in the general case.

**Recognizing non-distortion.** We have just demonstrated that for an almost Postnikov pair \( X \xrightarrow{p} B \), while the volume distortion of elements of \( V_p \) is in some sense determined by the monodromy representation and the Euler class, this relationship can be complicated and perhaps even impossible to encapsulate. However, there is a fairly simple criterion that can be used to identify pairs for which all of \( V_p \) is volume-undistorted.

**Definition** (\cite{Gro91}). Let \( X \) be a compact piecewise Riemannian space. A form \( \omega \in \Omega^n(X) \) is called \( \bar{d}(\text{bounded}) \) if its lift \( \tilde{\omega} \) to the universal cover \( \tilde{X} \) is the differential of a bounded form.

Being \( \bar{d}(\text{bounded}) \) is a Lipschitz homotopy invariant and (in the given setting) exact forms are \( \bar{d}(\text{bounded}) \). Indeed, this definition is just another way of saying that the pullback of a form to the universal cover is zero in \( L_\infty \) cohomology.

In the following theorem, we put together this as well as a few other equivalent conditions for non-distortion. In particular, the presence of condition (5) gives a weak converse to Lemma \ref{lem:5.2}.

**Theorem 6.7.** Let \( X \xrightarrow{p} B, n \geq 3, \) be a normal almost Postnikov pair with elliptic monodromy representation \( \rho : V_p \to GL(H_\pi^*(\mathbb{R}; \mathbb{Q})) \) and Euler class \( e_u \in H^{n+1}(B; M_\rho) \). Write \( \tilde{X} \) and \( \tilde{B} \) for the universal covers of \( X \) and \( B \). Then the following are equivalent:

\( \bar{d}(\text{bounded}) \) if its lift \( \tilde{\omega} \) to the universal cover \( \tilde{X} \) is the differential of a bounded form.
The subspace $V_p \subseteq \pi_n(X) \otimes \mathbb{Q}$ is volume-undistorted.

For some (any) representative $w$ of $\text{eu}$, there is a constant $C$ such that for all spherical boundaries $\sigma \in B_n(\tilde{B})$, $\|\langle w, \text{Fill}(\sigma) \rangle\| \leq C \text{vol} \sigma$.

For some (any) representative $\omega$ of $\text{eu}$, there is a constant $C$ such that for all boundaries $\sigma \in B_n(\tilde{B})$, $\|\langle \omega, \text{Fill}(\sigma) \rangle\| \leq C \text{vol} \sigma$.

The class $\text{eu}$ is $d(\text{bounded})$, i.e. $\pi^* \text{eu} = 0 \in H^{n+1}_{(\infty)}(\tilde{B}; V_p)$.

There is a bounded cellular cocycle $w \in C^n_{(\infty)}(\tilde{X}; V_p)$ so that $\langle w, f_\ast[S^n] \rangle = [f]$ for any $f : S^n \to \tilde{X}$ with $[f] \in V_p$. Equivalently, if $X$ is given a piecewise Riemannian structure, there is a bounded closed piecewise smooth form $\omega \in \Omega^n(\tilde{X})$ such that $\int_{S^n} f^* \omega = [f]$ for any such $f : S^n \to \tilde{X}$.

Proof. The only part which we have not already essentially proved is (4)\textRightarrow(5). In proving it, we abuse notation by using $\pi$ and $p$ for the maps $\tilde{X} \xrightarrow{\pi} X$ and $\tilde{X} \xrightarrow{p} \tilde{B}$ which complete the commutative square. We write $\Gamma$ for $\pi_1 B = \pi_1 X$.

By perhaps taking a mapping cylinder, we assume that $X \subset B$. Let $j_\ast : C_\ast(\tilde{B}; \mathbb{Q}) \to C_\ast(\tilde{X}; \mathbb{Q})$ be a lifting homomorphism, and let $\alpha$ be the cellular cocycle representing $\text{eu}$ which we previously discussed, which takes a cell $c$ to the preimage in $V_p$ of the homology class of $j_\ast(\partial c) \in H_n(\tilde{X}; \mathbb{Q})$ for any lift $\tilde{c}$ of $c$ to $B$. By assumption, there is a bounded cellular $\beta \in C_\ast(\tilde{B}; V_p)$ such that $d \beta = \pi^* \alpha$. But from the definition of $\alpha$ we see that the restriction $w = p^* \beta$ is a cellular cocycle on $\tilde{X}$ which satisfies the condition of (5).

The technical report [AB1] contains a proof of a de Rham theorem which equates simplicial $L_p$ cohomology with the cohomology of $L_p$ forms, for $p$ including $\infty$. They state this theorem for manifolds, but in fact it works for piecewise smooth forms on any simplicial complex of bounded geometry. If $X$ has a piecewise Riemannian structure, then there is a compatible cellular, Lipschitz homotopy equivalence with a simplicial complex, so this theorem carries over to a cellular version. Thus we can also produce a form with the desired properties in $\tilde{X}$ as a stratified space, or in any homotopy equivalent manifold with boundary.

(5)\textRightarrow(1) is Lemma 3.2.

(1)\textRightarrow(2) is a special case of Theorem 6.4.

(2)\textRightarrow(3) is Lemma 4.5: this is the only place we use the stipulation that $n \neq 2$.

To get (3)\textRightarrow(4), apply Corollary 5.2 to a cellular cochain representing $\text{eu}$.

\hfill \Box

Proof of Theorem 4.3. We have already shown that if a finite CW complex $X$ has no distortion in its homotopy groups, then conditions (1) and (2) of Theorem 4.3 are satisfied. In particular, we can find a tower of maps

$X = X_m \to X_{m-1} \to \cdots \to X_0$

where each $X_i$ is a finite complex which is rationally equivalent up to a large dimension $N$ to $X_{(n,i)}$, and where each step $X_k \to X_{k-1}$ is a normal almost Postnikov pair. By Theorem 6.7, $\pi_{n_k}(X_k)$ is undistorted if and only if the Euler class of $X_k \to X_{k-1}$ is $d(\text{bounded})$. Since $X_k$ is rationally equivalent to $X$ up to dimension $k+1$, this is also the case for $\pi_{n_k}(X)$. Thus if $X$ is a delicate space, then the lack of distortion in its homotopy groups is equivalent to condition (3).

\hfill \Box

Proof of Theorem 4.3. Let $X \xrightarrow{p} B$ be an almost Postnikov pair. Theorem 8.3 and Corollary 8.4 show that if it is not normal, then $V_p$ has infinite distortion. When it is normal, nondistortion is equivalent to the condition that $\pi^* \text{eu} = 0 \in H^{n+1}_{(\infty)}(\tilde{B}; V_p)$ by Theorem 6.7. Thus in general, nondistortion is equivalent to the two given conditions.

