REVIEW OF PARTICLE PHYSICS*

Particle Data Group

Abstract

This biennial Review summarizes much of Particle Physics. Using data from previous editions, plus 1600 new measurements from 550 papers, we list, evaluate, and average measured properties of gauge bosons, leptons, quarks, mesons, and baryons. We also summarize searches for hypothetical particles such as Higgs bosons, heavy neutrinos, and supersymmetric particles. All the particle properties and search limits are listed in Summary Tables. We also give numerous tables, figures, formulae, and reviews of topics such as the Standard Model, particle detectors, probability, and statistics. A booklet is available containing the Summary Tables and abbreviated versions of some of the other sections of this full Review. All tables, listings, and reviews (and errata) are also available on the Particle Data Group website: http://pdg.1bl.gov.

©1998 Regents of the University of California

*The publication of the Review of Particle Physics is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098; by the U.S. National Science Foundation under Agreement No. PHY-9703140; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development; and by the Italian National Institute of Nuclear Physics (INFN).

PARTICLE DATA GROUP AUTHORS:

INTRODUCTION

1. Overview

The Review of Particle Physics and the abbreviated version, the Particle Physics Booklet, are reviews of the field of Particle Physics. This complete Review includes a compilation/evaluation of data on particle properties, called the "Particle Listings." These Listings include 1900 new measurements from 700 papers, in addition to the 14,000 measurements from 4000 papers that first appeared in previous editions.

Both books include Summary Tables with our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as an extensive summary of searches for hypothetical particles. In addition, we give a long section of "Reviews, Tables, and Plots" on a wide variety of theoretical and experimental topics, a quick reference for the practicing particle physicist.

The Review and the Booklet are published in evennumbered years. This edition is an updating through December 1995 (and, in some areas, well into 1996). As described in the section "Using Particle Physics Databases" following this introduction, the content of this Review is available on the World-Wide Web, and is updated between printed editions (http://pdg.lbl.gov/).

The Summary Tables give our best values of the properties of the particles we consider to be well established, a summary of search limits for hypothetical particles, and a summary of experimental tests of conservation laws.

The Particle Listings contain all the data used to get the values given in the Summary Tables. Other measurements considered recent enough or important enough to mention, but which for one reason or another are not used to get the best values, appear separately just beneath the data we do use for the Summary Tables. The Particle Listings also give information on unconfirmed particles and on particle searches, as well as short "reviews" on subjects of particular interest or controversy.

The Particle Listings were once an archive of all published data on particle properties. This is no longer possible because of the large quantity of data. We refer interested readers to earlier editions for data now considered to be obsolete.

We organize the particles into six categories:

Gauge and Higgs bosons

Leptons Quarks

Mesons

Baryons

Searches for monopoles,

supersymmetry, compositeness, etc.

The last category only includes searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, by contrast, are with the leptons.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors, and also list our large number of consultants, without whom we would not have been able to produce this Review. In Sec. 3, we mention briefly the naming scheme for hadrons. In Sec. 4, we discuss our procedures for choosing among measurements of particle

properties and for obtaining best values of the properties from the measurements.

The accuracy and usefulness of this Review depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to the LBNL addresses below.

To order a copy of the Review or the Particle Physics Booklet from North and South America, Australia, and the Far East, write to

> Particle Data Group, MS 50-308 Lawrence Berkeley National Laboratory Berkeley, CA 94720, USA or send e-mail to PDG@LBL.GOV.

To order more than one copy of the Review or booklet, write to

> c/o Anne Fleming Technical Information Division, MS 50B-4206 Lawrence Berkeley National Laboratory Berkeley, CA 94720, USA or send e-mail to ASFLEMINGCLBL.GOV.

From all other areas, write to

CERN Scientific Information Service CH-1211 Geneva 23 Switzerland

or send e-mail to LIBDESK@CERN.CH. or via the WWW from CERN (http://www.cern.ch/library)

The Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review*. Of special value is the advice of the PDG Advisory Committee which meets annually and thoroughly reviews all aspects of our operation. The members of the 1996 committee were:

- D. Besson (University of Kansas), Chair
- A. Ali (DESY)
- P. Bloch (CERN)
- P. Kreitz (SLAC)
- P. Lepage (Cornell)
- J. LoSecco (Notre Dame)

We have especially relied on the expertise of the following people for advice on particular topics:

- L. Addis (SLAC)
- S.I. Alekhin (COMPAS Group, IHEP, Serpukhov)
- A. Ali (DESY)
- G. Altarelli (CERN)
- J. Annala (Fermilab)
- J.N. Bahcall (Institute for Advanced Study)
- R. Bailey (CERN)
- R. Ball (University of Edinburgh)
- A.R. Barker (University of Colorado)
- T. Barnes (University of Tennessee)
- J.-L. Basdevant (University of Paris)
- E. Berger (ANL)
- S. Bilenky (Joint Inst. for Nuclear Research, Dubna)
- M. Billing (Cornell University)
- A. Blondel (Ecole Polytechnique)
- T. Bolton (Kansas State University)

- R.A. Briere (Harvard University)
- T.E. Browder (University of Hawaii)
- E. Browne (LBNL)
- A. Buras (Tech. University of Munich)
- P. Burrows (MIT)
- M. Carena (Fermilab)
- A. Chao (SLAC)
- R. Clare (MIT)
- E.D. Commins (University of California, Berkeley)
- R.D. Cousins (University of California, Los Angeles)
- D.G. Coyne (University of California, Santa Cruz)
- M. Demarteau (Fermilab)
- L. Di Ciaccio (Rome University)
- M. Dine (University of California, Santa Cruz)
- S. Dittmaier (CERN)
- J. Donoghue (University of Massachusetts, Amherst)
- J. Dorfan (SLAC)
- I. Dunietz (Fermilab)
- J. Ellis (CERN)
- S. Ellis (University of Washington)
- L.R. Evans (CERN)
- G. Farrar (Rutgers University)
- R.W. Fast (Fermilab)
- A. Favara (California Institute of Technology)
- G.J. Feldman (Harvard University)
- E. Fischbach (Purdue University)
- R. Fleischer (CERN)
- G. Fogli (University of Bari)
- S. Freedman (LBNL and UC, Berkeley)
- H. Fritzsch (University of Munich)
- B. Fujikawa (LBNL)
- M. Fukugita (Yukawa Institute for Theo. Phys., Kyoto)
- J. Gasser (University of Bern)
- K. Griest (University of California, San Diego)
- Y. Grossman (SLAC)
- E.M. Gullikson (LBNL)
- R. Hagstrom (ANL)
- O. Hayes (University of Wisconsin)

3. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the F^{\pm} became the D_s^{\pm} . None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 80) of this Review.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^- , p, Λ , π^0 , K_L , D_s^+ , b. Charge is indicated by a superscript: B^- , Δ^{++} . Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0 . Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+ , K^- . Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, \overline{t} , \overline{p} , \overline{K}^0 , and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

4. Procedures

4.1. Selection and treatment of data: The Particle Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Particle Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.
- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion, which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, none of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Particle Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Particle Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data
- OUR FIT—From a constrained or overdetermined multiparameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Particle Listings all reported states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Particle Listings.

- 4.2. Averages and fits: We divide this discussion on obtaining averages and errors into three sections:
- (1) treatment of errors; (2) unconstrained averaging;
- (3) constrained fits.
- **4.2.1.** Treatment of errors: In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error is Gaussian, δx is the usual one standard deviation (1 σ). Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the two errors in quadrature and use this combined error for δx

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit \overline{x} is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are

determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ . In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ . One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum (1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i , each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, e.g., m_1 , m_2 , and $\Delta = m_2 - m_1$. We cannot enter all of m_1 , m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1 , m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

4.2.2. Unconstrained averaging: To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta \overline{x} = \frac{\sum_{i} w_{i} \ x_{i}}{\sum_{i} w_{i}} \pm \left(\sum_{i} w_{i}\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2 .$$

Here x_i and δx_i are the value and error reported by the *i*th experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with N-1, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta \overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2 / (N - 1) \right]^{1/2} . \tag{2}$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes N-1, and of course the output error $\delta \overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2} \, \delta \overline{x} \, ,$$

where $\delta \overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values \overline{x} and $\delta \overline{x}$, they can make significant contributions to the χ^2 , and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i , then $\delta \overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta \overline{x}$ is approximately half the interval between the two discrepant values.

We emphasize that our scaling procedure for errors in no way affects central values. And if you wish to recover the unscaled error $\delta \overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Particle Listings an ideogram of the data. Figure 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

Each measurement in an ideogram is represented by a Gaussian with a central value x_i , error δx_i , and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

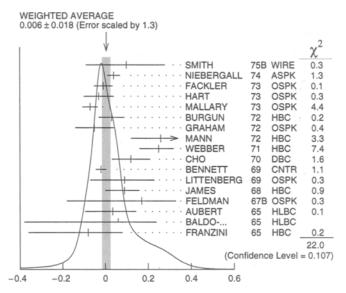

Figure 1: A typical ideogram. The arrow at the top shows the position of the weighted average, while the width of the shaded pattern shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag (\bot) , is not used in the calculation of S (see the text).

4.2.3. Constrained fits: Except for trivial cases, all branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i , the partial widths Γ_i , the full width Γ (or mean life), and the associated error matrix

Assume, for example, that a state has m partial decay fractions P_i , where $\sum P_i = 1$. These have been measured in N_r different ratios R_r , where, e.g., $R_1 = P_1/P_2$, $R_2 = P_1/P_3$, etc. [We can handle any ratio R of the form $\sum \alpha_i P_i / \sum \beta_i P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_i P_j$ and $R = (P_i P_j)^{1/2}$ are also allowed.] Further assume that each ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the m-1 independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r} \sum_{k=1}^{N_k} \left(\frac{R_{rk} - R_r}{\delta R_{rk}} \right)^2 , \qquad (3)$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values \overline{P}_i , we calculate an error matrix $\langle \delta \overline{P}_i \ \delta \overline{P}_j \rangle$. We tabulate the diagonal elements of $\delta \overline{P}_i = \langle \delta \overline{P}_i \ \delta \overline{P}_i \rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Particle Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

Three comments on the example above:

(1) There was no connection assumed between measurements of the full width and the branching ratios. But

often we also have information on partial widths Γ_i as well as the total width Γ . In this case we must introduce Γ as a parameter in the fit, along with the P_i , and we give correlation matrices for the widths in the Particle Listings.

- (2) We do not allow for correlations between input data. We do try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent.
- (3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2 . According to Eq. (3), the double sum for χ^2 is first summed over experiments k=1 to N_k , leaving a single sum over ratios $\chi^2 = \sum \chi_r^2$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi_r^2/\langle \chi_r^2 \rangle$. However, since $\langle \chi_r^2 \rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_{r}^{2} = \frac{1}{N_{k}} \sum_{k=1}^{N_{k}} \frac{\left(R_{rk} - \overline{R}_{r}\right)^{2}}{(\delta R_{rk})^{2} - (\delta \overline{R}_{r})^{2}} , \qquad (4)$$

where $\delta \overline{R}_r$ is the fitted error for ratio r. With this definition the expected value of S_r^2 is one.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new and often larger errors $\delta \overline{P}_i'$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta \overline{P}_i'/\delta \overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of \overline{P}_i obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) \overline{P}_i turns out to be less than three standard deviations $(\delta \overline{P}_i')$ from zero, a new smaller error $(\delta \overline{P}_i'')^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta \overline{P}_i'')^-$ and \overline{P}_i to be 68.3% of the area between zero and \overline{P}_i . A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

4.3. Discussion: The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this

quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Particle Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like \hbar , etc. Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting the uncertainty introduced by the new and inconsistent data. By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the Review of Particle Physics is supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098; by the U.S. National Science Foundation under Agreement No. PHY-9703140; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development; and by the Italian National Institute of Nuclear Physics (INFN).

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors.

ONLINE PARTICLE PHYSICS INFORMATION

Revised April 1998 by P. Kreitz (SLAC).

The purpose of this list is to organize a broad set of online catalogs, databases, directories, World-Wide Web (WWW) pages, etc., that are of value to the particle physics physics community. While a substantial amount of particle physics physics information is computer accessible through the Internet's World-Wide Web, most listings do not provide descriptions of a resource's scope and content so that searchers know which source to use for a specific information need. This compilation lists the main information sources with brief annotations and basic Internet WWW addresses (URL's). Because this list must be fixed in print, it is important to consult the updated version of this compilation which includes newly added resources and hypertext links to more complete information at:

http://www.slac.stanford.edu/library/pdg/hepinfo.html

In this edition, a resource is excluded if it provides information primarily of interest to one institution. In some cases, multiple databases covering much the same material have been included with the assumption that users will make subsequent choices based on Internet speeds, search system interfaces, or differences in scope, presentation, and coverage. Databases and resources focusing primarily on accelerator physics have been excluded in deference to the excellent compilation at the World Wide Web Virtual Library of Accelerator Physics:

http://www.slac.stanford.edu/grp/arb/dhw/dpb/w3v1/w3.html

My thanks to Betty Armstrong, Particle Data Group, Richard Dominiak, SLAC Library, and the many particle physics Web site and database maintainers who have all given me their generous assistance. Please send suggestions, additions, changes, ideas for category groupings, exclusions, etc., via the WWW form linked to the URL above, or by e-mail to pkreitz@slac.stanford.edu.

1. Particles & Properties Data:

• REVIEW OF PARTICLE PHYSICS (RPP): A comprehensive review of the field of Particle Physics produced by the Particle Data Group (PDG). Includes a compilation/evaluation of data on particle properties, summary tables with best values and limits for particle properties, extensive summaries of searches for hypothetical particles, and a long section of reviews, tables, and plots on a wide variety of theoretical and experimental topics of interest to particle and astrophysicists. The linked table of contents provides access to particle listings, reviews, summary tables, errata, indices, etc. The current printed version is European Physical Journal C3, 1 (1998). Maintained at:

http://pdg.lbl.gov/

 PARTICLE PHYSICS BOOKLET: An extract from the most recent edition of the full Review of Particle Physics. Contains images in an easy-to-read print useful for classroom studies:

http://pdg.lbl.gov/rpp/booklet/contents.html

 PARTICLE PROPERTIES Database: Durham/RAL provides a simple index to the PDG particle properties information contained in the Review of Particle Physics. Maintained at:

http://durpdg.dur.ac.uk/HEPDATA/PART

 COMPUTER-READABLE FILES: Currently available from the PDG: tables of masses, widths, and PDG Monte Carlo particle numbers and cross section data, including hadronic total and elastic cross sections vs laboratory momenta and total center-of-mass energy. Overview page at:

http://pdg.lbl.gov/computer_read.html

 PARTICLE PHYSICS DATA SYSTEM: Maintained by the COM-PAS group at IHEP, this system, currently under construction, provides an online version of the Guide to Experimental Elementary Particle Physics Literature (1895-1995). Permits searching by author, title, accelerator, detector, reaction, particle, etc. For research from 1950 to the present, it will provide online searching of compilations of integrated cross section data and numerical data on observables in reactions. Also provides a chronology of key events in particle physics:

http://mesa.lbl.gov:8001/ppds.html

REACTION DATA Database: (Durham) This is the main reaction
data database containing numerical results for a wide variety of
particle physics topics. Included are cross sections (differential and
total), polarization measurements, structure functions, spin-density
matrices, etc., from e⁺e⁻ annihilation, inclusive hadron and lepton
physics, deep inelastic scattering, photoproduction and two-body
(and quasi-two-body) scattering. This database is a collaboration
of Durham and the COMPAS Group for the PDG.

http://durpdg.dur.ac.uk/HEPDATA/REAC

 PHYSICS AROUND THE WORLD: Reference: From the subsection entitled 'Reference,' choose links to pages of data and tables, fundamental or material constants, physics laws, periodic tables, patents, and standards.

http://www.tp.umu.se/TIPTOP/paw

2. Collaborations & Experiments:

EXPERIMENTS Database: Contains more than 1,800 experiments
in elementary particle physics. Search and browse by author; title;
experiment number or prefix; institution; date approved, started
or completed; accelerator or detector; polarization, reaction, final
state or particle; or by papers produced. Maintained at SLAC for
the Particle Data Group. Supplies the information for "Current
Experiments in Particle Physics (LBL-91)." Updated every second
year (next: Summer 1998):

http://www.slac.stanford.edu/find/experiments

EXPERIMENTS ONLINE: Home Pages of HEP Experiments: A
list from SLAC of accelerator and non-accelerator experiments
with an active link to each home page. Accelerator experiments
are organized by institution, machine, and experiment name.
Non-accelerator experiments are alphabetical by name:

http://www.slac.stanford.edu/find/explist.html

 HIGH ENERGY PHYSICS EXPERIMENTS: A HEPNET page providing links to HEP collaborations around the world. Arranged alphabetically by institution and then collaboration or experiment

http://www.hep.net/experiments/collabs.html

3. Conferences:

• CONFERENCES: Contains conferences, schools, and meetings of interest to high-energy physicists with links, when available, to the conference home page. Searchable database produced jointly by the SLAC and DESY libraries of over 8,000 listings covering 1973 to 1999+. Search or browse by title, acronym, date, location. Includes information about published proceedings, links to submitted papers from the SPIRES-HEP database, and links to the electronic versions of the papers if available:

http://www.slac.stanford.edu/ spires/form/confspif.html

• CONFERENCES AND CONFERENCES: (Subtitled: There Are Too Many Conferences!): Lists current and future meetings in many fields of physics. Searchable by research area. Provides links to the conference Web page and the contact. Most useful as a listsery to which you can subscribe to get conference announcements. Web conference pages and an e-mail interface (robot@physics.umd.edu with CONFMENU in the subject line):

http://www.physics.umd.edu/robot/confer/confmenu.html

CONFERENCES, WORKSHOPS, AND SUMMER SCHOOLS:
 By The Internet Pilot to Physics. Covers national and regional meetings worldwide for all subfields of physics. Searchable by

sub-discipline or by free text words. Provides a Web form and email address for adding a conference. Automatically uploads new entries to the EPS EurophysNet meeting list.

http://www.tp.umu.se/TIPTOP/FORUM/CONF/

• EUROPHYSICS MEETINGS LIST: Meta-level international list of other conference lists with active links to the URL'S of the organization's meeting calendar, the conference database, etc. Useful for searching by organization, and for providing access to meetings and conferences that are of peripheral interest. Maintained by the European Physical Society. Organized alphabetically by the name of the resource or organization:

http://epswww.epfl.ch/conf/urls.html

 HEP EVENTS: A list maintained by CERN of upcoming conferences, schools, workshops, seminars, and symposia of interest to high-energy physics organized by type of meeting, e.g.: school, workshop:

http://www.cern.ch/Physics/Conferences

PHYSICS CONFERENCE ANNOUNCEMENTS by Thread:
 Lists current year's conference announcements with links to Web pages. Posting is voluntary. List can be browsed by date, subject, or author:

http://xxx.lanl.gov/Announce/Conference/

4. Current Notices & Announcement Services:

CONFERENCES, WORKSHOPS, AND SUMMER SCHOOLS:
 By The Internet Pilot to Physics. Provides a Web form or an
 email address for adding a conference and automatically uploads
 new entries to the EPS EurophysNet meeting list. Directions on
 the top-level page enable you to sign up to receive weekly email
 notification about conferences and deadlines.

http://www.tp.umu.se/TIPTOP/FORUM/CONF/

- CONFNEWS & WEBNEWS: Provides a system for broadcasting a conference or job opening to "a large number of physicists worldwide." For further information, e-mail: kim@umdhep.umd.edu
- E-PRINT ARCHIVES Listserv Notices: The LANL-based E-Print Archives provides daily notices of high-energy physics preprints submitted to the archives as full text electronic documents. Use the Web-accessible listings:

http://xxx.lanl.gov/ or subscribe:

http://xxx.lanl.gov/help/subscribe

Note: Use the library pages below to find announcement lists for recently received preprints, books, and proceedings. Use the online journal links below for journal table of contents. Conference announcements can also be sent via e-mail to most of the conference database providers listed above who often supply their e-mail address at the bottom of their Web pages.

