HIGHLIGHTS

- A 3D-V$_2$O$_5$/NC nanocomposite is fabricated by a self-templating strategy.
- 3D-V$_2$O$_5$/NC has dual enzyme-mimetic activity (oxidase-like and catalase-like).
- Synergistic effect between N-doped carbon lamellae and multivalent V$_2$O$_5$ nanoparticles.
- This method provides a low detection limit and suitable recovery for TAC.
- Developed a smartphone-based colorimetric application (APP).

ABSTRACT

Total antioxidant capacity (TAC) can be evaluated by detecting the content of antioxidants, such as ascorbic acid, based on the enzyme-mimetic activity of nanomaterials. Herein, we fabricated a 3D-V$_2$O$_5$/NC nanocomposite using a self-templating strategy, which achieved ultrafine particles (~2.5 nm), a porous carbon layer, large specific surface area (152.4 m^2/g), N-doping and heterogeneous structure. The strong catalytic activity of 3D-V$_2$O$_5$/NC resulted from the integrated effect between the ultrafine structure of V$_2$O$_5$ nanoparticles and the 3D porous nitrogen-doped carbon framework, effectively increasing the number of active sites. This nanozyme presented a higher catalytic activity than its components or precursors in the nanocomposite (e.g., VN/NC, NC, V$_2$O$_5$, and VO$_2$/g-C$_3$N$_4$). ROS scavenging experiments confirmed that the dual enzyme-like activity of 3D-V$_2$O$_5$/NC (catalase-like and oxidase-like) resulted from their co-participation of ·O$_2^-$, h$^+$ and ·OH, among which ·O$_2^-$ played a crucial role in the catalytic color reaction. By virtue of the 3D-V$_2$O$_5$/NC nanoenzyme activity and TMB as a chromogenic substrate, the mixed system of 3D-V$_2$O$_5$/NC + TMB + H$_2$O$_2$ provided a low detection limit (0.03 μM) and suitable recovery (93.0–109.5%) for AA. Additionally, a smartphone-based colorimetric application was developed employing "Thing Identify" software to evaluate TAC in beverages. The colorimetric sensor and smartphone-detection platform provide a better or comparable analytical performance for TAC assessment in

comparison to commercial ABTS test kits. The newly developed smartphone-based colorimetric platform presents several prominent advantageous, such as low cost, simple/rapid operation, and feasibility for outdoor use.

1. Introduction

Owing to high catalytic efficiency, convenient large-scale preparation, and easy long-term storage, nanozymes are widely employed in biological and chemical sensing platforms [1,2]. Single enzyme activity of nanomaterials has been widely reported, especially for peroxidase (POD)-like activity [3,4]. In recent years, nanomaterials with multi-enzyme activities elicited great interest as they participate in multi-step/tandem reactions, where each enzyme is responsible for a single reaction step, thereby realizing the simultaneous assay of multiple chemicals. Moreover, the synergistic effects of multi-enzyme catalysts improve the catalytic efficiency of a single enzyme. For example, $Co_2V_2O_7$ possesses oxidase (OXD)-, POD-, and catalase (CAT)-like activities [5], 2D $MoSe_2$@PVP nanosheets have CAT, POD, superoxide dismutase (SOD), and glutathione peroxidase (GPx)-like activities [6], and NSC/Co_{1-x}S has OXD and POD-like activities [7]. Notably, the underlying mechanisms regarding multi-enzyme activities of nanomaterials remain unclear as compared to single enzyme activity. However, it is clear from the literature that development of new nanozymatic materials with multi-enzyme activities holds great potential for analytical applications given their superior catalytic performance.

The strong catalytic activities of various vanadium-based hybrid materials (VO_x) have recently been demonstrated making them an excellent candidate for several practical applications. Due to its multiple oxidation states (V^{2+}, V^{3+}, V^{4+}, V^{5+}), VO_x easily forms nanocomposites with multivalence properties, which facilitates the construction of defect sites and the rapid transfer of electrons within nanomaterials. Consequently, these superior characteristics of VO_x offer great potential for use in procedures involving catalytic color development. For example, André and colleagues demonstrated that V_2O_5 nanowires had POD-like activity related to surface properties of the (010) lattice surface [8]. Further, Zeb and coworkers synthesized VO_x nanosheets containing a mixture of oxidation states, structures and phases using a simple "one-pot" method [9]. V_2O_5 nanoribbons have dual enzyme-mimetic activities (e.g., glucose oxidase-like (GOx) activity and POD-like activity) and can be used as a tandem nanoenzyme to construct an online optical detection platform for glucose assay [10]. Thus, VO_x has strong attributes for use as a highly stable and catalytic activity-regulated nanoenzyme for colorimetric analysis in biosensing due to their unique structural properties.

The synergistic effect among the components of composite nanomaterials can effectively enhance their enzyme-like activities. Layered porous carbon materials are beneficial in increasing exposure of active sites and promoting electron transfer [11]. The combination of porous carbon materials with metal oxide nanoparticles can increase the specific surface area of nanocomposites, while also serving as a diffusion substrate to prevent their agglomeration [12]. Among carbon materials, N-doped nanomaterials have several prominent advantages, such as high electrical conductivity, large specific surface area, and ease of functionalized modification. As a result, N-doped nanomaterials are widely used in the fields of energy storage, catalysis and chemical analysis. Hou and coworkers designed N-doped porous carbon with active magnesium sites (Mg/NC), which increased OXD-like activity by 10.9-fold compared to N-doped carbon (NC) [13]. Similarly, Lu's group synthesized Cu–N co-doped carbon (Cu-NC) nanosheets with highly exposed Cu-Nx sites, which increased POD-like activity of Cu-NC-700 by 15–19-fold as compared to Cu-doped carbon (Cu–C) and N-doped carbon (N–C) [14]. Liang et al. generalized some reports of composite carbon nanomaterials based on metal oxides or metal sulfides, and found that they all had highly enzyme-mimetic catalytic activities and superior physico-chemical properties [15]. Thus, the integration of carbon

materials with hierarchical porous structure and metal oxides can be an effective strategy to improve the catalytic performance of nanoenzymes.

Common nanozyme-based colorimetric methods have some limitations for widespread practical applications, such as dependence on a spectrophotometer, in-lab operational requirements, and inconvenience for outdoor use. With the development of digital communication techniques, many smartphone-based analytical platforms have gained widespread application and provide several advantages, such as an integrated sensor system, low cost, ease of use, and portability [16]. Zhu and colleagues developed a portable colorimetric sensor using a smartphone platform based on the novel nanoenzyme MnCo@C for rapid/sensitive detection of ascorbic acid (AA), 2,4-dichlorophenol and epinephrine [17]. Similarly, our group pioneered a colorimetric platform for glucose assay employing a high vacancy Fe_3S_4 nanozyme and "Thing identify" software deployed on a smartphone [18].

Informed by previous research developments, we herein prepared a 3D-V_2O_5/NC nanocomposite using a self-templating strategy in which V_2O_5 nanoparticles were dispersed and anchored onto N-doped carbon nanosheets (NCs). Based on the high catalytic activity of 3D-V_2O_5/NC and TMB as a chromogenic substrate, a colorimetric platform was developed for quantification of total antioxidant capacity (TAC). TAC represents the total antioxidants that regulate oxidative stress and ensure redox homeostasis in organisms. In this study, we used AA as a representative species of TAC. Further, a colorimetric sensing platform based on smartphone visualization was constructed using "Thing Identify" application (APP) software, which enables rapid field detection of trace TAC concentrations. The newly developed colorimetric method demonstrates great potential for conventional monitoring of TAC in complex pharmaceutical and food matrices.

