Edited by Dennis R. Voelker

Heavy metals released into the environment have a significant effect on respiratory health. Lung macrophages are important in mounting an inflammatory response to injury, but they are also involved in repair of injury. Macrophages develop mixed phenotypes in complex pathological conditions and polarize to a predominant phenotype depending on the duration and stage of injury and/or repair. Little is known about the reprogramming required for lung macrophages to switch between these divergent functions; therefore, understanding the mechanism(s) by which macrophages promote metabolic reprogramming to regulate lung injury is essential. Here, we show that lung macrophages polarize to a pro-inflammatory, classically activated phenotype after cadmium-mediated lung injury. Because metabolic adaptation provides energy for the diverse macrophage functions, these classically activated macrophages show metabolic reprogramming to glycolysis. RNA-Seq revealed up-regulation of glycolytic enzymes and transcription factors regulating glycolytic flux in lung macrophages from cadmium-exposed mice. Moreover, cadmium exposure promoted increased macrophage glycolytic function with enhanced extracellular acidification rate, glycolytic metabolites, and lactate excretion. These observations suggest that cadmium mediates the persistence of classically activated lung macrophages to exacerbate lung injury.

Environmental exposure to heavy metals is often overlooked in disease development (1, 2). Although smoking tobacco is an important source of heavy metal exposure in humans, cadmium exposure has been shown to double the risk of lung disease (2). The lung is the primary exposure route to environmental toxins and cadmium is absorbed more efficiently by the lungs with 50% of inhaled cadmium absorbed compared with 5% when orally ingested (3). Cadmium is widely distributed in the environment and natural air emission sources coming from volcanoes, airborne soil particles, and forest fires (3, 4). People residing near coal fired power plants, coke ovens, municipal waste, or strip mines are exposed to anthropogenic sources of cadmium due to movement of soil through wind, vehicles, and equipment (5).

Lung macrophages have a critical role in mounting an immune response to injury (6–8). Cadmium has been shown to suppress the innate immune response of macrophages. Lung

macrophages are also essential in mediating remodeling of the alveolar wall that is necessary following lung injury. To accommodate these diverse functions, macrophages are highly plastic and are able to adapt to their local environment (9–12). Macrophages switch between phenotypically distinct subpopulations, the classically activated, pro-inflammatory and the alternatively activated, anti-inflammatory macrophages. Macrophage polarization is tightly regulated, and mixed populations exist in complex pathological conditions (9–12).

Peroxisome proliferator-activated receptor γ (PPAR γ), a ligand-activated nuclear receptor, is essential for the differentiation of alveolar macrophages from fetal monocytes (13). PPAR γ has been implicated as a negative regulator of the inflammatory response by inhibiting production of pro-inflammatory cytokines (14). PPAR γ has also been reported to control the alternative activation of monocytes and macrophages (15).

With environmental levels of cadmium steadily rising (16) and the high morbidity and mortality associated with acute lung injury, understanding the pathogenesis and progression of cadmium-mediated lung injury is essential. Here, we aimed to identify the mechanism(s) regulating the metabolic reprogramming of lung macrophages that contributes to lung injury after cadmium exposure.

Results

Cadmium promoted the persistence of the pro-inflammatory macrophage phenotype

Lung macrophages have a critical role in mounting an immune response to injury (6–8). Cadmium has been shown to suppress the innate immune response of macrophages (6, 17). We have shown that cadmium inhibits lung macrophage host defense by inhibiting the Rho GTPase, Rac2 (6); however, it is not known if cadmium regulates the phenotypic switching of macrophages to influence lung repair. We found that cadmium promotes macrophage polarization to the pro-inflammatory, classically activated phenotype. TNF α and iNOS mRNA expression were increased 3–8-fold, respectively, in macrophages exposed to CdCl₂ (Fig. 1, A and B). The alternatively activated markers, arginase 1, TGF- β 1, IL-10, and PDGF-B were significantly reduced compared with vehicle exposed (Fig. 1, C–F).

To determine whether cadmium mediated the persistence of a pro-inflammatory phenotype, macrophages were exposed to