5. Directories:

5.1. Directories—Research Institutions:

 CERN RESEARCH INSTITUTES: Contains HEP Institutes used in the CERN Library catalog. Provides addresses, and, where available, the following: phone and fax numbers; e-mail addresses; active Web links; and information about the institution's physics program. Search by free text, organization, country, or town:

http://alice.cern.ch/Institutes

• HEP INSTITUTIONS ONLINE: Active links to the home pages of more than 200 HEP-related institutions with Web servers. Maintained by SLAC. Organized by country, and then alphabetically by institution:

http://www.slac.stanford.edu/find/instlink.html

INSTITUTIONS: Database of over 5,500 high-energy physics
institutes, laboratories, and university departments in which some
research on elementary particle physics is performed. Covers six
continents and almost one hundred countries. Searchable by name,
acronym, location, etc. Provides address, phone and fax numbers,
and e-mail and Web links where available. Has pointers to the
recent HEP papers from an institution. Maintained by SLAC:

http://www.slac.stanford.edu/ spires/form/instspif.html

 DIRECTORY FOR PHYSICS DEPARTMENTS: Maintained by TIPTOP Physics Around the World. Lists departments worldwide. Searchable by field of research or by country or a combination of both.

http://www.tp.umu.se/TIPTOP/paw/dsearch.html

WWW VIRTUAL LIBRARY—HIGH ENERGY PHYSICS: An
alphabetical listing of organizations involved in high-energy physics
with links to the institution's Web pages. Maintained by CERN.
Because the listings are by institutional acronym or by short
name, this is less useful for people unfamiliar with the institution's
nickname.

http://www.cern.ch/Physics/HEP.html

5.2. Directories—People:

 HEPNAMES: Searchable database of 33,200 e-mail addresses of people related to high-energy physics. Access by individual name, and, in the near future, by institution or place.

http://www-spires.slac.stanford.edu/find/hepnames

This site is mirrored at Durham under a different name (EMAIL-ID) and with a search interface written and maintained by Durham:

http://durpdg.dur.ac.uk/HEPDATA/ID

 HEP VIRTUAL PHONEBOOK: A list of links to phonebooks and directories of high-energy physics sites and collaborations around the world. Maintained by HEPNET:

http://www.hep.net/sites/directories.html

 US-HEPFOLK: A searchable database of almost 3,500 physicists from 155 U.S. institutions based on a survey conducted in 1997.
 Searchable by first or last name, by affiliation, and/or by email address. Also provides some interesting demographic plots of the survey data:

http://pdg.lbl.gov/us-hepfolk/index.html

5.3. Directories—Libraries:

• Argonne National Lab Library:

http://www.ipd.anl.gov/aim/alec/

• Berkeley Lab (LBNL) Library:

http://www-library.lbl.gov/

• Brookhaven National Lab Library:

http://www.bnl.gov/RESLIB/reslib.html

• (CERN) European Laboratory for Particle Physics Library: http://wwwas.cern.ch/library/library_general/ welcome.html

• Deutsches Elektronen-Synchrotron (DESY) Library:

http://www.desy.de/library/homepage.html

• Fermilab Library:

http://fnalpubs.fnal.gov/library/welcome.html

• Jefferson Lab Library:

http://www.jlab.org/div_dept/admin/library/

- (KEK) National Laboratory for High Energy Physics Library: http://www-lib.kek.jp/publib.html
- Lawrence Livermore National Laboratory Library: http://www.llnl.gov/tid/Library.html
- Los Alamos National Laboratory Library: http://lib-www.lanl.gov/
- Oak Ridge National Laboratory Library:
 http://www.ornl.gov/Library/library-home.html
- Sandia National Laboratory Library: http://www.sandia.gov/library.htm
- Stanford Linear Accelerator Center Library:
 http://www.slac.stanford.edu/FIND/spires.html

5.4. Directories—Publishers:

 COMPANIES/PUBLISHERS: Contains 44 links to institutions, societies, or companies involved in supplying physics-related information:

http:www.tp.umu.se/TIPTOP/paw/paw.html/ ?k=Companies/Publishers&t=k&f=1

 DIRECTORY OF PUBLISHERS AND VENDORS: Contains hundreds of links to publishers and vendors divided by type (government or university) and by subject. The science section is extensive. Secondary page to "Other Links" leads to more arcane and specialized suppliers and information:

http://www.library.vanderbilt.edu/law/acqs/pubr.html

5.5. Directories—Scholarly Societies:

- American Association for the Advancement of Science: http://www.aaas.org/
- American Association of Physics Teachers: http://www.aapt.org/
- American Astronomical Society: http://www.aas.org
- American Institute of Physics: http://aip.org/
- American Physical Society: http://aps.org
- American Mathematical Society: http://www.ams.org/
- European Physical Society: http://epswww.epfl.ch/
- IEEE Nuclear and Plasma Sciences Society:: http://hibp7.ecse.rpi.edu/~connor/ieee/npss.html
- Institute of Physics: http://www.iop.org/
- RESOURCES OF SCHOLARLY SOCIETIES—PHYSICS: Maintained by the University of Waterloo Electronic Library's Scholarly Societies Project. Links to the home pages of close to a hundred scholarly societies worldwide. Very up to date:

http://www.lib.uwaterloo.ca/society/physics_soc.html

6. E-Prints/Pre-Prints, Papers, & Reports:

 CERN PREPRINTS CATALOGUE: The CERN Library's database which contains citations to more than 200,000 monographs, series, preprints, and official committee documents held by the Library or the Archives:

http://alice.cern.ch/Preprints

Also provides links to CERN's full text preprint server:

http://preprints.cern.ch/weeklist.html#preprints

• HEP DATABASE (SLAC/SPIRES): Contains over 350,000 bibliographic summaries for particle physics papers (e-prints, journal articles, preprints, reports, theses, etc.). Covers 1974 to the present and is updated daily with links to electronic texts (e.g. from LANL, CERN, KEK, and other HEP servers). Searchable by all authors and authors' affiliations, title, topic, report number, citation (footnotes), e-print archive number, date, journal, etc.: A joint project of the SLAC and DESY libraries with the collaboration of many other research institutions and scholarly societies such as the APS:

http://www.slac.stanford.edu/find/hep

 KISS (KEK Information Service System) for Preprints: KEK Library preprint database. Contains bibliographic records of preprints and technical reports held in the KEK library with links to the full text images of close to 100,000 items in their collection:

http://www-lib.kek.jp/KISS.v3/kiss_prepri.html

• LANL E-PRINT ARCHIVES: An automated electronic repository of physics, mathematics, and nonlinear science preprints. Used heavily by the sub-disciplines of high-energy physics. Began with a core set of archives in 1991. Provides access to the full text of the electronic versions of these preprints. Permits searching by author, title, keyword in abstract. Allows limiting by subfield archive or by date. Papers are sent electronically to the archives by authors:

http://xxx.lanl.gov

ONE-SHOT WORLD-WIDE PREPRINTS SEARCH: This is a
prototype service for a global lookup search throughout most
on-line scientific preprint repositories in the world. A very efficient
system permitting author or title searching, limiting by year and
by broad geographical regions:

http://www.ictp.trieste.it/indexes/preprints.html

PARTICLE PHYSICS DATA SYSTEM—PPDS: A search interface
to the bibliography of the print publication "A Guide to
Experimental Elementary Particle Physics Literature" (LBL-90).
This bibliography covers the published literature of theoretical
and experimental particle physics. Coverage is from 1895 to the
present:

http://mesa.lbl.gov:8001/ppds.html

• PPF: PREPRINTS IN PARTICLES AND FIELDS: A weekly listing of approximately 220 new preprints of interest to the high-energy physics community. Contains bibliographic listings for and, in the Web version, full text links to, the new preprints received by and cataloged into the SPIRES-HEP database. Approximately 30% of new titles are not available from the LANL e-print archives. Directions for subscribing to an email version can be found on the page listing the most recent week's preprints received:

http://www.slac.stanford.edu/library/documents/newppf.html

7. Particle Physics Journals & Reviews:

7.1. Online Journals and Tables of Contents:

Note: Only a selection of direct title URL's have been listed. Where many titles are available from the same publisher, a link to a summary online journals page from that publisher has been listed. Also please note, some of these journals and publishers may limit access to subscribers; check with your institution's library.

 American Astronomical Society: Astrophysical Journal Electronic Edition:

http://www.journals.uchicago.edu/ApJ/

 American Institute of Physics: The top-level page for their electronic journals may be found at:

http://www.aip.org/ojs/service.html

• American Journal of Physics:

http://www.amherst.edu/~ajp/

 American Physics Society: The top-level page for the APS research journals is:

http://publish.aps.org/

 Elsevier Science (Publishers): The top-level page for Nuclear Physics Electronic is:

http://www.nucphys.nl/www/pub/nucphys/npe.html

 European Physical Society: Their journals are handled by various publishers but may be reached from this top-level page:

http://epswww.epfl.ch/pub/index.html

 Institute of Physics: This page provides links to their online services, electronic journals and magazines, and Physics Express Letters:

http://www.iop.org

 Journal of High Energy Physics: A refereed journal written, run, and distributed by electronic means:

http://jhep.sissa.it/

• Modern Physics Letters: A and B

http://www.wspc.com.sg/journals/mpla/mpla.html http://www.wspc.com.sg/journals/mplb/mplb.html

• Journal of the Physical Society of Japan:

http://wwwsoc.nacsis.ac.jp/jps/jpsj/index.html

 Springer Publishing: Physics: This link provides a list of Springer journals covering topics of interest to physicists. Small bullets containing the letter 'E' beside each title indicate which journals are also in electronic format:

http://link.springer.de/ol/pol/all.htm

• Physics—Uspekhi

http://ufn.ioc.ac.ru/

• Reviews of Modern Physics

http://www.phys.washington.edu/~rmp/Welcome.html

Science

http://www.sciencemag.org/

• DESY Library Electronic Journals: Use this Web page for upto-date links to electronic journals of interest to particle physics. Contains a broader list than is included in this compilation:

http://www.desy.de/library/eljnl.html

• WWW Virtual Library of E-Journals: An excellent source to use when you are wondering if a title is available electronically. This Web site attempts to catalog all electronic journals, newsletters, magazines, and newspapers. Organized by broad subject or source e.g.: academic and reviewed journals, email newsletters, political journals. Also permits a title search across all categories:

http://www.edoc.com/ejournal/

7.2. Online Review Publications:

Net Advance of Physics: A free electronic service providing review
articles and tutorials in an encyclopedic format. Covers all areas
of physics. Includes hypertext links to the items reviewed when
available, including e-prints, book announcements, full text of
electronic books, and other resources. Welcomes contributions of
original review articles:

http://web.mit.edu/afs/athena.mit.edu/ user/r/e/redingtn/www/netadv/welcome.html

• Physics Reports:

http://www.elsevier.nl:80/inca/publications/store/5/0/5/7/0/3

• Reviews of Modern Physics

http://www.phys.washington.edu/~rmp/Welcome.html

Particle Physics: An independent online review service providing
the field of experimental and theoretical particle physics (including
cosmology) with a selected list of preprints from the established
public domain preprint servers. Selections are made by independent
nomination and then are reviewed by consulting editors. Listed
preprints include links to the papers' full text online versions.
 While hosted by a commercial site, this is an independent and
voluntary service for the international physics community.

http://www.eagle.co.uk/ppj/home.html

8. Particle Physics Education Sites:

8.1. Particle Physics Education: DOE Sites:

 Argonne National Laboratory Gee Whiz!: Includes links to other interesting and publically-accessible information such as the Rube Goldberg Machine Contest; Arts in Science; and the parts of the movie 'Chain Reaction' that were filmed at Argonne:

http://www.anl.gov/OPA/geewhiz.htm

 Brookhaven National Laboratory: Science Museum Programs: http://www.pubaf.bnl.gov/bnl_museum.htm

 Contemporary Physics Education Project (CPEP): Provides charts, brochures, Web links, and classroom activities:

http://pdg.lbl.gov/cpep.html

Center for Particle Astrophysics in Berkeley:
 http://physics7.berkeley.edu/home.html

Fermilab: Education and Outreach Resources for Particle Physicists: Outstanding collection of resources from the 'grandmother' of all physics lab educational programs:

http://www-ed.fnal.gov/trc/phys_resc.html

• Stanford Linear Accelerator Center: Check here soon for the Virtual Visitor's Center:

http://www.slac.stanford.edu/gen/edu/education.html

8.2. Particle Physics Education: Meta-Sites:

ESTEEM: The Department of Energy's exciting and visually appealing meta-site for Education in Science, Technology, Energy, Engineering and Math. Organized both textually and graphically as a 'city'. Users can explore resources by source (energy and science museums), by subject (windmills, 'playground'—virtual experiments, computers), or by targeted audience (university, middle or elementary students). Provides a rich access to many other sites including other meta-sites such as NASA and NSF and and the White House.

http://www.sandia.gov/ESTEEM/home.html

 PhysicsEd: Physics Education Resources: From a group renowned for doing research on physics education. Provides links to courses and topics; curriculum development; resources for demonstrations; software; research and projects in physics education; textbooks, journals, newsletters, and discussion groups; reference resources, organizations and companies; and much more:

http://www-hpcc.astro.washington.edu/scied/physics.html

8.3. Particle Physics Education: Ask-a-Scientist Sites:

 Ask A Scientist: Questions are answered by volunteer scientists throughout the world. Service provided by the Newton BBS through Argonne National Lab:

http://newton.dep.anl.gov/#AAS

 Mad Scientist's Network: Ask A Question: Responds to hundreds of questions a week. Contains an extensive archive of answered questions:

http://www.madsci.org/submit.html

 The Science Club: An excellent compilation of places to ask science questions. Organized by 'general' sites and then by sites that specialize in specific subjects or professions:

http://www.halcyon.com/sciclub/kidquest.html

8.4. Particle Physics Education: Experiments, Demos, & Fun

 Albert Einstein: A meta-Einstein site with links to dozens of places with resources by and about this scientist:

http://www/sas/upenn.edu/~smfriedm/einstein.html

Mad Scientist's Network: The Edible/Inedible Experiments
 Archive: Organized by scientific field. For each experiment, uses
 common materials and identifies whether the experiment is edible,
 inedible, or (in one case!?) 'partially drinkable':

http://www.madsci.org/experiments/

Physics Around the World: There are several useful links to collections of resources on this page, particularly the links to: Hands-On Experiments; Exercises and Problems; and Demonstrations.
 Targeted to the university level:

http://www.tp.umu.se/TIPTOP/paw/

 Science for the Millenium: Expo Web: Aimed at diverse audiences, this site focuses chiefly on astronomy, astrophysics, advanced computation, and virtual environments to showcase recent advances in these fields. The content is deep and the site is well-designed, permitting hierarchical and serendipitous use. Maintained by NCSA with significant help from the Electronic Visualization Laboratory:

http://www.ncsa.uiuc.edu/Cyberia/Expo/ information-pavilion.html

The Virtual Laboratory: A series of experiments using Java
that are targeted at physics classes for non-majors where there
are no physical lab sections. The experiments provide conceptual
interfaces to the equations of physics and represent interaction
with data that simulates a real physics experiment. Includes links
to a broader collection of physics experiments:

http://physics.hallym.ac.kr/education/oregon/ vlab/index.html

9. Software Directories:

 CERNLIB: CERN PROGRAM LIBRARY: Includes the CERN Program Library (Fortran), a new C++ Libraries (a C++ 'replacement' for CERNLIB), and CERNLIB and related Software including complete programs for GEANT, PAW and PAW++. Also includes links to commercial, free, and other software:

http://wwwcn.cern.ch/pl/index.html

 FREEHEP: A collection of software and information about software useful in high-energy physics. Searching can be done by title, subject, date acquired, or date updated, or by browsing an alphabetical list of all packages:

http://heplibw3.slac.stanford.edu:80/FIND/FHMAIN.HTML

FERMILAB SOFTWARE TOOLS PROGRAM: Software repository of Fermilab-developed software packages of value to the HEP community. Permits searching for packages by title or subject, by browsing FTP site, and by recent acquisitions:

http://www.fnal.gov/fermitools/

HEPIC: SOFTWARE AND TOOLS USED IN HEP RESEARCH:
 A meta-level site with links to major other sites of HEP-related software and computing tools:

http://www.hep.net/software.html

 PHYSICS AROUND THE WORLD: COMPUTING: An excellent meta-list with links to separate Web listings of: software archives; hands-on experiments; graphics & visualization; parallel computing; Java applets; and computing centers. Provides links to other Web compendia of software repositories and directories:

http://www.tp.umu.se/TIPTOP/paw/

SUMMARY TABLES OF PARTICLE PROPERTIES

Extracted from the Particle Listings of the Review of Particle Physics Published in Eur. Jour. Phys. C3, 1 (1998) Available at http://pdg.lbl.gov

Particle Data Group Authors:

C. Caso, G. Conforto, A. Gurtu, M. Aguilar-Benitez, C. Amsler, R.M. Barnett, P.R. Burchat, C.D. Carone, O. Dahl, M. Doser, S. Eidelman, J.L. Feng, M. Goodman, C. Grab, D.E. Groom, K. Hagiwara, K.G. Hayes, J.J. Hernández, K. Hikasa, K. Honscheid, F. James, M.L. Mangano, A.V. Manohar, K. Mönig, H. Murayama, K. Nakamura, K.A. Olive, A. Piepke, M. Roos, R.H. Schindler, R.E. Shrock, M. Tanabashi, N.A. Törnqvist, T.G. Trippe, P. Vogel, C.G. Wohl, R.L. Workman, W.-M. Yao

Technical Associates: B. Armstrong, J.L. Casas Serradilla, B.B. Filimonov, P.S. Gee, S.B. Lugovsky, S. Mankov, F. Nicholson

Other Authors who have made substantial contributions to reviews since the 1994 edition:

K.S. Babu, D. Besson, O. Biebel, R.N. Cahn, R.L. Crawford, R.H. Dalitz, T. Damour, K. Desler, R.J. Donahue, D.A. Edwards, J. Erler, V.V. Ezhela, A. Fassò, W. Fetscher, D. Froidevaux, T.K. Gaisser,

- L. Garren, S. Geer, H.-J. Gerber, F.J. Gilman, H.E. Haber, C. Hagmann, I. Hinchliffe, C.J. Hogan, G. Höhler, J.D. Jackson, K.F. Johnson,
- D. Karlen, B. Kayser, K. Kleinknecht, I.G. Knowles, C. Kolda, P. Kreitz, P. Langacker, R. Landua, L. Littenberg, D.M. Manley, J. March-Russell,
- T. Nakada, H. Quinn, G. Raffelt, B. Renk, M.T. Ronan, L.J. Rosenberg, M. Schmitt, D.N. Schramm, D. Scott, T. Sjöstrand, G.F. Smoot,
 - S. Spanier, M. Srednicki, T. Stanev, M. Suzuki, N.P. Tkachenko, G. Valencia, K. van Bibber, R. Voss, L. Wolfenstein, S. Youssef

(c) Regents of the University of California (Approximate closing date for data: January 1, 1998)

GAUGE AND HIGGS BOSONS

$$I(J^{PC}) = 0.1(1^{-})$$

Mass $m < 2 \times 10^{-16}$ eV Charge $q < 5 \times 10^{-30}$ e Mean life $\tau = Stable$

$$I(J^P) = 0(1^-)$$

Higgs Bosons — H^0 and H^{\pm} , Searches for

```
H^0 Mass m > 77.5 GeV, CL = 95%
```

 H_1^0 in Supersymmetric Models $(m_{H_1^0} < m_{H_2^0})$

Mass m > 62.5 GeV, CL = 95%

A⁰ Pseudoscalar Higgs Boson in Supersymmetric Models [/]

Mass m > 62.5 GeV, CL = 95% $tan \beta > 1$

 H^{\pm} Mass m > 54.5 GeV, CL = 95%

See the Particle Listings for a Note giving details of Higgs Bosons.

Heavy Bosons Other Than Higgs Bosons, Searches for

Additional W Bosons

W_R — right-handed W

Mass m > 549 GeV

(assuming light right-handed neutrino)

W' with standard couplings decaying to $e \nu$, $\mu \nu$

Mass m > 720 GeV. CL = 95%

Additional Z Bosons

 Z'_{SM} with standard couplings

Mass m > 690 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass m > 779 GeV, CL = 95% (electroweak fit)

 Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$

(with $g_L = g_R$)

Mass m > 630 GeV, CL = 95% ($p\overline{p}$ direct search)

Mass m > 389 GeV, CL = 95% (electroweak fit)

 Z_{χ} of SO(10) \rightarrow SU(5)×U(1) χ

(coupling constant derived from G.U.T.)

Mass m > 595 GeV, CL = 95% ($p\overline{p}$ direct search)

Mass m > 321 GeV, CL = 95% (electroweak fit)

 Z_{ψ} of $E_6 \rightarrow SO(10) \times U(1)_{\psi}$

(coupling constant derived from G.U.T.)

Mass m > 590 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass m > 160 GeV, CL = 95% (electroweak fit)

 Z_{η} of $E_6 \rightarrow SU(3)\times SU(2)\times U(1)\times U(1)_{\eta}$

(coupling constant derived from G.U.T.);

charges are $Q_{\eta}=\sqrt{3/8}Q_{\chi}-\sqrt{5/8}Q_{\psi}$)

Mass m > 620 GeV, CL = 95% ($p\bar{p}$ direct search)

Mass m > 182 GeV, CL = 95% (electroweak fit)

Scalar Leptoquarks

Mass m > 225 GeV, CL = 95% (1st generation, pair prod.)

Mass m > 237 GeV, CL = 95% (1st gener, single prod.)

Mass m > 119 GeV, CL = 95% (2nd gener., pair prod.)

Mass m > 73 GeV, CL = 95% (2nd gener., single prod.)

Mass m > 99 GeV, CL = 95% (3rd gener., pair prod.)

(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)

Axions (A^0) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b] ℓ indicates each type of lepton $(e, \mu, \text{ and } \tau)$, not sum over them.
- [c] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.
- [d] This partial width takes into account Z decays into $\nu\overline{\nu}$ and any other possible undetected modes.
- [e] This ratio has not been corrected for the τ mass.
- [f] Here $A \equiv 2g_V g_A / (g_V^2 + g_A^2)$.
- [g] The value is for the sum of the charge states of particle/antiparticle states indicated.
- [h] See the Z Particle Listings for the γ energy range used in this measurement.
- [i] For $m_{\gamma\gamma}=(60\pm 5)$ GeV.
- [j] The limits assume no invisible decays.

Heavy Charged Lepton Searches

L± - charged lepton

Mass m > 80.2 GeV, CL = 95% $m_{\nu} \approx 0$

L± - stable charged heavy lepton

Mass m > 84.2 GeV, CL = 95%

Neutrinos

See the Particle Listings for a Note "Neutrino Mass" giving details of neutrinos, masses, mixing, and the status of experimental searches.

$$J=\frac{1}{2}$$

Mass m: Unexplained effects have resulted in significantly negative m² in the new, precise tritium beta decay experiments. It is felt that a real neutrino mass as large as 10–15 eV would cause observable spectral distortions even in the presence of the end-point count excesses.

Mean life/mass, $\tau/m_{\nu_e} > 7 \times 10^9$ s/eV (solar) Mean life/mass, $\tau/m_{\nu_e} > 300$ s/eV, CL = 90% (reactor) Magnetic moment $\mu < 1.8 \times 10^{-10}~\mu_B$, CL = 90%

$$J=\frac{1}{2}$$

Mass m<0.17 MeV, CL = 90% Mean life/mass, $\tau/m_{\nu_{\mu}}>15.4$ s/eV, CL = 90% Magnetic moment $\mu<7.4\times10^{-10}~\mu_{B}$, CL = 90%

$$J=\frac{1}{2}$$

Mass m<18.2 MeV, CL = 95% Magnetic moment $\mu<5.4\times10^{-7}~\mu_B$, CL = 90% Electric dipole moment $d<5.2\times10^{-17}~e$ cm, CL = 95%

Number of Light Neutrino Types

(including $\nu_e, \, \nu_\mu, \, {\rm and} \, \, \nu_ au)$

Number $N=2.994\pm0.012$ (Standard Model fits to LEP data) Number $N=3.07\pm0.12$ (Direct measurement of invisible Z width)

Massive Neutrinos and Lepton Mixing, Searches for

For excited leptons, see Compositeness Limits below.

See the Particle Listings for a Note "Neutrino Mass" giving details of neutrinos, masses, mixing, and the status of experimental searches.

While no direct, uncontested evidence for massive neutrinos or lepton mixing has been obtained, suggestive evidence has come from solar neutrino observations, from anomalies in the relative fractions of ν_e and ν_μ observed in energetic cosmic-ray air showers, and possibly from a $\overline{\nu}_e$ appearance experiment at Los Alamos. Sample limits are:

Stable Neutral Heavy Lepton Mass Limits

Mass m > 45.0 GeV, CL = 95% (Dirac) Mass m > 39.5 GeV, CL = 95% (Majorana)

Neutral Heavy Lepton Mass Limits

Mass m>69.0 GeV, CL = 95% (Dirac ν_L coupling to e, μ, τ with $\left|U_{\ell J}\right|^2>10^{-12}$)
Mass m>58.2 GeV, CL = 95% (Majorana ν_L coupling to e, μ, τ with $\left|U_{\ell J}\right|^2>10^{-12}$)

Solar Neutrinos

Detectors using gallium ($E_{\nu}\gtrsim 0.2$ MeV), chlorine ($E_{\nu}\gtrsim 0.8$ MeV), and Čerenkov effect in water ($E_{\nu}\gtrsim 7$ MeV) measure significantly lower neutrino rates than are predicted from solar models. The deficit in the solar neutrino flux compared with solar model calculations could be explained by oscillations with $\Delta m^2 \leq 10^{-5}$ eV² causing the disappearance of ν_e .