2. Experimental section

2.1. Chemicals and materials

All chemicals used in this study were of analytical or chromatographic grade and purchased from Adams (Shanghai, China), including ascorbic acid (AA, 99.0%), hydrogen peroxide (H_2O_2, 30%), acetic acid (ACA, $\geq$98.0%), sodium acetate (CH_3COONa, 99.0%), ethanol (99.7%), dimethyl sulfoxide (DMSO, $\geq$99.0%), *p*-benzoquinone (PBQ, 99.2%), ethylene diamine tetraacetic acid (EDTA, 99.5%), sucrose (Suc, $\geq$99.0%), D-histidine (His, 99.5%), D-galactose (Gal, 99.5%), D-serine (Ser, 99.5%), L-tyrosine (Tyr, 99%), glycine (Gly, 99.0%), D(+)-tryptophan (Try, 99.0%), glucose (Glu, 99.0%), fructose (Fru, 99.0%), citric acid (CA, 98%), L(−)-malic acid (H_2Mi, 98.0%), L-cysteine (L-Cys, 98.0%), glutathione (GSH, 98.0%), uric acid (UA, 98.0%), 2,2′-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid) (ABTS, 97.0%), and O-phenylenediamine (OPD, 99%). Ammonium metavanadate (NH_4VO_3) with purity $\geq$99.0% was obtained from Sigma-Aldrich (Shanghai, China) and isopropyl alcohol (IPA, $\geq$99.7%) and 3,3′,5,5′-tetramethylbenzidine (TMB) were procured from Aladdin (Shanghai, China). Anhydrous oxalic acid (OXA, 98.0%) and dicyandiamide (DCA, 99.0%) were obtained from Maclean (Shanghai, China). TAC assay kits using the ABTS method were procured from Beyotime Biochemical Technology (Shanghai, China). All reagents were used without further purification, and ultrapure water (>18.2 MΩ) was generated with a Milli-Q system (Bedford, MA, USA).

2.2. Analytical instruments

A model OTF-1200 tube furnace (Hefei, China) was used to calcine the required nanomaterials. Crystalline-phase identification was

assessed using X-ray diffraction (XRD) with Cu Kα radiation (D8 Advance, Bruker, Germany). Morphology of the synthesized nanocomposites was observed using a Zeiss Merlin Sigma 300 SEM (Carl Zeiss SMT AG, Germany), as well as a Talos F200X G2 TEM (TEM; FEI, USA). Fourier transform infrared (FT-IR) spectra were recorded on a Nicolet iN 10 instrument (Thermo Fisher Scientific, USA) using a KBr matrix. Brunauer-Emmett-Teller (BET) surface area was determined by N_2 adsorption at 77K using a Quadrasorb SI system (USA). Additional characterization of physicochemical properties for the synthesized nanomaterials included X-ray photoelectron spectroscopy (K-Alpha + type; Thermo Scientific, USA), thermal analysis by DSC/DTA-TG (STA449 F3; NETZSCH, Germany), microscopic laser Raman spectroscopy (Renishaw inVia, UK), and electron paramagnetic resonance/electron spin resonance (EPR/ESR) spectroscopy (EMXplus-6/1; Bruker, Germany).

2.3. Preparation of the 3D-V₂O₅/NC nanocomposite and intermediate products

2.3.1. Preparation of 3D-V₂O₅/NC nanocomposite

The 3D-V₂O₅/NC nanocomposite was synthesized using a self-templating strategy. Firstly, 0.42 g OXA and 0.23 g NH_4VO_3 were dissolved in 80 mL of deionized water to form a homogeneous solution. Then, 4.0 g of DCA was added and dried in an oil bath at 80 °C. The resulting precursors were calcined at 800 °C for 2 h in a N_2 atmosphere at a heating rate of 2 °C/min to obtain the VN/NC composites. Finally, the VN/NC was heated to 280 °C in an air atmosphere at a heating rate of 1 °C/min and held for 8 h to prepare the 3D-V₂O₅/NC nanocomposite.

2.3.2. Preparation of VO₂/g-C₃N₄

The operational procedures were similar as the synthesis of 3D-V₂O₅/NC, except that the precursors were heated in a N_2 atmosphere to 550 °C and held for 2 h.

2.3.3. Preparation of NC

Briefly, 0.1 g of glucose and 1.0 g of DCA were dissolved in deionized water. After stirring and drying in an oil bath at 80 °C, the resultant precursor was calcined in a N_2 atmosphere at 800 °C for 2 h at a heating rate of 2 °C/min.

2.4. Enzyme-like activity of 3D-V₂O₅/NC and its steady-state kinetics

By employing TMB as a chromogenic substrate, a series of colorimetric reactions were conducted to investigate the enzyme-mimetic activity of the 3D-V₂O₅/NC nanocomposite. After the reaction of 3D-V₂O₅/NC with H_2O_2, the absorbance intensity at 652 nm (A_{652}) was measured by a UV-5500PC spectrophotometer. Briefly, 60 μL of 250 μg/mL 3D-V₂O₅/NC suspension was added to 1700 μL of NaAc-HAc buffer solution (20 mM, pH = 3.6). Then, 200 μL of 6 mM TMB and 40 μL of 5 mM H_2O_2 were added sequentially to the above solution. The A_{652} values were determined after a 20-min incubation at 30 °C and filtration through a 0.45-μm cellulose membrane filter.

The steady-state kinetics of 3D-V₂O₅/NC were analyzed at 30 °C and a constant H_2O_2 level (5 mM) using a varying TMB concentration (0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, and 1.0 mM). The catalytic kinetics were also investigated at a constant TMB level (6 mM) and varying H_2O_2 concentration (0.01, 0.03, 0.04, 0.06, 0.07, 0.08, 0.09, 0.1, 0.2, 0.4, 0.6, 0.8 mM). Catalytic parameters for the steady-state kinetics were determined by fitting the A_{652} data to the Michaelis-Menten equation (1), which presents the relationship between the conversion rate of a given substrate and the substrate concentration by an enzyme (in this case 3D-V₂O₅/NC):

$$1/V = (K_m/V_{max})(1/[S]) + 1/V_{max} \tag{1}$$

where Km is the Michaelis-Menten constant, V_{max} is the maximum

reaction rate, and *[S]* is the TMB concentration.

2.5. Catalytic mechanisms associated with the enzyme-like activity of 3D-V₂O₅/NC

Previous studies have confirmed the scavenging capacity of IPA, EDTA, NaN_3 and PBQ for hydroxyl radicals (·OH), electron vacancies (h^+), singlet oxygen ($^1O_2$) and superoxide radicals (·O_2^-), respectively [19,20]. To determine the type of ROS involved in the catalytic reaction, we added 200 μL of each scavenger and 100 μL of 3D-V₂O₅/NC nanocomposite to 1.7 mL of H_2O_2-TMB solution and measured the A_{652} values after a 20-min incubation. According to changes in Km values, the predominant ROS promoting the catalytic reaction in the 3D-V₂O₅/N-C-H_2O_2-TMB system was identified.

The generation of ·OH, h^+, $^1O_2$, and·O_2^- was determined by EPR spectroscopy using DMPO spin-trapping adducts (DMPO: 5,5′-dimethyl-1-pyrroline N-oxide). ·OH, h^+, and $^1O_2$ were detected under the conditions of NaAc buffer (0.2 M, pH = 3.6) as a solvent and the concentration of 3D-V₂O₅/NC at 1 mg/mL. After holding light for 5 min at room temperature, the solution was sucked into a quartz capillary for EPR analysis. The detection of ·O_2^- was carried out using methanol as a solvent, and the other operations were similar as the detection of ·OH, h^+, and $^1O_2$.

2.6. Construction of a colorimetric sensing platform based on the 3D-V₂O₅/NC

2.6.1. Colorimetric analysis of H₂O₂

A total volume of 2 mL NaAc-HAc buffer (pH 3.6, 200 mM), containing H_2O_2 (0–5 mM), 0.25 mg/mL 3D-V₂O₅/NC and 6 mM TMB, was incubated at 30 °C for 20 min. After transferring the resultant solution into a cuvette, the A_{652} value was determined by UV–vis spectroscopy, and the corresponding calibration plot was constructed between A_{652} and H_2O_2 concentration.

2.6.2. Colorimetric analysis of AA

As described above, a total volume of 2 mL NaAc-HAc buffer (pH 3.6, 200 mM) containing 5 mM H_2O_2, 0.25 mg/mL 3D-V₂O₅/NC, 6 mM TMB, and varying concentrations of AA (0.1–500 μM) was incubated at 30 °C for 20 min. Other operational conditions were held similar to the colorimetric analysis for H_2O_2.