Cadmium promotes lung macrophage phenotypic switching

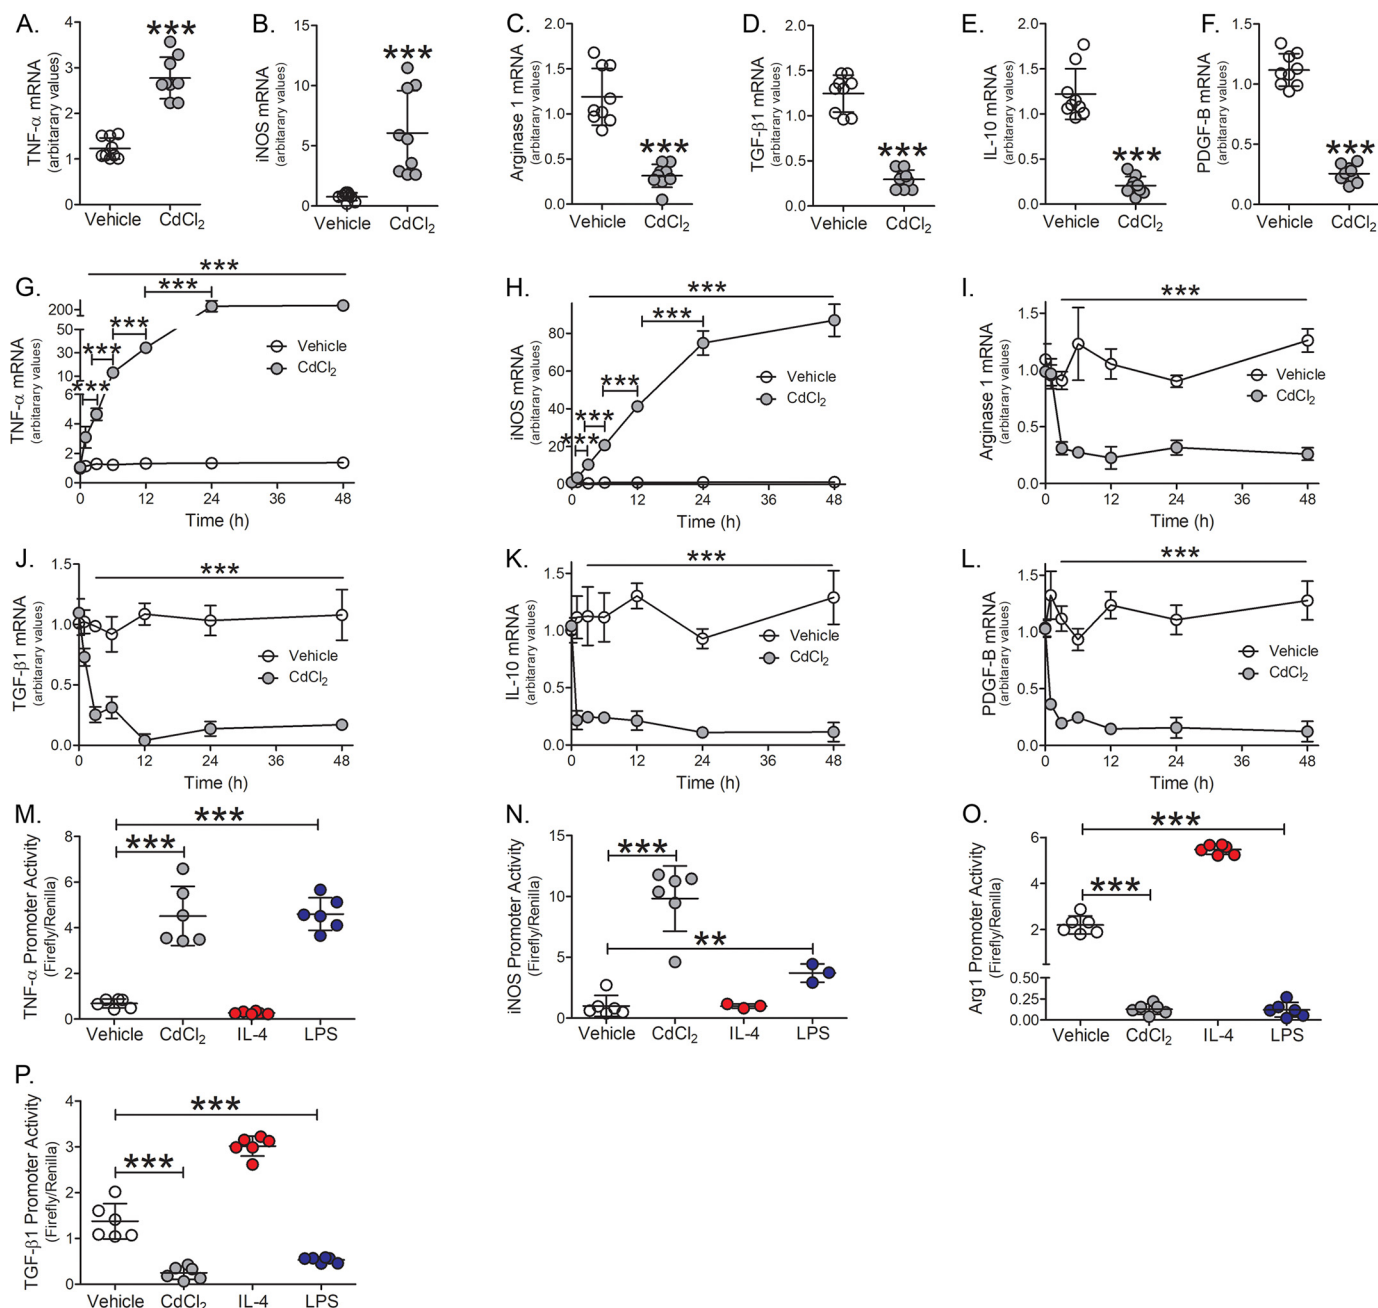

Figure 1. Cadmium promotes the persistence of the pro-inflammatory macrophage phenotype. THP-1 macrophages were exposed to vehicle or CdCl₂ (50 μM, 3 h). A, TNFα; B, iNOS; C, arginase 1; D, TGF-β1; E, IL-10; and F, PDGF-B mRNA expression (n = 9). THP-1 cells were treated with vehicle or CdCl₂ for the indicated times. G, TNFα; H, iNOS; I, arginase 1; J, TGF-β1; K, IL-10; and L, PDGF-B mRNA expression (n = 3). THP-1 cells were exposed to vehicle, CdCl₂ (50 μM), IL-4 (20 ng/ml, negative control), or LPS (100 μg/ml, positive control) for 3 h. M, TNFα; N, iNOS; O, arginase 1; and P, TGF-β1 promoter activity were measured by luciferase assay (n = 6). **, p < 0.001; ***, p < 0.0001. Values are shown as mean ± S.D.

cadmium for 0, 1, 3, 6, 12, 24, or 48 h. Cadmium-exposed macrophages showed a time-dependent increase in TNFα and iNOS mRNA expression with maximal expression seen 24-48 h after exposure (Fig. 1, G and H). Arginase 1 and TGF-β1 expression were drastically reduced in macrophages exposed to cadmium for 3 h (Fig. 1, I and J), whereas IL-10 and PDGF-B were significantly reduced 1 h after cadmium exposure (Fig. 1, K and L). The reduction in anti-inflammatory gene expression from cadmium-exposed macrophages persisted over the duration of the time course.

Further examining the role of cadmium gene regulation, TNFα promoter activity showed nearly 4-fold increase in cadmium-exposed macrophages and was similar to LPS-exposed macrophages, which was used as a positive control (Fig. 1M). iNOS promoter activity increased nearly 10-fold in cadmium-exposed macrophages (Fig. 1N). In contrast, arginase 1 and TGF-β1 promoter activities were significantly reduced in cadmium-exposed macrophages (Fig. 1, O and P). Cadmium exposure did not alter macrophage apoptosis as no changes were detected in the mitochondrial or cytoplasmic localization of

Cadmium promotes lung macrophage phenotypic switching

Bcl-2, *cytochrome c*, or Bax expression (Fig. S1, A and B). Moreover, caspase-3 activity remained unchanged over the duration in cadmium-exposed macrophages (Fig. S1C). These data suggest that cadmium induces a rapid and persistent polarization of macrophages to a pro-inflammatory phenotype.

Cadmium-induced lung injury and the pro-inflammatory phenotype of lung macrophages

To determine the biological relevance of our *in vitro* observations, we exposed WT mice to cadmium at the mean concentration found in bronchioalveolar lavage (BAL) fluid from cigarette smoke-exposed mice (6). BAL was performed 7 days later. Cadmium-exposed mice showed over 2.5-fold increase in the number of BAL cells (Fig. 2A) and greater than 95% of the cells were macrophages (Fig. 2B). Cadmium exposure induced the polarization of lung macrophages to a pro-inflammatory phenotype. Lung macrophages isolated from cadmium-exposed WT mice showed over 5-fold increase in TNF α and iNOS mRNA expression compared with vehicle-exposed (Fig. 2, C and D). In contrast, arginase 1, TGF- β 1, IL-10, and PDGF-B mRNA expression were significantly reduced in lung macrophages from cadmium-exposed mice (Fig. 2, E–H). Cadmium exposure did not alter the expression or localization of Bcl-2, *cytochrome c*, or Bax in lung macrophages (Fig. S2, A and B) and caspase-3 activity remained unchanged between vehicle and cadmium-exposed mice (Fig. S2C).

Because macrophages are phagocytic cells and to confirm that there is uptake and accumulation of cadmium in lung macrophages, transmission EM (TEM) analysis of isolated lung macrophages from cadmium-exposed mice revealed an accumulation of dark aggregates (\sim 1 nm in diameter, *blue arrows*, for reference ribosomes are indicated with *orange arrowheads*) found in the cytoplasm of macrophages, whereas this was absent in vehicle-exposed (Fig. 2I). Lung histology from cadmium-exposed mice revealed increased lobar consolidation associated with hemorrhage, whereas vehicle-exposed mice showed normal lung architecture (Fig. 2, J and K). These results were confirmed by increased albumin concentration in the BAL fluid indicating the presence of lung injury in cadmium-exposed mice (Fig. 2L). Moreover, the ratio of wet to dry lung weight was significantly increased in the cadmium-exposed mice (Fig. 2M). These results suggest a correlation between the cadmium-mediated lung macrophage phenotype and lung injury.

