24 **Abstract**

25 **Background:** Aging is associated with declines in circadian functions. The effects of aging on
26 circadian patterns of behavior are insufficiently described. We characterized age-specific
27 features of rest-activity rhythms (RAR) in community dwelling older adults, both overall, and in
28 relation, to sociodemographic characteristics.

29 **Methods:** We analyzed baseline assessments of older adults with wrist-worn free-living wrist-
30 worn actigraphy data (N=820, Age=76.4 yrs, 58.2% women) participating in the Study of
31 Muscle, Mobility and Aging (SOMMA). We applied an extension to the traditional cosine curve
32 to map RAR to activity data, calculating the parameters: rhythmic strength (amplitude);
33 robustness (pseudo-F statistic); and timing of peak activity (acrophase). We also used function
34 principal component analysis to determine 4 components describing underlying patterns of
35 activity accounting for RAR variance. Linear models were used to examine associations
36 between RAR and sociodemographic variables.

37 **Results:** Age was associated with several metrics of dampened RAR; women had stronger and
38 more robust RAR metrics vs. men (all $P < 0.05$). Total activity (56%) and time of activity (20%)
39 accounted for most the RAR variance. Compared to the latest decile of acrophase, those in the
40 earliest decile had higher average amplitude ($P < 0.001$). Compared to the latest decile of
41 acrophase, those in the earliest and midrange categories had more total activity ($P=0.02$). RAR
42 was associated with some sociodemographic variables.

43 **Conclusions:** Older age was associated with dampened circadian behavior; and behaviors were
44 sexually dimorphic. We identified a behavioral phenotype characterized by early time-of-day of
45 peak activity, high rhythmic amplitude, and more total activity.

46 **Key Words:** aging, circadian clock, circadian rhythms, physical activity, longevity, SOMMA

47 **Introduction**

48 Aging is characterized by declines in physical function and mobility. The determinants
49 of these changes are still under investigation. Numerous aging biological processes have been
50 linked to circadian timing, patterns, or rhythms and, thus, the role of circadian biology in age-
51 related changes is now being considered(1). Circadian rhythms are approximate 24hr patterns in
52 behavior and physiology that are regulated by molecular clock mechanisms found in virtually all
53 cells in the body. Endogenous circadian clocks confer benefit to an organism by supporting
54 homeostasis and resilience, and this ultimately promotes longevity and healthy aging(2-4).
55 Mounting evidence suggests that aging itself is characterized by weakened circadian functions(5,
56 6). In addition, there is a growing interest in linking circadian timing to interventions for healthy
57 aging, including diet(7) and physical activity(8). Nonetheless, there is a need to first establish
58 the fundamental relation between aging and circadian biology.

59 One observable aspect of circadian biology is the repeated, rhythmic change in rest and
60 activity behaviors. These behavioral circadian patterns are measurable in humans, in free-living
61 settings, with wearable activity monitors(9). Specifically, rest-activity data obtained from such
62 monitors worn for several consecutive days, can be mathematically assessed for a daily circadian
63 rhythm; and the shape of these rhythmic patterns may reveal insight into health and disease
64 status. For example, a remarkably consistent observation across numerous cohort studies is that
65 a dampened rhythmic amplitude is associated with age-related chronic conditions and
66 pathologies, including changes in cognitive functioning, signs of Alzheimer’s disease, fatigue,
67 markers of inflammation, reduced cardiometabolic and bone health, and even mortality (10-20).
68 While these relationships between altered rest-activity rhythms and disease outcomes are
69 striking, what remains unaddressed is the impact of aging itself on rest-activity patterns.

