## 11 *Abstract*

12 The  $M_w$ 6.4 and  $M_w$ 7.1 Ridgecrest, California, earthquakes of July 2019 occurred within 34 hours  
13 of each other on conjugate strike-slip faults in the Mojave Desert, just north of the central  
14 Garlock Fault. Here we present the results of a survey of 18 Global Navigation Satellite Systems  
15 (GNSS) sites conducted in the immediate aftermath of the earthquakes, including five sites  
16 which recorded the motion of the second earthquake, after having been set up immediately  
17 following the first, as well as processed results from continuous GNSS sites throughout the  
18 region. Our field work in response to the earthquakes provides additional constraints on the  
19 ground displacement due to both earthquakes, complementing data from a spatially sparser  
20 network of continuously recording GNSS sites in the area, as well as temporally sparser  
21 Interferometric Synthetic Aperture Radar (InSAR) data that were able to capture a combined  
22 deformation signal from the two earthquakes.

## 23 *1. Introduction*

24 The pair of large earthquakes near Ridgecrest, California, in July 2019—an  $M_w$ 6.4 event on July  
25 4th and an  $M_w$ 7.1 event on July 5th, local time (July 6th, Universal Time)—occurred 34 hours  
26 apart in a region with a number of geodetic monuments with many years of archived Global

27 Navigation Satellite Systems (GNSS), specifically Global Positioning System (GPS), survey data.  
28 The earthquakes occurred on conjugate faults in a region of active deformation and seismicity in  
29 the Eastern California Shear zone, and in proximity to the Coso geothermal field and to the  
30 Garlock Fault, both of which had been targets for study in these earlier GNSS surveys, in the  
31 1990s and early 2000s (e.g., McClusky et al., 2001; Miller et al., 2001a; Figure 1; Table 1).

32 In more recent years, some of these survey sites were reoccupied with GNSS equipment,  
33 in order to improve uncertainties of the secular velocities at those sites (e.g., Funning et al.,  
34 2019a). These recent surveys, and the knowledge gained from them, facilitated a rapid response  
35 to the first Ridgecrest earthquake (and therefore to the second earthquake as well), enabling the  
36 separation of the coseismic displacements of the two events. Additional, and ongoing, survey  
37 measurements made in the days following the second,  $M_w7.1$  earthquake will enable the study  
38 of postseismic deformation due to the Ridgecrest events. When combined with data from  
39 continuous GNSS stations in the region, from the Network of the Americas (NOTA) operated as  
40 part of the Geodesy Advancing Geoscience and EarthScope (GAGE) facility at UNAVCO, as  
41 well as stations operated by the United States Geological Survey (USGS), they provide a  
42 detailed picture of the Ridgecrest events and their aftermath. In contrast to Interferometric  
43 Synthetic Aperture Radar (InSAR) measurements of the coseismic displacements, which can  
44 only constrain the total displacement from the two earthquakes and the first few days of  
45 postseismic response (e.g., Fielding et al., 2019; Wang and Bürgmann, 2019; Xu and Sandwell,  
46 2019), the available GNSS data can measure coseismic displacements due to the  $M_w6.4$  and  
47  $M_w7.1$  events individually, as well as separate coseismic signals from any postseismic  
48 deformation. As such, they provide a useful resource for researchers interested in constraining  
49 models of coseismic slip or postseismic response, in addition to providing a foundation for  
50 potential future investigations regarding fault interactions and stress transfer.

51 In this study, we describe the archived survey data sets from the region, the survey  
52 response to the Ridgecrest earthquakes, and present a new, combined solution from both  
53 survey and continuous GNSS sites for the displacements during the Ridgecrest earthquakes.