Cadmium-increased lung macrophage mitochondrial ROS

The redox-sensitive transcription factor, nuclear factor (NF)- κ B, is a critical mediator of the macrophage inflammatory response and is required for pro-inflammatory gene expression (18–21). Using a promoter construct driven by NF- κ B, we found that cadmium-exposed macrophages had significantly greater NF- κ B-driven luciferase activity than vehicle exposed and the cadmium-induced increase in activity was significantly greater than LPS-exposed (Fig. 3A). Moreover, the transcription factors associated with classical activation, *p*-STAT1, and the p65 subunit of NF- κ B, were localized to the nuclear fraction

in macrophages exposed to cadmium, whereas p65 remained in the cytosol in vehicle-exposed (Fig. 3, B and C).

Mitochondrial ROS (mtROS) are suggested to act as signal-transducing molecules that trigger inflammation by driving pro-inflammatory cytokine production (22, 23). We determined that cadmium-exposed macrophages showed a significant increase in mtROS generation (Fig. 3, D and E). These results were validated *in vivo*. The increased mtROS production in lung macrophages from cadmium-exposed mice (Fig. 3F) correlated with the activation of redox-regulated transcription factors. Lung macrophages from cadmium-exposed mice showed increased nuclear localization of the p65 subunit of NF- κ B and *p*-STAT1 (Fig. 3G), whereas the p65 subunit of NF- κ B remained in the cytosol in macrophages from vehicle-exposed mice (Fig. 3H).

Validating that cadmium-mediated regulation of transcription factor expression was induced by mtROS generation, cadmium-exposed macrophages were treated with mitoTEMPO, a specific scavenger of mtROS. MitoTEMPO treatment significantly reduced cadmium-mediated mtROS generation to the level seen in vehicle control (Fig. 3I). Nuclear localization of the p65 subunit of NF- κ B and *p*-STAT1 were reduced with mitoTEMPO treatment, whereas the p65 subunit of NF- κ B was increased in the cytosolic fraction with mitoTEMPO treatment in macrophages exposed to vehicle or cadmium. (Fig. 3, J and K).

Abrogating cadmium-mediated mtROS generation in macrophages influenced macrophage phenotypic switching. Treatment with mitoTEMPO reduced TNF α and iNOS gene expression to the level seen with vehicle alone (Fig. 3, L and M). In contrast, mitoTEMPO treatment rescued anti-inflammatory gene expression in cadmium-exposed macrophages similar to vehicle-exposed levels (Fig. 3, N–Q). These data suggest that cadmium-induced mtROS regulates redox-regulated transcription factors.

Cadmium promoted glycolytic flux in lung macrophages

Because hypoxia-inducible factor 1 α (HIF-1 α) is a critical regulator of macrophage inflammation (24), we determined that cadmium-exposed macrophages had increased HIF-1 α expression in the nuclear fraction (Fig. 4A). Inhibiting cadmium-mediated mtROS generation with mitoTEMPO treatment abolished HIF-1 α expression. Studies suggest classically activated macrophages utilize glycolytic metabolism, which can be rapidly activated to fuel responses for injury (25–27). Additionally, HIF-1 α influences the metabolic reprogramming of macrophages to glycolysis (28). A critical activator of glucose metabolism, 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase 3 (PFKFB3), was similarly increased in macrophages exposed to cadmium and the expression of PFKFB3 was redox-regulated (Fig. 4B).

To measure glycolytic flux, lactate excretion was measured in conditioned media from cadmium-exposed macrophages. Lactate was significantly increased in cell culture media from cadmium-exposed macrophages, whereas mitoTEMPO reduced lactate to control levels (Fig. 4C). Measuring glycolytic function via extracellular acidification rate (ECAR), cadmium-exposed macrophages showed increased ECAR compared with vehicle-exposed macrophages (Fig. 4D).