Atmospheric Neutrinos

Underground detectors observing neutrinos produced by cosmic rays in the atmosphere have measured a ν_{μ}/ν_{e} ratio much less than expected and also a deficiency of upward going ν_{μ} compared to downward. This could be explained by oscillations leading to the disappearance of ν_{μ} with $\Delta m^{2}\approx 10^{-3}$ to 10^{-2} eV².

 ν oscillation: $\nabla_{\boldsymbol{\theta}} \not \rightarrow \nabla_{\boldsymbol{\theta}} (\boldsymbol{\theta} = \text{mbdng angle})$ $\Delta m^2 < 9 \times 10^{-4} \text{ eV}^2, \text{ CL} = 90\% \quad (\text{if } \sin^2 2\theta = 1)$

 $\sin^2 2\theta < 0.02$, CL = 90% (if $\Delta(m^2)$ is large) ν oscillation: $\nu_{\mu} (\bar{\nu}_{\mu}) \rightarrow \nu_{e} (\bar{\nu}_{e})$ (any combination)

 $\begin{array}{lll} \Delta \textit{m}^2 &<~0.075~\text{eV}^2,~\text{CL} = 90\% & \text{(if } \sin^2\!2\theta = 1)\\ \sin^2\!2\theta &<~1.8\times10^{-3},~\text{CL} = 90\% & \text{(if } \Delta(\textit{m}^2)~\text{is large)} \end{array}$

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements, For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] The uncertainty in the electron mass in unified atomic mass units (u) is ten times smaller than that given by the 1986 CODATA adjustment, quoted in the Table of Physical Constants (Section 1). The conversion to MeV via the factor 931.49432(28) MeV/u is more uncertain because of the electron charge uncertainty. Our value in MeV differs slightly from the 1986 CODATA result.
- [b] This is the best "electron disappearance" limit. The best limit for the mode $e^- \to \nu \gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).
- [c] The muon mass is most precisely known in u (unified atomic mass units). The conversion factor to MeV via the factor 931.49432(28) MeV/u is more uncertain because of the electron charge uncertainty.
- [d] See the "Note on Muon Decay Parameters" in the μ Particle Listings for definitions and details.
- [e] P_{μ} is the longitudinal polarization of the muon from pion decay. In standard V-A theory, $P_{\mu}=1$ and $\rho=\delta=3/4$.
- [f] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\nu_\mu$ and $e^-\overline{\nu}_e\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [g] See the μ Particle Listings for the energy limits used in this measurement.
- [h] A test of additive vs. multiplicative lepton family number conservation.
- [i] Basis mode for the τ .

Quark Summary Table

QUARKS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\rm MS}$ at a scale $\mu\approx 2$ GeV. The c- and b-quark masses are estimated from charmonium, bottomonium, D, and B masses. They are the "running" masses in the $\overline{\rm MS}$ scheme. These can be different from the heavy quark masses obtained in potential models.

$$I(J^P)=\tfrac{1}{2}(\tfrac{1}{2}^+)$$

Mass m = 1.5 to 5 MeV [a] $m_u/m_d = 0.20$ to 0.70

$$I(J^P)=0(\tfrac{1}{2}^+)$$

$$Charge = \frac{2}{3} e \qquad Top = +1$$

Mass $m=173.8\pm5.2$ GeV (direct observation of top events) Mass $m=170\pm7$ (+14) GeV (Standard Model electroweak fit, assuming $M_H=M_Z$. Number in parentheses is shift from changing M_H to 300 GeV.

b' (4th Generation) Quark, Searches for

Mass m > 128 GeV, CL = 95% ($p\overline{p}$, charged current decays) Mass m > 46.0 GeV, CL = 95% (e^+e^- , all decays)

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

[a] The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of u and d masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

LIGHT UNFLAVORED MESONS (S=C=B=0)

For I=1 $(\pi,\,b,\,\rho,\,a)$: $u\overline{d},\,(u\overline{u}-d\overline{d})/\sqrt{2},\,d\overline{u};$ for I=0 $(\eta,\,\eta',\,h,\,h',\,\omega,\,\phi,\,f,\,f')$: $c_1(u\overline{u}+d\overline{d})+c_2(s\overline{s})$

BOTTOM MESONS $(B = \pm 1)$

 $B^+ = u\overline{b}$, $B^0 = d\overline{b}$, $\overline{B}{}^0 = \overline{d}b$, $B^- = \overline{u}b$, similarly for B^* 's

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: " B^\pm/B^0 Admixture" for $\Upsilon(4S)$ results and " $B^\pm/B^0/B_s^0/B$ -baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. $B^0-\overline{B^0}$ mixing data are found in the B^0 section, while $B_s^0-\overline{B^0}$ mixing data and $B-\overline{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP-violation data are found in the B^0 section. B^0 -baryons are found near the end of the Baryon section.

The organization of the ${\it B}$ sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

B⁰

$$I(J^P) = \frac{1}{2}(0^-)$$

 ${\it I}, {\it J}, {\it P}$ need confirmation. Quantum numbers shown are quark-model predictions.

Mass
$$m_{B^0} = 5279.2 \pm 1.8$$
 MeV $m_{B^0} - m_{B^\pm} = 0.35 \pm 0.29$ MeV (S = 1.1) Mean life $\tau_{B^0} = (1.56 \pm 0.04) \times 10^{-12}$ s $c\tau = 468~\mu\text{m}$ $\tau_{B^+}/\tau_{B^0} = 1.02 \pm 0.04$ (average of direct and inferred) $\tau_{B^+}/\tau_{B^0} = 1.04 \pm 0.04$ (direct measurements) $\tau_{B^+}/\tau_{B^0} = 0.95^{+0.15}_{-0.12}$ (inferred from branching fractions)

$B^0-\overline{B}{}^0$ mixing parameters

$$\chi_d = 0.172 \pm 0.010$$

 $\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L} = (0.464 \pm 0.018) \times 10^{12} \ \hbar \ s^{-1}$
 $\chi_d = \Delta m_{B^0} / \Gamma_{B^0} = 0.723 \pm 0.032$

CP violation parameters

$$\left| \mathrm{Re}(\epsilon_{B^0}) \right| = 0.002 \pm 0.008$$

 B^0 modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the T(45). We have attempted to bring older measurements up to date by rescaling their assumed Υ (45) production ratio to 50:50 and their assumed D, D_5 , D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

B±/B0 ADMIXTURE

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the 'one-or-more' definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