70 In addition to the features of rest-activity patterns, the time-of-day in which activity occurs is
71 gaining attention as a new parameter of physical activity that is important to health. Studies have
72 reported associations between times of day when activity is performed (e.g. morning, afternoon,
73 or evening) with outcomes that are relevant for age-related chronic diseases, such as obesity,
74 metabolic function, type 2 diabetes, cardiovascular risk, and all-cause mortality(21-25). These
75 findings support an emerging concept of circadian timing of physical activity for health benefit.
76 The circadian patterns of rest and activity in the context of the 24h day-cycle cycle, and whether
77 this relates to healthy aging is unknown. The Study of Muscle, Mobility and Aging (SOMMA)
78 offers opportunity in this regard, enabling large-scale behavior phenotyping of rest-activity
79 rhythms, as well as determination of the temporal distribution of activity in a cohort of older
80 adults (70 to 85+ yrs), free of life-threatening illnesses, did not suffer from mobility disability,
81 and inclusive of men and women(26), which has not been done previously.

82 The purpose of this study was to determine age-specific features of circadian patterns of rest
83 and activity behavior, assessed with wearable activity trackers, in a cohort of community
84 dwelling older adults in the SOMMA cohort(26). In addition to rhythmic parameters, the
85 temporal distribution of physical activity across the 24h day was also characterized. Finally,
86 associations between parameters of rest-activity-rhythms and demographic variables were
87 examined.

88 **Methods**

89 *Study Cohort and Design*

90 From April 2019 to December 2021, participants aged 70 and older were recruited from 2
91 clinical sites—the University of Pittsburgh and Wake Forest University School of Medicine for
92 the Study of Muscle, Mobility and Aging (SOMMA) (<https://sommaonline.ucsf.edu>). The
93 unique cohort study design of SOMMA has been previously described elsewhere (26). Briefly,
94 individuals were eligible to participate if they were 70 years old or older, willing and able to
95 complete a skeletal muscle biopsy and undergo magnetic resonance (MR). Individuals were
96 excluded if they reported an inability to walk one-quarter of a mile or climb a flight of stairs; had
97 body mass index (BMI) ≥ 40 kg/m²; had an active malignancy or dementia; or any medical
98 contraindication to biopsy or MR. Finally, participants must have been able to complete the 400-
99 meter walk; those who appeared as they might not be able to complete the 400-meter walk at the
100 in-person screening visit completed a short distance walk (4 meters) to ensure their walking
101 speed as ≥ 0.6 m/s. SOMMA was approved by the Western IRB-Copernicus Group (WCG)
102 Institutional Review Board (WCGIRB, study number 20180764). All participants provided
103 written informed consent. This current study used baseline SOMMA data for cross-sectional
104 assessments.

105

106 *Demographic Variables*

107 Data collected included age based on self-reported date of birth, self-reported gender, and
108 race and self-reported ethnicity based on current census categories. Data on work schedule,
109 education level and finances were gathered. Data on behavior and lifestyle were collected (e.g.,
110 smoking status, marital status), self-reported health status and medical history. Multimorbidity

111 was classified using a modification to the Rochester Epidemiology Project multimorbidity scale
112 (0-13) (27). Height was measured by stadiometers and weight by balance beam or digital scales.
113 Body mass index (BMI) was then calculated as weight (kg)/height (m²).

114

115 *Actigraphy*

116 Actigraphy data was collected using the ActiGraph GT9X (ActiGraph, Pensacola, FL),
117 which has a 3-axis accelerometer with a sampling rate of 80 Hertz. ActiGraph GT9X is a watch-
118 like device placed on a participant's nondominant wrist in person at a clinic visit. Participants
119 were asked to wear the Actigraph continuously for 7 days(28). Data were processed in one-
120 minute epochs (activity counts/minute) and scored using ActiGraph Corp's ActiLife Software.
121 The first day of wear was excluded from these analyses, as participants were required to do a
122 number of physical performance tests during their clinic visit and the activity level may not be
123 representative of their usual activity patterns. Sleep diaries were used to aid in setting intervals
124 for when the participants were in bed trying to sleep. Nonwear time was determined by a
125 combination of an off-wrist detector in the device, a nonwear algorithm, and review by an
126 actigraphy data scorer(28, 29). Nonwear times were set to missing. The Cole-Kripke sleep
127 scoring algorithm was used to determine sleep from wake(30). Total sleep time during the in-bed
128 interval was averaged over all nights of wear, to obtain a more representative characterization of
129 usual sleep patterns. Total activity count per 24-hour day was also averaged over all days to get
130 an estimate of overall activity level.