54 2. Previous surveys and velocity solutions

55 Surveys throughout the Mojave Desert in the region of the Garlock Fault were conducted  
56 mostly in the 1990s and early 2000s (see Table 1). These focused on two aspects of the region,  
57 the relative motion of faults, including the Garlock Fault, throughout the Eastern California  
58 Shear Zone (ECSZ) from the California-Nevada state line in the northeast to the San Andreas  
59 Fault in the southwest, and the deformation of the Coso geothermal field where the geothermal  
60 energy production is associated with subsidence at a rate of a few centimeters per year (e.g.,  
61 Fialko and Simons, 2000; Tymofyeyeva and Fialko, 2015). The GNSS survey results related to  
62 the former were presented by Miller et al. (2001) and McClusky et al. (2001). The latter study  
63 inferred a strike-slip motion across the Airport Lake Fault (the previously-mapped fault most  
64 closely, although not exactly, associated with the  $M_w$ 7.1 Ridgecrest earthquake) to be  $5.7 \pm 0.7$   
65 mm/yr. Shen et al. (2011) presented a rigorous reprocessing and combination of surveys  
66 throughout California for the Southern California Earthquake Center (SCEC) Crustal Motion  
67 Map (CMM) (Figure 1; blue vectors and circles). The region also contains a network of  
68 continuously operating sites (Figure 1; red vectors and circles), which are processed routinely  
69 and derived products such as velocity solutions are generated and available publicly from  
70 UNAVCO. The continuous velocity solution shown in Figure 1 is that of Herring et al. (2018a).

71 The profile shown in Figure 1b across this latest velocity solution shows a similar  
72 velocity gradient across the region, although we do not model it explicitly using elastic  
73 dislocations here to update the model of McClusky et al. (2001).

74 In more recent years, a group from the University of California, Riverside (UCR)  
75 conducted a survey in 2014 which mostly covered the southern and eastern Mojave Desert, but  
76 also measured a couple of sites (HAW0 and LNWD) further north in the Mojave, to the  
77 southwest of the July 2019 earthquakes (Funning, 2016). In addition to site occupations, the  
78 group conducted extensive site reconnaissance, that was leveraged for later visits.

79 The most recent pre-earthquake surveys were conducted in February and March 2019,  
80 again by a group from UCR. As part of a project funded by SCEC to update deformation  
81 velocities in the Mojave desert region, 21 sites were occupied for durations of between 17 and 26  
82 hours each (Figure S1), including a transect of the Garlock Fault southwest of Ridgecrest.

83 3. Survey response to the July 2019 earthquakes

84 A field team from UCR responded promptly to the July 4th event, arriving in the field in the  
85 afternoon. On the afternoon of July 4th and morning of July 5th, we occupied four sites to the  
86 west and southwest of the epicenter (H701, J701, F048 and ATOL) that had previously been  
87 measured in February 2019, as well as one site to the south (PNCL) that had been measured in  
88 2001. The first of these measurements were started within seven hours of the  $M_w6.4$  earthquake,  
89 with all five sites operating within 30 km of the rupture within 26 hours (see Figure S2). All five  
90 remained standing and running during and after the second,  $M_w7.1$  earthquake that occurred 34  
91 hours after the  $M_w6.4$ , providing a unique, near-field constraint on the deformation from each  
92 event separately; as we will show below, site PNCL, fortuitously located only 600 m from the  
93 surface rupture of the  $M_w7.1$  event, detected the highest displacements—over 80 cm of  
94 horizontal displacement in the  $M_w7.1$  earthquake.

95 In the days that followed the two events, multiple additional sites were occupied in the  
96 epicentral region by groups from Scripps Institute of Oceanography (SIO), the University of  
97 Nevada, Reno (UNR) and the USGS, as well as by UCR. Coordination between these groups  
98 enabled an efficient field response, maximizing coverage while minimizing duplication of  
99 effort. Given the difficulties of obtaining access to the Navy Air Weapons Station (NAWS)  
100 China Lake (see Figure 1), within which the majority of the surface ruptures occurred, the effort  
101 from UCR, SIO and UNR focused on the area outside of the NAWS, leaving the responsibility of  
102 occupying sites within the NAWS to the USGS (Brooks et al., 2019). By the end of July 9th, local  
103 time, 19 survey sites had been occupied by UCR (yellow triangles in Figures 2, 3 and 4), SIO  
104 (green triangles in Figure 3 and 4) and UNR combined, and a further 13 sites, including 8  
105 stations forming 4 cross-fault arrays targeted at detecting shallow afterslip, had been installed  
106 by the USGS (Brooks et al., 2019). Some of the monuments are metal rods cemented in  
107 competent rocks, occupied with a GNSS antenna mounted on a tripod, while others involve a  
108 concrete block with a threaded metal rod on which an antenna could be attached directly,  
109 without the need for a tripod (see Figure S3 for several examples). Each of the survey sites  
110 recorded data at a standard low rate (e.g., 15 or 30 seconds) for daily processing, using an  
111 Ashtech Z-12, Septentrio PolaRx5, Topcon GB-1000 or Trimble R7, NetRS or NetR9 receiver

112 with an Ashtech Choke Ring, Topcon PG-A1 or Trimble Geodetic L1/L2 Compact, Zephyr  
113 Geodetic or Zephyr Geodetic 2 antenna.