To investigate the selectivity of the 3D-V₂O₅/NC/TMB/H_2O_2 system toward AA detection, a range of interfering substances were added, including metal ions (Na^+, K^+, Ca^{2+}, Mg^{2+}), amino acids (His, Ser, Gly, Try, L-Cys, and Tyr), saccharide (Fru, Suc and Gal), GSH, and UA. Also, Glu, CA, and H_2Mi commonly present in beverage ingredients were selected as interfering substances. The concentrations of AA, L-Cys, GSH, and UA were set at 1.0 mM, whereas metal ions and biological molecules were set at 10.0 mM.

To determine the reproducibility of the constructed colorimetric sensor for AA assay, the post-reaction solution was centrifuged at 5000 rpm for 3 min. The filtered 3D-V₂O₅/NC nanocomposites were washed and dried for colorimetric assay as described above, and the corresponding A_{652} values were determined to assess changes in absorbance intensity during reuse cycles.

2.7. AA assay for vitamin C tablets and TAC assessment for real-world beverage

To further verify the reliability and accuracy of this proposed method, we determined the contents of AA in various Vitamin C tablets, which were purchased from a local drugstore using TMB assay method. Vitamin C tablets were ground into powder and diluted by 20–40-fold with ultrapure water to ensure that the AA concentrations fell within the linear range of the calibration curve.

Using AA as a representative antioxidant, TAC was defined as molar

equivalent per liter of AA (AA mM/L). TAC tests were performed in six beverages procured from a local supermarket in Suzhou, China. Beverage samples were filtered through a 0.22-μm membrane filter and further diluted by 20–30-fold with ultrapure water. For the TAC assessment, 5 mM of H_2O_2, 0.25 mg/mL of 3D-V_2O_5/NC, 6 mM of TMB and 0.3 mL of the aforementioned diluted samples were added to 50 mL of 0.2 M NaAc-HAc buffer (pH 3.6). The mixed solution was incubated at 30 °C for 20 min, and then the A_{652} value was recorded and used for calculating molar equivalent of AA based on the linear equation of AA detection. Finally, TAC's evaluation was obtained by the absorbance conversion and multiplying by dilution fold. To perform recovery test, varying amounts of AA solution with a known concentration were fortified to the real samples and determined to obtain the value of equivalent AA.

2.8. Visual assessment of TAC using a smartphone-based platform

A practicable smartphone-based colorimetric sensor was developed as a low-cost and convenient assessment for TAC. The AA concentration was determined under optimized conditions in the mixed system of 3D-V_2O_5/NC + H_2O_2+TMB. A smartphone was used to capture chromaticity images, and the color intensity of the images were quantified using "Thing Identify" APP software, which was previously developed by our group [7,18]. The APP automatically recognized the images and converts them to RGB intensity values. Based on the relationship between color intensity and input concentration, a calibration curve is automatically established. Finally, the corresponding linear equation, correlation coefficient, and detected concentration are rapidly displayed on the screen. Fig. S1 provides detailed operational procedures for the smartphone-based TAC assessment.

3. Results and discussion

3.1. Synthesis and characterization of 3D-V_2O_5/NC

3.1.1. The synthesis of 3D-V_2O_5/NC

The mixed precursors of OXA, DCA, and NH_4VO_3 were first annealed at 550 °C under a N_2 atmosphere, during which DCA was converted to an intermediate graphitic carbon nitride (g-C_3N_4) and NH_4VO_3 was reduced to VO_2 [21] (See Scheme 1). The intermediates consist of crystals with varying nanometer sizes and a smooth surface with some agglomerated nanoparticles appearing on the surface to produce VO_2/g-C_3N_4 nanocomposites (Fig. S2a). After continuing the annealing at 800 °C in a N_2 atmosphere, a flake-like NC material was obtained with small nanoparticles uniformly dispersed on the NC surface (VN/NC, Fig. S2b) [22]. Finally, the resultant product was exposed to ambient air and calcined at 280 °C to acquire the final targeted nanocomposite (3D-V_2O_5/NC), which exhibited amorphous flakes coated with some fine particles (Fig. 1a and b). Process-wise, DCA was converted to g-C_3N_4 at

~530 °C and completely decomposed at a temperature above 700 °C [23]. Kuai and coworkers found that g-C_3N_4 was carbonized into the 3D mesoporous N-doped carbon network at 800 °C and formed VN with VO_2 due to the electrostatic interaction between the protonation of lone pair electrons of pyridinic N in g-C_3N_4 and $(VO)_2(C_2O_4)_3^{2-}$ pieces [24]. The 3D carbon network formed during the later pyrolysis protected the V_2O_5 from irreversible polymerization and aggregation, resulting in the formation of a porous composite with ultrafine nanoparticles.

#### 3.1.2. The morphology of 3D-V_2O_5/NC

SEM images of NC showed a smooth and porous surface (Fig. S2c). After attaching NC to V_2O_5 nanomaterials, it was observed that some small particles adhered to the surface of the porous carbon layer, forming a heterogeneous structure (Fig. 1a). Further, SEM and TEM observations of V_2O_5 nanocrystals showed ultra-small average size of 2.5 nm that were uniformly immobilized on the porous carbon surface (Fig. 1a and b). HRTEM observation found different lattice layers with a spacing of 0.21 nm for the (211) crystal axis of V_2O_5 and 0.34 nm for the (002) crystal axis of carbon (Fig. 1c). The uniform distribution of C, N, V and O in the nanocomposites was clearly exhibited by EDS mapping (Fig. 1d), which further demonstrated the uniform dispersion of V_2O_5 nanoparticles. The mass percentages of C, N, V and O in the 3D-V_2O_5/NC were 21.8%, 4.9%, 43.1% and 30.2%, respectively (Fig. S3).

3.1.3. Specific surface area of 3D-V_2O_5/NC

The specific surface area of 3D-V_2O_5/NC was assessed via a series of N_2 adsorption/desorption analyses. A wide type-II isotherm with hysteresis lines and a pore distribution of 2–30 nm was observed in the 3D-V_2O_5/NC evidencing its mesoporous structure (Fig. S4). The BET surface area of 3D-V_2O_5/NC was 152.4 m^2/g, while those of NC, VO_2/g-C_3N_4, VN\NC and commercial V_2O_5 were 321.9 m^2/g, 53.1 m^2/g, 446.3 m^2/g and 7.9 m^2/g, respectively. By way of contrast, the BET surface area of 3D-V_2O_5/NC was larger than that of commercial V_2O_5, but lower than NC (Table S1). This was mainly due to the loading of smaller V_2O_5 nanoparticles on the surface and pore channels of the carbon material, thereby leading to a slight decrease in surface area. Notably, the porous structure and larger surface area of 3D-V_2O_5/NC increase its surface adsorption and active sites, which enhance the potential for reaction with target molecules and promote electron transfer, thus improving the enzyme-mimetic catalytic activity.

3.1.4. FT-IR analysis of 3D-V_2O_5/NC

The FT-IR spectrum of 3D-V_2O_5/NC was divided into three main regions: 450-1050 cm^{-1}, 1200-1650 cm^{-1} and 3100-3500 cm^{-1} (Fig. 1e). Peaks at 3100 and 3500 cm^{-1} are attributed to the stretching vibrations of N–H and O–H, respectively [25]. The absorption peaks located at ~565 cm^{-1} and 765 cm^{-1} belong to V–O–V stretching vibration, and 1015 cm^{-1} to the stretching vibration of V=O, highlighting the presence of V_2O_5 particles in the sample [26]. Additional peaks at
**Scheme 1.** Schematic for the synthesis of 3D-V_2O_5/NC nanocomposite.

Fig. 1. (a) SEM image; (b) TEM image and size distribution (insert); (c) HRTEM image; (d) Elemental mapping; (e) FTIR spectra; (f) Raman spectra; and (g) XRD patterns of 3D-V$_2$O$_5$/NC.

1636 and 1398 cm^{-1} are attributable to the C–N and C≡N stretching vibrations, respectively, providing compelling evidence for the presence of NC in the 3D-V$_2$O$_5$/NC nanocomposite [27].