131

132 *Rest-Activity Rhythm Parameters*

133 The activity data gathered was used to calculate both parametric and non-parametric
134 RAR variables. The parametric approach assumes the activity data has an underlying
135 distribution similar to the cosine curve. The nonparametric approach does not assume RAR fit to
136 a cosine wave *a priori* but rather fits to regular pattern of activity.

137 Parametric Approach: A 5-parameter extension to the traditional 24-hr cosine curve was
138 used to map the RAR to activity data. This extension allows for a more squared-shape wave than
139 a cosine curve, as often observed with activity data (31). The RAR parameters include the
140 following: amplitude, which is an indicator of the strength of the rhythm, calculated as the peak
141 to nadir difference in activity (units of activity [counts/min]); midline (midpoint between the
142 rhythmic maximum and minimum), estimating statistic of rhythm (mesor), which is the mean
143 level of activity (units of activity [counts/min]); robustness of the RAR, or pseudo-F statistic for
144 goodness of extended cosine fit, with higher values indicate stronger rhythms; and acrophase,
145 which is the timing of peak activity of the fitted curve, measured as time of day (portions of
146 hours).

147 Non-Parametric Approach: Inter-day stability (IS), which describes day-to-day stability
148 of RAR (range 0 to 1); and intra-daily variability (IV) which describes fragmentation across 24h
149 ranges (range 0 to 2); the average activity level of the most active consecutive 10-hour period
150 (M10); the average activity of the least active consecutive 5-hour period (L5); relative amplitude
151 (RA), the difference in activity between M10 and L5 in the average 24-hour pattern, normalized
152 by their sum, with higher RA reflecting relatively lower activity during the night and greater
153 activity when awake (32, 33).

154 Functional Principal Component Analysis (fPCA): We also used fPCA to describe
155 underlying patterns of activity, as this analytical approach does not rely on *a priori* assumptions

156 about the activity shape. Participant data was fit with a nine-Fourier-based function. fPCA was
157 then used to derive the top four components determined as these typically explain the majority of
158 the variance, and an eigenvalue was assigned for each of the four components and each
159 participant(34, 35).

160 Temporal Distribution of Physical Activity: The average of activity level across all
161 participants by clock time were plotted, stratified by acrophase category. Participants were
162 categorized as having early timing if they fell within the lowest decile of acrophase, midrange for
163 those 10% of participants around the median value, and late timing as those in the highest decile
164 of acrophase.

165

166 **Statistical Analysis**

167 Cohort characteristics were categorized and described using proportions (N% of). RAR
168 parameters were described using means and standard deviations. Associations of each
169 characteristic with the RAR parameters was examined using linear regression models, with
170 results presented as adjusted means and their 95% confidence intervals. For characteristics with
171 more than 2 categories, tests for a linear trend across categories were performed by including
172 each characteristic (ordinal variable) as an independent variable in models. Tests were also
173 performed comparing categories to the reference. Minimally adjusted models included the
174 characteristic and an adjustment for clinic site. Multivariable adjusted models included clinic site
175 and all characteristics examined in the same model, to determine if adjustment for other
176 characteristics attenuated any associations observed.

177 We explored differences in associations by sex by performing formal tests for interaction
178 with sex and each characteristic with linear regression models that included clinic site, the
179 characteristic, sex, and a term for sex*characteristic.

180 Total activity level across categories of acrophase used to describe the temporal
181 distribution of activity were compared using t-tests, comparing the participants in the midrange
182 group to those in the lowest and highest decile of acrophase. In addition, area-under-the-curve
183 (AUC) for the graphical representation of average activity stratified by category of acrophase
184 was calculated using the trapezoidal rule.

185 All significance levels reported were two-sided and all analyses were conducted using
186 SAS version 9.4 (SAS Institute Inc, Cary, NC).