\hfill \Box

Having proven our main theorem, we break for a meditation on what Theorem 6.7 really means. If $F \to X \to B$ is an honest fiber bundle with $F \to \tilde{X} \to \tilde{B}$ homotopically trivial, one can think of condition (4) as specifying that there is a section $\sigma : \tilde{B} \to \tilde{X}$ with a bounded amount of “twisting” around the fiber for every $n$-cell. What is bounded \textit{a priori} is the number of twists, but this is equivalent to being able to find a section with a bounded Lipschitz constant, or, say, $n$-dilation. This in turn induces a trivializing map $X \to F \times B$ which is also bounded in all the same senses, that is, the bundle $\tilde{X} \to \tilde{B}$ is “coarsely trivial” in a natural sense. It is tempting to assert that when $X$ has undistorted homotopy groups, its universal cover must necessarily be coarsely trivial as a rational homotopy fibration, whatever that may mean. However, outside the important special case of actual fiber bundles, and especially when $\rho$ is outside $GL(r, \mathbb{Z})$, it’s much harder to make such an assertion precise.
We now explore how this result applies to specific classes of groups and spaces.

**Example 6.8 (Amenable groups).** If \( \Gamma = \pi_1 B \) is an amenable group, then only the zero class in \( H^{n+1}(B; M_\rho) \) is \( \bar{d} \)-bounded, i.e. the pullback map \( H^{n+1}(B; M_\rho) \to H^{n+1}_\infty(\tilde{B}; \mathbb{Q}^r) \) is injective. A special case of this fact was noted in [ABIW]. In general, we can see this as follows. An invariant mean \( \mu \) on \( \Gamma \) provides a map \( f : C^*(\tilde{B}; \mathbb{Q}^r) \to C^*(B; M_\rho) \), where for any cell \( e \),

\[
(f(\omega), e) = \int_{\gamma \in \Gamma} \rho(\gamma)^{-1}(\langle \omega, \gamma \cdot e \rangle) d\mu.
\]

This map commutes with the coboundary operator and thus is a well-defined projection on the level of homology which inverts the pullback map. Thus in spaces with amenable fundamental group, any nonzero Euler class induces distortion.

**Example 6.9 (Unit tangent bundles of aspherical manifolds).** Suppose that \( \Gamma \) is a group such that \( M = B\Gamma \) is an \( n \)-dimensional smooth manifold, and let \( X \) be the unit tangent bundle of \( M \). If \( \Gamma \) is amenable, the Euler characteristic of \( \tilde{M} \), i.e. the pullback map \( \pi_* : H^1(\tilde{M}; \mathbb{Q}^r) \to H^1(\tilde{X}; \mathbb{Q}^r) \) is injective.

Following a standard proof such as that of Theorem 5.15 in [Hat5], one shows that the spectral sequence

\[
E_2^{p,q} = H^p(\tilde{B}; H^q(F; \mathbb{Q}^r))
\]

leads to an exact sequence

\[
0 \to \pi_* H^1(\tilde{M}; \mathbb{Q}^r) \to H^1(\tilde{X}; \mathbb{Q}^r) \to \lim_{\to \to} H^1(\tilde{X}_k; \mathbb{Q}^r) \to 0.
\]

Thus the \( L_\infty \) cohomology of \( B \) is concentrated in dimensions 0 and 1. In particular, this means that if \( X \) is the total space of a fibration \( (S^n)^r \to X \to B\Gamma \), then \( \pi_* \gamma(X) \) is always undistorted.

To answer this question, we need to analyze \( L_\infty \) cohomology more closely.

It turns out that in dimension 1, the \( L_\infty \) cohomology is as large as possible, as far as we’re concerned.

**Lemma 6.11.** For any finite complex \( B \) with universal covering map \( \pi : \tilde{B} \to B \) and any elliptic monodromy representation \( \rho : \pi_1 B \to GL(H_n((S^n)^r; \mathbb{Q}^r)) \), the pullback map \( \pi^* : H^1(\tilde{X}; M_\rho) \to H^1(\tilde{X}; \mathbb{Q}^r) \) is injective.

**Proof.** Suppose \( \omega \in C^1(B\Gamma; M_\rho) \) is a representative of a nonzero cohomology class; in other words, there is a loop \( \gamma : [0,1] \to B\Gamma \) such that \( \bar{v} = \langle \omega, \gamma \rangle \notin \text{im}(\rho(\gamma)) - I \). Then \( \rho(\gamma) \) is conjugate to a rotation and \( \bar{v} \) has a nonzero projection onto its invariant subspace in \( \mathbb{R}^r \). Thus \( \sum_{i=0}^k \rho^i(\bar{v}) \) is unbounded length, so if \( \sigma_k \) is a lift of \( k\gamma \) to \( \tilde{B} \), then \( \langle \pi^* \omega, \sigma_k \rangle \) grows linearly in \( k \) but \( \text{vol}(\partial \sigma_k) = 2 \). By Corollary 5.2, this means that

\[
\langle \pi^* \omega, \sigma_k \rangle = 0 \quad \text{for} \quad k \in \mathbb{N}.
\]

To extend this dichotomy to other spaces with the same fundamental group, we can use a Serre spectral sequence.

**Lemma 6.12.** Let \( F \to X \to B \) be a rational homotopy fibration of finite complexes with \( F = \bigoplus_i S^{2n_i+1} \). Then the \( L_\infty \) cohomology of the universal cover of this fibration obeys a Serre spectral sequence: that is, \( H^*(\tilde{X}; \mathbb{Q}^r) \) can be assembled from the \( E_\infty \) page of a spectral sequence with \( E_2^{p,q} = H^p(\tilde{B}; H^q(F; \mathbb{Q}^r)) \).

**Proof.** There is nothing tricky to this argument, and we will merely sketch it.

We can assume that \( X \) is built inductively over the skeletal of \( B \) as in the proof of Theorem [110] with \( X_k \) approximating the total space of a fibration over \( B^{(k)} \). This gives a filtration of \( X \) and hence of \( C^n(\tilde{X}; \mathbb{Q}^r) \).

Following a standard proof such as that of Theorem 5.15 in [Hat5], one shows that the spectral sequence associated to this filtration satisfies the requirements we have given.