3.1.5. Raman analysis of 3D-V$_2$O$_5$/NC

Raman spectroscopy identified two characteristic peaks at 1334 cm^{-1} (D band) and 1570 cm^{-1} (G band) in both NC and 3D-V$_2$O$_5$/NC (Fig. 1f). The D-band represents the disordered carbon or graphite structural defects, whereas the G-band is related to the graphitization level [28]. The peak intensity ratios of the D band to G band (I$_D$/I$_G$) were 1.04 and 0.98 for NC and 3D-V$_2$O$_5$/NC, respectively, documenting the presence of abundant defects in the porous carbon structure. Compared to NC, the slightly lower I$_D$/I$_G$ value for 3D-V$_2$O$_5$/NC may be attributed to the pyrolysis process incorporating some V$_2$O$_5$ nanoparticles into defect sites, thereby reducing the disorder [29].

3.1.6. XRD analysis of 3D-V$_2$O$_5$/NC

XRD was used to evaluate the phase purity and crystallinity of the 3D-V$_2$O$_5$/NC nanocomposites (Fig. 1g). As for VO$_2$/g-C$_3$N$_4$, the peak at 2θ = 26.1 implies the formation of g-C$_3$N$_4$ during annealing [30], whereas the absence of a VO$_2$ signal may be ascribed to its amorphous structure at low annealing temperatures (≤550 °C). In contrast, the high crystallinity of 3D-V$_2$O$_5$/NC was apparent from the sharp peaks at 15.3, 20.3, 21.7, 26.1 and 31.0, belonging to the (200), (001), (101), (110) and (301) crystal planes, respectively, which matched with the standard card of vanadium pentoxide (PDF#41–1426). However, the peak

intensities for 3D-V$_2$O$_5$/NC were significantly weaker compared to pure V$_2$O$_5$, which is attributed to the substantially reduced particle size, a common phenomenon with constructed nanomaterials having ultrafine particle sizes [31]. These diffraction data provide compelling evidence for the successful preparation of a 3D-V$_2$O$_5$/NC nanocomposite with a high purity level.

3.1.7. XPS analysis of 3D-V$_2$O$_5$/NC

The elemental composition and surface oxidation state of the 3D-V$_2$O$_5$/NC nanocomposite were assessed by XPS. The percentages of V, C, N and O in the nanocomposites were 19.3%, 47.4%, 4.6% and 28.7%, respectively, demonstrating the presence of N-doped carbon nanosheets of VO$_x$ (Fig. S5). The two peaks at 516.8 eV and 524.0 eV denote V^{5+} (2p 3/2) and V^{5+} (2p 1/2), respectively (Fig. 2a), whereas the peak at 515.4 eV represents V^{4+} (2p 3/2). The presence of V^{4+} in the nanocomposite confirms that the reducing atmosphere (CO and NO) during calcination caused the reduction of some V^{5+} to V^{4+} [32]. As exhibited in Fig. 2b, the N1s spectra were deconvoluted into three peaks (398.7, 399.6, and 401 eV) attributable to pyridine-N, pyrrole-N and graphite-N, respectively [33]. N doping was conducive to improving electron transfer in the 3D-V$_2$O$_5$/NC nanocomposite, thereby greatly enhancing the catalytic performance. Pyridine-N and pyrrole-N in nitrogen-doped carbon-based nanomaterials have been well documented [34]. The deconvolution of the C1s spectrum produced three peaks at 284.1, 285.3 and 287.7 eV, corresponding to C–C, C≡N–C and C–N, respectively (Fig. 2c). The formation of C≡N–C and C–N further confirms the
Fig. 2. High-resolution XPS spectra for 3D-V$_2$O$_5$/NC composite: (a) V 2p, (b) N 1s, (c) C 1s and (d) O 1s.

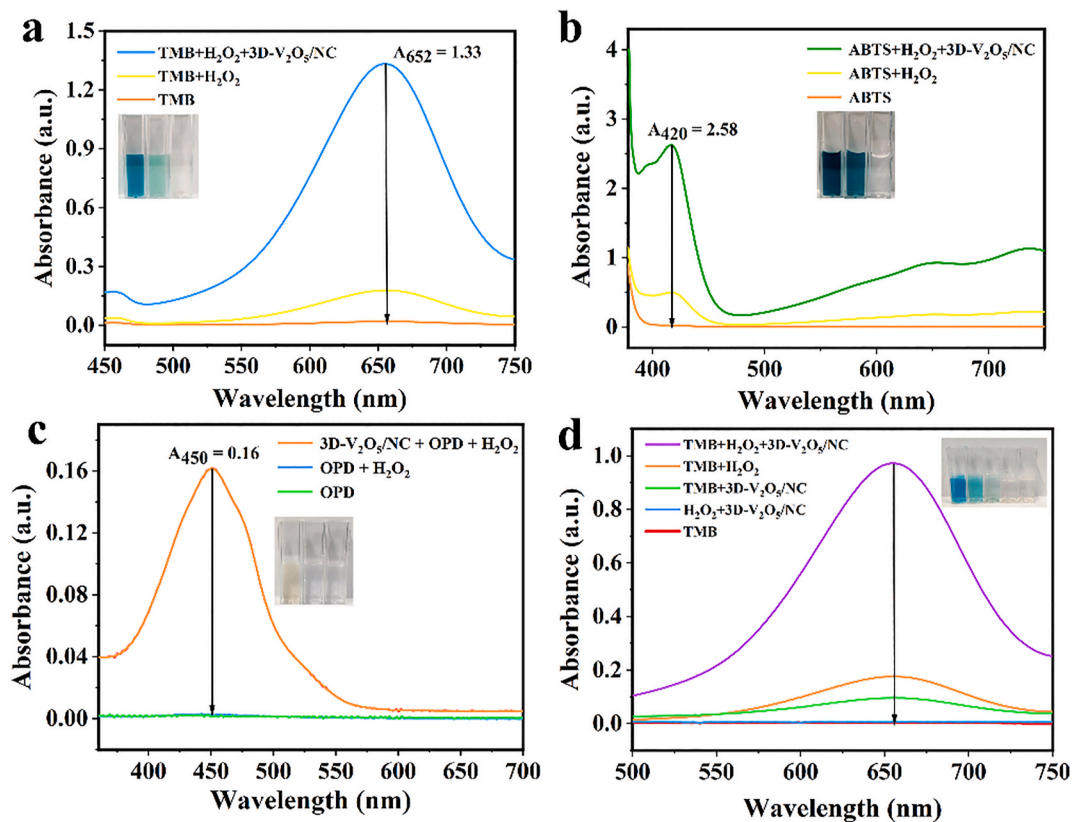

Fig. 3. UV–vis absorption spectra of TMB (a), ABTS (b) and OPD (c) catalyzed by 3D-V$_2$O$_5$/NC. successful doping of N atoms into the carbon-based materials. Further, the O1s spectrum was deconvoluted into two main peaks at 529.6 eV and 530.4 eV, which corresponded to lattice oxygen and O–V^{5+} functional groups in the 3D-V_2O_5/NC (Fig. 2d). The minor peak at 532.6 eV was attributable to C–O, and these observations highlighted the presence of V_2O_5 [35]. The overall results from SEM, XRD, EDS, XPS, Raman and FT-IR analyses provide compelling evidence that a 3D-V_2O_5/NC nanocomposite was successfully prepared.

3.2. Construction of a colorimetric sensing platform based on the 3D-V_2O_5/NC-TMB-H_2O_2 mixed system

3.2.1. Screening of the chromogenic substrates

To investigate the enzyme-like activity of the 3D-V_2O_5/NC nanocomposite, three common chromogenic substrates (TMB, ABTS and OPD) were assessed for their color development. The reaction system without a chromogenic substrate was used as a blank control. The reaction systems with TMB, ABTS and OPD yielded three corresponding absorption peaks at 652, 420 and 450 nm, respectively (Fig. 3a–c), indicating that the enzyme-like activity of the 3D-V_2O_5/NC nanocomposite was not specific to the three chromogenic substrates. Under identical experimental conditions, the absorbance at 450 nm (A_{450}) in the presence of OPD was as low as 0.16 with no obvious color variation. In sharp contrast, the A_{420} value reached as high as 2.58 in the presence of ABTS. Compared to the chromogenic substrates OPD and ABTS, TMB gave the more appropriate absorbance value (1.33) at 652 nm. As for OPD, it not only provided the lower A_{450} value (0.16), but also had strong carcinogenicity compared to TMB. Although the color development reaction of TMB resulted from the similar redox reaction as OPD, the reaction of the former was reversible. If there was a reducing agent, such as vitamin C, in the solution, the color development could quickly

subside. With regard to ABTS, its A_{420} value reached as high as 2.58. When the absorbance value was greater than 2.0, the saturated optical density led to a significant decrease in color recognition sensitivity, which would result in a large experimental error due to inaccurate absorbance data. Moreover, the price of ABTS with purity >99.0% is much higher than that of TMB. Based on the above considerations, we selected TMB as the appropriately chromogenic substrate.