Results

Participants

Of the 879 participants enrolled in SOMMA, our analytic subset consists of 820 participants with actigraphy data. Some participants (n=59) missing or excluded were due to several reasons; either the participant wore the device but there was a malfunction with the datafile (n=33), no device was available (n=12), the participant refused (n=1), the participant was unable (n=1), the actigraphy file did not have activity data in the correct format (n=9) or had too little data collected (n=3). The 820 men (41.8%) and women (58.2%) were on average 76.4 years old, had a BMI of 27.6 kg/m², and mostly identified as White (85.0%). Most (62.0%) graduated from college and about half were in a married-like relationship. Most (61.6%) reported very good or excellent health compared to others their age and 83.3% reported a history of one or more of the 13 medical conditions in the multimorbidity index. Most said their finances met their needs very well (64.1%) and some (39.4%) reported having a regular work or volunteer schedule (Table 1). Only 20% of participants reported regularly waking with an alarm, and remaining 80% had different self-wake behaviors, potentially indicating that they were not constrained by scheduled requirements. The participants on average slept 6 hours, 51 minutes ± 61 minutes.

Parametric and Non-Parametric Rest-Activity Rhythmic Parameters

Representative examples of rest-activity rhythms are shown in Figure 1. On average, participants wore the ActiGraph for 8 ± 0.8, 24-hr periods. The average acrophase was at 2:19 PM. The average IS and IV were 0.58 and 0.59, respectively (Table 1, Supplemental Figure S1).

Function Principal Component Analysis

212 The four components of the fPCA analysis explained 91% of the variance in the activity
213 data. The first component primarily described overall activity level (fPCA1: 56% of the
214 variance), the second component primarily described timing of activity (fPCA2: 20% of the
215 variance), the third component primarily described a lower level of midday activity (fPCA3: 9%
216 of the variance), and the fourth component primarily differentiated between a morning activity
217 peak and an afternoon peak (fPCA4: 6% of the variance). Figure 2 shows the plots of activity
218 level for the average of the cohort, those with positive eigenvalues and those with negative
219 eigenvalues for each of the 4 fPCA.

220

221 *Associations Between RAR Parameters*

222 Measures that are primarily related to activity level from the 3 approaches of defining
223 RAR were highly correlated to each other ($r > 0.50$ for amplitude, mesor, M10, fPCA component
224 1; Supplemental Figure 1). Acrophase and fPCA component 2, both measures of timing were
225 correlated at $r = 0.75$. Measures of rhythm robustness or fragmentation were also highly correlated
226 ($abs(r) > 0.64$ for pseudo F-statistic, IS, IV; Supplemental Figure S2).

227

228 *Associations of RAR Parameters with Demographic Variables*

229 In models adjusted for clinic site alone, age was primarily related to parameters that are
230 driven by activity level and strength of rhythm, in which younger participants had higher average
231 values of amplitude, mesor, M10, and fPCA1; lower values of IV. Sex was primarily related to
232 the strength of patterns of activity (pseudo f-statistic, IS, IV, M10, RA, fPCA1, fPCA2). Figure 3
233 shows sex differences in parametric and non-parametric parameters. Race was not related to any
234 shape-based parameters, but was related to nonparametric measures, with those identifying as

235 White having higher stability (IS), lower variability (IV) and lower L5 (Table 1, Supplemental
236 Table 1).

237 The most consistent association seen was that of marital status and RAR (Table 1,
238 Supplemental Table 1). Being in a married-like relationship was associated with more robust
239 rhythms as seen by the parametric parameters, more stability of activity (IS), lower levels of L5,
240 implying more consolidated sleep, and higher M10 (more active while out of bed). Those with
241 higher education level had less strength of rhythm (pseudo f-statistic, IV, L5, RA). Financial
242 situation was related to timing of activity and strength of rhythm (acrophase and pseudo f-
243 statistic), and most nonparametric measures (IS, L5, M10, RA, fPCA1, fPCA2). The associations
244 of work were primarily activity level based (amplitude, M10, fPCA1). Reporting poor/good
245 health status was primarily related to lower average activity levels. There were no associations
246 observed between smoking or the multimorbidity index and RAR parameters.