 $\overline{{\it B}}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

```

 $au_{
m charged}$ $b_{
m -hadron}/ au_{
m neutral}$ $b_{
m -hadron}=1.09\pm0.13$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, SPPS) are used in the branching fraction averages. The production fractions give our best current estimate of the admixture at LEP

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, lust as inclusive cross sections can exceed total cross sections.

The modes below are listed for a \widetilde{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Confidence level (MeV/c)

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at the Z have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the LEP B Oscillation Working Group as described in the note "Production and Decay of b-Flavored Hadrons" in the B^\pm Particle Listings. Values assume

$$\begin{array}{ll} \mathsf{B}(\overline{b} \to B^+) = \mathsf{B}(\overline{b} \to B^0) \\ \mathsf{B}(\overline{b} \to B^+) + \mathsf{B}(\overline{b} \to B^0) + \mathsf{B}(\overline{b} \to B^0) + \mathsf{B}(b \to \Lambda_b) = 100 \ \%. \end{array}$$

The notation for production fractions varies in the literature $(f_{\overline{B}^0}, f(b \to \overline{B}^0), Br(b \to \overline{B}^0))$. We use our own branching fraction notation here, $B(\overline{b} \to B^0)$.

₿*

$$I(J^P) = \frac{1}{2}(1^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model

Mass
$$m_{B^*} = 5324.9 \pm 1.8 \text{ MeV}$$

 $m_{B^*} - m_B = 45.78 \pm 0.35 \text{ MeV}$

B* DECAY MODES	Fraction $(\Gamma_{\hat{I}}/\Gamma)$	p (MeV/c)
Βγ	dominant	46

BOTTOM, STRANGE MESONS $(B = \pm 1, S = \mp 1)$

 $B_s^0 = s\overline{b}, \overline{B}_s^0 = \overline{s}b,$ similarly for B_s^* 's

 B_s^0

$$I(J^P) = 0(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass
$$m_{B_s^0}=5369.3\pm2.0$$
 MeV Mean life $\tau=(1.54\pm0.07)\times10^{-12}$ s $c au=462~\mu{\rm m}$

$B_s^0 - \overline{B}_s^0$ mixing parameters

$$\chi_B$$
 at high energy = $f_d \chi_d + f_s \chi_s = 0.118 \pm 0.006$
 $\Delta m_{B_s^0} = m_{B_s^0} - m_{B_s^0} > 9.1 \times 10^{12} \ h \ s^{-1}$, CL = 95% $\chi_s = \Delta m_{B_s^0} / \Gamma_{B_s^0} > 14.0$, CL = 95% $\chi_s > 0.4975$, CL = 95%

These branching fractions all scale with $B(\overline{b} \to B_S^0)$, the LEP B_S^0 production fraction. The first four were evaluated using $B(\overline{b} \rightarrow B_s^0) =$ $(10.5^{+1.8}_{-1.7})\%$ and the rest assume B($\overline{b} \rightarrow B_s^0$) = 12%.

The branching fraction B(B_S^0 ightarrow D_S^- $\ell^+
u_\ell$ anything) is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times$ $B(B_0^0 \to D_b^- \ell^+ \nu_\ell$ anything) was used to determine $B(\overline{b} \to B_0^0)$, as described in the note on "Production and Decay of *b*-Flavored Hadrons."

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] See the "Note on $\pi^\pm \to \ell^\pm \nu \gamma$ and $K^\pm \to \ell^\pm \nu \gamma$ Form Factors" in the π^\pm Particle Listings for definitions and details.
- [b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\text{total}} = 100\%$.
- [c] See the π^\pm Particle Listings for the energy limits used in this measurement; low-energy γ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order 10^{-13} ; see the π^0 Particle Listings.
- [f] See the "Note on the Decay Width $\Gamma(\eta\to\gamma\gamma)$ " in our 1994 edition, Phys. Rev. **D50**, 1 August 1994, Part I, p. 1451.
- $[g]\ C$ parity forbids this to occur as a single-photon process.
- [\hbar] See the "Note on scalar mesons" in the $f_0(1370)$ Particle Listings . The interpretation of this entry as a particle is controversial.
- [i] See the "Note on $\rho(770)$ " in the $\rho(770)$ Particle Listings .
- [j] The e^+e^- branching fraction is from $e^+e^- \to \pi^+\pi^-$ experiments only. The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.
- [k] See the "Note on scalar mesons" in the $f_0(1370)$ Particle Listings .
- [/] See the "Note on $a_1(1260)$ " in the $a_1(1260)$ Particle Listings
- [m] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.
- [n] See the "Note on the $f_1(1420)$ " in the $\eta(1440)$ Particle Listings.
- [o] See also the $\omega(1600)$ Particle Listings.
- [p] See the "Note on the $\eta(1440)$ " in the $\eta(1440)$ Particle Listings.
- [q] See the "Note on the ho(1450) and the ho(1700)" in the ho(1700) Particle
- [r] See the "Note on non-q \overline{q} mesons" in the Particle Listings (see the index for the page number).
- [s] See also the $\omega(1420)$ Particle Listings.
- [t] See the "Note on $f_J(1710)$ " in the $f_J(1710)$ Particle Listings .
- [u] See the note in the K^{\pm} Particle Listings.
- [ν] The definition of the slope parameter g of the $K \to 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \to 3\pi$ Decays" in the K^{\pm} Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \cdots$$

Meson Summary Table

- [w] For more details and definitions of parameters see the Particle Listings.
- [x] See the K^\pm Particle Listings for the energy limits used in this measurement.
- [y] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [z] Direct-emission branching fraction.
- [aa] Structure-dependent part.
- [bb] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K_L^0}-m_{K_S^0}|$, and $\tau_{K_L^0}$, as described in the introduction to "Tests of Conservation Laws."
- [cc] The CP-violation parameters are defined as follows (see also "Note on CP Violation in $K_S\to 3\pi$ " and "Note on CP Violation in K_L^0 Decay" in the Particle Listings):

$$\begin{split} \eta_{+-} &= \left| \eta_{+-} \right| \mathrm{e}^{\mathrm{i}\phi_{+-}} = \frac{A(K_{0}^{1} \to \pi^{+}\pi^{-})}{A(K_{S}^{0} \to \pi^{+}\pi^{-})} = \epsilon + \epsilon' \\ \eta_{00} &= \left| \eta_{00} \right| \mathrm{e}^{\mathrm{i}\phi_{00}} = \frac{A(K_{0}^{1} \to \pi^{0}\pi^{0})}{A(K_{S}^{0} \to \pi^{0}\pi^{0})} = \epsilon - 2\epsilon' \\ \delta &= \frac{\Gamma(K_{0}^{1} \to \pi^{-}\ell^{+}\nu) - \Gamma(K_{0}^{0} \to \pi^{+}\ell^{-}\nu)}{\Gamma(K_{0}^{1} \to \pi^{-}\ell^{+}\nu) + \Gamma(K_{0}^{1} \to \pi^{+}\ell^{-}\nu)} , \\ \mathrm{Im}(\eta_{+-0})^{2} &= \frac{\Gamma(K_{S}^{0} \to \pi^{+}\pi^{-}\pi^{0})^{CP \ viol.}}{\Gamma(K_{0}^{1} \to \pi^{+}\pi^{-}\pi^{0})} , \\ \mathrm{Im}(\eta_{000})^{2} &= \frac{\Gamma(K_{S}^{0} \to \pi^{0}\pi^{0}\pi^{0})}{\Gamma(K_{0}^{1} \to \pi^{0}\pi^{0}\pi^{0})} . \end{split}$$

where for the last two relations *CPT* is assumed valid, i.e., ${\rm Re}(\eta_{+-0})\simeq 0$ and ${\rm Re}(\eta_{000})\simeq 0$.

- [dd] See the K_5^0 Particle Listings for the energy limits used in this measurement
- [ee] Calculated from K_L^0 semileptonic rates and the K_S^0 lifetime assuming ΔS
- [ff] ϵ'/ϵ is derived from $\left|\eta_{00}/\eta_{+-}\right|$ measurements using theoretical input on phases.
- [gg] The value is for the sum of the charge states of particle/antiparticle states indicated
- [hh] See the K_L^0 Particle Listings for the energy limits used in this measurement.
- [ii] Allowed by higher-order electroweak interactions.
- [jj] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- [kk] See the "Note on $f_0(1370)$ " in the $f_0(1370)$ Particle Listings and in the 1994 edition.
- [II] See the note in the L(1770) Particle Listings in Reviews of Modern Physics **56** No. 2 Pt. II (1984), p. S200. See also the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings .
- [mm] See the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings .

- [nn] This is a weighted average of D^\pm (44%) and D^0 (56%) branching fractions. See " D^+ and $D^0 \to (\eta \text{ anything}) / (\text{total } D^+ \text{ and } D^0)$ " under " D^+ Branching Ratios" in the Particle Listings.
- [oo] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+ .
- [pp] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [qq] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.
- [rr] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [ss] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.
- [tt] The D_1^0 - D_2^0 limits are inferred from the D^0 - \overline{D}^0 mixing ratio $\Gamma(K^+\ell^-\overline{\nu}_\ell({\rm via}\ \overline{D}^0)) / \Gamma(K^-\ell^+\nu_\ell)$.
- [uu] The larger limit (from E791) allows interference between the doubly Cabibbo-suppressed and mixing amplitudes; the smaller limit (from E691) doesn't. See the papers for details.
- [vv] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [ww] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [xx] For now, we average together measurements of the $Xe^+\nu_e$ and $X\mu^+\nu_\mu$ branching fractions. This is the average, not the sum.
- [yy] This branching fraction includes all the decay modes of the final-state resonance.
- [zz] This value includes only K^+K^- decays of the $f_J(1710)$, because branching fractions of this resonance are not known.
- [aaa] This value includes only $\pi^+\pi^-$ decays of the $f_0(1500)$, because branching fractions of this resonance are not known.
- $[bbb]\ B^0$ and B^0_s contributions not separated. Limit is on weighted average of the two decay rates,
- [ccc] These values are model dependent. See 'Note on Semileptonic Decays' in the ${\cal B}^+$ Particle Listings.
- [ddd] D^{**} stands for the sum of the $D(1\,^1\!P_1)$, $D(1\,^3\!P_0)$, $D(1\,^3\!P_1)$, $D(1\,^3\!P_2)$, $D(2\,^1\!S_0)$, and $D(2\,^1\!S_1)$ resonances.
- [eee] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [fff] D_j represents an unresolved mixture of pseudoscalar and tensor D** (P-wave) states.
- [ggg] Not a pure measurement. See note at head of B_s^0 Decay Modes.
- [hhh] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.
- [iii] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.
- [jjj] Spectroscopic labeling for these states is theoretical, pending experimental information.

See also the table of suggested $q\overline{q}$ quark-model assignments in the Quark Model section.

- Indicates particles that appear in the preceding Meson Summary Table. We do not regard
 the other entries as being established.
- \dagger Indicates that the value of J given is preferred, but needs confirmation.

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3-or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. See our 1986 edition (Physics Letters 170B) for listings of evidence for Z baryons (KN resonances).

^{****} Existence is certain, and properties are at least fairly well explored.

^{***} Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

^{**} Evidence of existence is only fair.

^{*} Evidence of existence is poor.

N BARYONS (S=0, I=1/2)p, $N^+ = uud$; n, $N^0 = udd$

 $I(J^P)=\tfrac{1}{2}(\tfrac{1}{2}{}^+)$

Mass $m = 938.27231 \pm 0.00028$ MeV [a] $= 1.007276470 \pm 0.000000012 \ u$ $\left|\frac{q_{\overline{p}}}{m_{\overline{p}}}\right|/\left(\frac{q_{\overline{p}}}{m_{\overline{p}}}\right) = 1.0000000015 \pm 0.0000000011$ $|q_p + q_{\overline{p}}|/e < 2 \times 10^{-5}$ $|q_p + q_e|/e < 1.0 \times 10^{-21} [b]$ Magnetic moment $\mu = 2.79284739 \pm 0.00000006 \, \mu_N$ Electric dipole moment $d = (-4 \pm 6) \times 10^{-23} e \text{ cm}$ Electric polarizability $\overline{\alpha} = (12.1 \pm 0.9) \times 10^{-4} \text{ fm}^3$ Magnetic polarizability $\overline{\beta} = (2.1 \pm 0.9) \times 10^{-4} \text{ fm}^3$ Mean life $\tau > 1.6 \times 10^{25}$ years (independent of mode) $> 10^{31}$ to 5×10^{32} years ^[c] (mode dependent)

Below, for N decays, p and n distinguish proton and neutron partial lifetimes. See also the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1673) for a short review.

The "partial mean life" limits tabulated here are the limits on au/B_I , where au is the total mean life and $B_{\hat{I}}$ is the branching fraction for the mode in question.

p DECAY MODES	Partial mean life (10 ³⁰ years)	Confidence level	<i>p</i> (MeV/c)
	Antilepton + meson

Nearly all branching fractions of the Λ_c^+ are measured relative to the $\rho K^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $\mathrm{B}(\Lambda_c^+\to\rho K^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements, in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates in Z decay (or high-energy $p\overline{\rho}$), branching ratios, and detection efficiencies. They scale with the LEP Λ_b production fraction $B(b\to\Lambda_b)$ and are evaluated for our value $B(b\to\Lambda_b)=(10.1,\frac{+3.9}{3.1})\%.$

The branching fractions $B(b\text{-baryon} \to \Lambda \ell^- \overline{\nu}_\ell$ anything) and $B(\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with $B(b \to \Lambda_b)$ were used to determine $B(b \to \Lambda_b)$, as described in the note "Production and Decay of b-Flavored Hadrons."

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The Note on N and Δ Resonances and the Note on N and Σ Resonances in the Particle Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

- [a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, $1~u=931.49432\pm0.00028$ MeV, is less well known than are the masses in u.
- [b] The limit is from neutrality-of-matter experiments; it assumes $q_n=q_p+q_e$. See also the charge of the neutron.
- [c] The first limit is geochemical and independent of decay mode. The second entry, a range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \bar{p} 's is $\tau_{\bar{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\bar{p}}/B(\bar{p} \to e^-\gamma) > 1848$ yr.
- [d] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The second limit here is from reactor experiments with free neutrons.
- [e] The parameters g_A , g_V , and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V+g_A\gamma_5)+i(g_{WM}/m_{B_i})\ \sigma_{\lambda\nu}\ \phi']B_i$, and ϕ_{AV} is defined by $g_A/g_V=|g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.
- [f] Time-reversal invariance requires this to be 0° or 180° .
- [g] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-lpha^2}\cos\phi$$
 , $\tan\Delta = -rac{1}{lpha}\,\sqrt{1-lpha^2}\sin\phi$.

See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

- [h] See the Particle Listings for the pion momentum range used in this measurement
- [i] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [j] A theoretical value using QED.
- [k] See the "Note on Λ_c^+ Branching Fractions" in the Branching Fractions of the Λ_c^+ Particle Listings.
- [I] This branching fraction includes all the decay modes of the final-state resonance.
- [m] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [n] The value is for the sum of the charge states of particle/antiparticle states indicated
- [o] Assuming isospin conservation, so that the other third is $\Lambda_c^+ \pi^0 \pi^0$.
- [p] Not a pure measurement. See note at head of Λ_h^0 Decay Modes.

MONOPOLES, SUPERSYMMETRY, COMPOSITENESS, etc., SEARCHES FOR

Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

 $< 1.0 \times 10^{-15} \text{ cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$ for $1.1 \times 10^{-4} < \beta < 0.1$

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model. Assumptions include: 1) $\widetilde{\chi}_1^0$ (or $\widetilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) All scalar quarks (except \widetilde{t}_L and \widetilde{t}_R) are degenerate in mass, and $m_{\widetilde{q}_R} = m_{\widetilde{q}_L}$. 4) Limits for selectrons and smuons refer to the $\widetilde{\ell}_R$ states.

See the Particle Listings for a Note giving details of supersymmetry.

$$\begin{array}{lll} \widetilde{\chi}_{I}^{0} - \text{neutralinos (mixtures of } \widetilde{\gamma}, \, \widetilde{Z}^{0}, \, \text{and } \widetilde{H}_{I}^{0}) \\ & \text{Mass } m_{\widetilde{\chi}_{1}^{0}} \ \, > \ \, 10.9 \,\, \text{GeV, CL} = 95\% \\ & \text{Mass } m_{\widetilde{\chi}_{2}^{0}} \ \, > \ \, 45.3 \,\, \text{GeV, CL} = 95\% \\ & \text{Mass } m_{\widetilde{\chi}_{3}^{0}} \ \, > \ \, 75.8 \,\, \text{GeV, CL} = 95\% \\ & \text{Mass } m_{\widetilde{\chi}_{2}^{0}} \ \, > \ \, 127 \,\, \text{GeV, CL} = 95\% \\ & \text{Mass } m_{\widetilde{\chi}_{2}^{0}} \ \, > \ \, 127 \,\, \text{GeV, CL} = 95\% \\ \end{array} \label{eq:constraint}$$

$$\widetilde{\chi}_{I}^{\pm}$$
 — charginos (mixtures of \widetilde{W}^{\pm} and \widetilde{H}_{I}^{\pm})

Mass $m_{\widetilde{\chi}_{1}^{\pm}} > 65.7$ GeV, CL = 95% $[m_{\widetilde{\chi}_{1}^{\pm}} - m_{\widetilde{\chi}_{1}^{0}} \geq 2 \text{ GeV}]$

Mass $m_{\widetilde{\chi}_{2}^{\pm}} > 99$ GeV, CL = 95% [GUT relations assumed]

 $\tilde{\nu}$ — scalar neutrino (sneutrino)

Mass m > 37.1 GeV, CL = 95% [one flavor] Mass m > 43.1 GeV, CL = 95% [three degenerate flavors]

 \widetilde{e} — scalar electron (selectron) Mass m>58 GeV, CL = 95% $[m_{\widetilde{e}_R}-m_{\widetilde{\chi}^0_1} \ge 4$ GeV]

 $\widetilde{\mu}$ — scalar muon (smuon) Mass m > 55.6 GeV, CL = 95% $[m_{\widetilde{\mu}_R} - m_{\widetilde{\chi}_1^0} \ge 4$ GeV]

 $ilde{ au}$ — scalar tau (stau) Mass m>45 GeV, CL = 95% [if $m_{\widetilde{\chi}_1^0}<38$ GeV]

q — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}^0_1} \approx m_{\widetilde{g}}/6$.

$$\begin{array}{ll} \text{Mass } m > \ 176 \ \text{GeV}, \ \text{CL} = 95\% & [\text{any } m_{\widetilde{g}} < 300 \ \text{GeV}, \\ \mu = -250 \ \text{GeV}, \ \tan\beta = 2] \\ \text{Mass } m > \ 224 \ \text{GeV}, \ \text{CL} = 95\% & [m_{\widetilde{g}} \leq m_{\widetilde{q}}, \\ \mu = -400 \ \text{GeV}, \ \tan\beta = 4] \end{array}$$

 \tilde{g} — gluino

There is some controversy on whether gluinos in a low-mass window (1 $\lesssim m_{\widetilde{g}} \lesssim$ 5 GeV) are excluded or not. See the Supersymmetry Listings for details.

The limits summarised here refere to the high-mass region $(m_{\widetilde{g}}\gtrsim 5~{\rm GeV}),$ and include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta.$ The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}_1^0} \approx m_{\widetilde{g}}/6.$

$$\begin{array}{ll} \text{Mass } m > 173 \text{ GeV, CL} = 95\% & [\text{any } m_{\overline{q}}, \ \mu = -200 \text{ GeV,} \\ & \tan\beta = 2] \\ \text{Mass } m > 212 \text{ GeV, CL} = 95\% & [m_{\overline{g}} \geq m_{\overline{q}}, \ \mu = -250 \text{ GeV,} \\ & \tan\beta = 2] \end{array}$$

Quark and Lepton Compositeness, Searches for

Scale Limits A for Contact Interactions (the lowest dimensional Interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \overline{\psi}_L \gamma_\mu \psi_L \overline{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^{\pm}$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$$\begin{array}{lll} \Lambda_{LL}^{+}(eeee) &> 2.4 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{-}(eeee) &> 3.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(ee\mu\mu) &> 2.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(ee\mu\mu) &> 2.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(ee\tau\tau) &> 1.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(ee\tau\tau) &> 3.0 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(\ell\ell\ell\ell) &> 3.5 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(\ell\ell\ell\ell) &> 3.8 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(eeqq) &> 2.5 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(eeeqq) &> 3.7 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(eebb) &> 3.1 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(eebb) &> 2.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(\mu\mu qq) &> 2.9 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LL}^{+}(\mu\mu qq) &> 4.2 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \Lambda_{LR}^{+}(\nu_{\mu}\nu_{e}\mu e) &> 3.1 \; {\rm TeV}, \; {\rm CL} = 90\% \\ \Lambda_{LL}^{+}(qqqq) &> 1.6 \; {\rm TeV}, \; {\rm CL} = 95\% \\ \end{array}$$

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ -dependent limits assume chiral coupling, except for the third limit for e^* which is for nonchiral coupling. For chiral coupling, this limit corresponds to $\lambda_{\gamma}=\sqrt{2}$.

e*± — excited electron

 $\mu^{*\pm}$ — excited muon

Mass
$$m > 85.3$$
 GeV, CL = 95% (from $\mu^{*+}\mu^{*-}$)
Mass $m > 91$ GeV, CL = 95% (if $\lambda_Z > 1$)

 $au^{*\pm}$ — excited tau

Mass
$$m > 84.6$$
 GeV, CL = 95% (from $\tau^{*+}\tau^{*-}$)
Mass $m > 90$ GeV, CL = 95% (if $\lambda_Z > 0.18$)

 ν^* — excited neutrino

Mass
$$m>84.9$$
 GeV, CL = 95% (from $\nu^*\overline{\nu}^*$)
Mass $m>91$ GeV, CL = 95% (if $\lambda_Z>1$)
Mass $m=$ none 40–96 GeV, CL = 95% (from $ep\to\nu^*X$)

q* — excited quark

Mass
$$m > 45.6$$
 GeV, CL = 95% (from $q^* \overline{q}^*$)
Mass $m > 88$ GeV, CL = 95% (if $λ_Z > 1$)
Mass $m > 570$ GeV, CL = 95% ($p\overline{p} \rightarrow q^*X$)

Color Sextet and Octet Particles

Color Sextet Quarks (q₆)

Mass
$$m > 84$$
 GeV, $CL = 95\%$ (Stable q_6)

Color Octet Charged Leptons (\ell_8)

Mass
$$m > 86$$
 GeV, CL = 95% (Stable ℓ_8)

Color Octet Neutrinos (ν_8)

Mass
$$m > 110$$
 GeV, CL = 90% $(\nu_8 \rightarrow \nu g)$

TESTS OF CONSERVATION LAWS

Revised by L. Wolfenstein and T.G. Trippe, May 1998.

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full Review of Particle Physics, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. Limits in this text are for CL=90% unless otherwise specified. The Table is in two parts: "Discrete Space-Time Symmetries," i.e., C, P, T, CP, and CPT; and "Number Conservation Laws," i.e., lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the Review. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and \overline{K}^0 . Any such difference contributes to the CP-violating parameter ϵ . Assuming CPT invariance, ϕ_{ϵ} , the phase of ϵ should be very close to 44°. (See the "Note on CP Violation in K^0_L Decay" in the Particle Listings.) In contrast, if the entire source of CP violation in K^0_L decays were a $K^0 - \overline{K}^0_L$ mass difference, ϕ_{ϵ} would be $44^\circ + 90^\circ$. Assuming that there is no other source of CPT_L violation than this mass difference, it is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K^0_L} - m_{K^0_S}) \, |\eta| \, (\frac{2}{3}\phi_{+-} + \frac{1}{3}\phi_{00} - \phi_0)}{\sin\phi_0} \; ,$$

where $\phi_0=43.5^\circ$ with an uncertainty of less than 0.1°. Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0}-m_{K^0})/m_{K^0}| \leq 10^{-18}$. Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1-|\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00}-\phi_{+-}$ provides a measure of CPT violation in $K_L^0 \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. So far the only evidence for CP or T violation comes from the measurements of $\eta_{+-},\,\eta_{00},$ and the semileptonic decay charge asymmetry for K_L , e.g., $|\eta_{+-}| = |A(K_L^0 \to \pi^+\pi^-)/A(K_S^0$ $\rightarrow \pi^{+}\pi^{-})| = (2.285 \pm 0.019) \times 10^{-3} \text{ and } [\Gamma(K_L^0 \to \pi^- e^+ \nu) - 10^{-3}]$ $\Gamma(K_L^0 \to \pi^+ e^- \overline{\nu}) / [\text{sum}] = (0.333 \pm 0.014)\%$. Other searches for CP or T violation divide into (a) those that involve weak interactions or parity violation, and (b) those that involve processes otherwise allowed by the strong or electromagnetic interactions. In class (a) the most sensitive are probably the searches for an electric dipole moment of the neutron, measured to be $< 1.0 \times 10^{-25}$ e cm, and the electron $(-0.18 \pm 0.16) \times$ 10^{-26} e cm. A nonzero value requires both P and T violation. Class (b) includes the search for C violation in η decay, believed to be an electromagnetic process, e.g., as measured by $\Gamma(\eta \to \mu^+ \mu^- \pi^0)/\Gamma(\eta \to \text{all}) < 5 \times 10^{-6}$, and searches for T violation in a number of nuclear and electromagnetic reactions.

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e , muon number L_{μ} , and tau number L_{τ} . Searches for violations are of the following types:

- a) $\Delta L=2$ for one type of lepton. The best limit comes from the search for neutrinoless double beta decay $(Z,A) \rightarrow (Z+2,A)+e^-+e^-$. The best laboratory limit is $t_{1/2}>1.1\times 10^{25}$ yr (CL=90%) for ⁷⁶Ge.
- b) Conversion of one lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e\gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e\gamma)/\Gamma(\mu \to \text{all}) < 5 \times 10^{-11}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z,A) \to e^- + (Z,A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e\mu$ and $K^+ \to \pi^+e^-\mu^+$, measured as $\Gamma(K_L \to e\mu)/\Gamma(K_L \to \text{all}) < 3.3 \times 10^{-11}$ and $\Gamma(K^+ \to \pi^+e^-\mu^+)/\Gamma(K^+ \to \text{all}) < 2.1 \times 10^{-10}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, e.g., $\Gamma(\tau \to \mu\gamma)/\Gamma(\tau \to \text{all}) < 3.0 \times 10^{-6}$ and $\Gamma(\tau \to e\gamma)/\Gamma(\tau \to \text{all}) < 2.7 \times 10^{-6}$.