Now suppose that we have a complex \( B \) which is built up to rational homotopy as a fibration \( F = \bigoplus_i S^{2n_i+1} \to B \to BT \). In the case that the base is \( B^r \) for a hyperbolic group \( \Gamma \), the columns of the \( E_2 \) page are zero for \( p \geq 1 \). Thus if \( X \) is the total space of a further fibration \( (S^n)^r \to X \to B \), distortion occurs in \( \pi_* \gamma(X) \) if and only if the relevant Euler class is represented in the \( E_2 \) page of the spectral sequence by a nonzero element of \( H^1(\Gamma; H^n(F; \mathbb{Q}^r)) \). As will be proved in Theorem [11] such distortion is always weakly infinite, and so if \( X \) has a hyperbolic fundamental group, then all subspaces of \( \pi_* \gamma(X) \) are either undistorted or weakly infinitely distorted.

41
The work of Gersten [Ger96] and Mineyev [Min] shows that hyperbolic groups are completely characterized by $L_\infty$ cohomology: that is, they are exactly those $\Gamma$ for which $H^{n+1}_c(\Gamma; V) = 0$ for every $n \geq 2$ and every normed real vector space $V$; or, equivalently, for which $H^2_c(\Gamma; \ell^\infty) = 0$. It is therefore tempting to conjecture that the dichotomy outlined above holds if and only if $\Gamma$ is hyperbolic. In other words, if $\Gamma$ is not hyperbolic, one ought to always be able to hit nonzero elements of $H^n_\pi(\Gamma; Q^p)$ by pulling back elements of $H^n(\Gamma; M_p)$ for some module $M_p$, and thus find distortion in higher homotopy groups which is not weakly infinite. In fact, the Baumslag-Solitar group $BS(1, 2)$ is a counterexample: it is not hyperbolic, but has a classifying space of dimension 2, and $H^2(BS(1, 2); M_p) = 0$ for every finite-dimensional module $M_p$ corresponding to an elliptic representation. Thus the above dichotomy also holds for spaces $X$ with fundamental group $BS(1, 2)$.

Example 6.13 (Bounded cohomology classes). It is well known that bounded cohomology classes of groups are zero in $L_\infty$ cohomology: for example, this is Lemma 10.3 in [Ger92]. Thus bounded Euler classes always give rise to undistorted homotopy groups. However, the converse is not true: for example, let $e = [M^n \times S^1]$, where $M^n$ is any hyperbolic $n$-manifold. This fundamental class is not bounded, since geodesic simplices in $\mathbb{H}^n \times \mathbb{R}$ have volume proportional to their height in the $\mathbb{R}$-direction, rather than bounded volume. On the other hand, given a map $f : S^n \to \mathbb{H}^n \times \mathbb{R}$, we can deform $f$ slightly so that it is an immersion whose projection to the $\mathbb{R}$ factor is Morse. Then both the area of $f$ and the volume of a filling are determined by integrating hyperbolic areas and volumes over $\mathbb{R}$, and hence one is linear in the other. Thus for any bundle $S^n \to X \to M^n \times S^1$, $\pi_n(X)$ is undistorted.

7. Infinite and weakly infinite distortion

We now turn to the characterization of infinite distortion promised in Theorem C. As pointed out in the introduction, given a finite CW complex $X$, we can define a minimal cellular volume functional on the homology groups $H_n(X)$ of its universal cover. By Lemma 11.5 when $n \geq 3$, this extends the minimal volume functional on $\pi_n(X)$, and so we can consider the possibility that $\pi_n(X)$ is weakly infinitely distorted in $H_n(X)$. Later in the section we will also discuss the extent to which this implies infinite distortion.

The theorem that follows characterizes the extent to which the resulting subspace is weakly infinitely distorted if $X$ is a delicate space; it plays the role in the proof of Theorem C that Theorem B.7 played for Theorem B.

Theorem 7.1. Suppose $X \xrightarrow{\tilde{\rho}} B$ is a normal almost Postnikov pair with monodromy representation $\rho : \Gamma := \pi_1(B) \to GL(V_p)$ and Euler class $\text{eu} \in H^{n+1}(B; M_p)$. Assume also that $\pi_k(B) \otimes Q$ is finitely generated for $k \leq n$, so that we can find a sequence of finite complexes $F \to B \xrightarrow{\tilde{\rho}} A$ which is a rational homotopy fibration up to dimension $n$ and such that the universal cover $\tilde{A}$ is $n$-connected. Let $\tilde{F}$ be a rational homotopy fiber with finite $n$-skeleton of $p' \circ p : X \to A$. Then the following are equivalent:

1. There is no weakly infinite volume distortion in $V_p \subseteq \pi_n(X) \otimes Q$ as a subset of $H_n(X; Q)$.
2. For every $\gamma \in \Gamma$, $0 = \gamma^\ast \text{eu} \in H^{n+1}(U; M_p(\gamma))$, where $U$ is the total space of $\gamma^\ast p'$.  
3. $H_n(X; Q)$ splits as a direct sum of $Q\Gamma$-modules $h_n(V_p) \oplus P$.
4. For every $\gamma \in \Gamma, (\eta)^{-1}(A^{(1)}) : M_{p+1}$, where $\eta^1$ is the inclusion of the 1-skeleton $A^{(1)} \to A$.
5. In the Serre spectral sequence for $L_\infty$ cohomology, the Euler class $\text{eu} \in H^{n+1}(\tilde{X}; V_p)$ is represented by $0 \in E_2^{0,n} = H_c^{n+1}(\tilde{A}; H^n(F; V_p))$.

Example 7.2. Let $B = S^1 \times (S^3)^3$ and $X$ be an $S^9$-bundle over $B$ with Euler class $\text{eu} = [B] \in H^{10}(X; Q)$. Then the $\pi_8(X)$ is infinitely distorted, informally because arbitrarily long tubes have the same size boundary. To see this, consider the product CW structure on $B$ with one cell for each of the spheres, and fix a lift of the $n$-skeleton to $X$. Then the generator of $\pi_8(X)$ is homotopic to a lift of the attaching map of the 10-cell; in $\tilde{B}$, this attaching map induces the chain $(i + 1) \cdot a - i \cdot a$, where $a$ is the top-dimensional cell of $(S^3)^3$ and $i \in \mathbb{Z} \cong \pi_1(X)$. By Lemma 4.5, we can find an admissible map $f : S^9 \to \tilde{B}$ with $f_\#([S^9]) = k \cdot [(S^3)^3] - [(S^3)^3]$.
and thus volume 2. This map has filling class \( \text{Fill}(f) = k[B] \) and hence lifts to \( k \) times the generator of \( \pi_9(\tilde{X}) \).