3.2.2. Enzymatic activity of 3D-V_2O_5/NC

The 3D-V_2O_5/NC nanocomposite had a large specific surface area, multiple active sites, and an abundance of structural vacancies, which led us to rigorously explore its enzyme-mimetic activity and its underlying catalytic mechanisms. When the solution contained only TMB or 3D-V_2O_5/NC-H_2O_2, the solution was colorless with no corresponding UV–vis absorption (Fig. 3d). The TMB + H_2O_2 system exhibited a weak absorption (A_{652} of 0.17), which possibly originated from the decomposition of some H_2O_2 molecules. When the reaction system included 3D-V_2O_5/NC and TMB, the solution turned light blue and produced a weak absorption peak at 652 nm, suggesting that the 3D-V_2O_5/NC may have a weak OXD-like activity. Only when 3D-V_2O_5/NC, TMB and H_2O_2 were present simultaneously, the solution turned bright blue with pronounced A_{652} values. According to the report by Jing and colleagues, CAT could catalyze H_2O_2 to produce O_2, while POD could decompose H_2O_2 into ·OH [36]. Based on the as-described phenomena and the previous literature, we infer that the 3D-V_2O_5/NC nanocomposite possesses POD-like and/or CAT-like activities along with OXD-like property.

To demonstrate whether the prepared nanocomposites have OXD-like activity and whether O_2 plays a role in the reaction, solution color changes were observed in the presence of 3D-V_2O_5/NC and in the absence of H_2O_2 under an O_2 (oxic) or N_2 (anoxic) atmosphere. A bright

**Fig. 4.** (a) The UV–vis spectra of the TMB+3D-V_2O_5/NC system in air, O_2 and N_2. (b) Catalytic activities of five nanomaterials (NC, V_2O_5, VN/NC, VO_2/g-C_3N_4, 3D-V_2O_5/NC) on TMB. Effects of (c) pH and (d) temperature on the enzymatic activity of 3D-V_2O_5/NC.

blue color was observed in the presence of O_2, whereas only a weak blue color developed in the N_2 atmosphere (Fig. 4a). To demonstrate whether or not the as-prepared nanocomposite possessed CAT-like activity and H_2O_2 played a crucial role in the reactive system, the following experiments were conducted. Firstly, 250 μg mL^{-1} of 3D-V_2O_5/NC and 50 mM H_2O_2 were added to NaAc-HAc buffer solution (20 mM, pH = 3.6) and incubated for 6 min. Then, the 240-nm absorbance values were recorded using a UV–vis spectrophotometer. As shown in Fig. S7, when the 3D-V_2O_5/NC and H_2O_2 co-existed, the A240 values were significantly reduced, which implied that H_2O_2 was decomposed to a large extent. Building upon the above analyses, it can be concluded that the 3D-V_2O_5/NC nanocomposite might possess both OXD-like and CAT-like activities. More importantly, the CAT-mimetic activity of 3D-V_2O_5/NC is related to the reduction of H_2O_2. To sum up, these phenomena provide compelling evidence that H_2O_2 plays an important role in the chromogenic system. As a result. we selected the 3D-V_2O_5/NC + TMB + H_2O_2 system for further exploration.

3.2.3. Comparison of enzyme activity of 3D-V_2O_5/NC with components and intermediates

To investigate the effect of each component in the nanocomposite on chromogenesis, three experiments were conducted to compare the differential enzyme-like activities for the contrasting nanomaterials (3D-V_2O_5/NC, NC, and V_2O_5). The 3D-V_2O_5/NC + TMB + H_2O_2 system showed the strongest 652-nm absorbance (A_{652} = 3.1), followed by the V_2O_5+TMB + H_2O_2 system (A_{652} = 1.25), and the NC + TMB + H_2O_2 system (A_{652} = 1.2) (Fig. 4b). Obviously, the 3D-V_2O_5/NC nanocomposite with the strongest catalytic capacity might be explained by the fact that the 3D porous nitrogen-doped carbon framework and the ultrafine structure of V_2O_5 nanoparticles effectively improve the number of active sites. Further, the homogeneous anchoring of V_2O_5 nanoparticles onto the carbon substrate facilitates electron transfer in the catalytic reaction, thereby enhancing interactions between the nanozyme and chromogenic substrate. Thus, we posit that compared to its precursors, the enhanced enzyme-like activity of 3D-V_2O_5/NC resulted from synergistic effects between NC and V_2O_5. In addition, the intermediates VN/NC and VO_2/g-C_3N_4 in the material synthesis process were selected for comparative enzymatic activity experiments. Both the VN/NC + TMB + H_2O_2 system (A_{652} = 1.3) and the VO_2/g-C_3N_4+TMB + H_2O_2 system(A_{652} = 0.5) showed much lower absorbance than the 3D-V_2O_5/NC system (Fig. 4b).

3.2.4. Optimization of the important experimental conditions

Across the pH range of 3.2–6.0, the highest A_{652} value was observed at the solution pH 3.6 (Fig. 4c). Further increases or decreases in the pH of the reaction system would lead to the decreasing catalytic activity. Especially, when the pH was close to 6.0, the 3D-V_2O_5/NC almost lost its catalytic activity, indicating that the reaction system is more active in the weakly acidic solutions, which was consistent with previous report [37]. This pH-dependent activity was similar for V_2O_5 and NC nanomaterials (Figs. S8a and d). The acid-enhanced catalytic reactivity of TMB resulted from its limited solubility in aqueous solution, which was improved due to the protonation of one amino group under weak acid conditions [38]. However, the excessive lower solution pH caused the protonation of two amino groups in the TMB molecules, which led to the substrate insusceptibility to catalytic oxidation and further decrease the enzyme-like activity. Similar to natural enzymes, too high or low temperature values significantly inhibit the catalytic effect. For example, A_{652} values gradually increased from 2.12 to 3.02 as the temperature increased from 25 to 30 °C; however, as the temperature further increased from 30 to 50 °C, the 652-nm absorbance decreased dramatically to 1.25. The high temperature possibly affected the nanosheet stability resulting in the lower catalytic capacity.

Increasing the 3D-V_2O_5/NC concentration from 0 to 1 mg/mL resulted in a monotonic increase in the A_{652} value from 0.51 to 3.52 (Fig. S9b). However, as the 3D-V_2O_5/NC concentration exceeded 0.7

mg/mL, there was no further increase in 652-nm absorption. This suggests that the catalytic activity of this nanozyme reached a plateau, and due to substrate limitation, an excessive amount of nanoenzyme did not contribute to further color development [39]. Notably, when A_{652} values exceed 2.0, absorption saturation leads to a decrease in color recognition sensitivity. Moreover, with increasing incubation time from 0 to 30 min, the 652-nm absorbance prominently increased from 0.21 to 1.18 a.u. within 20 min, whereas it remained nearly unchanged (~1.20 a.u.) from 20 to 30 min (Fig. S9a). Synthesizing these experimental results, we ascertained the optimized experimental conditions as follows: incubation temperature, 30 °C; initial solution pH, 3.6; 3D-V_2O_5/NC concentration, 0.25 mg/mL; and incubation time, 20 min.

3.3. Steady-state kinetics of the 3D-V_2O_5/NC nanoenzyme

We next investigated the steady-state kinetics of 3D-V_2O_5/NC nanocomposites under optimized conditions across variable TMB (0.01–0.1 mM) and H_2O_2 (0.01–0.8 mM) concentrations. The Michaelis-Menten constant (K_m) and maximum rate (V_{max}) were calculated based on Lineweaver-Burk plots (Fig. 5a–d). The K_m value for the 3D-V_2O_5/NC-TMB-H_2O_2 mixed system was 0.13 for TMB and 0.12 for H_2O_2. These values were much lower than those for HRP, V_2O_5 and selected vanadium-based nanoenzymes (Table 1), thereby confirming the greater affinity of 3D-V_2O_5/NC for the substrate [40–45]. This nanozyme has better catalytic activity than common HRP, which may be attributable to the multiple active sites on the surface of 3D-V_2O_5/NC nanoparticles.