- c) Conversion of one type of lepton into another type of antilepton. The case most studied is $\mu^- + (Z,A) \rightarrow e^+ + (Z-2,A)$, the strongest limit being $\Gamma(\mu^- \text{Ti} \rightarrow e^+ \text{Ca})/\Gamma(\mu^- \text{Ti} \rightarrow \text{all}) < 9 \times 10^{-11}$.
- d) Relation to neutrino mass. If neutrinos have mass, then it is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo quark mixing. However, in this case lepton-number-violating processes such as $\mu \to e\gamma$ are expected to have extremely small probability. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental searches. For example, searches for $\overline{\nu}_e$ disappearance, which we label as $\overline{\nu}_e \not \to \overline{\nu}_e$, give measured limits $\Delta(m^2) < 9 \times 10^{-4} \text{ eV}^2 \text{ for } \sin^2(2\theta) = 1, \text{ and } \sin^2(2\theta) < 0.02$ for large $\Delta(m^2)$, where θ is the neutrino mixing angle. Possible evidence for mixing has come from two sources. The deficit in the solar neutrino flux compared with solar model calculations could be explained by oscillations with $\Delta(m^2) \leq 10^{-5} \text{ eV}^2$ causing the disappearance of ν_e . In addition underground detectors observing neutrinos produced by cosmic rays in the atmosphere have measured a ν_{μ}/ν_{e} ratio much less than expected and also a deficiency of upward going ν_{μ} compared to downward. This could be explained by oscillations leading to the disappearance of ν_{μ} with $\Delta(m^2)$ of the order 10^{-2} – 10^{-3} eV².

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, *i.e.* the conversion of a quark of one flavor (d, u, s, c, b, t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

a) $\Delta S = \Delta Q$ rule. In the semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as

 $\Gamma(\Sigma^+ \to n e^+ \nu)/\Gamma(\Sigma^+ \to {\rm all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e \nu$, which yields the parameter x, measured to be $({\rm Re}\, x, {\rm Im}\, x) = (0.006 \pm 0.018, -0.003 \pm 0.026)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.

- b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S=2$ via $K^0-\overline{K}^0$ mixing, which is directly measured by $m(K_S)-m(K_L)=(3.489\pm0.009)\times10^{-12}$ MeV. There is now evidence for $B^0-\overline{B}^0$ mixing $(\Delta B=2)$, with the corresponding mass difference between the eigenstates $(m_{B_1^0}-m_{B_1^0})=(0.723\pm0.032)\Gamma_{B^0}=(3.05\pm0.12)\times10^{-10}$ MeV, and for $B_s^0-\overline{B}_s^0$ mixing, with $(m_{B_{sH}^0}-m_{B_{sL}^0})>14\Gamma_{B_s^0}$ or $>6\times10^{-9}$ MeV (CL=95%). No evidence exists for $D^0-\overline{D}^0$ mixing, which is expected to be much smaller in the Standard Model.
- c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+ \mu^-)/\Gamma(K_L \to \text{all}) = (7.2 \pm 0.5) \times 10^{-9} \text{ puts}$ limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from $K^+ \to \pi^+ \nu \overline{\nu}$, which occurs in the Standard Model only as a second-order weak process with a branching fraction of $(1 \text{ to } 8) \times 10^{-10}$. Observation of one event has been reported [4], yielding $\Gamma(K^+ \to$ $\pi^+\nu\overline{\nu})/\Gamma(K^+\to \text{all})=(4.2^{+9.7}_{-3.5})\times 10^{-10}$. Limits for charmchanging or bottom-changing neutral currents are much less stringent: $\Gamma(D^0 \to \mu^+\mu^-)/\Gamma(D^0 \to \text{all}) < 4 \times 10^{-6}$ and $\Gamma(B^0 \to \mu^+ \mu^-)/\Gamma(B^0 \to \text{all}) < 7 \times 10^{-7}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S=\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

- [a] C parity forbids this to occur as a single-photon process.
- [b] Time-reversal invariance requires this to be 0° or 180°.
- [c] Allowed by higher-order electroweak interactions.
- [d] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- $[e]~\epsilon'/\epsilon$ is derived from $\left|\eta_{00}/\eta_{+-}\right|$ measurements using theoretical input on phases.
- [f] Neglecting photon channels. See, e.g., A. Pais and S.B. Treiman, Phys. Rev. D12, 2744 (1975).
- [g] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K_L^0}-m_{K_S^0}|$, and $\tau_{K_L^0}$, as described in the introduction to "Tests of Conservation Laws."
- [h] The value is for the sum of the charge states of particle/antiparticle states indicated.
- $[\emph{i}]$ A test of additive vs. multiplicative lepton family number conservation.
- $[j] \Delta(m^2) = 100 \text{ eV}^2.$
- $[k] 190 \text{ eV}^2 < \Delta(m^2) < 320 \text{ eV}^2.$
- [/] Derived from an analysis of neutrino-oscillation experiments.
- [m] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The second limit here is from reactor experiments with free neutrons.
- [n] This is the best "electron disappearance" limit. The best limit for the mode e $^ \to$ $\nu\gamma$ is $> 2.35 \times 10^{25}$ yr (CL=68%).
- [o] The D_1^0 - D_2^0 limits are inferred from the D^0 - \overline{D}^0 mixing ratio $\Gamma(K^+\ell^-\overline{\nu}_\ell({\rm via}\ \overline{D}^0)) / \Gamma(K^-\ell^+\nu_\ell)$.
- [p] The larger limit (from E791) allows interference between the doubly Cabibbo-suppressed and mixing amplitudes; the smaller limit (from E691) doesn't. See the papers for details.
- [q] See the K⁰_L Particle Listings for the energy limits used in this measurement.

Table 1.1. Reviewed 1998 by B.N. Taylor (NIST). Based mainly on the "1986 Adjustment of the Fundamental Physical Constants" by E.R. Cohen and B.N. Taylor, Rev. Mod. Phys. 59, 1121 (1987). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding uncertainties in parts per million (ppm) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology).

Since the 1986 adjustment, new experiments have yielded improved values for a number of constants, including the Rydberg constant R_{∞} , the Planck constant h, the fine-structure constant α , and the molar gas constant R, and hence also for constants directly derived from these, such as the Boltzmann constant k and Stefan-Boltzmann constant σ . The new results and their impact on the 1986 recommended values are discussed extensively in "Recommended Values of the Fundamental Physical Constants: A Status Report," B.N. Taylor and E.R. Cohen, J. Res. Natl. Inst. Stand. Technol. 95, 497 (1990); see also E.R. Cohen and B.N. Taylor, "The Fundamental Physical Constants," Phys. Today, August 1997 Part 2, BG7. In general, the new results give uncertainties for the affected constants that are 5 to 7 times smaller than the 1986 uncertainties but the changes in the values themselves are smaller than twice the 1986 uncertainties. Because the output values of a least-squares adjustment are correlated, the new results cannot readily be incorporated with the 1986 values. Until the next complete adjustment of the constants (expected by the end of 1998), the 1986 CODATA set, given (in part) below, remains the set of choice. The full 1986 set (to be replaced by the new set, when available) may be found at http://physics.nist.gov/cuu.

^{*} The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second.

 $^{^{\}dagger}$ At $Q^2=0.$ At $Q^2\approx m_W^2$ the value is approximately 1/128.

[‡] Absolute lab measurements of G_N have been performed only on scales of $10^{-1\pm1}$ m.

^{**} See discussion in Sec. 10 "Electroweak model and constraints on new physics."

2. ASTROPHYSICAL CONSTANTS

Table 2.1. Revised 1997 by D.E. Groom (LBNL) with the help of G.F. Smoot, M.S. Turner, and R.C. Willson. The figures in parentheses after some values give the one-standard deviation uncertainties in the last digit(s). While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference.

 The set of constants resulting from this adjustment has been recommended for international use by CODATA (Committee on Data for Science and Technology).

In the context of the scale dependence of field theoretic quantities, it should be remarked that absolute lab measurements of G_N have been performed only on scales of $10^{-1\pm 1}$ m.

- The Astronomical Almanac for the year 1994, U.S. Government Printing Office, Washington, and Her Majesty's Stationary Office, London (1993). Where possible, the values as adjusted for the fitting of the ephemerides to all the observational data are used.
- JPL Planetary Ephemerides, E. Myles Standish, Jr., private communication (1989).
- 5. 1 AU divided by $\pi/648000$; quoted error is from the JPL Planetary Ephemerides value of the AU [4].
- 6. Heliocentric gravitational constant from Ref. 3 times $2/c^2$. The given 9-place accuracy appears to be consistent with uncertainties in actually defining the earth's orbital parameters.
- 7. Obtained from the heliocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation of G_N .
- 8. 1996 mean total solar irradiance (TSI) = 1367.5 ± 2.7 [23]; the solar luminosity is $4\pi \times (1 \text{ AU})^2$ times this quantity. This value increased by 0.036% between the minima of solar cycles 21 and 22. It was modulated with an amplitude of 0.039% during solar cycle 21 [24].

Sackmann et al. [25] use TSI = 1370 ± 2 W m⁻², but conclude that the solar luminosity ($L_{\odot} = 3.853 \times 10^{26}$ J s⁻¹) has an uncertainty of 1.5%. Their value is based on three 1977-83 papers, and they comment that the error is based on scatter among the reported values, which is substantially in excess of that expected from the individual quoted errors.

The conclusion of the 1971 review by Thekaekara and Drummond [26] $(1353 \pm 1\% \ W \ m^{-2})$ is often quoted [27]. The conversion to luminosity is not given in the Thekaekara and Drummond paper, and we cannot exactly reproduce the solar luminosity given in Ref. 27.

Finally, a value based on the 1954 spectral curve due to Johnson [28] $(1395\pm1\%~W~m^{-2}, {\rm or}~L_{\odot}=3.92\times10^{26}~{\rm J~s}^{-1})$ has been used widely, and may be the basis for higher value of the solar luminosity and corresponding lower value of the solar absolute bolometric magnitude (4.72) still common in the literature [10].

- Obtained from the geocentric gravitational constant [3] and G_N [2]. The error is the 128 ppm standard deviation of G_N.

4. PERIODIC TABLE OF THE ELEMENTS

(u). Errors range from 1 to 9 in the last digit quoted. Relative isotopic abundances often vary considerably, both in natural and commercial samples. A number in parentheses is the mass of the longest-lived isotope of that element—no stable isotope exists. However, although Th, Pa, and U have no stable isotopes, they do have characteristic terrestrial compositions, and meaningful weighted masses can be given. For elements 110–112, the atomic numbers of known isotopes are given. Adapted from the Commission of Atomic Weights and Isotopic Abundances, "Atomic Weights of the Elements 1995," Pure and Applied Chemistry 68, 2339 (1996), and G. Audi and A.H. Wapstra, "The 1993 Mass Evaluation," Nucl. Phys. A565, 1 (1993). The names given below for elements 104 to 109 are those recommended by the Table 4.1. Revised 1997 by C.G. Wohl (LBNL). The atomic number (top left) is the number of protons in the nucleus. The atomic mass (bottom) is weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of the carbon-12 isotope, defined to be exactly 12 unified atomic mass units international Union of Pure and Applied Chemistry in late 1997.

5. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 5.1. Reviewed 1998 by W.C. Martin (NIST). The electronic configurations and the ionization energies (except for a few newer values, marked with an *) are taken from "Atomic Spectroscopy," W.C. Martin and W.L. Wiese, in Atomic, Molecular, and Optical Physics Reference Book, G.W.F. Drake, ed., Amer. Inst. Phys., 1995. The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six 3d electrons and two 4s electrons. The ionization energy is the least energy necessary to remove to infinity one electron from an atom of the element.

			Electron configuration			Ground state	Ionization energy
	Elen	nent	$(3d^5 = \text{five } 3d \text{ electron})$	s, etc.)		$^{2S+1}L_J$	(eV)
1	H	Hydrogen	18			² S _{1/2}	13.5984

6. ATOMIC AND NUCLEAR PROPERTIES OF MATERIALS

Table 6.1. Revised April 1998 by D.E. Groom (LBNL). Gases are evaluated at 20°C and 1 atm (in parentheses) or at STP [square brackets]. Densities and refractive indices without parentheses or brackets are for solids or liquids, or are for cryogenic liquids at the indicated boiling point (BP) at 1 atm. Refractive indices are evaluated at the sodium D line. Data for compounds and mixtures are from Refs. 1 and 2.

7. ELECTROMAGNETIC RELATIONS

Quantity	Gaussian CGS	SI
Conversion factors:		
Charge:	$2.99792458 \times 10^9 \text{ esu}$	= 1 C = 1 A s
Potential:	(1/299.792 458) statvolt (ergs/esu)	$= 1 V = 1 J C^{-1}$
Magnetic field:	$10^4 \text{ gauss} = 10^4 \text{ dyne/esu}$	$= 1 T = 1 N A^{-1}m^{-1}$
Lorentz force:	$\mathbf{F} = q\left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B}\right)$	$\mathbf{F} = q(\mathbf{E} + \mathbf{v} \times \mathbf{B})$
Maxwell equations:	$\nabla \cdot \mathbf{D} = 4\pi \rho$	$\nabla \cdot \mathbf{D} = \rho$
	$\mathbf{ abla} imes \mathbf{H} - rac{1}{c} rac{\partial \mathbf{D}}{\partial t} = rac{4\pi}{c} \mathbf{J}$	$\nabla \times \mathbf{H} - \frac{\partial \mathbf{D}}{\partial t} = \mathbf{J}$
	$\nabla \cdot \mathbf{B} = 0$	$\nabla \cdot \mathbf{B} = 0$
	$\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0$	$\mathbf{ abla} imes \mathbf{E} + rac{\partial \mathbf{B}}{\partial t} = 0$
Constitutive relations:	$\mathbf{D} = \mathbf{E} + 4\pi \mathbf{P}, \mathbf{H} = \mathbf{B} - 4\pi \mathbf{M}$	$\mathbf{D} = \epsilon_0 \mathbf{E} + \mathbf{P}, \mathbf{H} = \mathbf{B}/\mu_0 - \mathbf{M}$
Linear media:	$\mathbf{D} = \epsilon \mathbf{E}, \mathbf{H} = \mathbf{B}/\mu$	$\mathbf{D} = \epsilon \mathbf{E}, \mathbf{H} = \mathbf{B}/\mu$
Permitivity of free space:	1	$\epsilon_0 = 8.854 \ 187 \dots \times 10^{-12} \ \mathrm{F \ m^{-1}}$
Permeability of free space:	1	$\mu_0 = 4\pi \times 10^{-7} \text{ N A}^{-2}$
Fields from potentials:	$\mathbf{E} = -\nabla V - \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t}$	$\mathbf{E} = -\nabla V - \frac{\partial \mathbf{A}}{\partial t}$
	$\mathbf{B} = \mathbf{\nabla} \times \mathbf{A}$	$\mathbf{B} = \mathbf{\nabla} \times \mathbf{A}$
Static potentials: (coulomb gauge)	$V = \sum_{\mathrm{charges}} rac{q_i}{r_i} = \int rac{ ho\left(\mathbf{r'} ight)}{\left \mathbf{r}-\mathbf{r'} ight } d^3x'$	$V = rac{1}{4\pi\epsilon_0} \sum_{ ext{charges}} rac{q_i}{r_i} = rac{1}{4\pi\epsilon_0} \int rac{ ho\left(ext{r}' ight)}{ ext{r}- ext{r}' } \ d^3x'$
	$\mathbf{A} = \frac{1}{c} \oint \frac{I \mathrm{d}\boldsymbol{\ell}}{ \mathbf{r} - \mathbf{r}' } = \frac{1}{c} \int \frac{\mathbf{J}(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3 x'$	$\mathbf{A} = \frac{\mu_0}{4\pi} \oint \frac{I \mathrm{d}\ell}{ \mathbf{r} - \mathbf{r}' } = \frac{\mu_0}{4\pi} \int \frac{\mathbf{J}(\mathbf{r}')}{ \mathbf{r} - \mathbf{r}' } d^3x'$
Relativistic transformations:	$\mathbf{E}'_{\parallel} = \mathbf{E}_{\parallel}$	$\mathbf{E}'_{\parallel} = \mathbf{E}_{\parallel}$
(v is the velocity of the primed frame as seen	$\mathbf{E}'_{\perp} = \gamma (\mathbf{E}_{\perp} + rac{1}{c} \mathbf{v} imes \mathbf{B})$	$\mathbf{E}'_{\perp} = \gamma(\mathbf{E}_{\perp} + \mathbf{v} \times \mathbf{B})$
in the unprimed frame)	$\mathbf{B}'_{\parallel} = \mathbf{B}_{\parallel}$	$\mathbf{B}'_{\parallel} = \mathbf{B}_{\parallel}$
	$\mathbf{B}_{\perp}' = \gamma (\mathbf{B}_{\perp} - \frac{1}{c} \mathbf{v} \times \mathbf{E})$	$\mathbf{B}'_{\perp} = \gamma (\mathbf{B}_{\perp} - \frac{1}{c^2} \mathbf{v} \times \mathbf{E})$
$\frac{1}{4\pi\epsilon_0} = c^2 \times 10^{-7} \text{ N A}^{-2} = 8.98$	$37.55 \times 10^9 \text{ m F}^{-1}$; $\frac{\mu_0}{4\pi} = 10^{-7} \text{ N A}^{-1}$	$c = \frac{1}{\sqrt{\mu_0 \epsilon_0}} = 2.99792458 \times 10^8 \text{ m s}^{-1}$

7.1. Impedances (SI units)

 ρ = resistivity at room temperature in $10^{-8} \Omega$ m:

~ 1.7 for Cu ~ 5.5 for W ~ 2.4 for Au ~ 73 for SS 304 ~ 2.8 for Al ~ 100 for Nichrome (Al alloys may have double the Al value.)

For alternating currents, instantaneous current I, voltage V, angular frequency ω :

$$V = V_0 e^{j\omega t} = ZI. ag{7.1}$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance C: $Z = 1/j\omega C$.

Impedance of free space: $Z=\sqrt{\mu_0/\epsilon_0}=376.7~\Omega$.

High-frequency surface impedance of a good conductor:

$$Z=rac{\left(1+j
ight)
ho}{\delta}$$
 , where $\delta= ext{skin depth}$; (7.2)

$$\delta = \sqrt{\frac{\rho}{\pi \nu \mu}} \approx \frac{6.6 \text{ cm}}{\sqrt{\nu (\text{Hz})}} \text{ for Cu}.$$
 (7.3)

7.2. Capacitance \widehat{C} and inductance \widehat{L} per unit length (SI units) [negligible skin depth]

Flat rectangular plates of width w, separated by $d \ll w$ with linear medium (ϵ, μ) between:

$$\widehat{C} = \epsilon \frac{w}{d} \; ; \qquad \widehat{L} = \mu \frac{d}{w} \; ; \tag{7.4}$$

 $\epsilon/\epsilon_0 = 2$ to 6 for plastics; 4 to 8 for porcelain, glasses; (7.5)

$$\mu/\mu_0 \simeq 1 \ . \tag{7.6}$$

Coaxial cable of inner radius r_1 , outer radius r_2 :

$$\widehat{C} = \frac{2\pi \epsilon}{\ln (r_2/r_1)}; \quad \widehat{L} = \frac{\mu}{2\pi} \ln (r_2/r_1). \tag{7.7}$$

Transmission lines (no loss):

Impedance:
$$Z = \sqrt{\widehat{L}/\widehat{C}}$$
 . (7.8)

Velocity:
$$v = 1/\sqrt{\widehat{L} \ \widehat{C}} = 1/\sqrt{\mu \epsilon}$$
. (7.9)

7.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v=\beta c$, and energy $E=\gamma mc^2$, traveling in a circular orbit of radius R, the classical energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3} \, \frac{e^2}{R} \, \beta^3 \, \gamma^4 \, . \tag{7.10}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E \text{ (in MeV)} \approx 0.0885 \ [E(\text{in GeV})]^4 / R(\text{in m}) \ .$$
 (7.11)

For $\gamma\gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9} \alpha \gamma F(\omega/\omega_c) d(\hbar\omega) , \qquad (7.12)$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{7.13}$$

is the critical frequency. The normalized function F(y) is

$$F(y) = \frac{9}{8\pi} \sqrt{3} y \int_{y}^{\infty} K_{5/3}(x) dx , \qquad (7.14)$$

where $K_{5/3}(x)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_{\rm c} ({\rm in~keV}) \approx 2.22 \ [E({\rm in~GeV})]^3/R({\rm in~m}) \ .$$
 (7.15)

Fig. 7.1 shows F(y) over the important range of y.

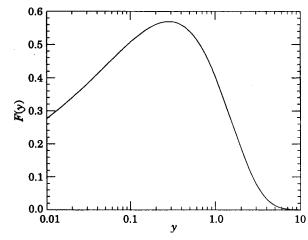

Figure 7.1: The normalized synchrotron radiation spectrum F(y).

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha (\omega R/c)^{1/3} , \qquad (7.16)$$

whereas for

$$\gamma \gg 1$$
 and $\omega \gtrsim 3\omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx \sqrt{\frac{3\pi}{2}} \alpha \gamma \left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c} \left[1 + \frac{55}{72} \frac{\omega_c}{\omega} + \ldots\right] . \tag{7.17}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion. The mean number of photons emitted per revolution is

$$N_{\gamma} = \frac{5\pi}{\sqrt{3}}\alpha\gamma \ , \tag{7.18}$$

and the mean energy per photon is

$$\langle \hbar \omega \rangle = \frac{8}{15\sqrt{3}} \hbar \omega_c \ . \tag{7.19}$$

When $\langle \hbar \omega \rangle \gtrsim O(E)$, quantum corrections are important.

See J.D. Jackson, Classical Electrodynamics, $2^{\rm nd}$ edition (John Wiley & Sons, New York, 1975) for more formulae and details. In his book, Jackson uses a definition of ω_c that is twice as large as the customary one given above.

8. NAMING SCHEME FOR HADRONS

Maintained 1996 by M. Roos (University of Finland) and C.G. Wohl (LBNL).

8.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light (u, d, and s) quarks. Old and new names were listed alongside until 1994. Names also change from edition to edition because some characteristic like mass or spin changes. The Summary Tables give both the new and old names whenever a change occurred.

8.2. "Neutral-flavor" mesons (S=C=B=T=0)

Table 8.1 shows the names for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all ordinary non-exotic mesons, but it will work for many exotic types too, if needed.

Table 8.1: Symbols for mesons with the strangeness and all heavy-flavor quantum numbers equal to zero.

,	$J^{PC} =$	{0 ^{−+} 2 ^{−+} ⋮	1+- 3+- :	1 2 :	0 ⁺⁺ 1 ⁺⁺ :
$q\overline{q}$ content	$^{2S+1}L_J =$	$^1(L{\rm even})_J$	$^1(L \operatorname{odd})_J$	$^3(L{\rm even})_J$	$^3(L \operatorname{odd})_J$
$u\overline{d}, u\overline{u} - d\overline{d},$	$d\overline{u}$ $(I=1)$	π	b	ρ	a
$d\overline{d} + u\overline{u}$ and/or $s\overline{s}$	$\left.\begin{array}{l} I = 0 \end{array}\right)$	η,η'	h, h'	ω,ϕ	f, f'
$c\overline{c}$	•	η_c	h_c	ψ^\dagger	χc
$b\overline{b}$		η_b	h_b	r	χ_b
$t\bar{t}$		η_t	h_t	θ	χ_t

[†]The J/ψ remains the J/ψ .

First, we assign names to those states with quantum numbers compatible with being $q\bar{q}$ states. The rows of the Table give the possible $q\bar{q}$ content. The columns give the possible parity/charge-conjugation states,

$$PC = -+, +-, --, \text{ and } ++;$$

these combinations correspond one-to-one with the angular-momentum state ${}^{2S+1}L_J$ of the $q\overline{q}$ system being

$$^{1}(L \text{ even})_{J}$$
, $^{1}(L \text{ odd})_{J}$, $^{3}(L \text{ even})_{J}$, or $^{3}(L \text{ odd})_{J}$.

Here $S,\ L$, and J are the spin, orbital, and total angular momenta of the $q\overline{q}$ system. The quantum numbers are related by

$$P = (-1)^{L+1}$$
, $C = (-1)^{L+S}$, and G parity $= (-1)^{L+S+I}$,

where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the meson names. The spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for mesons that decay strongly. However, for the lightest meson resonances, we omit the mass.

Measurements of the mass, quark content (where relevant), and quantum numbers I, J, P, and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\overline{u}$ and $d\overline{d}$ or is mainly $s\overline{s}$. A prime (or pair ω , ϕ) may be used to distinguish two such mixing states.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ , Υ , and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternative, and as the primary name when the spectroscopic identity is not known.

Names are assigned for $t\bar{t}$ mesons, although the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\overline{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\overline{q}$ mesons. Such states will probably be difficult to distinguish from $q\overline{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\overline{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\overline{q}$ system cannot have, namely $J^{PC}=0^{--},0^{+-},1^{-+},2^{+-},3^{-+},\cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. But then the J subscript may still distinguish it; for example, an isospin-0 1^{-+} meson could be denoted ω_1 .

8.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

 The main symbol is an upper-case italic letter indicating the heavier quark as follows:

$$s o \overline{K} \qquad c o D \qquad b o \overline{B} \qquad t o T$$
 .

We use the convention that the flavor and the charge of a quark have the same sign. Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: Any flavor carried by a charged meson has the same sign as its charge. Thus the K^+ , D^+ , and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3 . The D_s^+ has positive charm and strangeness. Furthermore, the $\Delta({\rm flavor}) = \Delta Q$ rule, best known for the kaons, applies to every flavor.

- If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s⁺ is an example.
- 3. If the spin-parity is in the "normal" series, $J^P = 0^+, 1^-, 2^+, \cdots$, a superscript "*" is added.
- The spin is added as a subscript except for pseudoscalar or vector mesons.

8.4. Baryons

The symbols N, Δ , Λ , Σ , Ξ , and Ω used for more than 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols used for the baryons containing one or more heavy quarks (c, b, and t quarks). The rules are:

- Baryons with three u and/or d quarks are N's (isospin 1/2) or Δ's (isospin 3/2).
- Baryons with two u and/or d quarks are A's (isospin 0) or Σ's (isospin 1). If the third quark is a c, b, or t quark, its identity is given by a subscript.
- Baryons with one u or d quark are \(\mathcal{\pi}\)'s (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus \(\mathcal{\pi}_c\), \(\mathcal{\pi}_{cc}\), \(\mathcal{\pi}_b\), etc.
- Baryons with no u or d quarks are \(\Omega\)'s (isospin 0), and subscripts indicate any heavy-quark content.

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0, etc.

9. QUANTUM CHROMODYNAMICS

9.1. The QCD Lagrangian

Revised September 1997 by I. Hinchliffe (LBNL).