114 With additional deployments in the days and weeks that followed, by September 7th 27  
115 sites had been occupied by UCR, SIO and UNR, and a further 16 by the USGS, the majority of  
116 these in a “semi-continuous” mode (e.g., Blewitt et al., 2009), whereby the stations are powered  
117 to run for weeks at a time, and infrequently serviced to retrieve data, check the centering of  
118 antennas, and perform maintenance. The majority of these semi-continuous stations will be  
119 operated into 2020, in order to capture details of any postseismic transient motion following the  
120 earthquakes. High-rate data during the earthquakes themselves is available for most of the  
121 continuous sites in the region operated by UNAVCO (Mattioli et al., 2019, UNAVCO  
122 Community, 2019).

#### 123 *4. GNSS processing*

124 The solutions were processed using a pre-release version of GAMIT/GLOBK 10.71 (update of  
125 Herring et al., 2018b). The results of the surveys were then combined with processed solutions  
126 for continuous sites from the Network of the Americas (NOTA) within the surrounding region.  
127 These solutions differ slightly from the official GAGE solutions in that they were split on the  
128 days of the earthquakes to avoid artifacts in the time series, where the usual 00:00 GPST (GPS  
129 Time) to 00:00 GPST processing day straddles a major displacement, resulting in a time series  
130 points which “hangs” at a weighted average between the positions before and after the  
131 earthquake on the day of the event itself.

132 The data from the continuously running GNSS receivers in the region were processed  
133 for the period between July 2nd (day 183) and July 9th (day 190), 2019, in nominally 24-hour  
134 sessions. On the days of the earthquakes, the 24-hour sessions were divided into two sessions.  
135 The first session ran from 00:00 GPST to the minute before the earthquake on that day and the  
136 second session started 5 minutes after the earthquake origin time and finished at 23:59:30 GPST.  
137 The processing was carried out in eight sub-networks each containing 66 to 67 stations. The 507  
138 stations processed spanned a region about twice the diameter of the area likely to have  
139 undergone more than 1 mm of the coseismic displacement from the July 6th  $M_w$ 7.1 event. The

140 satellite orbits were fixed to the International GNSS Service (IGS) global orbits. The division of  
141 the networks and the processing of the data followed that same approach described for the  
142 GAMIT processing in Herring et al. (2016). The realization of the reference frame was the same  
143 as that described in Herring et al. (2016) but the newer North America 2014 (NAM14) was used.  
144 The positions, velocities and reference frame sites for NAM14 are available from UNAVCO  
145 ([ftp://data-out.unavco.org/pub/products/velocity/pbo.final\\_nam14.vel](ftp://data-out.unavco.org/pub/products/velocity/pbo.final_nam14.vel)).

146 The data from the survey sites (five yellow triangles in Figures 2–4) were set up from  
147 July 5th (day 186) onwards (see Figure S2), therefore capturing the second earthquake. The sites  
148 were processed in one session for the 27 hours between their deployment and the second  
149 earthquake at 03:12 UTC on 2019-07-06 (day 187), for the 21 hours remaining after the  
150 earthquake on 2019-07-06, and for standard 24-hour UTC-day sessions thereafter. These results  
151 were then combined with the similarly-arranged sessions from the processing of continuous  
152 sites.