Cadmium promotes lung macrophage phenotypic switching

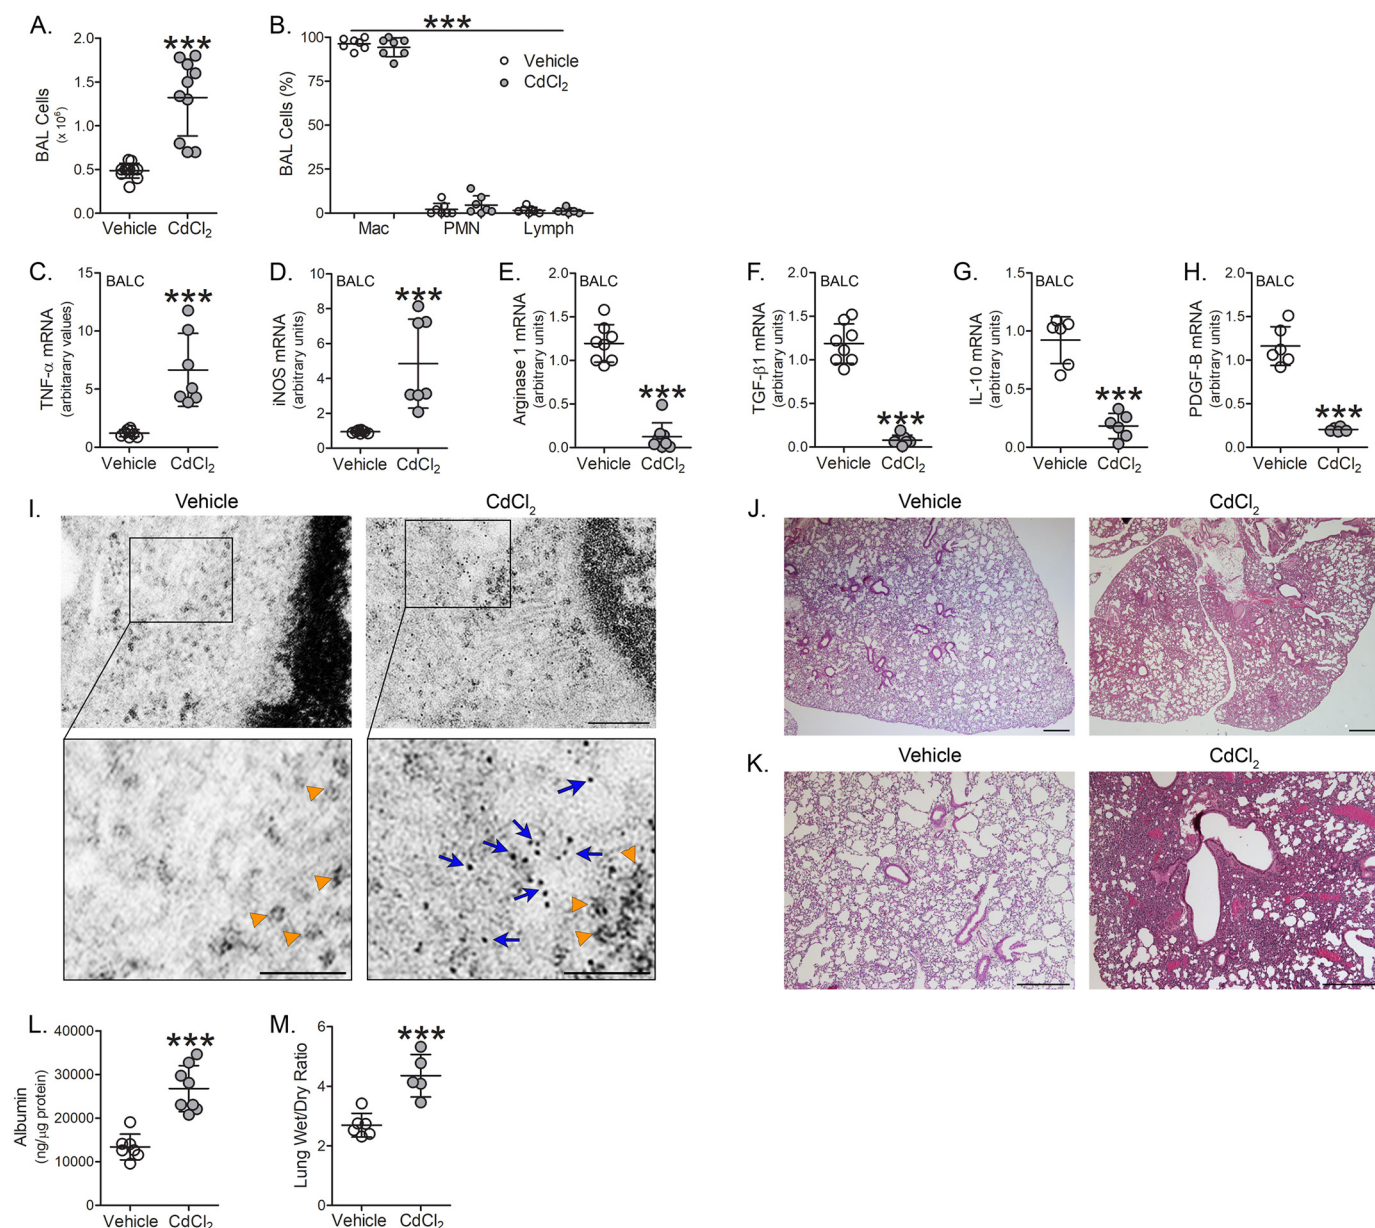

Figure 2. Cadmium induces lung injury and the pro-inflammatory phenotype of lung macrophages. WT mice were exposed to vehicle or CdCl₂ (100 ng/kg, intratracheal). After 7 days, BAL was performed. *A*, total number of BAL cells ($n = 10-11$) and *B*, cell differential ($n = 7$) from exposed mice. *C*, TNF α ; *D*, iNOS; *E*, arginase 1; *F*, TGF- β 1; *G*, IL-10; and *H*, PDGF-B mRNA expression in isolated BAL cells from exposed mice ($n = 6-8$). *I*, representative TEM analysis of BAL cells from exposed mice. *Orange arrowheads* indicate ribosomes. *Blue arrows* indicate cadmium particles. *Scale bars*: 200 nm (main), 100 nm (insets) ($n = 3$). *J* and *K*, representative H & E staining of lung tissue from exposed mice ($n = 3$). *Scale bars*: 500 nm. *L*, albumin levels in BAL fluid from exposed mice ($n = 7-8$). *M*, wet to dry ratio of lung weight from exposed mice ($n = 5-6$). $p < 0.0001$. *Mac*, macrophage; *PMN*, polymorphonuclear leukocyte; *Lymph*, lymphocyte. Values are shown as mean \pm S.D.