Quantum Chromodynamics (QCD), the gauge field theory which describes the strong interactions of colored quarks and gluons, is one of the components of the SU(3)×SU(2)×U(1) Standard Model. A quark of specific flavor (such as a charm quark) comes in 3 colors; gluons come in eight colors; hadrons are color-singlet combinations of quarks, anti-quarks, and gluons. The Lagrangian describing the interactions of quarks and gluons is (up to gauge-fixing terms)

$$L_{\text{QCD}} = -\frac{1}{4} F_{\mu\nu}^{(a)} F^{(a)\mu\nu} + i \sum_{q} \overline{\psi}_{q}^{i} \gamma^{\mu} (D_{\mu})_{ij} \psi_{q}^{j} - \sum_{q} m_{q} \overline{\psi}_{q}^{i} \psi_{qi}, \qquad (9.1)$$

$$F_{\mu\nu}^{(a)} = \partial_{\mu} A_{\nu}^{a} - \partial_{\nu} A_{\mu}^{a} + g_{s} f_{abc} A_{\mu}^{b} A_{\nu}^{c} , \qquad (9.2)$$

$$(D_{\mu})_{ij} = \delta_{ij} \,\,\partial_{\mu} - ig_s \,\,\sum_{\alpha} \frac{\lambda_{i,j}^{\alpha}}{2} A_{\mu}^{\alpha} \,\,, \tag{9.3}$$

where g_s is the QCD coupling constant, and the f_{abc} are the structure constants of the SU(3) algebra (the λ matrices and values for f_{abc} can be found in "SU(3) Isoscalar Factors and Representation Matrices," Sec. 33 of this Review). The $\psi_q^i(x)$ are the 4-component Dirac spinors associated with each quark field of (3) color i and flavor q, and the $A^a_\mu(x)$ are the (8) Yang-Mills (gluon) fields. A complete list of the Feynman rules which derive from this Lagrangian, together with some useful color-algebra identities, can be found in Ref. 1.

The principle of "asymptotic freedom" (see below) determines that the renormalized QCD coupling is small only at high energies, and it is only in this domain that high-precision tests-similar to those in QED-can be performed using perturbation theory. Nonetheless, there has been in recent years much progress in understanding and quantifying the predictions of QCD in the nonperturbative domain, for example, in soft hadronic processes and on the lattice [2]. This short review will concentrate on QCD at short distances (large momentum transfers), where perturbation theory is the standard tool. It will discuss the processes that are used to determine the coupling constant of QCD. Other recent reviews of the coupling constant measurements may be consulted for a different perspective [3].

9.2. The QCD coupling and renormalization scheme

The renormalization scale dependence of the effective QCD coupling $\alpha_s=g_s^2/4\pi$ is controlled by the β -function:

$$\mu \frac{\partial \alpha_s}{\partial \mu} = -\frac{\beta_0}{2\pi} \alpha_s^2 - \frac{\beta_1}{4\pi^2} \alpha_s^3 - \frac{\beta_2}{64\pi^3} \alpha_s^4 - \cdots, \qquad (9.4a)$$

$$\beta_0 = 11 - \frac{2}{3}n_f \,, \tag{9.4b}$$

$$\beta_1 = 51 - \frac{19}{3} n_f \,, \tag{9.4c}$$

$$\begin{split} \beta_1 &= 51 - \frac{19}{3} n_f \; , \\ \beta_2 &= 2857 - \frac{5033}{9} n_f + \frac{325}{27} n_f^2 \; ; \end{split} \tag{9.4c}$$

where n_f is the number of quarks with mass less than the energy scale μ . The expression for the next term in this series (β_3) can be found in Ref. 4. In solving this differential equation for α_s , a constant of integration is introduced. This constant is the one fundamental constant of QCD that must be determined from experiment. The most sensible choice for this constant is the value of α_s at a fixed-reference scale μ_0 , but it is more conventional to introduce the dimensional parameter Λ , since this provides a parametrization of the μ dependence of α_s . The definition of Λ is arbitrary. One way to define it (adopted here) is to write a solution of Eq. (9.4) as an expansion in inverse powers of $\ln (\mu^2)$:

$$\alpha_{s}(\mu) = \frac{4\pi}{\beta_{0} \ln(\mu^{2}/\Lambda^{2})} \left[1 - \frac{2\beta_{1}}{\beta_{0}^{2}} \frac{\ln\left[\ln(\mu^{2}/\Lambda^{2})\right]}{\ln(\mu^{2}/\Lambda^{2})} + \frac{4\beta_{1}^{2}}{\beta_{0}^{4} \ln^{2}(\mu^{2}/\Lambda^{2})} \right] \times \left(\left(\ln\left[\ln(\mu^{2}/\Lambda^{2})\right] - \frac{1}{2} \right)^{2} + \frac{\beta_{2}\beta_{0}}{8\beta_{1}^{2}} - \frac{5}{4} \right) \right]. \tag{9.5a}$$

The last term in this expansion is

$$\mathcal{O}\left(\frac{\ln^2\left[\ln\left(\mu^2/\Lambda^2\right)\right]}{\ln^3\left(\mu^2/\Lambda^2\right)}\right) , \qquad (9.5b)$$

and is usually neglected in the definition of Λ . We choose to include it. For a fixed value of $\alpha_s(M_Z)$, the inclusion of this term shifts the value of Λ by ~ 15 MeV. This solution illustrates the asymptotic freedom property: $\alpha_s \to 0$ as $\mu \to \infty$. Alternative definitions of Λ are possible. We adopt this as the standard. Values given by experiments using other definitions are adjusted as needed to meet our definition.

Consider a "typical" QCD cross section which, when calculated perturbatively, starts at $\mathcal{O}(\alpha_s)$:

$$\sigma = A_1 \alpha_s + A_2 \alpha_s^2 + \cdots . \tag{9.6}$$

The coefficients A_1 , A_2 come from calculating the appropriate Feynman diagrams. In performing such calculations, various divergences arise, and these must be regulated in a consistent way. This requires a particular renormalization scheme (RS). The most commonly used one is the modified minimal subtraction (\overline{MS}) scheme [5]. This involves continuing momentum integrals from 4 to 4-2 ϵ dimensions, and then subtracting off the resulting $1/\epsilon$ poles and also $(\ln 4\pi - \gamma_E)$, which is another artifact of continuing the dimension. (Here γ_E is the Euler-Mascheroni constant.) To preserve the dimensionless nature of the coupling, a mass scale μ must also be introduced: $g \to \mu^{\epsilon} g$. The finite coefficients A_i (i > 2) thus obtained depend implicitly on the renormalization convention used and explicitly on the scale μ .

The first two coefficients (β_0, β_1) in Eq. (9.4) are independent of the choice of RS's. In contrast, the coefficients of terms proportional to α_s^n for n > 3 are RS-dependent. The form given above for β_2 is in the MS scheme. It has become conventional to use the MS scheme for calculating QCD cross sections beyond leading order.

The fundamental theorem of RS dependence is straightforward. Physical quantities, in particular the cross section, calculated to all orders in perturbation theory, do not depend on the RS. It follows that a truncated series does exhibit RS dependence. In practice, QCD cross sections are known to leading order (LO), or to next-to-leading order (NLO), or in a few cases, to next-to-next-to-leading order (NNLO); and it is only the latter two cases, which have reduced RS dependence, that are useful for precision tests. At NLO the RS dependence is completely given by one condition which can be taken to be the value of the renormalization scale μ . At NNLO this is not sufficient, and μ is no longer equivalent to a choice of scheme; both must now be specified. One, therefore, has to address the question of what is the "best" choice for μ within a given scheme, usually $\overline{\text{MS}}$. There is no definite answer to this question-higher-order corrections do not "fix" the scale, rather they render the theoretical predictions less sensitive to its variation.

One could imagine that choosing a scale μ characteristic of the typical energy scale (E) in the process would be most appropriate. In general, a poor choice of scale generates terms of order $\ln (E/\mu)$ in the A_i 's. Various methods have been proposed including choosing: the scale for which the next-to-leading-order correction vanishes ("Fastest Apparent Convergence [6]"); the scale for which the next-toleading-order prediction is stationary [7], (i.e., the value of μ where $d\sigma/d\mu = 0$); or the scale dictated by the effective charge scheme [8] or by the BLM scheme [9]. By comparing the values of α_s that different reasonable schemes give, an estimate of theoretical errors can be obtained. It has also been suggested to replace the perturbation series by its Pade approximant [10]. Results obtained using this method have, in certain cases, a reduced scale dependence [11,12].

An important corollary is that if the higher-order corrections are naturally small, then the additional uncertainties introduced by the μ dependence are likely to be less than the experimental measurement errors. There are some processes, however, for which the choice of scheme can influence the extracted value of $\Lambda_{\overline{MS}}$. There is no resolution to this problem other than to try to calculate even more terms in the perturbation series. It is important to note that,

since the perturbation series is an asymptotic expansion, there is a limit to the precision with which any theoretical quantity can be calculated. In some processes, the highest-order perturbative terms may be comparable in size to nonperturbative corrections (sometimes called higher-twist or renormalon effects, for a discussion see [13]); an estimate of these terms and their uncertainties is required if a value of α_s is to be extracted.

In the cases where the higher-order corrections to a process are known and are large, some caution should be exercised when quoting the value of α_s . In what follows, we will attempt to indicate the size of the theoretical uncertainties on the extracted value of α_s . There are two simple ways to determine this error. First, we can estimate it by comparing the value of $\alpha_s(\mu)$ obtained by fitting data using the QCD formula to highest known order in α_s , and then comparing it with the value obtained using the next-to-highest-order formula (μ is chosen as the typical energy scale in the process). The corresponding Λ 's are then obtained by evolving $\alpha_s(\mu)$ to $\mu=M_Z$ using Eq. (9.4) to the same order in α_s as the fit. Alternatively, we can vary the value of μ over a reasonable range, extracting a value of Λ for each choice of μ . This method is of its nature imprecise, since "reasonable" involves a subjective judgment. In either case, if the perturbation series is well behaved, the resulting error on $\alpha_s(M_Z)$ will be small.

In the above discussion we have ignored quark-mass effects, i.e., we have assumed an idealized situation where quarks of mass greater than μ are neglected completely. In this picture, the β -function coefficients change by discrete amounts as flavor thresholds are crossed when integrating the differential equation for α_s . It follows that, for a relationship such as Eq. (9.5) to remain valid for all values of μ , A must also change as flavor thresholds are crossed. This leads to the concept of a different Λ for each range of μ corresponding to an effective number of massless quarks: $\Lambda \to \Lambda^{(n_f)}$. There is some arbitrariness in how this relationship is set up. As an idealized case, consider QCD with $n_f - 1$ massless quarks and one quark of mass M. Now imagine an experiment at energy scale μ ; for example, this could be $e^+e^- \to \text{hadrons}$ at center-of-mass energy μ . If $\mu \gg M$, the mass M is negligible and the process is well described by QCD with n_f massless flavors and its parameter $\Lambda^{(n_f)}$ up to terms of order M^2/μ^2 . Conversely if $\mu \ll M$, the heavy quark plays no role and the process is well described by QCD with $n_f - 1$ massless flavors and its parameter $\Lambda^{(n_f-1)}$ up to terms of order μ^2/M^2 . If $\mu \sim M$, the effects of the quark mass are process-dependent and cannot be absorbed into the running coupling.

A mass scale μ' is chosen where the relationship between $\Lambda^{(n_f-1)}$ and $\Lambda^{(n_f)}$ will be fixed. μ' should be of order M and the relationship should not depend on it. A prescription has been given [14] which has this property. We use this procedure choosing $\mu' = M_Q$, where M_Q is the mass of the value of the running quark mass defined in the $\overline{\rm MS}$ scheme (see the note on "Quark Masses" in the Particle Listings for more details), i.e., where $M_{\overline{\rm MS}}(M_Q) = M_Q$. Then [14]

$$\begin{split} \beta_0^{n_f-1} \ln \left(\frac{\Lambda^{(n_f)}}{\Lambda^{(n_f-1)}} \right)^2 &= (\beta_0^{n_f} - \beta_0^{n_f-1}) \ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right) \\ &+ 2 \Big(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \Big) \ln \left[\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2 \right] \\ &- \frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \ln \left(\frac{\beta_0^{n_f}}{\beta_0^{n_f-1}} \right) \\ &+ \frac{4 \frac{\beta_1^{n_f}}{(\beta_0^{n_f})^2} \Big(\frac{\beta_1^{n_f}}{\beta_0^{n_f}} - \frac{\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \Big) \ln \left[\ln \left(\frac{M_Q}{\Lambda^{n_f}} \right)^2 \right]}{\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2} \\ &+ \frac{\frac{1}{\beta_0^{n_f}} \Big[\Big(\frac{2\beta_1^{n_f}}{\beta_0^{n_f}} \Big)^2 - \Big(\frac{2\beta_1^{n_f-1}}{\beta_0^{n_f-1}} \Big)^2 - \frac{\beta_2^{n_f}}{2\beta_0^{n_f}} + \frac{\beta_2^{n_f-1}}{2\beta_0^{n_f-1}} - \frac{22}{9} \Big]}{\ln \left(\frac{M_Q}{\Lambda^{(n_f)}} \right)^2} \,. \end{split}$$

This result is valid to order α_s^3 (or alternatively to terms of order $1/\ln^2[(M_O/\Lambda^{(n_f)})^2]$). The order α_s^4 expression is also available [15].

An alternative matching procedure can be used [16]. This procedure requires the equality $\alpha_s(\mu)^{(n_f)} = \alpha_s(\mu)^{(n_f-1)}$ for $\mu = M_Q$. This matching is somewhat arbitrary; a different relation between $\Lambda^{(n_f)}$ and $\Lambda^{(n_f-1)}$ would result if $\mu = M_Q/2$ were used. In practice, the differences between these procedures are very small. $\Lambda^{(5)} = 200$ MeV corresponds to $\Lambda^{(4)} = 289$ MeV in the scheme of Ref. 16 and $\Lambda^{(4)} = 280$ MeV in the scheme adopted above. Note that the differences between $\Lambda^{(5)}$ and $\Lambda^{(4)}$ are numerically very significant.

Data from deep-inelastic scattering are in a range of energy where the bottom quark is not readily excited, and hence, these experiments quote $\Lambda_{\overline{\rm MS}}^{(4)}$. Most data from PEP, PETRA, TRISTAN, LEP, and SLC quote a value of $\Lambda_{\overline{\rm MS}}^{(5)}$ since these data are in an energy range where the bottom quark is light compared to the available energy. We have converted it to $\Lambda_{\overline{\rm MS}}^{(4)}$ as required. A few measurements, including the lattice gauge theory values from the ψ system and from τ decay are at sufficiently low energy that $\Lambda_{\overline{\rm MS}}^{(3)}$ is appropriate.

In order to compare the values of α_s from various experiments, they must be evolved using the renormalization group to a common scale. For convenience, this is taken to be the mass of the Z boson. This evolution uses third-order perturbation theory and can introduce additional errors particularly if extrapolation from very small scales is used. The variation in the charm and bottom quark masses $(m_b=4.3\pm0.2$ and $m_c=1.3\pm0.3$ are used) can also introduce errors. These result in a fixed value of $\alpha_s(2\text{ GeV})$ giving an uncertainty in $\alpha_s(M_Z)=\pm0.001$ if only perturbative evolution is used. There could be additional errors from nonperturbative effects that enter at low energy. All values are in the $\overline{\text{MS}}$ scheme unless otherwise noted.

9.3. QCD in deep-inelastic scattering

The original and still one of the most powerful quantitative tests of perturbative QCD is the breaking of Bjorken scaling in deep-inelastic lepton-hadron scattering. In the leading-logarithm approximation, the measured structure functions $F_i(x,Q^2)$ are related to the quark distribution functions $q_i(x,Q^2)$ according to the naive parton model, by the formulae in "Cross-section Formulae for Specific Processes," Sec. 36 of this *Review*. (In that section, q_i is denoted by the notation f_q). In describing the way in which scaling is broken in QCD, it is convenient to define nonsinglet and singlet quark distributions:

$$F^{NS} = q_i - q_j F^S = \sum_i (q_i + \overline{q}_i) . (9.8)$$

The nonsinglet structure functions have nonzero values of flavor quantum numbers such as isospin or baryon number. The variation with Q^2 of these is described by the so-called DGLAP equations [17,18]:

$$Q^2 \frac{\partial F^{NS}}{\partial Q^2} = \frac{\alpha_s(|Q|)}{2\pi} P^{qq} * F^{NS}$$
 (9.9a)

$$Q^{2} \frac{\partial}{\partial Q^{2}} \begin{pmatrix} F^{S} \\ G \end{pmatrix} = \frac{\alpha_{s}(|Q|)}{2\pi} \begin{pmatrix} P^{qq} & 2n_{f}P^{qg} \\ P^{gq} & P^{gg} \end{pmatrix} * \begin{pmatrix} F^{S} \\ G \end{pmatrix}$$
(9.9b)

where * denotes a convolution integral:

$$f * g = \int_{x}^{1} \frac{dy}{y} f(y) g\left(\frac{x}{y}\right) . \tag{9.10}$$

The leading-order Altarelli-Parisi [18] splitting functions are

$$P^{qq} = \frac{4}{3} \left[\frac{1+x^2}{(1-x)_+} \right] + 2\delta(1-x) , \qquad (9.11a)$$

$$P^{qg} = \frac{1}{2} \left[x^2 + (1-x)^2 \right] , \qquad (9.11b)$$

$$P^{gq} = \frac{4}{3} \left[\frac{1 + (1 - x)^2}{x} \right] , \qquad (9.11c)$$

$$P^{gg} = 6 \left[\frac{1-x}{x} + x(1-x) + \frac{x}{(1-x)_{+}} + \frac{11}{12} \delta(1-x) \right] - \frac{n_f}{3} \delta(1-x) . \tag{9.11d}$$

Here the gluon distribution $G(x,Q^2)$ has been introduced and $1/(1-x)_+$ means

$$\int_0^1 dx \frac{f(x)}{(1-x)_+} = \int_0^1 dx \, \frac{f(x) - f(1)}{(1-x)} \,. \tag{9.12}$$

The precision of contemporary experimental data demands that higher-order corrections also be included [19]. The above results are for massless quarks. At low Q^2 values, there are also important "higher-twist" (HT) contributions of the form:

$$F_i(x,Q^2) = F_i^{(LT)}(x,Q^2) + \frac{F_i^{(HT)}(x,Q^2)}{Q^2} + \cdots$$
 (9.13)

Leading twist (LT) indicates a term whose behavior is predicted by perturbative QCD. These corrections are numerically important only for $Q^2 < \mathcal{O}(\text{few GeV}^2)$ except for x very close to 1. At very large values of x corrections proportional to $\log(1-x)$ can become important [20].

A detailed review of the current status of the experimental data can be found, for example, in Refs. [21–23], and only a brief summary will be presented here. We shall only include determinations of Λ from the recently published results; the earlier editions of this *Review* should be consulted for the earlier data. In any event, the recent results will dominate the average since their errors are smaller. Data now exist from HERA at much smaller values of x than the fixed-target data. They provide valuable information about the shape of the antiquark and gluon distribution functions at $x \sim 10^{-4}$ [24].

From Eq. (9.9), it is clear that a nonsinglet structure function offers in principle the most precise test of the theory, since the Q^2 evolution is independent of the unmeasured gluon distribution. The CCFR collaboration fit to the Gross-Llewellyn Smith sum rule [25] is known to order α_s^3 [26]

$$\int_{0}^{1} dx \left(F_{3}^{\nu p}(x, Q^{2}) + F_{3}^{\nu p}(x, Q^{2}) \right) = 3 \left[\left(1 - \frac{\alpha_{s}}{\pi} (1 + 3.58 \frac{\alpha_{s}}{\pi} + 19.0 (\frac{\alpha_{s}}{\pi})^{2} \right) - \Delta HT \right] , \quad (9.14)$$

where the higher-twist contribution $\Delta HT = (0.09 \pm 0.045)/Q^2$ [26,27]. Using the CCFR data [28], this gives α_s (1.76 GeV) = 0.26 ± 0.035 (expt.) ± 0.03 (theory). The error from higher-twist terms dominates the theoretical error, the higher-twist term being approximately 50% larger than the α_s^3 term. The CCFR data have been recalibrated since this result was published [29] so this result can be expected to change; it should not therefore be included in an average. An experiment at Serpukov [30] has measured the sum rule at $\langle Q^2 \rangle = 1.7 \text{ GeV}^2$ and obtains α_s (1.7 GeV) = 0.35 ± 0.03 (expt.) or $\Lambda_{\overline{\text{MS}}}^{(4)} = 359 \pm 59(\text{expt.})$ MeV. The error does not include (theoretical) errors arising from the choice of μ and the higher-twist terms. Estimating the uncertainty from the higher-twist terms as 50% of their effect gives ±60 MeV of additional error in the extracted value of $\Lambda_{\overline{\text{MS}}}^{(4)}$.

Measurements involving singlet-dominated structure functions, such as F_2 , result in correlated measurements of $\Lambda_{\overline{MS}}^{(4)}$ and the gluon distribution. By utilizing high-statistics data at large x (> 0.25) and

large Q^2 , where F_2 behaves like an nonsinglet and F_3 at smaller x, a nonsinglet fit can be performed with better statistical precision, and hence, the error on the measured value of $\Lambda_{\overline{\rm MS}}^{(4)}$ is much reduced. Recently, CCFR gives $\Lambda_{\overline{\rm MS}}^{(4)}=337\pm28\pm13$ (higher-twist) MeV [29] from $F_2(\nu N)$ and $F_3(\nu N)$. There is an additional uncertainty of ±59 MeV from the choice of scale. The NMC collaboration [31] gives $\alpha_s(7~{\rm GeV}^2)=0.264\pm0.018$ (stat.) ±0.070 (syst.) ±0.013 (higher-twist). The systematic error is larger than the CCFR result, partially because the data are at smaller values of x and the gluon distribution is more important. A reanalysis [32] of EMC data [33] gives $\Lambda_{\overline{\rm MS}}^{(4)}=211\pm80\pm80$ MeV from $F_2(\nu N)$. Finally a combined analysis [34] of SLAC [35] and BCDMS [36] data gives $\Lambda_{\overline{\rm MS}}^{(4)}=263\pm42\pm55$ MeV. Here the systematic error is an estimate of the uncertainty due to the choice of Q^2 used in the argument of α_s , and in the scale at which the structure functions (factorization scale) used in the QCD calculation are evaluated.

The results from Refs. [29–32], [34], and [37] can be combined to give $\Lambda_{\overline{MS}}^{(4)}=305\pm25\pm50$ MeV which corresponds to $\alpha_s(M_Z)=0.117\pm0.002\pm0.004$, Here the first error is a combination of statistical and systematic errors, and the second error is due to the scale uncertainty. This result is an average of the results weighted by their statistical and systematic errors. The scale error, which is common to all, is then reapplied to the average.

The spin-dependent structure functions, measured in polarized lepton nucleon scattering, can also be used to determine α_s . Here the values of $Q^2 \sim 2.5 \text{ GeV}^2$ are small and higher-twist corrections are important. A fit [38] using the measured spin dependent structure functions themselves [39] gives $\alpha_s(M_Z)=0.120^{+0.004}_{-0.005}(\text{expt.})^{+0.009}_{-0.006}(\text{theory})$. These authors also determine α_s from the Bjorken sum rule [40] and obtain $\alpha_s(M_Z) = 0.118^{+0.010}_{-0.024}$; consistent with an earlier determination [41], the larger error being due to the extrapolation into the (unmeasured) small x region. Theoretically, the sum rule is preferable as the perturbative QCD result is known to higher order and these terms are important at the low Q^2 involved. It has been shown that the theoretical errors associated with the choice of scale are considerably reduced by the use of Pade approximants [11] which results in $\alpha_s(1.7 \text{ GeV}) =$ $0.328 \pm 0.03 (\text{expt.}) \pm 0.025 (\text{theory})$ corresponding to $\alpha_s(M_Z)$ = $0.116^{+0.003}_{-0.005}(\text{expt.}) \pm 0.003(\text{theory})$. No error is included from the extrapolation into the region of x that is unmeasured. If data were to become available at smaller values of x so that this extrapolation could be more tightly constrained, the sum rule method would provide the best determination of α_s ; the more conservative result from the structure functions themselves is used in the average.

At very small values of x and Q^2 , the x and Q^2 dependence of the structure functions is predicted by perturbative QCD [42]. Here terms to all orders in $\alpha_s \ln(1/x)$ are summed. The data from HERA [24] on $F_2^{ep}(x,Q^2)$ can be fitted to this form [43], including the NLO terms which are required to fix the Q^2 scale. The data are dominated by $4 \text{ GeV}^2 < Q^2 < 100 \text{ GeV}^2$. The fit [45] using H1 data [46] gives $\alpha_s(M_Z) = 0.122 \pm 0.004 \text{ (expt.)} \pm 0.009 \text{ (theory)}$. (The theoretical error is taken from Ref. 43.) The dominant part of the theoretical error is from the scale dependence; errors from terms that are suppressed by $1/\log(1/x)$ in the quark sector are included [44] while those from the gluon sector are not.