247 Associations seen in the site-adjusted models remained statistically significant for most
248 demographic variables after combining all demographic variables in one model, with some
249 attenuation of effect size (Supplement Tables 2A, B, C). The demographic variables most
250 affected by adjustment for other variables examined were work schedule and self-reported health
251 status.

252 There were very few significant interactions between sex and other demographic
253 variables. There were no significant interactions of sex seen with age, race, education, financial
254 security, self-reported health status or smoking ($P > 0.05$). The interaction of sex with the
255 multimorbidity index was significant for amplitude and fPCA1 ($P < 0.05$), but associations were
256 not statistically significant after stratification by sex.

257

258 *Temporal Distribution of Activity*

259 As described above, acrophase is the time of day of peak activity. Figure 4 shows plots
260 of the average of activity across the day for all participants by category of acrophase. Those with
261 the earlier acrophase (<12:43 PM) had the highest peak activity and a sharp decline later in the
262 evening. Those with the latest acrophase (>3:55 PM) had more activity in the evening (11PM to
263 2 AM). Compared to the latest decile of acrophase, those in the earliest decile of acrophase had
264 a 70% higher average amplitude ($P < 0.001$).

265 The AUC of the plots show that average activity is similar for those in the earliest and
266 midrange acrophase categories (Figure 4, Panel A: 32648.15 vs. 33752.31); whereas those in the
267 latest category of activity timing had a lower AUC (30117.93). Women had a higher AUC than
268 men (midrange timing category: 34891.61 vs. 31634.91).

269 Total activity was compared among the three acrophases. The average activity level of
270 those in the midrange category of acrophase was 203.75 ± 46.67 counts*10,000. Compared to
271 those in the midrange groups of acrophase, on average, those in the earliest acrophase category
272 had a similar 24-hr activity level (197.27 ± 53.78 counts*10,000, $P = 0.41$), while those in the
273 latest acrophase category had lower 24-hr activity level compared to those in the midrange group
274 (183.68 ± 62.91 counts*10,000; $P = 0.02$).

275

276

Discussion

277 The primary finding of this study was that older age was associated with several metrics
278 of dampened rest-activity rhythms. This is in agreement with findings from a large cohort study
279 representative of the general population, from the National Health and Nutritional Examination
280 Survey (NHANES), which primarily focused on younger age categories (20-39, 40-59, ≥ 60 yrs)
281 (36). We also observed sexual dimorphism in circadian behavior, in that women had stronger
282 and more robust rest-activity rhythms compared to men. This finding is also consistent with two
283 previous large cohort studies, representative of the general population (NHANES and United
284 Kingdom Biobank) (36, 37). As SOMMA focused on older adults, our observations herein
285 indicate that sex-specific differences in circadian behavior may persist beyond reproductive
286 potential, which has not been previously demonstrated. Despite this sexual dimorphism, there
287 was lower rhythmic strength at higher age in both men and women, perhaps supporting the
288 notion that age is a central determinant of circadian patterns of behavior. Although this was a
289 cross-sectional analysis, our findings of dampened circadian rest-activity rhythms in older adults,
290 suggests that these changes are likely paralleled by age-related declines in function, mobility,
291 and energy. Future studies to disentangle cause and effect are warranted.

292 Function principal component analysis revealed that the two primary components
293 explained a majority of the variance in activity profiles. The first component was overall activity
294 (56%), in which a higher value corresponds with higher activity throughout the day. The second
295 component was time of activity (20%), which corresponds with activity timing (e.g early vs. later
296 “rises”. These findings are very similar to that observed in NHANES, which reported that
297 variance in activity profiles was also primarily explained by overall activity (50%) and timing of
298 activity (21%)(38). The consistency between SOMMA and NHANES cohorts, which, as noted

299 above focused on different age ranges, suggests that patterns of activity profiles are generally
300 preserved from middle to older age.