This space \( X \) may also be thought of as a bundle over \( S^1 \) with fiber \( (S^3)^3 \times S^9 \). In this formulation it has nontrivial homological monodromy: \( H_0((S^3)^3 \times S^9; \mathbb{Q}) = \mathbb{Q}^2 \) and the generator \( 1 \in \pi_1(X) \) acts on it via the matrix \( \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \). Thus as a \( \mathbb{Q}[Z] \)-module, \( H_0((S^3)^3 \times S^9; \mathbb{Q}) \cong \mathbb{Q}[\mathbb{Z}]/(\begin{vmatrix} 1 \\ 1 \end{vmatrix}) \), which does not decompose as a direct sum. In other words, condition (3) of the theorem is also not satisfied. This also offers another way of understanding why the lift of the chain \( k \cdot [(S^3)^3] - [(S^3)^3] \) gives a nontrivial element of \( \pi_9(\tilde{X}) \).

**Proof.** We will repeatedly use the fact that since the almost Postnikov pair \( X \xrightarrow{p} B \) is normal, 

\[
H_n(\tilde{F}; \mathbb{Q}) = H_n(F; \mathbb{Q}) \oplus H_n(K(V_p, n); \mathbb{Q}).
\]

We first show that (1) implies (2), by demonstrating that volume distortion over \( S^1 \) is always weakly infinite when it is present. We do this by constructing a sequence of chains with small boundary whose pairing with the Euler class grows without bound. One example of such a chain is \( \text{Fill}(f) \) in Example 2.

Let \( H \) be a finite complex with \( \pi_1(H) = \mathbb{Z} \) such that \( \tilde{H} \) is rationally \( n \)-equivalent to a finite complex. Suppose that \( V \xrightarrow{p} H \) is a normal almost Postnikov pair with monodromy \( \rho : \mathbb{Z} \rightarrow GL(V_p) \) and Euler class \( 0 \neq \text{eu} \in H^{n+1}(U; M_p) \).

Without loss of generality, by taking a factor, we may assume \( M_p \cong \mathbb{Q}[\mathbb{Z}]/I \) with \( I \) a primary ideal. Indeed, since \( \rho \) is elliptic, \( I \) then must be a prime ideal, and thus \( M_p \) is a simple module. Let \( q(x) = \sum q_j x^j \) be the polynomial generating \( I \).

Since \( \mathbb{Q}[Z] \) is a PID, the universal coefficient theorem gives a short exact sequence

\[
0 \rightarrow \text{Ext}_{\mathbb{Q}[\mathbb{Z}]}(H_n(\tilde{U}; \mathbb{Q}), M_p) \rightarrow H^{n+1}(U; M_p) \rightarrow \text{Hom}_{\mathbb{Q}[\mathbb{Z}]}(H_{n+1}(\tilde{U}; \mathbb{Q}), M_p) \rightarrow 0.
\]

By assumption, the Euler class pulls back to \( 0 \in H^{n+1}(\tilde{U}; \mathbb{Q}) \), and thus it has a preimage in \( H^{n+1}(U; M_p) \). Note that \( H_n(\tilde{U}; \mathbb{Q}) = Z_n(\tilde{U}; \mathbb{Q})/B_n(\tilde{U}; \mathbb{Q}) \), both of which are free modules; thus one can find bases \( z_1, \ldots, z_m \) for \( Z_n \) and \( b_1, \ldots, b_m \) for \( B_n \) such that

\[
H_n(\tilde{U}; \mathbb{Q}) = \bigoplus_{i=1}^m \mathbb{Q}[\mathbb{Z}]z_i/\mathbb{Q}[\mathbb{Z}]b_i,
\]

where each of the summands is indecomposable. Then \( \text{Ext}_{\mathbb{Q}[\mathbb{Z}]}(H_n(\tilde{U}; \mathbb{Q}), M_p) \) takes the form

\[
\text{Ext}_{\mathbb{Q}[\mathbb{Z}]}(H_n(\tilde{U}; \mathbb{Q}), M_p) = \bigoplus_{i=1}^m \frac{\text{Hom}(\mathbb{Q}[\mathbb{Z}]b_i, M_p)}{\text{Hom}(\mathbb{Q}[\mathbb{Z}]z_i, M_p)} \cong \bigoplus_{i=1}^m 0 \text{ or } M_p/M_i,
\]

where \( M_i \subseteq M_p \) is the set of possible images of \( b_i \) under a homomorphism \( \mathbb{Q}[\mathbb{Z}]z_i \rightarrow M_p \). Since \( M_p \) is simple, each \( M_i \) is either 0 or \( M_p \). If \( \text{eu} \neq 0 \), then it takes a nonzero value in one of these summands. That is, there is some \( i \) such that \( b_i \mid \mathbb{Q}[\mathbb{Z}]z_i \), in particular there is a \( t \) such that \( \mathbb{Q}[\mathbb{Z}]z_i/\mathbb{Q}[\mathbb{Z}]b_i \cong \mathbb{Q}[\mathbb{Z}]/I^t \); and there is a nonzero \( \mu \in M_p \) such that any representative of \( \text{eu} \) takes any chain \( c \in C_{n+1}(\tilde{U}; \mathbb{Q}) \) with \( \partial c = b_i \) to \( \mu \).

Let \( t \) be the least positive integer such that \( q([1])^t z_i \) is a boundary; we may set \( b_i = q([1])^t z_i \). Let \( z = q([1])^t z_i \). Recall that \( M_p \) is \( r \)-dimensional. Then \( z, z \cdot [1], \ldots, z \cdot [r-1] \) descends to a basis for \( \mathbb{Q}[\mathbb{Z}]z/\mathbb{Q}[\mathbb{Z}]b_i \subseteq \mathbb{Q}[\mathbb{Z}]z_i/\mathbb{Q}[\mathbb{Z}]b_i \). Let \( S \) be the vector subspace of \( Z_n(\tilde{U}; \mathbb{Q}) \) generated by

\[
\bar{e}_1 = z, \bar{e}_2 = z \cdot [1], \ldots, \bar{e}_r = z \cdot [r-1],
\]