153 Four of the survey sites had been measured previously during the February and March  
154 2019 surveys (Funning et al., 2019a; see Section 2) but did not have enough previous data to  
155 determine a velocity before the earthquake. We therefore assumed, in the four to five months  
156 between their first observation and the first earthquake (Funning et al., 2019b), motion  
157 consistent with a velocity constrained to within 0.5 mm/yr of nearby continuous site RAMT for  
158 survey site ATOL; of the mean velocity of nearby continuous sites CCCC and P616, whose  
159 velocities are within 1 mm/yr of each other, for survey sites F048, H701 and J701; and of the  
160 mean velocity of nearby continuous sites CCCC, P580 and P595 for survey site PNCL. This  
161 allowed us to estimate displacements at these sites during the first earthquake also.  
162 Furthermore, we similarly constrained the pre-earthquake velocity for a few survey sites with  
163 imprecise estimates due to short or few previous observations: 0806 was constrained in the  
164 same way as ATOL, above; survey site INYO in the same way as F048, H701 and J701, above;  
165 and V511 to the velocity of nearby survey site BM25. This allowed us to estimate cumulative  
166 displacements at these sites due to both earthquakes combined, having been observed again  
167 only after the second earthquake.

168 We processed all data from previous surveys that contained data from sites occupied in  
169 the aftermath of the earthquakes (see Table S1). We also include the results from McClusky et al.  
170 (2001) by incorporating their full solution and associated covariance matrix during combination  
171 of the survey and one-week continuous results.

## 172 5. Results

173 Figures 2, 3 and 4 show the estimated displacements after combination of the continuous and  
174 survey solutions described in Section 4, above, for the first  $M_w$ 6.4 earthquake, the second  $M_w$ 7.1  
175 earthquake and the two earthquakes combined, respectively. Unfortunately, many of the sites  
176 occupied immediately after the earthquakes (triangles in Figures 3 and 4) do not have sufficient  
177 data beforehand to allow reasonable estimation of coseismic displacements from prior  
178 observations alone. Many of them were last measured briefly around the time of the 1999  
179 Hector Mine earthquake, and therefore are subject not only a long period (20 years) of no  
180 observations but also short, segmented time series and perturbed tectonic velocities, both  
181 leading to poorly constrained pre-earthquake velocities. Nevertheless, we explain our approach  
182 to constraining their pre-earthquake velocities, and therefore coseismic displacements, in  
183 Section 4, above.

184 Four survey sites to the west and south of the first,  $M_w$ 6.4 earthquake help constrain the  
185 displacements in a region where only two nearby continuous sites otherwise exist in the near-  
186 field (Figure 3). The same four survey sites help constrain the southern west side of the second,  
187  $M_w$ 7.1 earthquake, as well as PNCL at the very southern end of the rupture.

188 The displacements for the  $M_w$ 6.4 earthquake (Figure 2) are consistent with a  
189 predominantly left-lateral rupture, as we observed in the immediate aftermath of the  
190 earthquake. The closest sites to the rupture show displacements of 3 cm and 11 cm (at H701 and  
191 P595, respectively) that are oriented oblique to the strike of the fault, a consequence of their  
192 locations beyond the ends of the rupture, and in keeping with the expected deformation pattern  
193 for a finite left-lateral strike-slip fault. For the  $M_w$ 7.1 earthquake (Figure 3), we observe a clear  
194 right-lateral displacement pattern overall, consistent with the north-west strike of the mapped  
195 ruptures in the area, with fault-parallel displacements at sites located within a zone

196 perpendicular to the major surface rupture and rotation of the displacement vectors at sites  
197 beyond the ends of the rupture. The largest recorded displacements of approximately 80 cm are  
198 at survey site PNCL, with a trend that is subparallel to the local fault strike.

## 199 *6. Summary*

200 We present a coseismic displacement solution for combined continuous and survey GNSS, for  
201 both the  $M_w$ 6.4 and  $M_w$ 7.1 July 2019 Ridgecrest earthquakes separately and combined. To obtain  
202 these results, we reprocessed previous surveys from the 1990s and 2000s, as well as presenting  
203 more recent surveys from February and March 2019 to the west and south of the Ridgecrest  
204 ruptures. These results help to constrain particularly the separate ground displacements, as well  
205 as eventually the continuing post-earthquake motions, if any, after more observations continue  
206 to be made at the same GNSS sites. All post-earthquake survey data collected by UCR and  
207 SIO/UCSD are archived at UNAVCO, which will be supplemented as further surveys are  
208 conducted.