3.4. Mechanisms associated with the catalytic activity of 3D-V_2O_5/NC

The individual chromotest yielded a preliminary assessment of the enzyme-mimetic activity of 3D-V_2O_5/NC. To elucidate the underlying mechanisms responsible for the catalytic performance of 3D-V_2O_5/NC, a series of ROS capture experiments were conducted using selective scavengers: EDTA for h$^+$, IPA for ·OH, NaN$_3$ for $^1O_2$ and PBQ for ·O_2^-. If the free radical species for catalyzing the reaction was captured by the scavenger, the corresponding response signal would prominently decline. Addition of PBQ scavenger resulted in a significant drop (>96.0%) in the relative activity of 3D-V_2O_5/NC (Fig. 6a), highlighting the crucial role that ·O_2^- plays in the catalytic reaction. After the addition of EDTA, the relative activity decreased by ~34.4% as compared to the control without fortification, implying the participation of some h$^+$ in the catalytic reaction. In contrast, the presence of IPA had no significant effect on the A_{652} value indicating that ·OH has a negligible effect on the catalytic process. That is to say, the synthesized nanocomposite does not have POD-like activity. Owing to the fact that CAT decomposed H_2O_2 to produce O_2, we preliminarily inferred that 3D-V_2O_5/NC has dual enzyme-mimetic activities (i.e., CAT and OXD) and ·OH does not play an important role in the catalytic reactions.

The presence of free radical participation in the 3D-V_2O_5/NC-based catalytic system was further inferred by EPR analysis. As elaborated in Fig. 6b-d and S10, strong characteristic signals for h$^+$, $^1O_2$, and ·O_2^- were detected, with a small ·OH signal due to the presence of H_2O_2. These results indicate that the 3D-V_2O_5/NC nanozyme was able to catalyze H_2O_2 to produce O_2, and further oxidize O_2 to ·O_2^- and $^1O_2$ due to its OXD-like activity (Scheme 2). This leads us to conclude that the 3D-V_2O_5/NC nanozyme possesses both CAT-like and OXD-like dual enzymatic activity. The multivalent state of vanadium in the synthesized nanocomposite and the synergistic interactions between vanadium and N-doped carbon accelerate electron transfer and enhance redox capacity, thereby facilitating the catalytic process.

3.5. Colorimetric detection of H_2O_2 and AA

3.5.1. H_2O_2 detection

Based on the 3D-V_2O_5/NC nanozyme, a simple method was developed as a sensing platform for quantitative detection of H_2O_2. In the
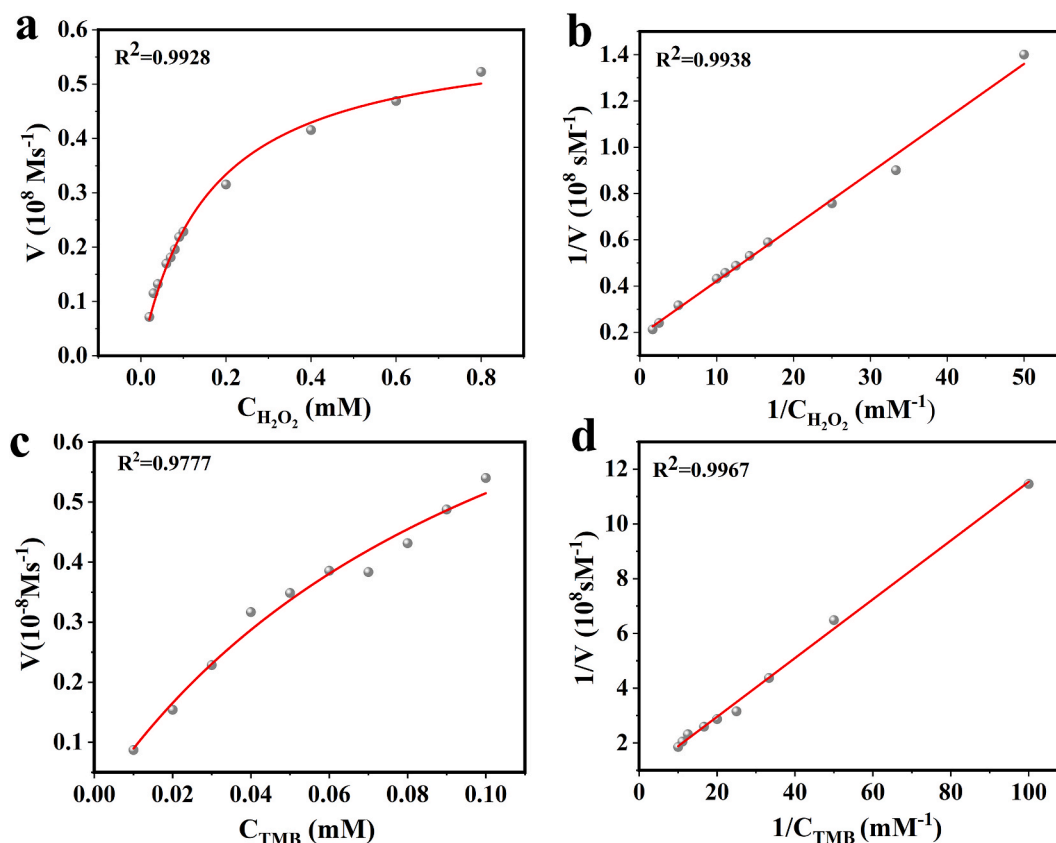

Fig. 5. Michaelis-Menten plots of 3D-V$_2$O$_5$/NC fitted for varying (a) H$_2$O$_2$ and (c)TMB concentrations; and the associated Lineweaver-Burk plots for (b) H$_2$O$_2$ and (d)TMB.

Table 1
Michaelis-Menten constants for H$_2$O$_2$ and TMB substrates and their comparison to HRP and other selected nanozymes.

Catalyst	K_m (mM)		V_{max} (10^{-8} M/s)		Refs.
	H$_2$O$_2$	TMB	H$_2$O$_2$	TMB	
HRP	0.21	2.46	2.46	1.24	[40]
N-doped carbon	0.28	95.8	2.44	410	This work
V$_2$O$_5$	0.96	3.30	8.36	3.11	This work
Fe$_3$O$_4$ MNPs	154	0.10	9.78	3.34	[41]
VO$_2$(B)	1.69	0.15	177	131	[42]
VO$_2$(A)	0.06	0.17	1.40	2.40	[43]
CeVO$_4$	0.16	0.33	8.53	3.61	[44]
V$_6$O$_{13}$	7.27	0.15	20.9	15.3	[45]
3D-V$_2$O$_5$/NC	0.12	0.13	5.16	12.4	This work

H$_2$O$_2$ concentration range of 0–5 mM, the 652-nm absorbance in the mixed system increased monotonically (Fig. 7a). A strong linear relationship was achieved with coefficients of determination (R^2) >0.9961 in the range of 10 μM-1.0 mM and 1.0–5.0 mM (inset of Fig. 7b). The corresponding limit of detection (LOD) was 3.0 μM based on a 3-fold ratio of signal to noise (S/N = 3). As summarized in Table S2, this 3D-V$_2$O$_5$/NC-based colorimetric sensor has a high sensitivity for H$_2$O$_2$ detection compared to previously reported nanozymes having an absence of 2D carbon nanosheets, such as MOF-818, CoS, V$_2$O$_5$–Mt, N-G-Fe$_3$O$_4$, CQDs, and V$_2$O$_5$–TiO$_2$ [46–51]. This phenomenon can be explained by the fact that the large specific surface area of 2D carbon nanosheets in the 3D-V$_2$O$_5$/NC nanocomposite effectively hinders the agglomeration of V$_2$O$_5$ and increases the active sites of the nanozyme. Moreover, owing to the mesoporous structure of carbon nanosheets, 3D-V$_2$O$_5$/NC accelerates the electron transfer rate and enhances the interactions between the nanozyme and substrate. These advantageous

properties of 3D-V$_2$O$_5$/NC enhance the overall sensitivity and improve the analytical performance for H$_2$O$_2$ quantification.