and let \( A_q : S \rightarrow S \) act on this basis via the companion matrix of \( q \). Thus \( \text{mod } \mathbb{Q}[\mathbb{Z}]b_i \), the action of \( A_q \) is the same as that of multiplication by \([1] \), and \( A_q \) is conjugate to \( \rho([-1]) \). Define a projection \( T : S[\mathbb{Z}] \rightarrow \mathbb{Q}[\mathbb{Z}] \) sending \( \bar{e}_j[j'] \mapsto [j+j'] \).
Now, let \( c \in C_{n+1}(\bar{U}; \mathbb{Q}) \) be a particular chain with \( \partial c = b_i \), and construct a sequence of chains \( (c_s)_{s \in \mathbb{N}} \in C_{n+1}(\bar{U}; \mathbb{Q}) \) by setting
\[
c_{s+1} = \sum_{j=0}^{s} T(A_q^j(\tilde{e}_1))[s-j])c.
\]
For every \( j \), \( T(A_q^j(\tilde{e}_1))[s-j]) \in I + [s-1] \), and thus \( \langle e_u, c_s \rangle = s\rho([1-s])(\mu) \). On the other hand, \( \partial c_{s+1} \) has bounded volume. To see this, note that for any \( s \geq r \), and for some \( \tilde{u}_j, \tilde{v}_j \in \mathbb{Q}' \) not depending on \( s \),
\[
\partial c_{s+1} = \sum_{j=0}^{s} T(A_q^j(\tilde{e}_1))[s-j])b_i = \sum_{j=0}^{s \deg q} qT(A_q^j(\tilde{e}_1))[s-j + \ell])z
\]
\[
= \sum_{j=0}^{s} T(q(A_q)A_q^j(\tilde{e}_1))[s-j])z + \sum_{j=0}^{r-1} T(A_q^s(\tilde{u}_j))[j])z
\]
\[
= : E(s + 1) + F(s + 1) + G(s + 1),
\]
where \( E(s), F(s), \) and \( G(s) \) are all cycles, but not necessarily boundaries, in \( \bar{U} \).

Now we analyze each of these cycles separately. For each \( s > r \), \( E(s) = 0 \) since by definition \( q(A_q) = 0 \), and \( G(s) \) has constant volume. Moreover, since \( A_q \) is elliptic,
\[
F(s) \in \langle T(z \cdot [j]) \rangle : 0 \leq j, j' < \deg q
\]
is a vector of bounded norm in a finite-dimensional vector subspace of \( Z_n(\bar{U}; \mathbb{Q}) \). Thus for any \( \omega \in C^n(\bar{U}; \mathbb{Q}') \) such that \( d\omega \) is a representative of \( e_u \), \( \langle \omega, F(s) \rangle \) is bounded as a function of \( s \), but \( \langle \omega, F(s) + G(s) \rangle = \langle e_u, c_s \rangle = s\rho([1-s])(\mu) \). Also, there is a constant \( K \) such that every \( KG(s) \) is integral.

So \( KG(s) \) is a sequence of integral \( n \)-cycles of bounded volume in \( \bar{U} \) which lift to elements of \( H_n(\bar{V}; \mathbb{Q}) \) which have norm increasing linearly in \( s \). This sequence is a bounded distance away from the sequence \( (KF(s) + KG(s)) \) whose terms are boundaries and therefore lift to \( h_n\pi_1((S^n)' \). Thus \( \pi_1\pi_n((S^n)') \) is weakly infinitely distorted.

\((2') \) is equivalent to \((2) \) more or less by definition. Similarly, it follows from the definition of the spectral sequence in Example 6.10 that \((2') \) is a restatement of \((2') \).

\((2') \Rightarrow (3) \). Write \( \iota_1^\gamma \mathbb{X} \) and \( \iota_1^\gamma \mathbb{B} \) for \( \rho^{-1}(A(1)) \) and \( (p')^{-1}(A(1)) \) respectively, and \( F_m \) for the finitely generated free group \( \pi_1(A(1)) \). Finally, write \( \iota_1^\gamma V_p \) for \( V_p \) seen as a \( \mathbb{Q}F_m \) module with the action \( \gamma \cdot v = \iota_1^\gamma \gamma \cdot v \) for \( \gamma \in F_m \).

Then it suffices to show that when \((2') \) holds, the short exact sequence of \( \mathbb{Q}F_m \)-modules
\[
0 \to \iota_1^\gamma V_p \xrightarrow{h} H_n(\iota_1^\gamma \mathbb{X}; \mathbb{Q}) \xrightarrow{h} H_n(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to 0
\]
splits, i.e. that there is a module homomorphism \( i : H_n(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to H_n(\iota_1^\gamma \mathbb{X}; \mathbb{Q}) \) such that \( p_\gamma \circ i = \text{id} \).

To prove \((3) \) from this, we tensor this sequence with \( \mathbb{Q} \Gamma \) as a \( \mathbb{Q}F_m \) module to obtain the sequence
\[
0 \to V_p \xrightarrow{\rho} H_n(\mathbb{X}; \mathbb{Q}) \xrightarrow{\rho} H_n(\mathbb{B}; \mathbb{Q}) \to 0,
\]

together with a splitting.

Suppose \( \iota_1^\gamma e_u = 0 \). Perhaps after taking a mapping cylinder so that \( \iota_1^\gamma \mathbb{X} \subset \iota_1^\gamma \mathbb{B} \), we can choose a lifting homomorphism \( j_n : C_{\leq n}(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to C_{\leq n}(\iota_1^\gamma \mathbb{X}; \mathbb{Q}) \), with a corresponding chain homotopy \( u_n \). In particular, \( j_n \) takes cycles to cycles. As before,
\[
id + u_n \partial : C_{n+1}(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to H_{n+1}(\iota_1^\gamma \mathbb{B}; \iota_1^\gamma \mathbb{X}; \mathbb{Q}) \to \iota_1^{\gamma} V_p
\]
defines a representative \( v \in C^{n+1}(\iota_1^\gamma \mathbb{B}; \iota_1^{\gamma} V_p) \) of the Euler class. We know that \( v = de \) for some \( n \)-cochain \( e \).

Then the chain map \( j_n - h_n \circ e : C_n(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to C_n(\iota_1^\gamma \mathbb{X}; \mathbb{Q}) \) induces a splitting homomorphism \( H_n(\iota_1^\gamma \mathbb{B}; \mathbb{Q}) \to H_n(\iota_1^\gamma \mathbb{X}; \mathbb{Q}) \) as desired.

A vector subspace of \( H_n(\mathbb{X}; \mathbb{Q}) \) is a \( \mathbb{Q}\Gamma \)-submodule if and only if it is \( \rho \)-invariant, and so \((3') \) is simply a restatement of \((3) \).

\((3') \Rightarrow (1) \). Suppose \((3') \) holds, and equip \( H_n(\mathbb{X}; \mathbb{Q}) \cong H_n(\mathbb{F}; \mathbb{Q}) \) with the seminorm which sends \( P \) to 0 and restricts to a \( \rho \)-invariant norm on \( V_p \). Note that \( \rho \) preserves this seminorm. Similarly to the proof in [Awp] that higher-order Dehn functions of groups are finite, we will show that when \((3') \) holds, the
homology classes of integral cycles of volume $k$ in $\tilde{X}$ have seminorm bounded by some $C(k)$. This is enough to show (1).