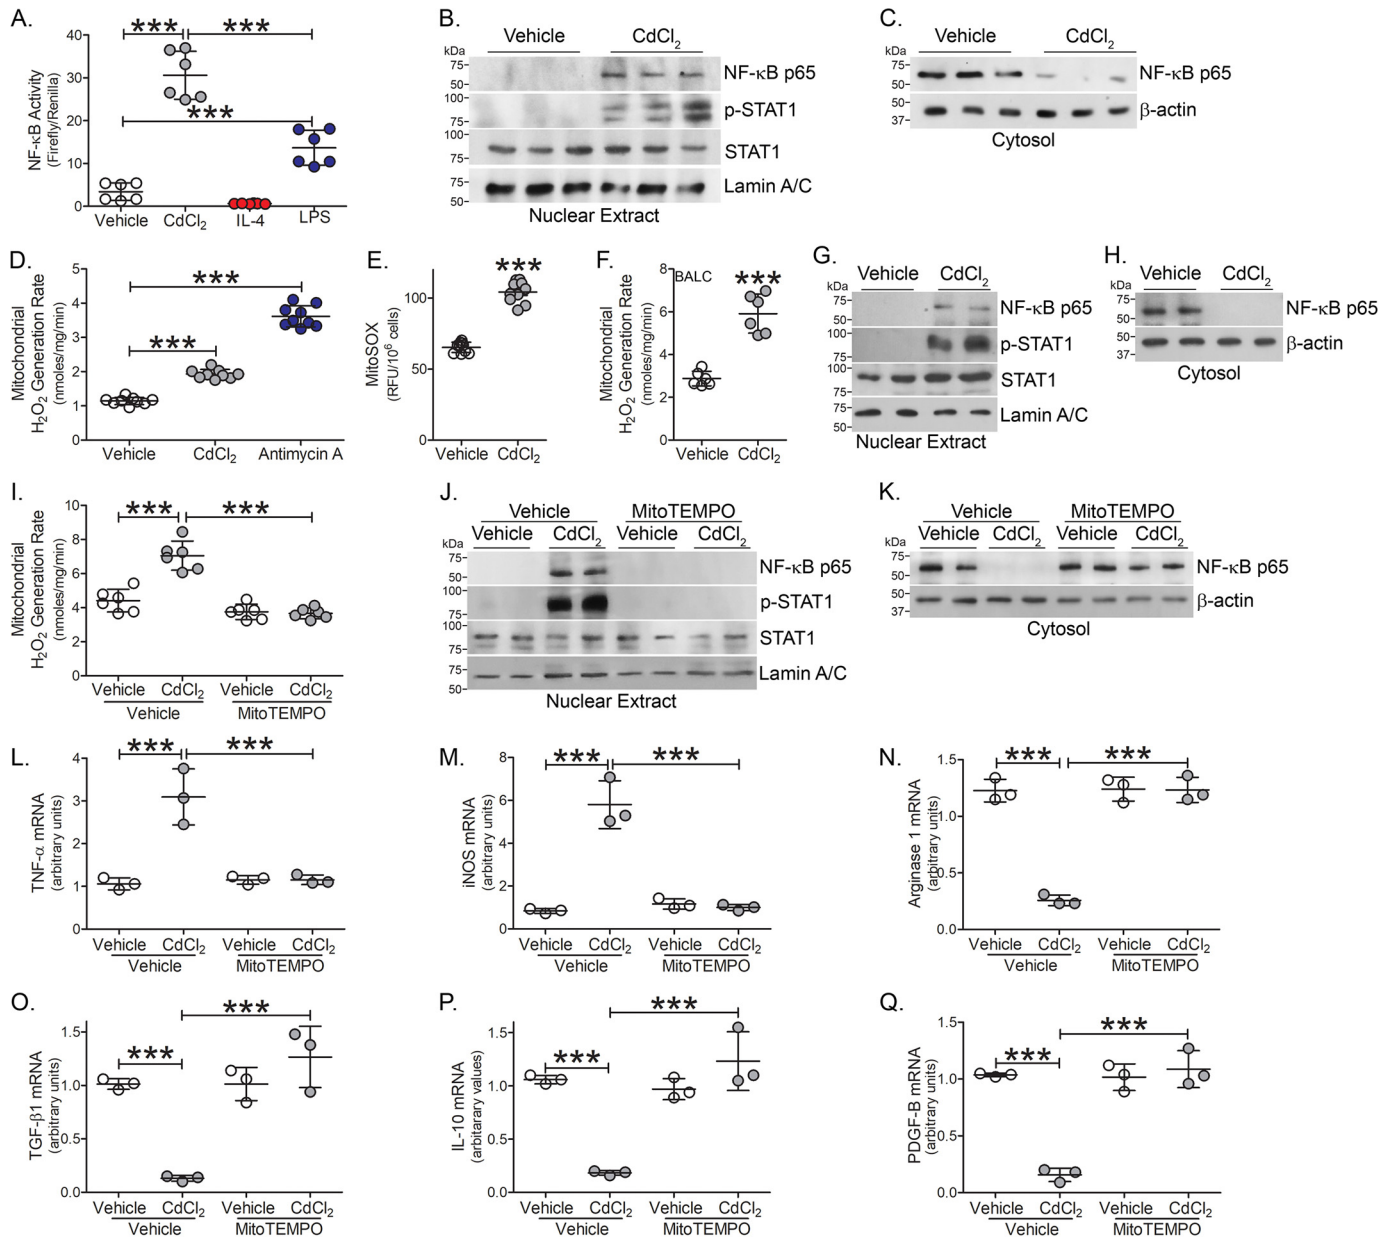

Studies indicate PPAR γ plays a critical role in mediating the alternative activation of macrophages (15, 29). We determined that PPAR γ expression was absent in CdCl₂-exposed macrophages (Fig. 4E). Treating macrophages with mitoTEMPO induced alternative activation with STAT6 activation and PPAR γ nuclear expression in cadmium-exposed macrophages. These data suggest that inhibiting mtROS generation in cadmium-exposed macrophages induces the phenotypic switching of macrophages and reduced glycolytic metabolism, a key feature of alternatively activated macrophages.

To further understand the bioenergetics in cadmium-exposed macrophages, RNA-Seq was performed in lung macro-

phages isolated from vehicle- and cadmium-exposed mice. Key glycolytic enzymes, hexokinase 2 (Hk2), phosphofructokinase (Pfkf), glyceraldehyde-3-phosphate dehydrogenase (GAPDH), pyruvate kinase (PKM), and lactate dehydrogenase A (LDHA) were greater in cadmium-exposed lung macrophages (Fig. 4F). The transcription factors, c-myc and Hif1 α , considered master regulators of glycolytic flux, were increased in lung macrophages from cadmium-exposed mice.

Because cellular metabolism plays an important role during macrophage polarization, we validated that HIF-1 α was increased in lung macrophages from cadmium-exposed mice

Cadmium promotes lung macrophage phenotypic switching

(Fig. 4G). Cadmium promoted a shift from mitochondrial oxidation toward glycolytic metabolism. Confirming the RNA-Seq data, lung macrophages isolated from cadmium-exposed mice showed increased PFKFB3 expression (Fig. 4H). Furthermore, BAL fluid from cadmium-exposed mice had elevated lactate levels, a measure of glycolytic flux (Fig. 4I). The increased flux was confirmed by an increase in ECAR in the cadmium-exposed mice (Fig. 4J). These data suggest that cadmium regulates the metabolic reprogramming to glycolysis, a critical bioenergetic characteristic in classically activated macrophages.

Cadmium altered macrophage glycolytic intermediates

Because cadmium treatment drastically reduced PPARγ expression and to understand the role of cadmium in promoting glycolysis, glycolytic intermediates and amino acid levels were measured by MS in macrophages expressing PPARγ and exposed to cadmium (Fig. 5A). Expression of PPARγ or treatment of cadmium did not alter glucose, glucose 6-phosphate, ribose 5-phosphate, or fructose 1,6-bisphosphate levels (Fig. 5, B–D). Although macrophages exposed to cadmium showed no change in glyceraldehyde 3-phosphate, PPARγ-expressing macrophages showed increased levels (Fig. 5E). Suggesting an

increase in glycolysis, cadmium-exposed macrophages had a significant increase in 3-phosphoglycerate (Fig. 5F). Whereas serine levels remained unchanged, cysteine and glycine synthesis were reduced in cadmium-exposed and PPAR γ -expressing macrophages. Further implicating enhanced glycolysis, phosphoenolpyruvate, and alanine levels were increased in cadmium-exposed macrophages and PPAR γ expression reduced levels to that seen in controls (Fig. 5G). These studies suggest that cadmium promotes glycolysis in lung macrophages and PPAR γ may provide a therapeutic mechanism to abrogate cadmium-mediated lung injury.

PPAR γ induced the alternative phenotype in cadmium-exposed macrophages

Because PPAR γ is a critical regulator of the anti-inflammatory phenotype in macrophages, we questioned if overexpression of PPAR γ could alter the cadmium-mediated phenotypic switching of macrophages. Macrophages expressing PPAR γ

showed significantly reduced mtROS generation after cadmium exposure (Fig. 6A). The down-regulation of cadmium-mediated mtROS completely abrogated gene expression of TNF α and iNOS mRNA in cadmium-exposed macrophages expressing PPAR γ (Fig. 6, B and C). The reverse was seen with the anti-inflammatory markers. PPAR γ -expressing macrophages had significantly greater arginase 1, TGF- β 1, IL-10, and PDGF-B mRNA expression (Fig. 6, D–G). More importantly, cadmium exposure did not alter expression of these genes in PPAR γ -expressing macrophages.