301 To better understand activity patterns within the context of the 24h day-night timescale,
302 we investigated the temporal distribution of physical activity. This analysis yielded new insight,
303 in that those with the earliest time-of-day of peak activity (<12:43 PM) had a higher rhythmic
304 peak; whereas, those with the latest time-of-day of peak activity (>3:55 PM) had a lower
305 rhythmic peak. This is the first time, of which we are aware, to describe this behavior
306 phenotype. There appears to be a relation between time-of-day of activity and total daily
307 activity, as those in the earliest and midrange categories performed more total activity compared
308 to those in the latest category of activity timing. Based on these observations, one might suspect
309 that a strong and robust circadian pattern of activity facilitates the accumulation of more total
310 daily activity. Although speculative, perhaps this is one way in which circadian rhythms enable
311 higher levels of physical activity, which in turn promotes healthy aging.

312 In addition to age and sex, there were some significant associations with rhythmic
313 parameters and sociodemographic variables. Being in a married-like relationship was associated
314 with stronger and more robust rhythms, higher education was associated with less rhythm
315 strength, and financial situation was associated with timing of activity and rhythm strength.
316 Previous analyses from NHANES have reported associations between race/ethnicity and
317 rhythmic parameters, which were not replicated herein, and this is mostly likely due to
318 differences in samples sizes of diverse races/ethnicities between study cohorts. However, our
319 current observations provide additional context, in which some sociodemographic variables, in
320 addition to age and sex, are associated with rest-activity patterns in community dwelling older
321 adults.

Conclusion

We found that age was associated with dampened circadian patterns of rest and activity, and this sheds light on a new temporal dimension by which aging impacts physical activity. In addition, women had stronger and more robust rhythms relative to men counterparts. Given the sex gap in longevity and lifespan(39), it is tempting to speculate that strong and robust rhythms in women confers some type of benefit that promotes resiliency or delays aging. We also observed that those active at earlier times in the 24 hour/day had a higher rhythmic peak and more total activity. This may suggest that a strong and robust circadian rhythm facilitates higher levels of, or greater engagement with, physical activity. This novel and comprehensive characterization of rest-activity rhythms in older, community dwelling adults, free of life-threatening disease, lays new groundwork for future hypothesis testing; indeed, future studies that determine how these rest-activity patterns intertwine with function and mobility are warranted.

461 All models are adjusted by clinic site (RAR parameter~clinic site + one descriptive characteristic
462 in separate models).

463 For predictors with >2 categories, a *P*-trend was calculated, looking for a linear trend across the
464 categories. Categories were also compared to the reference category.

465 The symbols represent the *P* -value for the comparison of the category to the reference category.

466 Symbols: *= *P*-value<0.05; **= *P*-value<0.01; *** *P*-value<0.001

467 **Figure Captions**

468 **Figure 1:**

469 **Title:** Representative examples of rest-activity rhythm profiles demonstrating differences
470 in rhythmic amplitude and rhythmic strength in community-dwelling men and women 70
471 and older: the SOMMA Cohort.

472 **Caption:** Comparison of representative rest-activity rhythm plots of individual
473 participants from the highest 10th percentile of amplitude (Panel A) versus lowest 10th
474 percentile of amplitude (Panel B). Amplitude, minimum, and mesor are labeled with red
475 dashed line. Acrophase (time of peak activity) is shown with a gray bar. Comparison of
476 representative rest-activity rhythms of individual participants from the lowest decile
477 values for pseudo F-statistic (Panel C) versus the highest decile values for pseudo F-
478 statistic (Panel D) to graphically illustrate stronger rhythmic strength with clear sleep-
479 wake patterns versus weaker rhythmic strength with less distinct sleep-wake patterns.
480 Mesor (yellow line), amplitude (red line), fitted curve (blue line) and acrophase (gray
481 bar) are labeled.

482

483 **Figure 2:**

484 **Title:** Four components of functional principal component analysis (fPCA).

485 **Caption:** The average pattern of activity for all participants (black line); average pattern
486 of activity in participants with the eigenvalue of positive fPCA scores (red line); average
487 pattern of activity in participants with the eigenvalue of negative fPCA scores (blue line).
488 fPCA1 represents high and low overall activity explaining 55.8% of variance (Panel A).
489 fPCA2 represents later activity timing (positive eigenvalues) and earlier (negative

490 eigenvalues) activity timing (Panel B) explaining 20.5% of variance. fPCA3 represents
491 longer, biphasic (low eigenvalues) and shorter, more monophasic (high eigenvalues),
492 activity patterns explaining 8.6% of variance (Panel C). fPCA4 represents morning (high
493 eigenvalues) and evening (low eigenvalues) peaks in activity explaining 5.6% of variance
494 (Panel D).