3.5.2. AA detection

Antioxidants inhibit oxidative reactions, to some extent, by virtue of their OXD activities. Herein, a typical and common antioxidant AA was chosen as a representative antioxidant for TAC assessment because of its ability to react with and consume free radicals. Several colorimetric tests were performed on varying AA concentrations under optimized experimental conditions as discuss above. Due to its dual enzyme-mimetic activity, the 3D-V$_2$O$_5$/NC promoted the oxidation of colorless TMB to a blue TMB$_{ox}$ form. The 652-nm absorbance intensities decreased with increasing AA concentrations from 0 to 500 μM (Fig. 7c). When the dissolved oxygen approached the 3D-V$_2$O$_5$/NC nanocomposite, electrons were transferred from the surface to oxygen molecules to produce ^{1}O$_2$ and ·O$_2^-$. The addition of AA was conducive to the concentration-dependent reduction of oxTMB, thereby decreasing the 652-nm absorption.

Two concentration-dependent linear relationships were constructed between the 652-nm absorbance change (ΔA) and AA concentration: 0.1–7.0 μM, ΔA = 0.05029[AA] + 0.00499 (R^2 = 0.9980) and 10–500 μM, ΔA = 0.00153[AA] + 0.34799 (R^2 = 0.9963) (Fig. 7d) [14]. Based on a S/N of 3, the LOD for this colorimetric sensor was 0.03 μM. As summarized in Table 2, the constructed sensing platform for the AA assay possesses a wider linear range and lower LOD than previously reported nanozymes [14,52–54], as well as several other electrochemical and chemiluminescent approaches [55–59].

3.6. Interference effects on the constructed sensing platform

To evaluate the selectivity and potential interference effects on this colorimetric method, several interfering substances were fortified into
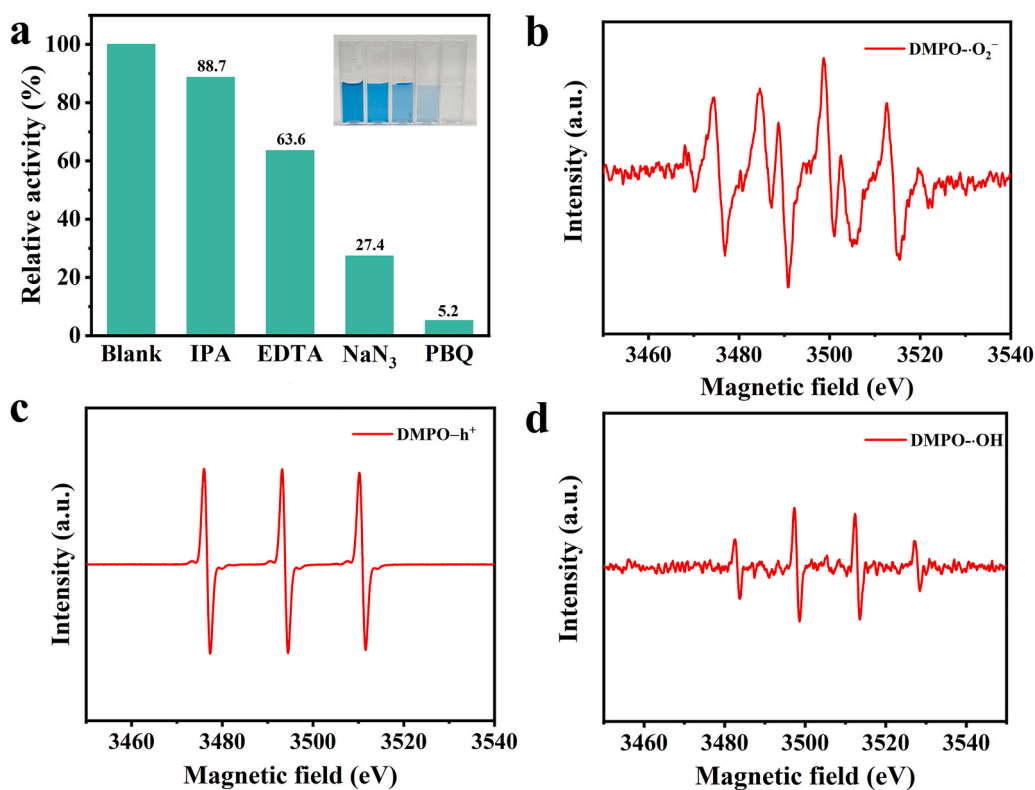

Fig. 6. (a) Effects of active scavengers on the catalysis of TMB in the presence of 3D-V$_2$O$_5$/NC; (b, c and d) EPR spectra of 3D-V$_2$O$_5$/NC.

Scheme 2. Proposed mechanism for CAT-like and OXD-like activity of 3D-V$_2$O$_5$/NC.

the 3D-V$_2$O$_5$/NC-TMB-H$_2$O$_2$ reaction system, including metal ions (Na$^+$, K$^+$, Ca^{2+}, Mg^{2+}), amino acids (His, Ser, Gly, Try, L-Cys, and Tyr), saccharide (Fru, Suc, Gal, Glu), GSH, CA, H$_2$Mi and UA. The effects of the aforementioned interfering substances on the AA assay were minimal, except for the antioxidants of L-Cys, UA and GSH (Fig. 8). At the same fortification level as AA, the Cys, UA and GSH biomolecules had lower inhibitory effects than AA, which might be related to their weaker reduction characteristics. These findings suggest that the interference effect from macromolecules and metal ions are in general very low, even at high fortification levels. Thus, we posit that the newly developed sensing platform, based on the 3D-V$_2$O$_5$/NC nanozyme, has high selectivity and low interference effects as a AA assay.

3.7. Reproducibility, storage stability and recyclability of the 3D-V$_2$O$_5$/ NC nanozyme

Upon addition of 0.3 mM AA, the 652-nm absorbance intensity did not differ significantly for five independent batches of 3D-V$_2$O$_5$/NC nanocomposite (Fig. 9a), and thus the nanozyme displayed good reproducibility. Similarly, the relatively catalytic activity of 3D-V$_2$O$_5$/NC remained >90% after 5 weeks of storage at room-temperature in a

sealed container confirming that the nanocomposite had a high storage stability. The reusability of the 3D-V$_2$O$_5$/NC nanoenzyme was evaluated by detecting its catalytic activity in reducing blue oxTMB to colorless TMB in the presence of 0.3 mM AA for five consecutive reaction cycles. The enzyme-like activity of 3D-V$_2$O$_5$/NC remained greater than 87% after five cycles, highlighting its excellent potential for reuse (Fig. 9c).

3.8. AA assay for vitamin C tablets and TAC assessment for real-world beverage

To validate the reliability and precision of the newly developed method in real-world samples, we determined the AA contents of six commercial vitamin C tablets (the three brands of bioflavonoid-vitamin tablets, multivitamin tablets and two simple vitamin tablets). As shown in Fig. 10a, the detected AA contents for the vitamin C tablets were in general agreement with the specified AA values (25–1000 mg for each tablet), which substantiated the accuracy and reliability of the 3D-V$_2$O$_5$/ NC based colorimetric method. Further, we estimated the TAC content of six commercial beverages (two juices, one lemon beverage, and three tea samples) based on the linear equation for AA detection. TAC was evaluated in the range of 3.89–21.16 mM with RSDs ≦3.4% in the unfortified samples (Table 3). The reliability of TAC assessment in real drinks was confirmed by adding the real samples with AA at known concentrations. At the two fortification levels (5 and 10 mM), the 3D-V$_2$O$_5$/NC-H$_2$O$_2$-TMB catalytic system provided relative AA recoveries from 93.0% to 109.5% with RSDs <5.70%.