The proof is by induction on $k$. Clearly there is a $C(1)$, since there’s a finite number of $\Gamma$-equivalence classes of cycles of volume 1. Now suppose we have determined $C(i)$ for $1 \leq i < k$. Given an $n$-cycle $c$ in $\tilde{X}$ of volume $k$, assume that it contains a cell from a fundamental domain $D$. Since the action of $\Gamma$ preserves the seminorm, we can do this without loss of generality. Then either $c$ consists entirely of cells within distance $k$ of $D$ (in the graph defined by adjacency of cells, in the sense of having common $(n - 1)$-cells in their boundaries) or it consists of two disjoint cycles. There are a finite number of cycles of the first kind, since there are a finite number of such cells, and so the seminorm of their homology classes is bounded by some $B(k)$. Thus we can set $C(k) = \max\{B(k)\} \cup \{C(i) + C(k - i) : 0 < i < k\}$. □

Proof of Theorem [4] We have already shown that if a finite CW complex $X$ has no infinite distortion in its homotopy groups, then conditions (1) and (2) of Theorem [4] are satisfied. In particular, we can find a tower of maps

$$X = X_m \to X_{m-1} \to \cdots \to X_0$$

where each $X_i$ is a finite complex which is rationally equivalent up to a large dimension $N$ to $X_{(n_i)}$, and where each step $X_k \to X_{k-1}$ is a normal almost Postnikov pair. By Theorem [7], $\pi_{n_k}(X_k)$ does not have weakly infinite distortion if and only if $H_{n_k}(\tilde{X}_k; \mathbb{Q})$ splits as a $\mathbb{Q}\pi_1 X$-module into the image of the Hurewicz map and its complement. Since $X_k$ is rationally equivalent to $X$ up to dimension $k + 1$, this is also the case for $\pi_{n_k}(X)$. Thus if $X$ is a delicate space, then the lack of weakly infinite distortion in its homotopy groups is equivalent to condition (3) of Theorem [4].

Note, however, that weakly infinite distortion inside the homotopy group does not imply that $\pi_n$ is actually infinitely distorted. As an example, it is sufficient to construct a space $X$ whose homological monodromy behaves as in Example [3,1,13]. That is, we want $\pi_1 X = \mathbb{Z}$ and $M := H_n(\tilde{X}; \mathbb{Q})$ to be a module which is isomorphic to $\mathbb{Q}^4$ as a vector space, with the fundamental group acting by the matrix $\tilde{A} = \begin{pmatrix} A & 0 \\ I & A \end{pmatrix}$, where $A = \begin{pmatrix} 3/5 & -4/5 \\ 4/5 & 3/5 \end{pmatrix}$. Moreover, we want the homotopy submodule $h_n \pi_n(\tilde{X}) \otimes \mathbb{Q}$ to be generated by the last two basis vectors. Then the argument of Example [3,1,13] will show that $\pi_n(X)$ is weakly infinitely but not infinitely distorted. Actually, it is enough to find a space $X$ such that $H_n(\tilde{X}; \mathbb{Q})$ has a copy of $M$ containing the homotopy submodule as a direct summand.

We build such a space $X$ as follows. Let $B$ be the “mapping torus” (in the sense of Section 3) of $(S^3)^4$ corresponding to the matrix $A = \begin{pmatrix} A^3 & 0 \\ 0 & I \end{pmatrix}$ acting on the four spheres. Then the monodromy of $H_0(\tilde{B}; \mathbb{Q}) \cong \bigwedge^3 H_3(\tilde{B}; \mathbb{Q})$ with respect to the action of $\pi_1$ is given by $\tilde{A}^{3\gamma}$; a computation shows that in the basis given by the Poincaré duals of the four spheres, $\tilde{A}^{3\gamma} = \begin{pmatrix} A & 0 \\ 0 & I \end{pmatrix}$. So let $X$ be the total space of a rational $(S^9)^2$-bundle over $B$ which has the monodromy representation $\rho : \mathbb{Z} \to GL(2, \mathbb{Q})$ which takes the generator to $A$, and Euler class

$$0 \neq \epsilonu \in H^{10}(B; M_\rho) \cong \text{Ext}_{\mathbb{Q}[\mathbb{Z}]}(M_\rho \oplus \mathbb{Q} \oplus \mathbb{Q}, M_\rho) \cong M_\rho.$$ 

By the argument in Example [7,2], $H_n(\tilde{X}; \mathbb{Q}) \cong M \oplus \mathbb{Q} \oplus \mathbb{Q}$.

On the other hand, suppose that we take an almost Postnikov pair $X \to B$ with $\pi_1 X = \pi_1 B = \Gamma$, with monodromy representation $\rho$ and Euler class $\epsilonu$, such that for some $\gamma \in \Gamma$, $\gamma^* \epsilonu$ is nontrivial when restricted to a direct summand $\mathbb{Q} \cong L \subseteq M_\gamma M_\rho$ (a module over $\mathbb{Q}[\mathbb{Z}]$) on which the action of $\gamma$ is trivial. Then it is in fact possible to find true infinite distortion via the method of Example [7,2].

In the case when $\rho$ is trivial, this is equivalent to condition (2) of Theorem [7,1] and hence is a necessary condition for finding infinite distortion. We conjecture that this is the case in general.

Conjecture. The condition stated above is equivalent to the presence of infinite distortion in $\pi_n(X)$.

The following theorem shows that this is true in the case $\pi_1(X) = \mathbb{Z}$. In other words, a counterexample to this conjecture must have infinite distortion which is in some sense “non-local”, that is, it would have
to rely on the interaction of weakly infinite distortions induced by the homological monodromy of multiple elements of \( \pi_1(X) \). However, because the algebra and geometry of a general fundamental group can make themselves relevant, this realization still leaves us quite far from a proof of the conjecture.

**Theorem 7.3.** Suppose \( V \xrightarrow{\rho} U \) is an almost Postnikov pair such that \( U \) is the total space of a rational homotopy fibration \( F \rightarrow U \rightarrow S^1 \). Let \( \rho : \mathbb{Z} \rightarrow GL(V_p) \) be its elliptic monodromy and \( \varphi^* : H^{n+1}(U; \mathbb{M}_p) \) be the Euler class. Then the following are equivalent:

1. There is infinite volume distortion in \( V_p \) as a subset of \( H_n(V; \mathbb{Q}) \).
2. There is a finite-sheeted cover \( \varphi : \hat{U} \rightarrow U \) such that \( \varphi^* M_\rho \) has a trivial submodule \( L \cong \mathbb{Q} \) for which the projection of \( \varphi^* \mathbb{M}_p \) in \( H^{n+1}(\hat{U}; \varphi^* \mathbb{M}_p) \) onto \( L \) is nonzero.

**Proof.** To show that (2)\( \Rightarrow \) (1), note that \( H_{n+1}(\hat{U}; \varphi^* M_\rho) \) has a submodule of the form in Example [\ref{example:module}]. Therefore, we can construct a sequence of \((n+1)\)-chains as in that example.