Typically, Λ is extracted from the deep inelastic scattering data by parameterizing the parton densities in a simple analytic way at some Q_0^2 , evolving to higher Q^2 using the next-to-leading-order evolution equations, and fitting globally to the measured structure functions to obtain $\Lambda_{\overline{\rm MS}}^{(4)}$. Thus, an important by-product of such studies is the extraction of parton densities at a fixed-reference value of Q_0^2 . These can then be evolved in Q^2 and used as input for phenomenological studies in hadron-hadron collisions (see below). To avoid having to evolve from the starting Q_0^2 value each time, a parton density is required; it is useful to have available a simple analytic approximation to the densities valid over a range of x and Q^2 values. A package is available from the CERN computer library that includes an exhaustive set of fits [47]. Most of these fits are obsolete. In using a parameterization to predict event rates, a next-to-leading

order fit must be used if the process being calculated is known to next-to-leading order in QCD perturbation theory. In such a case, there is an additional scheme dependence; this scheme dependence is reflected in the $\mathcal{O}(\alpha_s)$ corrections that appear in the relations between the structure functions and the quark distribution functions. There are two common schemes: a deep-inelastic scheme where there are no order α_s corrections in the formula for $F_2(x,Q^2)$ and the minimal subtraction scheme. It is important when these next-to-leading order fits are used in other processes (see below), that the same scheme is used in the calculation of the partonic rates.

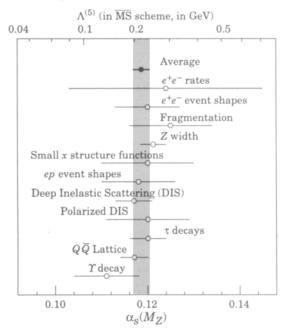

Figure 9.1: Summary of the values of $\alpha_s(M_Z)$ and $\Lambda^{(5)}$ from various processes. The values shown indicate the process and the measured value of α_s extrapolated up to $\mu=M_Z$. The error shown is the *total* error including theoretical uncertainties.

9.4. QCD in decays of the τ lepton

The semi-leptonic branching ratio of the tau $(\tau \to \nu_{\tau} + \text{hadrons}, R_{\tau})$ is an inclusive quantity. It is related to the contribution of hadrons to the imaginary part of the W self energy $(\Pi(s))$. However, it is more inclusive than R since it involves an integral

$$R_{ au} \sim \int_{0}^{m_{ au}^2} rac{ds}{m_{ au}^2} (1 - rac{s}{m_{ au}^2})^2 \ {
m Im} \left(\Pi(s)
ight) \ .$$

Since the scale involved is low, one must take into account nonperturbative (higher-twist) contributions which are suppressed by powers of the τ mass.

$$R_{\tau} = 3.058 \left[1 + \frac{\alpha_s(m_{\tau})}{\pi} + 5.2 \left(\frac{\alpha_s(m_{\tau})}{\pi} \right)^2 + 26.4 \left(\frac{\alpha_s(m_{\tau})}{\pi} \right)^3 + a \frac{m^2}{m_{\tau}^2} + b \frac{m\psi\overline{\psi}}{m_{\tau}^4} + c \frac{\psi\overline{\psi}\psi\overline{\psi}}{m_{\tau}^6} + \cdots \right]. \tag{9.15}$$

Here a,b, and c are dimensionless constants and m is a light quark mass. The term of order $1/m_\tau^2$ is a kinematical effect due to the light quark masses and is consequently very small. The nonperturbative terms are estimated using sum rules [48]. In total, they are estimated to be -0.014 ± 0.005 [49,50]. This estimate relies on there being no term of order Λ^2/m_τ^2 (note that $\frac{\alpha_s(m_\tau)}{\pi} \sim (\frac{0.5 \text{ GeV}}{m_\tau})^2$). The a,b, and c can be determined from the data [51] by fitting to moments of the $\Pi(s)$. The values so extracted [52,53] are consistent with the theoretical estimates. If the nonperturbative terms are omitted from the fit, the extracted value of $\alpha_s(m_\tau)$ decreases by ~ 0.02 .

For $\alpha_s(m_\tau)=0.35$ the perturbative series for R_τ is $R_\tau\sim 3.058(1+0.112+0.064+0.036)$. The size (estimated error) of the nonperturbative term is 20% (7%) of the size of the order α_s^3 term. The perturbation series in not very well convergent; if the order α_s^3 term is omitted, the extracted value of $\alpha_s(m_\tau)$ increases by 0.05. The order α_s^4 term has been estimated [54] and attempts made to resum the entire series [55,56]. These estimates can be used to obtain an estimate of the errors due to these unknown terms [57,58]. We assign an uncertainty of ± 0.02 to $\alpha_s(m_\tau)$ from these sources.

 R_{τ} can be extracted from the semi-leptonic branching ratio from the relation $R_{\tau}=1/(\mathrm{B}(\tau\to e\nu\bar{\nu})-1.97256;$ where $\mathrm{B}(\tau\to e\nu\bar{\nu})$ is measured directly or extracted from the lifetime, the muon mass, and the muon lifetime assuming universality of lepton couplings. Using the average lifetime of 290.7 \pm 1.3 fs and a τ mass of 1777.00 \pm 0.30 MeV from the PDG fit gives $R_{\tau}=3.642\pm0.024.$ The direct measurement of $\mathrm{B}(\tau\to e\nu\bar{\nu})$ can be combined with $\mathrm{B}(\tau\to \mu\nu\bar{\nu})$ to give $\mathrm{B}(\tau\to e\nu\bar{\nu})=0.1783\pm0.0007$ which $R_{\tau}=3.636\pm0.021.$ Averaging these yields $\alpha_s(m_{\tau})=0.350\pm0.008$ using the experimental error alone. We assign a theoretical error equal to 40% of the contribution from the order α^3 term and all of the nonperturbative contributions. This then gives $\alpha_s(m_{\tau})=0.35\pm0.03$ for the final result.

9.5. QCD in high-energy hadron collisions

There are many ways in which perturbative QCD can be tested in high-energy hadron colliders. The quantitative tests are only useful if the process in question has been calculated beyond leading order in QCD perturbation theory. The production of hadrons with large transverse momentum in hadron-hadron collisions provides a direct probe of the scattering of quarks and gluons: $qq \rightarrow qq$, $qg \rightarrow qg$, $gg \rightarrow gg$, etc. Recent higher-order QCD calculations of the jet rates [59] and shapes are in impressive agreement with data [60]. This agreement has led to the proposal that these data could be used to provide a determination of α_s [61]. Data are also available on the angular distribution of jets; these are also in agreement with QCD expectations [62,63].

QCD corrections to Drell-Yan type cross sections (i.e., the production in hadron collisions by quark-antiquark annihilation of lepton pairs of invariant mass Q from virtual photons, or of real W or Z bosons), are known [64]. These $\mathcal{O}(\alpha_s)$ QCD corrections are sizable at small values of Q. It is interesting to note that the corresponding correction to W and Z production, as measured in $p\bar{p}$ collisions at $\sqrt{s} = 0.63$ TeV and $\sqrt{s} = 1.8$ TeV, has essentially the same theoretical form and is of order 30%.

The production of W and Z bosons and photons at large transverse momentum can also be used to test QCD. The leading-order QCD subprocesses are $q\overline{q} \to \gamma g$ and $qg \to \gamma q$. If the parton distributions are taken from other processes and a value of $\Lambda_{\overline{MS}}^{(4)}$ assumed, then an absolute prediction is obtained. Conversely, the data can be used to extract information used to extract information on quark and gluon distributions and on the value of $\Lambda_{\overline{MS}}^{(4)}$. The next-to-leading-order QCD corrections are known [65,66] (for photons), and for W/Z production [67], and so a precision test is possible in principle. Data exist from the CDF and DØ collaborations [68,69]. The UA2 collaboration [70] has extracted a value of $\alpha_s(M_W) = 0.123 \pm 0.018(\text{stat.}) \pm 0.017(\text{syst.})$ from the measured ratio $R_W = \frac{\sigma(W+1\mathrm{jet})}{\sigma(W+0\mathrm{jet})}$. The result depends on the algorithm used to define a jet, and the dominant systematic errors due to fragmentation and corrections for underlying events (the former causes jet energy to be lost, the latter causes it to be increased) are connected to the algorithm. The scale at which $\alpha_s(M)$ is to be evaluated is not clear. A change from $\mu = M_W$ to $\mu = M_W/2$ causes a shift of 0.01 in the extracted α_s . The quoted error should be increased to take this into account. There is dependence on the parton distribution functions, and hence, α_s appears explicitly in the formula for R_W , and implicitly in the distribution functions. The DØ collaboration has performed an analysis similar to UA2. They are unable to obtain a fit where the two values of α_s are consistent with one another, and do not quote a value of α_s [71]. The values from this process are no longer used in determining the overall average value of

9.6. QCD in heavy-quarkonium decay

Under the assumption that the hadronic and leptonic decay widths of heavy $Q\overline{Q}$ resonances can be factorized into a nonperturbative part—dependent on the confining potential—and a calculable perturbative part, the ratios of partial decay widths allow measurements of α_s at the heavy-quark mass scale. The most precise data come from the decay widths of the $1^{--}J/\psi(1S)$ and Υ resonances. The total decay width of the Υ is predicted by perturbative QCD [72]

$$\begin{split} R_{\mu}(\varUpsilon) &= \frac{\Gamma(\varUpsilon \to \text{hadrons})}{\Gamma(\varUpsilon \to \mu^{+}\mu^{-})} \\ &= \frac{10(\pi^{2} - 9)\alpha_{s}^{3}(M)}{9\pi\alpha_{\text{em}}^{2}} \\ &\times \left[1 + \frac{\alpha_{s}}{\pi} \left(-19.4 + \frac{3\beta_{0}}{2} \left(1.162 + \ln\left(\frac{2M}{M_{\Upsilon}}\right)\right)\right)\right] \ (9.16) \end{split}$$

Data are available for the Υ , Υ' , Υ'' , and J/ψ . The result is very sensitive to α_s and the data are sufficiently precise $(R_{\mu}(T) = 32.5 \pm 0.9)$ [73] that the theoretical errors will dominate. There are theoretical corrections to this simple formula due to the relativistic nature of the $Q\overline{Q}$ system; $v^2/c^2 \sim 0.1$ for the Υ . They are more severe for the J/ψ . There are also nonperturbative corrections of the form Λ^2/m_T^2 ; again these are more severe for the J/ψ . A fit to Υ , Υ' , and Υ'' [74] gives $\alpha_s(M_Z)=0.113\pm0.001$ (expt.). The results from each state separately and also from the J/ψ are consistent with each other. There is an uncertainty of order ±0.005 from the choice of scale; the error from v^2/c^2 corrections is a little larger. The ratio of widths $\frac{T \to \gamma gg}{T \to ggg}$ has been measured by the CLEO collaboration who use it to determine $\alpha_s(9.45 \text{ GeV}) = 0.163 \pm 0.002 \pm 0.014$ [76] which corresponds to $\alpha_s(M_Z) = 0.110 \pm 0.001 \pm 0.007$. The error is dominated by theoretical uncertainties associated with the scale choice. The theoretical uncertainties due to the production of photons in fragmentation [75] are small [76].

9.7. Perturbative QCD in e^+e^- collisions

The total cross section for $e^+e^- \to \text{hadrons}$ is obtained (at low values of \sqrt{s}) by multiplying the muon-pair cross section by the factor $R=3\Sigma_q e_q^2$. The higher-order QCD corrections to this quantity have been calculated, and the results can be expressed in terms of the factor:

$$R = R^{(0)} \left[1 + \frac{\alpha_s}{\pi} + C_2 \left(\frac{\alpha_s}{\pi} \right)^2 + C_3 \left(\frac{\alpha_s}{\pi} \right)^3 + \cdots \right] , \qquad (9.17)$$

where $C_2 = 1.411$ and $C_3 = -12.8$ [77].

 $R^{(0)}$ can be obtained from the formula for $d\sigma/d\Omega$ for $e^+e^- \to f\overline{f}$ by integrating over Ω . The formula is given in Sec. 36.2 of this *Review*. This result is only correct in the zero-quark-mass limit. The $\mathcal{O}(\alpha_s)$ corrections are also known for massive quarks [78]. The principal advantage of determining α_s from R in e^+e^- annihilation is that there is no dependence on fragmentation models, jet algorithms, *etc*.

A comparison of the theoretical prediction of Eq. (9.17) (corrected for the b-quark mass), with all the available data at values of \sqrt{s} between 20 and 65 GeV, gives [79] $\alpha_s(35 \text{ GeV}) = 0.146 \pm 0.030$. The size of the order α_s^3 term is of order 40% of that of the order α_s^2 and 3% of the order α_s . If the order α_s^3 term is not included, a fit to the data yields α_s (34 GeV) = 0.142 ± 0.03, indicating that the theoretical uncertainty is smaller than the experimental error.

Measurements of the ratio of hadronic to leptonic width of the Z at LEP and SLC, Γ_h/Γ_μ probe, the same quantity as R. Using the average of $\Gamma_h/\Gamma_\mu=20.783\pm0.029$ gives $\alpha_s(M_Z)=0.124\pm0.0043$ [80] There are theoretical errors arising from the values of top-quark and Higgs masses which enter due to electroweak corrections to the Z width and from the choice of scale.

While this method has small theoretical uncertainties from QCD itself, it relies sensitively on the electroweak couplings of the Z to quarks [81]. The presence of new physics which changes these

couplings via electroweak radiative corrections would invalidate the value of $\alpha_s(M_Z)$. However, given the excellent agreement [82] of the many measurements at the Z, there is no reason not to use the value of $\alpha_s(M_Z)=0.1214\pm0.0031$ from the global fits of the various precision measurements at LEP/SLC and the W and top masses in the world average (see the section on "Electroweak model and constraints on new physics," Sec. 10 of this Review)

An alternative method of determining α_s in $e^+e^{-\bullet}$ annihilation is from measuring quantities that are sensitive to the relative rates of two-, three-, and four-jet events. A recent review should be consulted for more details [83] of the issues mentioned briefly here. In addition to simply counting jets, there are many possible choices of such "shape variables": thrust [84], energy-energy correlations [85], average jet mass, etc. All of these are infrared safe, which means they can be reliably calculated in perturbation theory. The starting point for all these quantities is the multijet cross section. For example, at order α_s , for the process $e^+e^- \to qqg$: [86]

$$\frac{1}{\sigma} \frac{d^2 \sigma}{dx_1 dx_2} = \frac{2\alpha_s}{3\pi} \frac{x_1^2 + x_2^2}{(1 - x_1)(1 - x_2)},$$
 (9.18)

where

$$x_i = \frac{2E_i}{\sqrt{s}} \tag{9.19}$$

are the center-of-mass energy fractions of the final-state (massless) quarks. A distribution in a "three-jet" variable, such as those listed above, is obtained by integrating this differential cross section over an appropriate phase space region for a fixed value of the variable. The order α_s^2 corrections to this process have been computed, as well as the 4-jet final states such as $e^+e^- \to qqgg$ [87].

There are many methods used by the e^+e^- experimental groups to determine α_s from the event topology. The jet-counting algorithm, originally introduced by the JADE collaboration [88], has been used by many other groups. Here, particles of momenta p_i and p_j are combined into a pseudo-particle of momentum $p_i + p_j$ if the invariant mass of the pair is less than $y_0\sqrt{s}$. The process is then iterated until no more pairs of particles or pseudo-particles remain. The remaining number is then defined to be the number of jets in the event, and can be compared to the QCD prediction. The Durham algorithm is slightly different: in computing the mass of a pair of partons, it uses $M^2 = 2\min(E_1^2, E_2^2)(1 - \cos\theta_{ij})$ for partons of energies E_i and E_j separated by angle θ_{ij} [89].

There are theoretical ambiguities in the way this process is carried out. Quarks and gluons are massless, whereas the observed hadrons are not, so that the massive jets that result from this scheme cannot be compared directly to the massless jets of perturbative QCD. Different recombination schemes have been tried, for example combining 3-momenta and then rescaling the energy of the cluster so that it remains massless. These schemes result in the same data giving a slightly different values [90,91] of α_s . These differences can be used to determine a systematic error. In addition, since what is observed are hadrons rather than quarks and gluons, a model is needed to describe the evolution of a partonic final state into one involving hadrons, so that detector corrections can be applied. The QCD matrix elements are combined with a parton-fragmentation model. This model can then be used to correct the data for a direct comparison with the parton calculation. The different hadronization models that are used [92-95] model the dynamics that are controlled by nonperturbative QCD effects which we cannot yet calculate. The fragmentation parameters of these Monte Carlos are tuned to get agreement with the observed data. The differences between these models contribute to the systematic errors. The systematic errors from recombination schemes and fragmentation effects dominate over the statistical and other errors of the LEP/SLD experiments.

The scale M at which $\alpha_s(M)$ is to be evaluated is not clear. The invariant mass of a typical jet (or $\sqrt{sy_0}$) is probably a more appropriate choice than the e^+e^- center-of-mass energy. While there is no justification for doing so, if the value is allowed to float in the fit

to the data, the data tend to prefer values of order $\sqrt{s}/10$ GeV for some variables, whereas others have only a preferred range of M>3 GeV [91,96]; the exact value depends on the variable that is fitted.

The perturbative QCD formulae can break down in special kinematical configurations. For example, the thrust distribution contains terms of the type $\alpha_s \ln^2(1-T)$. The higher orders in the perturbation expansion contain terms of order $\alpha_s^n \ln^m (1-T)$. For $T \sim 1$ (the region populated by 2-jet events), the perturbation expansion is unreliable. The terms with $n \leq m$ can be summed to all orders in α_s [97]. If the jet recombination methods are used higherorder terms involve $\alpha_A^n \ln^m(y_0)$, these too can be resummed [98]. The resummed results give better agreement with the data at large values of T. Some caution should be exercised in using these resummed results because of the possibility of overcounting; the showering Monte Carlos that are used for the fragmentation corrections also generate some of these leading-log corrections. Different schemes for combining the order α_s^2 and the resummations are available [99]. These different schemes result in shifts in α_s of order ± 0.002 . An average of the recent results at the Z resonance from SLD [91], OPAL [100], L3 [101], ALEPH [102], and DELPHI [103], using the combined α_s^2 and resummation fitting to a large set of shape variables, gives $\alpha_s(M_Z) = 0.122 \pm 0.007$. The errors in the values of $\alpha_s(M_Z)$ from these shape variables are totally dominated by the theoretical uncertainties associated with the choice of scale, and the effects of hadronization Monte Carlos on the different quantities fitted.

Similar studies on event shapes have been undertaken at TRISTAN, at PEP/PETRA, and at CLEO. A combined result from various shape parameters by the TOPAZ collaboration gives $\alpha_s(58~{\rm GeV})=0.125\pm0.009$, using the fixed order QCD result, and $\alpha_s(58~{\rm GeV})=0.132\pm0.008$ (corresponding to $\alpha_s(M_Z)=0.123\pm0.007$), using the same method as in the SLD and LEP average [104]. The measurements of event shapes at PEP/PETRA are summarized in earlier editions of this note. The results are consistent with those from Z decay, but have larger errors. We use $\alpha_s(34~{\rm GeV})=0.14\pm0.02$ [105]. A recent analysis by the TPC group [106] gives $\alpha_s(29~{\rm GeV})=0.160\pm0.012$, using the same method as TOPAZ. This value corresponds to $\alpha_s(M_Z)=0.131\pm0.010$

The CLEO collaboration fits to the order α_s^2 results for the two jet fraction at $\sqrt{s}=10.53$ GeV, and obtains $\alpha_s(10.93)=0.164\pm0.004$ (expt.) ±0.014 (theory) [107]. The dominant systematic error arises from the choice of scale (μ) , and is determined from the range of α_s that results from fit with $\mu=10.53$ GeV, and a fit where μ is allowed to vary to get the lowest χ^2 . The latter results in $\mu=1.2$ GeV. Since the quoted result corresponds to $\alpha_s(1.2)=0.35$, it is by no means clear that the perturbative QCD expression is reliable and the resulting error should, therefore, be treated with caution. A fit to many different variables as is done in the LEP/SLC analyses would give added confidence to the quoted error.

Recently studies have been carried out at ~130 GeV [108]. These can be combined to give $\alpha_s(130~\text{GeV}) = 0.114 \pm 0.008$. Preliminary data from ~ 165 GeV [109] are consistent with the decrease in α_s expected at the higher energy.

Since the errors in the event shape measurements are dominantly systematic, and are common to the experiments, the results from PEP/PETRA, TRISTAN, LEP, SLC, and CLEO are combined to give $\alpha_s(M_Z)=0.121\pm0.007$. All of the experiments are consistent with this average and, taken together, provide verification of the running of the coupling constant with energy.

The total cross section $e^+e^- \to b\bar{b} + X$ near threshold can be used to determine α_s [110]. The result quoted is $\alpha_s(M_Z) = 0.109 \pm 0.001$. The relevant process is only calculated to leading order and the BLM scheme [9] is used. This results in $\alpha_s(0.632\ m_b)$. If $\alpha_s(m_b)$ is used, the resulting $\alpha_s(M_Z)$ shifts to ~ 0.117 . This result is not used in the average.

9.8. Scaling violations in fragmentation functions

Measurements of the fragmentation function $d_i(z, E)$, being the probability that a hadron of type i be produced with energy zE in e^+e^- collisions at $\sqrt{s}=2E$, can be used to determine α_s . As in the case of scaling violations in structure functions, QCD predicts only the E dependence. Hence, measurements at different energies are needed to extract a value of α_s . Because the QCD evolution mixes the fragmentation functions for each quark flavor with the gluon fragmentation function, it is necessary to determine each of these before α_s can be extracted. The ALEPH collaboration has used data from energies ranging from $\sqrt{s} = 22$ GeV to $\sqrt{s} = 91$ GeV. A flavor tag is used to discriminate between different quark species, and the longitudinal and transverse cross sections are used to extract the gluon fragmentation function [111]. The result obtained is $\alpha_s(M_Z) = 0.126 \pm 0.007$ (expt.) ± 0.006 (theory) [112]. The theory error is due mainly to the choice of scale. The OPAL collaboration [113] has also extracted the separate fragmentation functions. DELPHI [114] has also performed a similar analysis using data from other experiments at lower energy with the result $\alpha_s(M_Z) = 0.124 \pm 0.007 \pm 0.009$ (theory). The larger theoretical error is due to the larger range of scales that were used in the fit. These results can be combined to give $\alpha_s(M_Z) = 0.125 \pm 0.005 \pm 0.008$ (theory).

 e^+e^- can also be used to study photon-photon interaction, which can be used to measure the structure function of a photon [115]. This process was included in earlier versions of this Review [115] which can be consulted for details on older measurements [116–119]. More recent data has become available from LEP [120,121] and from TRISTAN [122,123] which show Q^2 dependence of the structure function that is consistent with QCD expectations.

9.9. Jet rates in ep collisions

At lowest order in α_s , the ep scattering process produces a final state of (1+1) jets, one from the proton fragment and the other from the quark knocked out by the process $e + quark \rightarrow e + quark$. At next order in α_s , a gluon can be radiated, and hence a (2+1) jet final state produced. By comparing the rates for these (1+1) and (2+1) jet processes, a value of α_s can be obtained. A NLO QCD calculation is available [124]. The basic methodology is similar to that used in the jet counting experiments in e^+e^- annihilation discussed above. Unlike those measurements, the ones in ep scattering are not at a fixed value of Q^2 . In addition to the systematic errors associated with the jet definitions, there are additional ones since the structure functions enter into the rate calculations. Results from H1 [125] and ZEUS [126] can be combined to give $\alpha_s(M_Z) = 0.118 \pm 0.001$ (expt.) ± 0.008 (syst.). The contributions to the systematic errors from experimental effects (mainly the hadronic energy scale) in the case of ZEUS (H1) are comparable to (smaller than) the theoretical ones arising from scale choice, structure functions, and jet definitions. The theoretical errors are common to the two measurements; therefore, we have not reduced the systematic error after forming the average.

9.10. Lattice QCD