Because PPAR γ regulated macrophage phenotypic switching in cadmium-exposed macrophages, we determined if PPAR γ altered the activation of redox-regulated transcription factors. Macrophages expressing PPAR γ showed an absence of the transcription factors associated with classical activation, p-STAT1, and the p65 subunit of NF- κ B in the nuclear fraction in macrophages exposed to cadmium, whereas p-STAT6 was highly up-regulated (Fig. 6H). Furthermore, PPAR γ -expressing

Cadmium promotes lung macrophage phenotypic switching

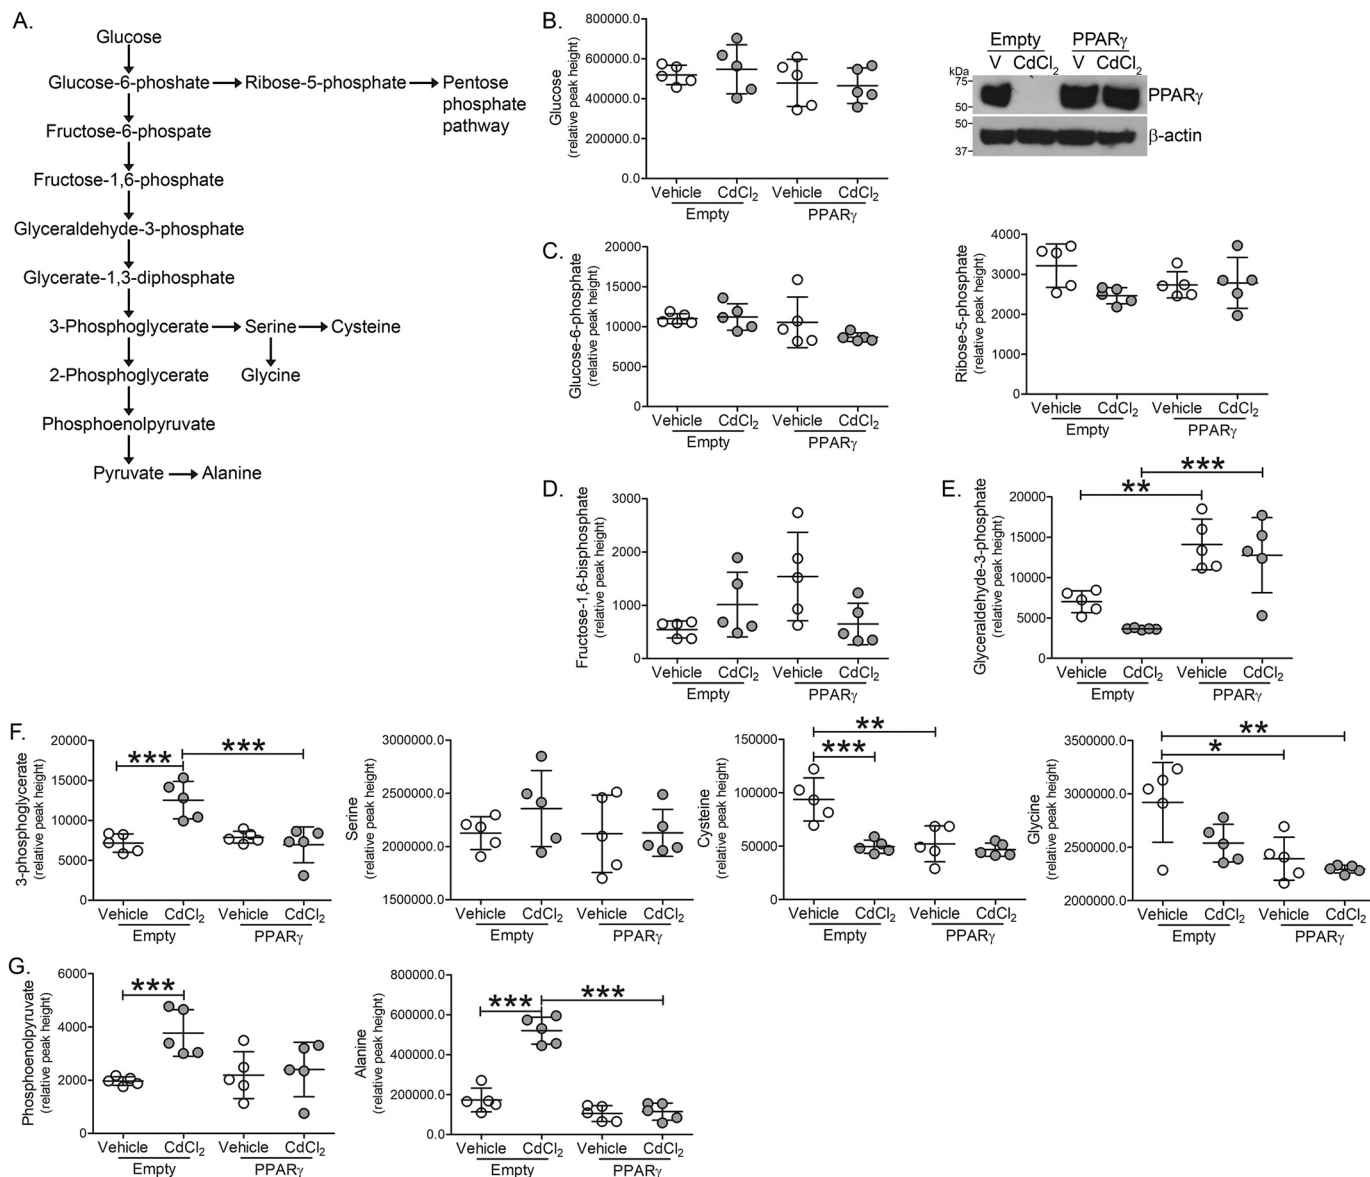

Figure 5. Cadmium alters macrophage glycolytic intermediates. Values are shown as mean \pm S.D.

macrophages decreased HIF-1 α expression, showed reduced lactate levels, and failed to undergo metabolic reprogramming toward glycolysis (Fig. 6, *I* and *J*). Cadmium exposure showed no effect in the presence of PPAR γ . Taken together, these studies suggest that PPAR γ -mediated phenotypic switching is associated with metabolic reprogramming in macrophages exposed to cadmium.

Discussion

Altered amino acid metabolism is a hallmark in defining macrophage phenotype. Pro-inflammatory macrophages convert L-arginine to nitric oxide by increasing iNOS activity, whereas anti-inflammatory macrophages have increased arginase 1, which converts L-arginine to urea (25). Classically activated, pro-inflammatory macrophages utilize glycolytic metab-

olism, which can be rapidly activated to fuel responses for injury (24, 25, 28). Although relatively inefficient in ATP production, the conversion of pyruvate into lactate is essential to restore NAD $^+$ and maintain flux through the glycolytic pathway. Glycolytic flux is controlled by several enzymes, including hexokinase, phosphofruktokinase, and pyruvate kinase. Although the nonoxidative part of glycolysis did not show accumulation of intermediates, oxidative glycolytic intermediates as well as exit products (alanine) were increased, suggesting that enzyme flux capacity was reached for pyruvate kinase and potentially GAPDH. This view is strengthened by the lack of significant differences of exit pathways, such as serine metabolism or pentose phosphate pathway intermediates. Moreover, changes in the concentration of metabolites can regulate flux via allosteric regulation of enzymes (26). Here, we show

Cadmium promotes lung macrophage phenotypic switching

that cadmium-mediated lung injury results in the persistence of classically activated lung macrophages and induces the metabolic reprogramming of these cells to glycolysis to exacerbate lung injury.

The exposure of cadmium is closely associated with the development of lung diseases. Cadmium is one of the metal compounds present in cigarette smoke and each pack of cigarettes contains 30 μ g of cadmium, but nearly 3 μ g of cadmium is present in a single cigarette (27). In total, cigarette smokers have at least twice as much cadmium in body content than non-smokers, and cadmium has no physiologic role in humans. Cadmium has an extremely long $t_{1/2}$, up to 15-20 years (27). Thus, the physiologic effect of cadmium may be acute as well as being prolonged. Our data demonstrates the accumulation of cadmium in lung macrophages in an acute exposure; however, the accumulation in macrophages is not known in the prolonged setting.