Now suppose that (2) is not true, and choose a simple direct summand \( M \) of \( M_\rho \) with projection map \( p_M : M_\rho \rightarrow M \) and dimension \( d = \dim M \). Since any elliptic element of \( GL(m, \mathbb{Z}) \) is of finite order, the transformation \( p_M \circ \rho(1) \) does not conjugate into \( GL(m, \mathbb{Z}) \). Let \( A \) be the \( d \times d \) matrix of \( p_M \circ \rho(1) \) in some basis.

To show that \( M \) is not infinitely distorted, we will reproduce in greater generality the argument in the example given above. Let \( \hat{\rho} : \mathbb{Z} \rightarrow GL(H_n(\hat{F}; \mathbb{Q})) \) be the homological monodromy of the total fibration \( \hat{F} \rightarrow \hat{V} \rightarrow S^1 \), and let \( M \) be the smallest direct summand of the module \( H_n(\hat{F}; \mathbb{Q}) \) which contains \( M \). Then we can find a basis for \( \hat{M} \) such that the action of \( \rho(1) \) on \( \hat{M} \) is given in this basis by a matrix which consists of generalized Jordan blocks of the form

\[
\hat{A}_i = \begin{pmatrix}
A & 0 & \cdots & 0 \\
I & A & \ddots & \\
\vdots & \ddots & \ddots & 0 \\
0 & \cdots & I & A
\end{pmatrix},
\]

each acting on an \( r_i d \)-dimensional submodule \( \hat{M}_i \). In this formulation, we can write \( M = \sum_i t_i M_i \), where the \( t_i \) are fixed constants and the \( M_i \) are the modules isomorphic to \( M \) generated by the last \( d \) coordinates of each \( \hat{M}_i \). It is enough for our purposes to show that each \( M_i \) is only finitely distorted inside \( \hat{M}_i \); the next two paragraphs make this idea more precise.

Perhaps after taking a mapping cylinder so that \( V \subset U \), we can choose a lifting homomorphism \( j_n : C_{\leq n}(\hat{U}; \mathbb{Q}) \rightarrow C_{\leq n}(\hat{V}; \mathbb{Q}) \). In particular, \( j_n \) takes cycles to cycles and induces a surjective homomorphism \( J : Z_n(\hat{U}; \mathbb{Q}) \rightarrow \hat{M} \subset H_n(\hat{V}; \mathbb{Q}) \). Note also that \( J \) takes boundaries into \( M \).

Consider a fundamental domain \( B \subset \hat{U} \) large enough that chains contained in \( B \) generate \( C_n(\hat{U}; \mathbb{Q}) \) as a \( \mathbb{Q}[\mathbb{Z}] \)-module. Fix a norm \( \| \cdot \| \) on \( M \) which is invariant under the action of \( \pi_1 U \). We want to show that \( M \subset \pi_1(V) \) is not infinitely distorted, i.e. that there is a function \( L : \mathbb{N} \rightarrow \mathbb{N} \) such that for every \( k \) and every integral boundary \( b \in B(\hat{U}) \) with \( \| J(b) \| \leq L(k) \). In fact, it is enough to show that for each \( i \), vectors of the form

\[
\hat{u} = \hat{A}^k p_i J(z_0) + \hat{A}^{k_1} p_i J(z_1) + \cdots + \hat{A}^{k_r} p_i J(z_k) \in M_i \subset \hat{M}_i,
\]

where \( p_i : H_n(\hat{V}; \mathbb{Q}) \rightarrow \hat{M}_i \) is a projection map and each \( z_j \in C_n(B) \) is an integral cycle of size at most \( k \), have norm bounded as a function of \( k \).

This last condition implies that the vectors \( \hat{u}_j = p_i J(z_j) \) are of size linear in \( k \) in some lattice \( \hat{A} \subset \hat{M}_i \), and so this is now purely a linear algebra problem similar, but not identical, to Lemma [\ref{lemma:linear-algebra}]. We solve it by induction on \( k \) and the number \( r \) of Jordan blocks in \( \hat{A}_i \).

When \( r = 1 \), then \( \hat{A}_i = A \) preserves the norm, and so \( \| \hat{u} \| \leq C k^2 \) for some constant \( C \).

When \( k = 0 \), then \( \hat{u} = \hat{A}^0 \hat{u}_0 \) and \( \hat{u}_0 \in M_0 \) is one of a finite number of vectors, and once again \( \hat{A}_i \) preserves the norm of such a vector, so \( \| \hat{u} \| \leq C \) for some constant \( C \). This completes the base case.

Now fix \( r \geq 2 \) and \( k \geq 2 \), and suppose we have a bound \( L_r(k') \) for every \( k' < k \). We will show that there is a bound \( L_r(k) \). Note that we can assume that the \( t_j \) are increasing and \( t_0 = 0 \), since multiplying by \( \hat{A}_i^t \) doesn’t change the length of a vector in \( M_i \). Moreover, since the \( M_i \)-coordinates of the \( \hat{u}_j \) only change \( \| \hat{u} \| \) by a linear amount, we can assume that they are zero.

46
Now, let \( p_{r-1} : \tilde{M}_i \to \tilde{M}_i \) be the projection onto the first \( (r-1)d \) coordinates. By assumption, \( p_{r-1} \tilde{u} = \tilde{0} \), and therefore either (1) \( \sum_{i=0}^{\ell} \tilde{A}_i^j \tilde{u}_j \neq \tilde{0} \) for every \( \ell < k \), or (2) we know that \( \|u\| \leq L_r(k_1) + L_r(k_2) \) for some \( k_1 + k_2 = k \).

**Lemma 7.4.** In case (1), for every \( 1 \leq \ell \leq k \), \( t_k \leq kf_r(k) \), where \( f_r(k) \sim \log k \) is a function depending on \( A \) and \( r \).