Unmarried	-2498.11 (-4292.79, -703.44)	-191.15 (-1349.40, 967.09)	349.83 (-399.41, 1099.07)	-17.61 (-636.27, 601.05)
<i>P</i> -trend	<0.001	0.67	0.06	0.89
Self-reported Health Status				
Good or fair	-1915.80 (-3912.03, 80.44)	1063.68 (-224.65, 2352.00)	-660.93 (-1494.31, 172.46)	152.29 (-535.85, 840.43)
Excellent or very good	1105.71 (-429.42, 2640.85)	-651.12 (-1641.86, 339.62)	103.00 (-537.88, 743.89)	-173.39 (-702.58, 355.81)
<i>P</i> -trend	0.02	0.05	0.17	0.48
Number of multimorbidities (0-13)***				
None (reference)	586.97 (-2371.12, 3545.06)	-159.37 (-2065.94, 1747.21)	-1328.10 (-2562.26, -93.95)	-654.70 (-1672.16, 362.76)
1	444.25 (-1546.75, 2435.24)	-640.63 (-1923.88, 642.62)	-149.79 (-980.46, 680.88)	6.71 (-678.11, 691.52)
2	-364.98 (-2503.20, 1773.23)	888.70 (-489.44, 2266.84)	113.62 (-778.47, 1005.72)	443.19 (-292.27, 1178.64)
3+	-1068.71 (-3973.70, 1836.27)	-104.13 (-1976.48, 1768.21)	286.05 (-925.95, 1498.04)	-460.71 (-1459.90, 538.48)
<i>P</i> -trend	0.36	0.50	0.08	0.60
Smoking Status				
Never smoked	-366.11 (-1954.20, 1221.98)	544.94 (-479.98, 1569.86)	-77.97 (-740.97, 585.02)	125.81 (-421.64, 673.25)
Current or past smoker	361.94 (-1421.37, 2145.24)	-681.50 (-1832.41, 469.41)	-324.79 (-1069.29, 419.70)	-269.51 (-884.25, 345.24)
<i>P</i> -trend	0.55	0.12	0.63	0.35

556 One model, adjusted by clinic site and all descriptive variables listed.

557 For predictors with >2 categories, a *p*-trend was calculated, looking for a linear trend across the
558 categories. Categories were also compared to the reference category.

559 The symbols represent the *p*-value for the comparison of this category to the reference category

560 Symbols: *= *p*-value<0.05; **= *p*-value<0.01; ***= *p*-value<0.001

561 *** Mutimorbidity index includes arthritis, cancer (excluding nonmelanoma skin cancer), atrial
562 fibrillation, chronic kidney disease, chronic obstructive pulmonary disease, heart disease,
563 congestive heart failure, dementia, depression, diabetes mellitus, osteoporosis, stroke and aortic
564 stenosis.

567

568 **Supplemental Figure 1**

569 **Title:** Graphical representations of low IS vs high IS, as well as low IV vs. high IV, from
570 rest-activity rhythm profiles.

571 **Caption:** Comparison of representative rest-activity rhythm plots of individual
572 participants from the lowest 10th percentile IS (Panel A) versus highest 10th percentile IS
573 (Panel B). Comparison of representative rest-activity rhythms of individual participants
574 from the lowest decile IV (Panel C) versus the highest decile values for IV (Panel D) to
575 graphically show variance in rhythmic stability across the 8-day period. Each plot point
576 represents an activity count.

A. Participant with low IS

B. Participant with high IS

C. Participant with low IV

D. Participant with high IV

579 **Supplemental Figure 2**

580 **Title:** Unadjusted correlations of rest-activity rhythm parameters.

581 **Caption:** Correlations matrix between RAR rhythms, revealing generally good
 582 agreement between parametric vs. non-parametric variables.