209 We recommend that, for the purposes of earthquake response, GNSS surveys remain a  
210 vital component of geodetic observations that should be undertaken regularly to avoid long  
211 gaps in time series, which decrease the precision of eventual pre-earthquake positions and may  
212 also be contaminated by otherwise unobserved non-secular velocity perturbations. We also  
213 suggest that the processed solutions (e.g., Solution Independent Exchange format; SINEX) for  
214 previous surveys be made readily available, in addition to the raw (e.g., Receiver-Independent  
215 Exchange format; RINEX) data currently archived on a routine basis by working groups. When  
216 the need for rapid response arises, well-informed field teams are required to target sites which  
217 are going to produce the best coseismic and post-earthquake measurements. Furthermore, we  
218 recommend that post-earthquake surveys are conducted at high rates of observation (i.e.,  
219 greater than 1 Hz frequency) for potential seismogeodetic studies in the case of large  
220 aftershocks or, as in the case of the Ridgecrest earthquakes, a larger secondary earthquake,  
221 although such an approach does proportionally increase the burden of regular recovery of data  
222 on field teams to conserve receiver disk storage.

223 *Data and Resources*

224 Table 1 contains a list of surveys processed for this work, each of which are available from  
225 UNAVCO via the digital object identifiers (DOIs) in the final column. Additional RINEX files  
226 processed for this work are available from the USGS via the Northern California Earthquake  
227 Data Center (NCEDC; <ftp://ftp.ncedc.org/pub/gps/survey/usgs/>) and from SCEC via the  
228 Southern California Earthquake Data Center (SCEDC; <https://service.scedc.caltech.edu/gps/>).  
229 Table S1 contains the coseismic displacements estimated due to the first,  $M_w$ 6.4 earthquake,  
230 shown in Figure 2. Table S2 contains the coseismic displacements estimated due to the second,  
231  $M_w$ 7.1 earthquake, shown in Figure 3. Table S3 contains the cumulative coseismic displacements  
232 estimated due to both earthquakes combined, shown in Figure 4.

233 *Acknowledgements*

234 This paper is dedicated to Meghan M. Miller, on her retirement as President of UNAVCO, upon  
235 whose foresight and data collection this study is built. Keith Richards-Dinger, Baoning Wu,  
236 Christos Kyriakopolous, Jordan Cortez, John Conrad, Lisa Knowles and Filiz Duda are thanked  
237 for assistance in the field. Duncan Agnew is thanked for his timely advice on possible survey  
238 targets in the aftermath of the earthquakes. We also thank Ronni Grapenthin and Tony Lowry  
239 for their reviews, which greatly improved the manuscript. This material is based on services  
240 provided by the GAGE Facility, operated by UNAVCO, Inc., with support from the National  
241 Science Foundation and the National Aeronautics and Space Administration under NSF  
242 Cooperative Agreement EAR-1724794. This research was supported by the Southern California  
243 Earthquake Center (Contribution No. 9995), Awards 14189 (Funning), 18201 (Funning and  
244 Terry) and 19106 (Floyd); and by NSF RAPID Awards 1945728 (Funning) and 1945760 (Fialko).  
245 SCEC is funded by NSF Cooperative Agreement EAR-1600087 & USGS Cooperative Agreement  
246 G17AC00047. This is SCEC contribution #9995.

347 *Figures*

348 *Figure 1* (a) GNSS velocity solution, relative to North America (Altamimi et al., 2017), across the  
349 Mojave Desert region from GAGE products for continuous sites (red; Herring et al., 2016),  
350 SCEC's Crustal Motion Map for survey sites (blue; Shen et al., 2011, rotated from their Stable  
351 North America Reference Frame, SNARF, to the same Altamimi et al., 2017, definition of North  
352 America), and updated or new velocities for sites observed since by Funning (2016) and  
353 Funning et al. (2019a) within our region of interest (yellow; this study). Orange and green lines  
354 are mapped faults with evidence of displacement during the last 15 kyr and 130 kyr,  
355 respectively, from the USGS Quaternary Fault and Fold Database (USGS and CGS, 2006). The  
356 white line is the boundary of the NAWS China Lake. (b) The profile, centered at the intersection  
357 of the  $M_w6.4$  and  $M_w7.1$  surface ruptures, shows the velocity gradient (mostly profile-  
358 perpendicular, i.e., fault-parallel, shear) across the region.