**Proof.** Given \( \ell \), let \( 1 \leq s \leq r-1 \) be the index of the first \( d \)-dimensional block such that the coordinates of

\[
\sum_{j=0}^{\ell-1} p_{r-1} \tilde{A}_i^j \tilde{u}_j = -\sum_{j=\ell}^k p_{r-1} \tilde{A}_i^j \tilde{u}_j
\]

in that block are nonzero, and let \( \tilde{v} \in \mathbb{Q}^d \) be the coordinates of this vector in the \( s \)th block. Then we can write

\[
\tilde{v} = \sum_{j=0}^{\ell-1} \sum_{a=0}^{s-1} P_{a,s}(t_j) A^{t_j-a} \tilde{u}_j,a \cap \sum_{j=\ell}^k \sum_{a=0}^{s-1} P_{a,s}(t_j) A^{t_j-a} \tilde{u}_j,a,
\]

where \( \tilde{u}_j,a \) is the projection of \( \tilde{u}_j \) to the \( a \)th block and \( P_{a,s} \) is a polynomial of degree \( s - a \). In particular, \( \|\tilde{u}_j,a\| \leq k \) and \( \tilde{u}_j,a \in \Lambda \), the lattice generated by the projections of \( \Lambda \) to each block. Applying Lemma A.1 and maximizing over \( s \), we see that for large \( k \),

\[
t_k \leq k\left[f\left(\|P_{1,r-1}(t_k)\| \cdot (r-1)k\right) + r - 2\right]
\]

where \( f \) is logarithmic. This forces \( t_k \lesssim k \log k \). \( \square \)

In case (1), this means that there is a finite number of choices for the vector \( \tilde{u} \), and so they are bounded by some \( L'_r(k) \). Thus we can set

\[
L_r(k) = \max\{L'_r(k), L_r(k-1) + L_r(1), L_r(k-2) + L_r(2), \ldots\}.
\]

Having shown this for every factor \( M \), we see that (1) does not hold. \( \square \)

**Appendix A. A number-theoretic lemma**

The following lemma is crucial for proving that certain kinds of twisting preclude distortion from monodromy from being infinite. Because it is somewhat technical and requires tools which have little to do with the rest of the paper, we have sequestered it here.

**Lemma A.1.** Let \( A \) be an irreducible \( n \times n \) matrix over \( \mathbb{Q} \) which is of infinite order, diagonalizable over \( \mathbb{C} \), and all of whose eigenvalues are on the unit circle, and let \( \Lambda \subset \mathbb{Q}^n \) be a lattice. Then there is a function \( f(V) = a + b \log V \), where \( a \) and \( b \) depend on \( A \) and \( \Lambda \), such that if for some \( k \) and \( \ell \) and vectors \( \tilde{u} \in \Lambda \) with \( \sum_{i=1}^{\ell} \|\tilde{u}_i\| \leq V \),

\[
\tilde{v}_1 + \tilde{v}_2 := \sum_{i=0}^{k} A^i \tilde{u}_i + \sum_{i=k+m}^{\ell} A^i \tilde{u}_i = \tilde{0},
\]

then either \( m \leq f(V) \) or \( \tilde{v}_1 = \tilde{v}_2 = \tilde{0} \).

We start with the following observation. Consider the matrix \( A = \begin{pmatrix} 3/5 & -4/5 \\ 4/5 & 3/5 \end{pmatrix} \), which represents multiplication in \( \mathbb{C} \) by \( \frac{3+4i}{5} \). Then if \( P \) is an integer polynomial, we can think of \( P(A)\tilde{v} \) as the complex number \( P \left( \frac{3+4i}{5} \right) \cdot (v_1 + v_2i) \). Then

\[
A \begin{pmatrix} 2 \\ -1 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix};
\]

this is directly related to the fact that this eigenvalue can be expressed as

\[
\frac{3 + 4i}{5} = \frac{2 + i}{2 - i}.
\]
which is a ratio of relatively prime Gaussian integers. Because the Gaussian integers are a UFD, if \( P \) has only high-degree terms but \( P \left( \frac{2+i}{2-i} \right) \) is a Gaussian integer, then coefficients of \( P \) must contain large powers of \( 2 - i \), forcing them to be large in absolute value.

The proof which follows generalizes this observation.

**Proof.** We can find a single vector \( \vec{w} \in \mathbb{Q}^n \) such that the lattice generated by \( \vec{w}, A\vec{w}, \ldots, A^{n-1}\vec{w} \) contains \( \Lambda \). In other words, every vector \( \lambda \in \Lambda \) can be expressed as \( P(\vec{A})\vec{w} \) for some integer polynomial \( P \) of degree \( n - 1 \). Therefore we can reexpress the given sum as \( (P(\vec{A}) + P(\vec{A}))\vec{w}, \) where \( P_1 \) and \( P_2 \) are integer polynomials whose non-zero terms \( p_i \) are in degrees \( 0 \) through \( k + n - 1 \) and degrees \( k + m \) through \( \ell \), respectively. Moreover, since \( A \) is irreducible and \( P_1(\vec{A}) + P_2(\vec{A}) \) does not have full rank, \( P_1(\vec{A}) + P_2(\vec{A}) = 0 \), and therefore, as polynomials, \( P_1(x) + P_2(x) = Q(x)\chi(x) \) where \( \chi \) is the characteristic polynomial of \( A \). We will show that if \( m \) is large enough, then \( Q \) must break into two polynomials \( Q_1 \) and \( Q_2 \) such that \( Q_1\chi = P_1 \) and \( Q_2\chi = P_2 \). This then implies that \( P_1(\vec{A}) = P_2(\vec{A}) = 0 \).

Note that since \( A \) is of infinite order, the roots of \( \chi \) are not algebraic integers; let \( r \in \mathbb{C} \) be one such root. Let \( K \) be the splitting field of \( \chi \) and \( \mathcal{O}_K \) its ring of integers. We can express \( r \) as the ratio of algebraic integers; suppose first that we can make these relatively prime, \( r = p/q \). Then we have

\[
P_1\left(\frac{p}{q}\right) \cdot q^{k+n-1} = -P_2\left(\frac{p}{q}\right) \cdot q^{k+n-1}.
\]

Here, the term on the left is evidently an algebraic integer. Because \( p \) and \( q \) are relatively prime, the right side demonstrates that this integer must be divisible by \( p^{k+m} \). Therefore, either \( P_1\left(\frac{p}{q}\right) = 0 \) or

\[
|P_1\left(\frac{p}{q}\right)| \cdot |q|^{k+n-1} \geq |p|^{k+f(V)}.
\]

Since \( |p| = |q| \), this would mean that \( V \geq |p|^{m-n+1} \). So whenever \( m > n - 1 + \log_p V \), \( P_1 \) must be divisible by \( \chi \). In other words, we can set

\[
f(V) = n - 1 + \log_p V.
\]

Since \( \mathcal{O}_K \) may not have unique factorization, we may not be able to set \( r = p/q \) with the \( p \) and \( q \) relatively prime. However, the ideal class group of \( \mathcal{O}_K \) is finite, meaning that every ideal has a power which is principal. Therefore, if we express \( r \) as the ratio of algebraic integers \( p/q \), there is some \( t \) such that the ideals \( (p^t) \) and \( (q^t) \) are products of principal primary ideals. This means that we can express \( r^t \) as the quotient of relatively prime algebraic integers \( p^t/q^t \). Then we can repeat the argument above to get

\[
f(V) = t(n - 1 + \log_p V),
\]

completing the proof. \( \square \)