Cadmium is not redox-active, but the generation of ROS is a critical mediator for cadmium-triggered tissue injury (30). Studies implicate cadmium-induced oxidative stress is mediated through cellular redox disruption by depletion of antioxidant enzymes (31). We show that cadmium-mediated mtROS generation regulates the polarization of macrophages, and studies indicate that mtROS are known to sustain inflammation by mediating pro-inflammatory cytokine secretion (32). Our data indicate that quenching mtROS induced the macrophage phenotype to become alternatively activated. Inhibiting cadmium-mediated mtROS reduced ECAR and may induce metabolic reprogramming to oxidative phosphorylation.

HIF-1 α is a key transcription factor that regulates cell metabolism (24). Oxidative stress has been implicated in HIF-1 α signaling, and mtROS has been shown to stabilize and activate HIF-1 α (33, 34). There is some controversy on the role of cadmium and ROS in the regulation of HIF-1 α . Cadmium-

Cadmium promotes lung macrophage phenotypic switching

mediated ROS increased HIF-1 α levels to induce malignant transformation of bronchial epithelial cells (35), whereas another study suggested that the inhibition of HIF-1 α by cadmium was not secondary to oxidative stress (36). Thus, the regulation of HIF-1 α by cadmium may be cell- and/or stimulus-specific.

The link between HIF-1 α and NF- κ B is also controversial. HIF-1 α has been suggested to regulate NF- κ B (37), and activation of HIF-1 α may result from the inhibition of NF- κ B (31). Other studies suggest NF- κ B is a direct modulator of HIF-1 α transcription during inflammatory conditions, such as hypoxia (38). Our data extended these findings by showing that cadmium-mediated mtROS generation regulates NF- κ B activation and increases HIF-1 α expression to potentially regulate metabolic reprogramming to glycolysis.

Evidence suggests that lactate competes with glucose as a mitochondrial substrate in the lung, and type II alveolar epithelial cells have been shown to readily utilize lactate (39). The effect of enhanced glycolysis is cell type-specific as increased glycolysis has been shown to protect alveolar epithelial cells from lung injury in an LPS model (40). Further studies are warranted to better understand the cross-talk between macrophages and alveolar epithelial cells, as we suggest the increased lactate is macrophage-derived and may play a critical role in lung injury.

PPAR γ is a key regulator of lipid metabolism and inflammation and is expressed in various cell types throughout the human body. Our data indicate PPAR γ may be a novel target for regulating macrophage metabolic reprogramming and influencing lung repair after cadmium exposure. PPAR γ can be activated by synthetic ligands. Rosiglitazone and pioglitazone belong to the thiazolidinedione class of PPAR γ agonists and are potent insulin-sensitizing drugs. Rosiglitazone has been shown to reduce bleomycin-induced lung fibrosis via inhibition of TGF- β 1-mediated differentiation of lung fibroblasts (41, 42). Rosiglitazone decreased pulmonary artery remodeling in a rat model of pulmonary hypertension (43). Moreover, pioglitazone prevented LPS-induced acute lung injury in mice (44). Although the use of thiazolidinediones is associated with many undesirable side effects, such as weight gain, edema, and heart disease in diabetic patients (45), new classes of PPAR γ agonists may be able to effectively target specific cells and tissues preserving the efficacy of these drugs whereas reducing their side effects.

Taken together, we show that cadmium-mediated mtROS in macrophages regulates redox-regulated transcription factors to maintain the persistence of a pro-inflammatory phenotype. These observations also suggest that the cadmium-induced pro-inflammatory phenotype in macrophages may hinder the resolution of lung injury.

Experimental procedures

Mice

All animal protocols were approved by the Institutional Animal Care and Use Committee of the University of Alabama at Birmingham and were performed in accordance with NIH guidelines. WT C57BL6 mice were purchased from JAX Laboratory (Bar Harbor, ME). 8- to 12-week-old male and female

mice were intratracheally administered 100 ng/kg of CdCl₂ or saline, as a vehicle control, after being anesthetized with 3% isoflurane using a precision Fortec vaporizer. Mice were fed *ad libitum* standard chow and kept at 12-h light/12-h dark cycles. Mice were euthanized 7 days after exposure and BAL was performed.

Cell culture

Human monocyte (THP-1) and mouse alveolar macrophage (MH-S) cell lines were obtained from American Type Culture Collection (Manassas, VA). Macrophages were maintained in RPMI 1640 media (Thermo Fisher Scientific) with 10% fetal bovine serum and penicillin/streptomycin supplements. All experiments were conducted in RPMI containing 0.5% serum. Cells were treated with vehicle or 50 μ M CdCl₂ for 3 h or the indicated time. Macrophages were treated with IL-4 (20 ng/ml, negative control) or LPS (100 μ g/ml) as a positive control.

Quantitative real-time PCR

Total RNA was isolated, reverse transcribed, and quantitative real-time PCR was performed as described previously using previously published primer sets (46, 47). Data were calculated by the cycle threshold ($\Delta\Delta C_T$) method, normalized to β -actin or HPRT, and expressed in arbitrary units.

Plasmids, transfections, and luciferase assays

The PPAR γ plasmid (8895) and iNOS promoter (19296) were purchased from Addgene (48, 49). TNF α promoter, arginase 1 promoter/enhancer, TGF- β 1 promoter, and NF- κ B gene expression were evaluated using luciferase reporter plasmids as previously described (19, 46, 47). The correct reading frame and sequence was verified by the Heflin Center Genomics Core at the University of Alabama. Cells were transfected using X-treme GENE 9 Transfection Reagent (Sigma) according to the manufacturer's protocol. *Renilla* and firefly luciferase activity was determined in cell lysates using the Dual Luciferase reporter assay kit (Promega) and normalized to control (firefly).

TEM

BAL cells were fixed in 2.5% paraformaldehyde and 2.5% glutaraldehyde in Sorenson's phosphate buffer as previously described (46). Cells were processed and sectioned with a diamond knife (Diatome, Electron Microscopy Sciences) at 70–80 nm and sections were placed on copper mesh grids. Sections were stained with uranyl acetate and lead citrate for contrast and viewed on a Tecnai Twin 120kV TEM (FEI).

ECAR

ECAR was determined using a Seahorse XF24 bioanalyzer (Seahorse Bioscience). In brief, 7.5×10^4 macrophages per well were subjected to ECAR measurement in the XF24 extracellular flux analyzer with sequential additions of the following conditions: glucose (10 mM), oligomycin (0.5 μ M), and 2-deoxyglucose (50 μ M).

Albumin

Albumin levels were determined in BAL fluid using the Mouse Albumin ELISA Kit (Immunology Consultants Laboratory) according to the manufacturer's protocol. Samples were diluted 1/500,000.

Lactate

Lactate was measured in conditioned media and BAL fluid using the Lactate Colorimetric/Fluorometric Assay Kit (BioVision) according to the manufacturer's protocol.