The analytical performance of the newly developed method was compared with commercial ABTS test kits, in which the absorbance of ABTS•$^+$ was measured and used to calculate the TAC content. Trolox is a vitamin E analogue with a similar antioxidant capacity to vitamin E and is commonly used as a TAC reference for other antioxidants. A calibration plot was constructed between the 734-nm absorbance and Trolox concentration generating an R^2 of 0.9777 (Fig. 10b). TAC was detected in the range of 4.24–21.91 mM by the commercial ABTS kits with RSDs ≦3.9% (Table 4). Thus, the 3D-V$_2$O$_5$/NC based colorimetric method
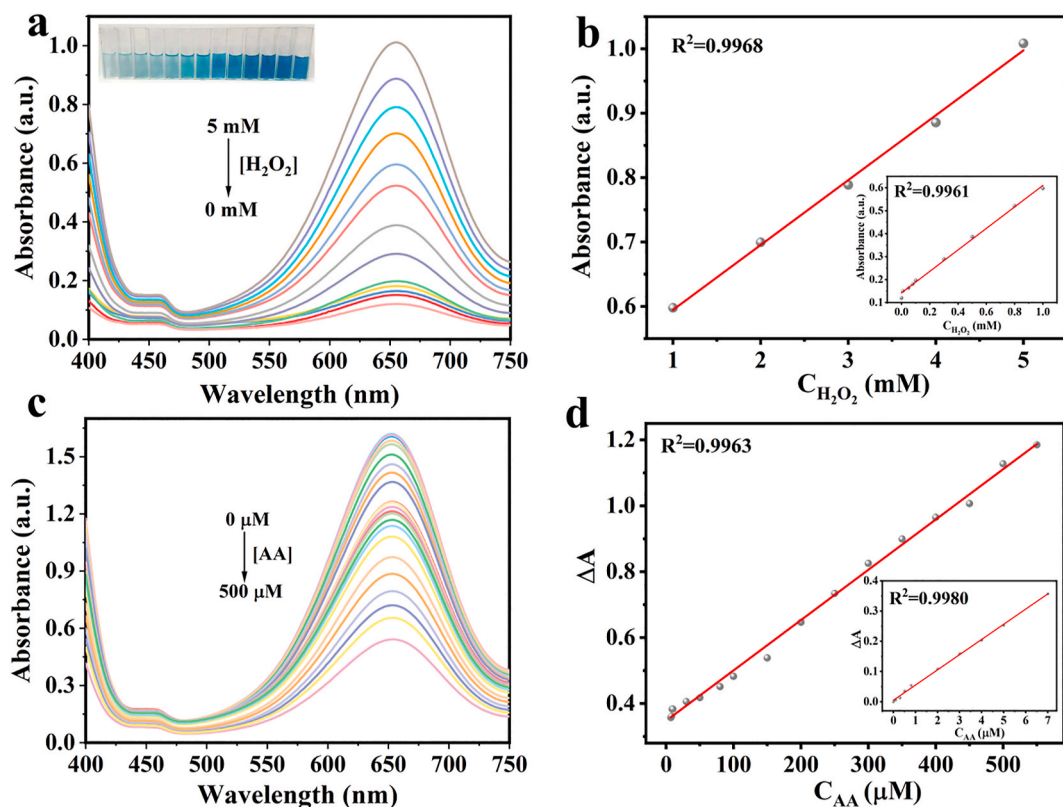

Fig. 7. (a) UV–vis absorbance spectra of TMB/H_2O_2/3D-V_2O_5/NC system in the presence of 0–5 mM H_2O_2. provides similar accuracy and reproducibility to the commercial ABTS kits, thereby documenting its potential for applications requiring TAC monitoring in pharmaceutical and food matrices.

3.9. TAC assessment using a smartphone-based platform

Based on the successful development of the 3D-V_2O_5/NC + TMB + H_2O_2 catalytic system, a smartphone-based colorimetric application (APP) was developed by employing "Thing Identify" software to quantify TAC (Fig. 11a). The overall operational procedures and detailed description for the APP are shown in Fig. S1. As exhibited on the smartphone screen of Fig. 11b, the color intensities monotonically decreases with increasing AA concentrations. Thus, a calibration curve was generated by plotting the color grayscale values for the reaction solution

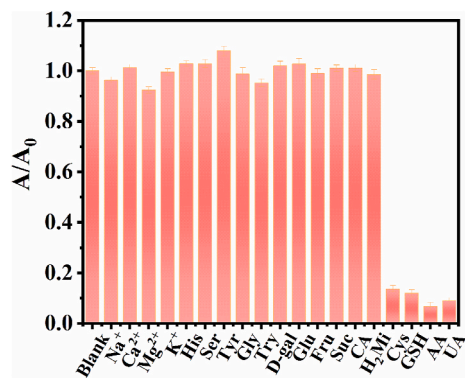

Fig. 8. Effects of potentially interfering substances on A_{652} of the TMB/H_2O_2/3D-V_2O_5/NC system relative to the non-fortified blank (mean ± SD). Experimental conditions: 10 mM of Na^+, Ca^{2+}, Mg^{2+}, K^+, His, Ser, Gly, Try, Tyr, Fru, Suc, Gal, Glu, CA, and H_2Mi; 1 mM of UA, AA, L-Cys, and GSH.

against the corresponding AA concentrations. A strong linear relationship was acquired across the AA concentration range of 1–500 μM with a regression equation of Y = 11.369 × X-861.89 (R^2 = 0.971), where X and Y are color grayscale value and the AA concentration, respectively. The LOD was 0.3 μM based on a S/N of 3, and the AA concentrations detected by the APP were comparable to the test results using conventional TAC assay kits (Table 4). In sum, the newly developed smartphone-based colorimetric platform possesses several prominent advantageous, such as simple, rapid and low-cost operation, portability, high throughput, feasibility for outdoor use, and adaptability for point-of-care applications.

4. Conclusions

Total antioxidant capacity (TAC) is an important parameter for evaluating the quality of antioxidant foods and monitoring the level of oxidative stress in humans. Herein, a 3D-V_2O_5/NC nanocomposite with OXD-like and CAT-like activities was successfully fabricated using a self-templating method. The synthesized nanocomposite had strong catalytic properties due to the generation of three free radicals ($^1O_2$, h^+, $\cdot O_2^-$) and
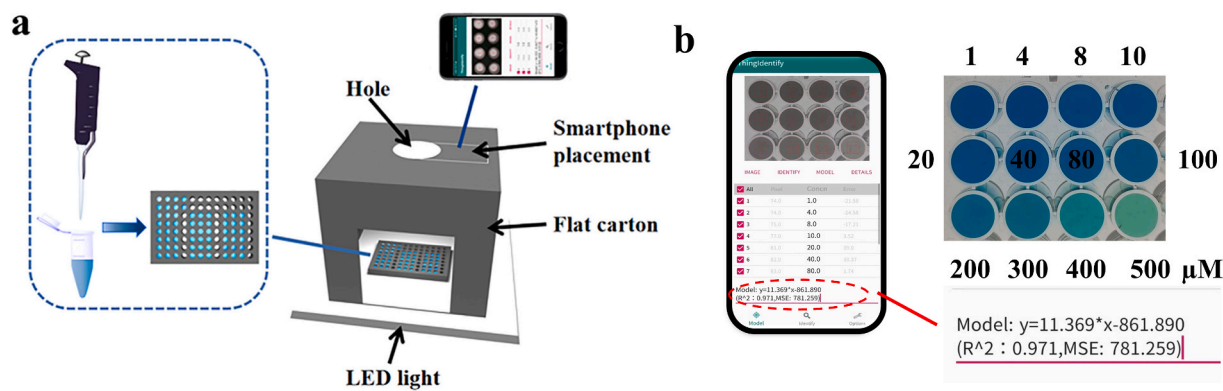

Fig. 11. (a) Schematic of smartphone-based platform for TAC quantification; and (b) Regression equation between absorbance and TAC concentrations (1–500 μM).

the synergistic effect between N-doped carbon lamellae and V_2O_5 nanoparticles that coexisted in multivalent states. Based on the dual enzyme-like activities of 3D-V_2O_5/NC, a highly selective/sensitive sensor was constructed for TAC assessment. The newly developed colorimetric platform had a detection limit of 0.03 μM for AA and relative recovery of 93.0–109.5% for AA, which were comparable with commercial ABTS test kits. The newly developed sensor was successfully deployed in a smartphone-based detection platform based on "Thing Identify" software. The method was successfully tested for *in-situ* TAC assessment of vitamin C tablets and a range of beverages, thereby demonstrating strong feasibility for remote outdoor or point-of-care applications.