359  
360 *Figure 2* Displacements of the July 4th, 2019,  $M_w6.4$  Ridgecrest earthquake. Red vectors are for  
361 continuous sites and blue are for survey sites (four UCR installed within hours of the first  
362 earthquake). Yellow triangles show the five survey sites occupied by UCR after the  $M_w6.4$   
363 earthquake and hence during the  $M_w7.1$  earthquake. The surface rupture is marked by the  
364 orange line (C. Milliner, pers. comm., via SCEC Response Forum at <https://response.scec.org/>)  
365 and the white line is the boundary of the NAWS China Lake, as in Figure 1. Displacements  
366 shown are listed in Table S1.

367  
368 *Figure 3* Displacements of the July 6th (5th, local time), 2019,  $M_w7.1$  Ridgecrest earthquake.  
369 Vector colors and fault rupture for the first earthquake are as in Figure 2, with the  $M_w7.1$   
370 rupture in light orange. Green triangles are sites occupied by SIO/UCSD after the  $M_w7.1$   
371 earthquake and therefore do not have coseismic displacement estimates for this second  
372 earthquake separately from the first. Displacements shown are listed in Table S2.

373  
374 *Figure 4* Cumulative displacements from the two earthquakes combined. Vector colors and fault  
375 ruptures are as in Figure 3. Displacements shown are listed in Table S3.

377 **Table 1** Summary of GNSS surveys used to determine pre-earthquake positions for this study.

## Survey and Continuous GNSS in the vicinity of the July 2019 Ridgecrest earthquakes

Michael Floyd, Gareth Funning, Yuri Fialko, Rachel Terry, Thomas Herring

### Supplemental Material

The supplemental material consists of three figures and three plain text tables.

*Figure S1* Summary of the occupation times for survey sites during the (a) February and (b) March 2019 surveys conducted in the region of the July 2019 earthquakes. The resulting position uncertainties are approximately 1.5–2.1 mm in the horizontal components (see main text for details).

*Figure S2* Summary of first survey observations during the post-earthquake response. Blue IDs are survey sites occupied by the UCR field team and gold IDs are survey sites occupied by the SIO/UCSD field team.

*Figure S3* Photographs of five survey sites demonstrating the type of monuments observed during the field response. (a) A threaded rod set in a concrete block at GS04; (b) A bronze disk on end of a metal pipe at BM25; (c) An aluminum disk on driven rod inside a protective pipe at V511; (d) A stainless steel pin cemented into a rock outcrop at ground level at PNCL; and (e) A bronze disk set in the top of a buried concrete pillar at H701. All photographs courtesy of Gareth Funning (UCR).

*Table S1* Coseismic displacements due to the first,  $M_w$ 6.4 earthquake. “Lon.” is longitude ( $^{\circ}$ E), “Lat.” is latitude ( $^{\circ}$ N), “de” is the estimated east displacement, “dn” is the estimated north displacement, “se” is the one-sigma formal uncertainty associated with the east displacement, “sn” is the one-sigma formal uncertainty associated with the north displacement, “rho” is the correlation coefficient between the east and north displacements, and “Site” is the four-character site ID.

*Table S2* Coseismic displacements due to the second,  $M_w$ 7.1 earthquake. “Lon.” is longitude ( $^{\circ}$ E), “Lat.” is latitude ( $^{\circ}$ N), “de” is the estimated east displacement, “dn” is the estimated north displacement, “se” is the one-sigma formal uncertainty associated with the east displacement, “sn” is the one-sigma formal uncertainty associated with the north displacement, “rho” is the correlation coefficient between the east and north displacements, and “Site” is the four-character site ID.

*Table S3* Cumulative displacements due to both earthquakes combined. “Lon.” is longitude ( $^{\circ}$ E), “Lat.” is latitude ( $^{\circ}$ N), “de” is the estimated east displacement, “dn” is the estimated north displacement, “se” is the one-sigma formal uncertainty associated with the east displacement, “sn” is the one-sigma formal uncertainty associated with the north displacement, “rho” is the correlation coefficient between the east and north displacements, and “Site” is the four-character site ID.