Next-generation RNA-Seq

mRNA-Seq was performed on the Illumina NextSeq500 as described by the manufacturer (Illumina Inc., San Diego, CA). Briefly, RNA quality was assessed using the Agilent 2100 Bioanalyzer. RNA with an RNA Integrity Number of ≥ 7.0 was used for sequencing library preparation. RNA passing quality control was converted to a sequencing ready library using the NEBNext Ultra II Directional RNA library kit as per the manufacturer's instructions (New England Biolabs, Ipswich, MA). The cDNA libraries were quantitated using quantitative PCR in a Roche LightCycler 480 with the Kapa Biosystems kit for Illumina library quantitation (Kapa Biosystems, Woburn, MA) prior to cluster generation. Cluster generation was performed according to the manufacturer's recommendations for onboard clustering (Illumina, San Diego, CA). 30–35 million paired end 75-bp sequencing reads were generated per sample for transcript level abundance.

Data assessment for RNA-Seq

STAR (version 2.5.3a) was used to align the raw RNA-Seq fastq reads to the reference genome from Gencode. Following alignment, HTSeq-count was used to count the number of reads mapping to each gene. Normalization and differential expression were applied to the count files using DESeq2. Data have been submitted to the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus database (GEO) with GEO accession number GSE155166.

Metabolite analysis

Glycolytic and amino acid intermediates were analyzed by Gas Chromatography Time-of-Flight mass spectrometry (GC-TOF) as previously described (50). Briefly, the Gerstel CIS4— with dual multipurpose sample injector and Agilent 6890 GC-Pegasus III TOF MS was used for analysis. Injector conditions include: 50 to 275°C final temperature at a rate of 12°C/s and holding for 3 min. Injection volume was 0.5 μ l with 10 μ l/s injection speed on a splitless injector with purge time of 25 s. GC conditions included: 30 m long, 0.25-mm inner diameter Rtx-5Sil MS column (0.25 μ m 95% dimethyl, 5% diphenyl polysiloxane film) with an additional 10-m integrated guard column (Restek, Bellefonte PA). 99.99% pure helium with built-in purifier (Airgas, Radnor PA) was set at a constant flow of 1 ml/min and the oven temperature was held constant at 50°C for 1 min, ramped at 20°C/min to 330°C, and held constant for 5 min. The Leco Pegasus IV TOF-MS was controlled by the Leco

Chroma TOF software *versus* 2.32 (St. Joseph, MI). The transfer line temperature was set to 280°C. Electron impact ionization at 70 V was employed with an ion source temperature of 250°C. The acquisition rate was 17 spectra/s, with a scan mass range of 85–500 Da.

Data assessment for metabolomics

Raw data files are preprocessed directly after data acquisition and stored as Chroma TOF-specific *.peg files, as generic *.txt result files and additionally as generic ANDI MS *.cdf files as previously described (50). ChromaTOF *versus* 2.32 is used for data preprocessing without smoothing, 3 s peak width, baseline subtraction just above the noise level, and automatic mass spectral deconvolution and peak detection at signal/noise levels of 5:1 throughout the chromatogram. Apex masses are reported for use in the BinBase algorithm. Result *.txt files are exported to a data server with absolute spectra intensities and further processed by a filtering algorithm implemented in the metabolomics BinBase database.

Isolation of mitochondria and cytoplasm fractions

Mitochondria were isolated by lysing the cells in mitochondria buffer containing 10 mM Tris, pH 7.8, 0.2 mM EDTA, 320 mM sucrose, and protease inhibitors. Lysates were homogenized using a Kontes Pellet Pestle Motor and centrifuged at 2000 $\times g$ for 8 min at 4°C. The supernatant was removed and incubated at 4°C, and the pellet was lysed, homogenized, and centrifuged again. The two supernatants were pooled and centrifuged at 12,000 $\times g$ for 15 min at 4°C. The pellet was washed in the mitochondrial buffer twice and then resuspended in mitochondria buffer without sucrose (10).

Isolation of nuclear fraction

Nuclear isolation was performed by resuspending cells in a lysis buffer (10 mM HEPES, 10 mM KCl, 2 mM MgCl₂, 2 mM EDTA) for 15 min on ice. Nonidet P-40 (10%) was added to lyse the cells, and the cells were centrifuged at 4°C at 14,000 rpm. The nuclear pellet was resuspended in an extraction buffer (50 mM HEPES, 50 mM KCl, 300 mM NaCl, 0.1 mM EDTA, 10% glycerol) for 20 min on ice. After centrifuging at 4°C at 14,000 rpm, the supernatant was collected as nuclear extract (10).

Determination of mitochondrial ROS generation

Mitochondrial H₂O₂ production was determined fluorometrically by *p*-hydroxyphenylacetic acid (pHPA) assay. Freshly isolated mitochondria were incubated in phenol red-free Hanks' balanced salt solution supplemented with 6.5 mM glucose, 1 mM HEPES, 6 mM sodium bicarbonate, 1.6 mM pHPA, and 0.95 μ g/ml of HRP. Fluorescence of pHPA-dimer was measured using a spectrofluorometer at excitation of 320 nm and emission of 400 nm (46). Treatment of cells with antimycin A (100 μ M for 30 min) was used as a positive control. MitoSOX, a mitochondrial superoxide indicator (Thermo Fisher Scientific), was used to detect mitochondrial superoxide anion according to the manufacturer's protocol. Equal numbers of cells were subjected to

Cadmium promotes lung macrophage phenotypic switching

fluorescent reading (excitation, 510 nm; emission, 580 nm) as previously described (51).

Immunoblot analysis

Primary antibodies used were: Bax (2772S), Bcl-2 (3498), cytochrome *c* (4272), HIF-1 α (79233), Lamin A/C (2032), PFKFB3 (13123), phospho-STAT1 (7649), phospho-STAT6 (9361), STAT1 (9172), VDAC (4866) (Cell Signaling); β -actin (A5441) (Sigma); NF- κ B p65 (sc-372) (Santa Cruz Biotechnology); and PPAR γ (A0270) (ABclonal).

Caspase-3 activity analysis

Caspase-3 activity was measured using EnzChek Caspase-3 Assay Kit Number 2 (Molecular Probes) according to the manufacturer's protocol. Cells were lysed in 1 \times lysis buffer, subjected to a freeze-thaw cycle, centrifuged to remove cellular debris, and loaded into individual microplate wells. The 2 \times reaction buffer with substrate was immediately added to the samples, and fluorescence was measured (excitation/emission 496/520 nm). A supplied inhibitor was used as a negative control in all experiments (11).

Statistics

Statistical comparisons were performed using a Student's *t* test when only two groups of data are presented, or one-way analysis of variance with a Tukey's post hoc test or two-way analysis of variance followed by Bonferroni post-test when multiple data groups are presents. All statistical analysis was expressed as mean \pm S.D. and *p* < 0.05 was considered to be significant. GraphPad Prism statistical software was used for all analysis.

Data availability

All data are contained within the manuscript. Data have been submitted to the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus database (GEO) with GEO accession number GSE155166.