Lattice gauge theory calculations can be used to calculate, using non-perturbative methods, a physical quantity that can be measured experimentally. The value of this quantity can then be used to determine the QCD coupling that enters in the calculation. For a recent review of the methodology see Ref. 127. For example, the energy levels of a $Q\overline{Q}$ system can be determined and then used to extract α_s . The masses of the $Q\overline{Q}$ states depend only on the quark mass and on α_s . A limitation is that calculations cannot be performed for three light quark flavors. Results are available for zero ($n_f = 0$, quenched approximation) and two light flavors, which allow extrapolation to three. The coupling constant so extracted is in a lattice renormalization scheme, and must be converted to the MS scheme for comparison with other results. Using the mass differences of Υ and Υ' and Υ'' and χ_b , Davies et al. [128] extract a value of $\alpha_s(M_Z) = 0.1174 \pm 0.0024$. A similar result with larger errors is reported by [129], where results are consistent with $\alpha_s(M_Z) = 0.111 \pm 0.006$. A combination of the results from quenched [130] and $(n_f = 2)$ [131] gives $\alpha_s(M_Z) = 0.116 \pm 0.003$ [132]. Calculations [133] using the strength of the force between two heavy quarks computed in the quenched approximation obtains a value of $\alpha_s(5 \text{ GeV})$ that is consistent with these results. There have also been investigations of the running of α_s [134]. These show remarkable agreement with the two loop perturbative result of Eq. (9.4).

There are several sources of error in these estimates of $\alpha_s(M_Z)$. The experimental error associated with the measurements of the particle masses is negligible. The conversion from the lattice coupling constant to the $\overline{\rm MS}$ constant is obtained using a perturbative expansion where one coupling expanded as a power series in the other. This series is only known to second order. A third order calculation exists only from the $n_f=0$ case [135]. Its inclusion leads to a shift in the extracted value of $\alpha_s(M_Z)$ of +0.002. Other theoretical errors arising from the limited statistics of the Monte-Carlo calculation, extrapolation in n_f , and corrections for light quark masses are smaller than this.

The result with a more conservative error $\alpha_s(M_Z) = 0.117 \pm 0.003$ will be used in the average.

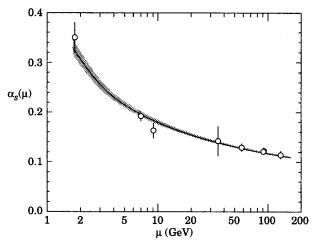

Figure 9.2: Summary of the values of $\alpha_s(\mu)$ at the values of μ where they are measured. The lines show the central values and the $\pm 1\sigma$ limits of our average. The figure clearly shows the decrease in $\alpha_s(\mu)$ with increasing μ .

9.11. Conclusions

The need for brevity has meant that many other important topics in QCD phenomenology have had to be omitted from this review. One should mention in particular the study of exclusive processes (form factors, elastic scattering, ...), the behavior of quarks and gluons in nuclei, the spin properties of the theory, the interface of soft and hard QCD as manifest, for example, by hard diffractive processes, and QCD effects in hadron spectroscopy.

We have focused on those high-energy processes which currently offer the most quantitative tests of perturbative QCD. Figure 9.1 shows the values of $\alpha_s(M_Z)$ deduced from the various experiments. Figure 9.2 shows the values and the values of Q where they are measured. This figure clearly shows the experimental evidence for the variation of $\alpha_s(Q)$ with Q.

An average of the values in Fig. 9.1 gives $\alpha_s(M_z)=0.1189$, with a total χ^2 of 3.3 for eleven fitted points, showing good consistency among the data. The error on the average, assuming that all of the errors in the contributing results are uncorrelated, is ± 0.0015 , and is an underestimate. Almost all of the values used in the average are dominated by systematic, usually theoretical errors. Only some of these, notably from the choice of scale, are correlated. Two of the results with the smallest errors are the ones from τ decay and lattice gauge theory. If these errors are increased to ± 0.006 , the average is unchanged and the error increases to 0.0020. We quote our average value as $\alpha_s(M_Z)=0.119\pm 0.002$, which corresponds to $\Lambda^{(5)}=219^{+25}_{-23}$ MeV using Eq. (9.5a), only the two-loop result (i.e. dropping the last term in Eq. (9.5a)) gives $\Lambda^{(5)}=237^{+26}_{-24}$ MeV. Future experiments can

be expected to improve the measurements of α_s somewhat. Precision at the 1% level may be achievable if the systematic and theoretical errors can be reduced [136].

10. ELECTROWEAK MODEL AND CONSTRAINTS ON NEW PHYSICS

Revised October 1997 by J. Erler and P. Langacker (Univ. of Pennsylvania).

- 10.1 Introduction
- 10.2 Renormalization and radiative corrections
- 10.3 Cross-section and asymmetry formulas
- $10.4 \quad W \text{ and } Z \text{ decays}$
- 10.5 Experimental results
- 10.6 Constraints on new physics

10.1. Introduction

The standard electroweak model is based on the gauge group [1] $\mathrm{SU}(2) \times \mathrm{U}(1)$, with gauge bosons W_{μ}^i , i=1,2,3, and B_{μ} for the $\mathrm{SU}(2)$ and $\mathrm{U}(1)$ factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields $\psi_i = \begin{pmatrix} \nu_i \\ \ell_i^- \end{pmatrix}$ and $\begin{pmatrix} u_i \\ d_i^i \end{pmatrix}$ of the i^{th} fermion family transform as doublets under $\mathrm{SU}(2)$, where $d_i' \equiv \sum_j V_{ij} \ d_j$, and V is the Cabibbo-Kobayashi-Maskawa mixing matrix. (Constraints on V are discussed in the section on the Cabibbo-Kobayashi-Maskawa mixing matrix.) The right-handed fields are $\mathrm{SU}(2)$ singlets. In the minimal model there are three fermion families and a single complex Higgs doublet $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$.

After spontaneous symmetry breaking the Lagrangian for the fermion fields is

$$\begin{split} \mathscr{L}_{F} &= \sum_{i} \overline{\psi}_{i} \left(i \, \partial - m_{i} - \frac{g m_{i} H}{2 M_{W}} \right) \psi_{i} \\ &- \frac{g}{2 \sqrt{2}} \sum_{i} \overline{\psi}_{i} \, \gamma^{\mu} \, (1 - \gamma^{5}) (T^{+} \, W_{\mu}^{+} + T^{-} \, W_{\mu}^{-}) \, \psi_{i} \\ &- e \sum_{i} q_{i} \, \overline{\psi}_{i} \, \gamma^{\mu} \, \psi_{i} \, A_{\mu} \\ &- \frac{g}{2 \cos \theta_{W}} \sum_{i} \overline{\psi}_{i} \, \gamma^{\mu} (g_{V}^{i} - g_{A}^{i} \gamma^{5}) \, \psi_{i} \, Z_{\mu} \, . \end{split}$$
(10.1)

 $\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e = g \sin \theta_W$ is the positron electric charge; and $A \equiv B \cos \theta_W + W^3 \sin \theta_W$ is the (massless) photon field. $W^{\pm} \equiv (W^1 \mp i W^2)/\sqrt{2}$ and $Z \equiv -B \sin \theta_W + W^3 \cos \theta_W$ are the massive charged and neutral weak boson fields, respectively. T^+ and T^- are the weak isospin raising and lowering operators. The vector and axial couplings are

$$g_V^i \equiv t_{3L}(i) - 2q_i \sin^2 \theta_W , \qquad (10.2)$$

$$g_A^i \equiv t_{3L}(i) , \qquad (10.3)$$

where $t_{3L}(i)$ is the weak isospin of fermion i (+1/2 for u_i and ν_i ; -1/2 for d_i and e_i) and q_i is the charge of ψ_i in units of e.

The second term in \mathscr{L}_F represents the charged-current weak interaction [2]. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W} \left[W_{\mu}^{-} \, \bar{e} \, \gamma^{\mu} (1 - \gamma^5) \nu + W_{\mu}^{+} \, \bar{\nu} \, \gamma^{\mu} \, (1 - \gamma^5) e \right] \, . \tag{10.4}$$

For momenta small compared to M_W , this term gives rise to the effective four-fermion interaction with the Fermi constant given (at tree level, *i.e.*, lowest order in perturbation theory) by $G_F/\sqrt{2} = g^2/8M_W^2$. CP violation is incorporated in the Standard Model by a single observable phase in V_{ij} . The third term in \mathcal{L}_F describes electromagnetic interactions (QED), and the last is the weak neutral-current interaction.

In Eq. (10.1), m_i is the mass of the i^{th} fermion ψ_i . For the quarks these are the current masses. For the light quarks, as described in the Particle Listings, $\overline{m}_u \approx 2-8$ MeV, $\overline{m}_d \approx 5-15$ MeV, and $\overline{m}_s \approx 100-300$ MeV (these are running $\overline{\text{MS}}$ masses evaluated at $\mu=1$ GeV). For the heavier quarks, the $\overline{\text{MS}}$ masses are $\overline{m}_c(\mu=\overline{m}_c)\approx 1.0-1.6$ GeV and $\overline{m}_b(\mu=\overline{m}_b)\approx 4.1-4.5$ GeV. The average of the recent CDF [4] and DØ [5] values for the top quark

"pole" mass is $m_t=175\pm5$ GeV. See "The Note on Quark Masses" in the Particle Listings for more information.

H is the physical neutral Higgs scalar which is the only remaining part of ϕ after spontaneous symmetry breaking. The Yukawa coupling of H to ψ_i , which is flavor diagonal in the minimal model, is $gm_i/2M_W$. The H mass is not predicted by the model. Experimental limits are given in the Higgs section. In nonminimal models there are additional charged and neutral scalar Higgs particles [6].

10.2. Renormalization and radiative corrections

The Standard Model has three parameters (not counting M_H and the fermion masses and mixings). A particularly useful set is:

- (a) The fine structure constant α = 1/137.0359895 (61), determined from the quantum Hall effect. In most electroweak-renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with α⁻¹ ~ 137 appropriate at low energy. (The running has recently been observed directly [7].) At energies of order M_Z, α⁻¹ ~ 128. For example, in the modified minimal subtraction (MS) scheme [8], one has α̂(M_Z)⁻¹ = 127.88 ± 0.09, while the conventional (on-shell) QED renormalization yields [9] α(M_Z)⁻¹ = 128.88 ± 0.09, which differs by finite constants from α̂(M_Z)⁻¹. The uncertainty, due to the low-energy hadronic contribution to vacuum polarization, is the dominant theoretical uncertainty in the interpretation of precision data. Other recent evaluations [10–14] of this effect are in reasonable agreement. Further improvement will require better measurements of the cross section for e⁺e⁻ → hadrons at low energy.
- (b) The Fermi constant, $G_F = 1.16639(1) \times 10^{-5} \text{ GeV}^{-2}$, determined from the muon lifetime formula [15],

$$\tau_{\mu}^{-1} = \frac{G_F^2 m_{\mu}^5}{192\pi^3} F\left(\frac{m_e^2}{m_{\mu}^2}\right) \left(1 + \frac{3}{5} \frac{m_{\mu}^2}{M_W^2}\right) \times \left[1 + \frac{\alpha(m_{\mu})}{2\pi} \left(\frac{25}{4} - \pi^2\right)\right] , \qquad (10.5a)$$

where

$$F(x) = 1 - 8x + 8x^3 - x^4 - 12x^2 \ln x , \qquad (10.5b)$$

and

$$\alpha(m_{\mu})^{-1} = \alpha^{-1} - \frac{2}{3\pi} \ln\left(\frac{m_{\mu}}{m_{\tau}}\right) + \frac{1}{6\pi} \approx 136$$
, (10.5c)

where the uncertainty in G_F is from the input quantities. There are additional uncertainties from higher order radiative corrections, which can be estimated from the magnitude of the known $\alpha^2 \ln(m_\mu/m_e)$ term of $\sim 1.8 \times 10^{-10}$ (alternatively, one can view Eq. (10.5) as the exact definition of G_F ; then the theoretical uncertainty appears instead in the formulae for quantities derived from G_F).

- (c) $\sin^2 \theta_W$, determined from the Z mass and other Z pole observables, the W mass, and neutral-current processes [16]. The value of $\sin^2 \theta_W$ depends on the renormalization prescription. There are a number of popular schemes [18–23] leading to $\sin^2 \theta_W$ values which differ by small factors which depend on m_t and M_H . The notation for these schemes is shown in Table 10.1. Discussion of the schemes follows the table.
 - (i) The on-shell scheme promotes the tree-level formula $\sin^2\theta_W=1-M_W^2/M_Z^2$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, i.e., $\sin^2\theta_W\to s_W^2\equiv 1-M_W^2/M_Z^2$. This scheme is simple conceptually. However, M_W is known much less precisely than M_Z and in practice one extracts s_W^2 from M_Z alone using

$$M_W = \frac{A_0}{s_W(1 - \Delta r)^{1/2}} , \qquad (10.6a)$$

$$M_Z = \frac{M_W}{c_W} \,, \tag{10.6b}$$

Table 10.1: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin \theta_W$ leads to values that differ by small factors depending on m_t and M_H .

Scheme	Notation
On-shell	$s_W = \sin \theta_W$
NOV	$s_{M_Z} = \sin \theta_W$
MS	$\widehat{s}_Z^- = \sin \theta_W$
$\overline{\text{MS}}$ ND	$\widehat{s}_{ND} = \sin heta_W$
Effective angle	$\overline{s}_f = \sin \theta_W$

where $s_W \equiv \sin\theta_W$, $c_W \equiv \cos\theta_W$, $A_0 = (\pi\alpha/\sqrt{2}G_F)^{1/2} = 37.2802$ GeV, and Δr includes the radiative corrections relating α , $\alpha(M_Z)$, G_F , M_W , and M_Z . One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 \approx 1 - \alpha/\alpha(M_Z) \approx 0.06$ is due to the running of α and $\rho_t = 3G_F m_t^2/8\sqrt{2}\pi^2 \approx 0.0096(m_t/175 \text{ GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on the Higgs mass M_H . One has $\Delta r = 0.0349 \mp 0.0019 \pm 0.0007$ for $(m_t, M_H) = (175 \pm 5 \text{ GeV}, M_Z)$, where the second uncertainty is from $\alpha(M_Z)$. Thus the value of s_W^2 extracted from M_Z includes a large uncertainty (∓ 0.0006) from the currently allowed range of m_t .

(ii) A more precisely determined quantity s_{MZ}^2 can be obtained from M_Z by removing the (m_t, M_H) dependent term from Δr [19], i.e.,

$$s_{M_Z}^2 c_{M_Z}^2 \equiv \frac{\pi \alpha(M_Z)}{\sqrt{2} G_F M_Z^2} \ . \tag{10.7}$$

This yields $s_{M_Z}^2=0.23116\pm0.00022$, with most of the uncertainty from α rather than M_Z . Scheme (ii) is equivalent to using M_Z rather than $\sin^2\theta_W$ as the third fundamental parameter. However, it recognizes that $s_{M_Z}^2$ is still a useful derived quantity. The small uncertainty in $s_{M_Z}^2$ compared to other schemes is because the m_t dependence has been removed by definition. However, the m_t uncertainty reemerges when other quantities $(e.g., M_W)$ or other Z pole observables) are predicted in terms of M_Z .

Both s_W^2 and $s_{M_Z}^2$ depend not only on the gauge couplings but also on the spontaneous-symmetry breaking, and both definitions are awkward in the presence of any extension of the Standard Model which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$.

(iii) In particular, the modified minimal subtraction $(\overline{\rm MS})$ scheme introduces the quantity $\sin^2 \widehat{\theta}_W(\mu) \equiv \widehat{g}^{\prime 2}(\mu) / [\widehat{g}^{2}(\mu) +$ $\widehat{g}^{\prime 2}(\mu)$, where the couplings \widehat{g} and \widehat{g}^{\prime} are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for electroweak processes. The value of $\widehat{s}_Z^2 = \sin^2 \widehat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s_W^2 to m_t (by a factor of $\tan^2 \theta_W$), and is less sensitive to most types of new physics than s_W^2 or $s_{M_Z}^2$. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2 \widehat{\theta}_W(M_Z)$, differing according to whether or how finite $\alpha \ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha \ln(m_t/M_Z)$ terms from all electroweak quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha \ln(m_t/M_Z)$ terms from the $\gamma - Z$ mixing [8,20], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in

terms of \hat{s}_{Z}^{2} . The various definitions are related by

$$\hat{s}_{Z}^{2} = c(m_{t}, M_{H}) s_{W}^{2} = \bar{c}(m_{t}, M_{H}) s_{M_{Z}}^{2},$$
 (10.8)

where $c=1.0376\pm0.0021$ for $m_t=175\pm5$ GeV and $M_H=M_Z$. Similarly, $\overline{c}=1.0003\mp0.0007$. The quadratic m_t dependence is given by $c\sim 1+\rho_t/\tan^2\theta_W$ and $\overline{c}\sim 1-\rho_t/(1-\tan^2\theta_W)$, respectively. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\widehat{s}_Z(1 - \Delta \widehat{r}_W)^{1/2}}$$
, (10.9a)

$$M_Z = \frac{M_W}{\widehat{\rho}^{1/2}\widehat{c}_Z} \ . \tag{10.9b}$$

One predicts $\Delta \hat{r}_W = 0.0698 \pm 0.0001 \pm 0.0007$ for $m_t = 175 \pm 5$ GeV and $M_H = M_Z$. $\Delta \hat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F , so that the error in $\Delta \hat{r}_W$ is dominated by $\Delta r_0 = 1 - \alpha/\alpha(M_Z)$, which induces the second quoted uncertainty. Similarly, $\hat{\rho} \sim 1 + \rho_t$. Including bosonic loops, $\hat{\rho} = 1.0109 \pm 0.0006$ for $(m_t, M_H) = (175 \pm 5 \text{ GeV}, M_Z)$.

(iv) A variant $\overline{\rm MS}$ quantity $\widehat{s}_{\rm ND}^2$ (used in the 1992 edition of this Review) does not decouple the $\alpha \ln(m_t/M_Z)$ terms [21]. It is related to \widehat{s}_Z^2 by

$$\widehat{s}_Z^2 = \widehat{s}_{\rm ND}^2 / \left(1 + \frac{\widehat{\alpha}}{\pi} d\right) , \qquad (10.10a)$$

$$d = \frac{1}{3} \left(\frac{1}{\widehat{s}^2} - \frac{8}{3} \right) \left[\left(1 + \frac{\widehat{\alpha}_s}{\pi} \right) \ln \frac{m_t}{M_Z} - \frac{15\widehat{\alpha}_s}{8\pi} \right] (10.10b)$$

where $\widehat{\alpha}_s$ is the QCD coupling at M_Z . Thus, $\widehat{s}_Z^2 - \widehat{s}_{\rm ND}^2 \sim -0.0002$ for $m_t=175$ GeV.

(v) Yet another definition, the effective angle [22,23] \bar{s}_f^2 for Z coupling to fermion f, is described at the end of Sec. 10.3.

Experiments are now at such a level of precision that complete $\mathcal{O}(\alpha)$ radiative corrections must be applied. For neutral-current and Z pole processes, these corrections are conveniently divided into two classes:

- QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs often yield finite and gaugeinvariant contributions to observable processes. However, they are dependent on energies, experimental cuts, etc., and must be calculated individually for each experiment.
- 2. Electroweak corrections, including γγ, γZ, ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs, etc., involving virtual W's and Z's. Many of these corrections are absorbed into the renormalized Fermi constant defined in Eq. (10.5). Others modify the tree-level expressions for Z pole observables and neutral-current amplitudes in several ways [16]. One-loop corrections are included for all processes. In addition, certain two-loop corrections are also important. In particular, two-loop corrections involving the top-quark modify ρ_t in ρ̂, Δr, and elsewhere by

$$\rho_t \to \rho_t [1 + R(M_H, m_t)\rho_t/3] .$$
(10.11)

 $R(M_H,m_t)$ is best described as an expansion in M_Z^2/m_t^2 . The unsuppressed terms were first obtained in Ref. 24, and are known analytically [25]. Contributions proportional to M_Z^2/m_t^2 were studied in Ref. 26 with the help of small and large Higgs mass expansions, which can be interpolated. These contributions are about as large as the leading ones in Refs. 24 and 25. Very recently, a subset of the relevant two-loop diagrams has been calculated numerically without any heavy mass expansion [27]. This serves as a valuable check on the M_H dependence of the leading terms obtained in Refs. 24–26. The difference turned out to be small. For M_H above its lower direct limit, -17 < R < -11. Mixed QCD-electroweak loops of order $\alpha \alpha_s m_t^2$ [28] and $\alpha \alpha_s^2 m_t^2$ [29]

increase the predicted value of m_t by 6%. This is, however, almost entirely an artifact of using the pole mass definition for m_t . The equivalent corrections when using the MS definition $\overline{m}_t(\overline{m}_t)$ increase m_t by less than 0.5%. The leading electroweak [24,25] and mixed [30] two-loop terms are also known for the $Z \to b\bar{b}$ vertex, but not the respective subleading ones.

10.3. Cross-section and asymmetry formulas

It is convenient to write the four-fermion interactions relevant to ν -hadron, νe , and parity violating e-hadron neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has

$$-\mathcal{L}^{\nu \text{Hadron}} = \frac{G_F}{\sqrt{2}} \, \overline{\nu} \, \gamma^{\mu} \, (1 - \gamma^5) \nu$$

$$\times \sum_i \left[\epsilon_L(i) \, \overline{q}_i \, \gamma_{\mu} (1 - \gamma^5) q_i + \epsilon_R(i) \, \overline{q}_i \, \gamma_{\mu} (1 + \gamma^5) q_i \right] , \quad (10.12)$$

$$-\mathscr{L}^{\nu e} = \frac{G_F}{\sqrt{2}} \, \overline{\nu}_{\mu} \, \gamma^{\mu} (1 - \gamma^5) \nu_{\mu} \, \overline{e} \, \gamma_{\mu} (g_V^{\nu e} - g_A^{\nu e} \gamma^5) e \qquad (10.13)$$

(for $\nu_e e$ or $\nu_e e$, the charged-current contribution must be included), and

$$-\mathscr{L}^{\mathrm{eHadron}} = -\frac{G_F}{\sqrt{2}}$$

$$\times \sum_{i} \left[C_{1i} \bar{e} \gamma_{\mu} \gamma^{5} e \bar{q}_{i} \gamma^{\mu} q_{i} + C_{2i} \bar{e} \gamma_{\mu} e \bar{q}_{i} \gamma^{\mu} \gamma^{5} q_{i} \right] . \quad (10.14)$$

(One must add the parity-conserving QED contribution.)

The Standard Model expressions for $\epsilon_{L,R}(i)$, $g_{V,A}^{\nu e}$, and C_{ij} are given in Table 10.2. Note that $g_{V,A}^{\nu e}$ and the other quantities are coefficients of effective four-fermi operators, which differ from the quantities defined in Eq. (10.2) and Eq. (10.3) in the radiative corrections and in the presence of possible physics beyond the Standard Model.

A precise determination of the on-shell s_W^2 , which depends only very weakly on m_t and M_H , is obtained from deep inelastic neutrino scattering from (approximately) isoscalar targets [31]. The ratio $R_{\nu} \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ of neutral- to charged-current cross sections has been measured to 1% accuracy by the CDHS [32] and CHARM [33] collaborations at CERN [34], and the CCFR collaboration at Fermilab [35,36] has obtained an even more precise result, so it is important to obtain theoretical expressions for R_{ν} and $R_{\nu} \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ (as functions of $\sin^2\theta_W$) to comparable accuracy. Fortunately, most of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio.

A simple zeroth-order approximation is

$$R_{\nu} = g_L^2 + g_R^2 r \; , \tag{10.15a}$$

$$R_{\nu} = g_L^2 + \frac{g_R^2}{r} \,, \tag{10.15b}$$

where

$$g_L^2 \equiv \epsilon_L (u)^2 + \epsilon_L (d)^2 \approx \frac{1}{2} - \sin^2 \theta_W + \frac{5}{9} \sin^4 \theta_W , \qquad (10.16a)$$

$$g_R^2 \equiv \epsilon_R (u)^2 + \epsilon_R (d)^2 \approx \frac{5}{9} \sin^4 \theta_W$$
, (10.16b)

and $r \equiv \sigma_{\overline{\nu}N}^{CC}/\sigma_{\nu N}^{CC}$ is the ratio of $\overline{\nu}$ and ν charged-current cross sections, which can be measured directly. (In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3} + \epsilon)/(1 + \frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by antiquarks to that carried by quarks.) In practice, Eq. (10.15) must be corrected for quark mixing, quark sea effects, c-quark threshold effects, nonisoscalarity, W-Z propagator differences, the finite muon mass, QED and electroweak radiative corrections. Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. The largest theoretical uncertainty is associated with the c-threshold, which

Table 10.2: Standard Model expressions for the neutral-current parameters for ν -hadron, νe , and e-hadron processes. At tree level, $\rho = \kappa = 1$, $\lambda = 0$. If radiative corrections are included, $\rho_{\nu N}^{NC} = 1.0084$, $\hat{\kappa}_{\nu N} = 0.9964$ (at $\langle Q^2 \rangle = 35 \text{ GeV}^2$), $\lambda_{uL} = -0.0031$, $\lambda_{dL} = -0.0025$, and $\lambda_{dR} = 2\lambda_{uR} = 7.5 \times 10^{-5}$ for $m_t = 175$ GeV and $M_H = M_Z = 91.1867$ GeV. For νe scattering, $\rho_{\nu e} = 1.0130$ and $\hat{\kappa}_{\nu e} = 0.9970$ (at $\langle Q^2 \rangle = 0$). For atomic parity violation and the SLAC polarized electron experiment, $\rho_{eq}' = 0.9879$, $\rho_{eq} = 1.0009$, $\hat{\kappa}_{eq}' = 1.0029$, $\hat{\kappa}_{eq} = 1.0304$, $\lambda_{1d} = -2\lambda_{1u} = 3.7 \times 10^{-5}$, $\lambda_{2u} = -0.0121$ and $\lambda_{2d} = 0.0026$. The dominant m_t dependence is given by $\rho \sim 1 + \rho_t$, while $\hat{\kappa} \sim 1$ (MS) or $\kappa \sim 1 + \rho_t / \tan^2 \theta_W$ (on-shell).

Quantity	Standard Model Expression
$\epsilon_L(u)$	$ ho_{ u N}^{NC} \left(rac{1}{2} - rac{2}{3} \widehat{\kappa}_{ u N} \widehat{\mathfrak{d}}_{Z}^{2} ight) + \lambda_{uL}$
$\epsilon_L(d)$	$ ho_{ u N}^{NC} \left(-rac{1}{2} + rac{1}{3} \widehat{\kappa}_{ u N} \ \widehat{s}_{m{Z}}^2 ight) + \lambda_{dL}$
$\epsilon_R(u)$	$ ho_{ u N}^{NC} \left(-rac{2}{3} \widehat{\kappa}_{ u N} \; \widehat{s}_{Z}^{2} ight) + \lambda_{u R}$
$\epsilon_R(d)$	$ ho_{ u N}^{NC} \left(rac{1}{3} \widehat{\kappa}_{ u N} \ \widehat{s}_{Z}^{2} ight) + \lambda_{dR}$
$g_V^{ u e}$	$ ho_{ u e} \left(-rac{1}{2} + 2 \widehat{\kappa}_{ u e} \; \widehat{s}_Z^2 ight)$
$g_A^{ u e}$	$ \rho_{\nu e}\left(-\frac{1}{2}\right) $
C_{1u}	$ ho_{eq}^{\prime}\left(-rac{1}{2}+rac{4}{3}\widehat{\kappa}_{eq}^{\prime}\;\widehat{s}_{Z}^{2} ight)+\lambda_{1u}$
C_{1d}	$ ho_{f eq}^\prime \left(rac{1}{2} - rac{2}{3} \widehat{\kappa}_{f eq}^\prime \; \widehat{s}_{f Z}^2 ight) + \lambda_{1d}$
C_{2u}	$ ho_{f eq}\left(-rac{1}{2}+2\widehat{\kappa}_{f eq}\;\widehat{m s}_{m Z}^2 ight)+\lambda_{m 2u}$
C _{2d}	$ ho_{eq}\left(rac{1}{2}-2\widehat{\kappa}_{eq}\;\widehat{s}_{Z}^{2} ight)+\lambda_{2d}$

mainly affects σ^{CC} . Using the slow rescaling prescription [37] the central value of $\sin^2\theta_W$ from CCFR varies as $0.0111(m_c$ [GeV] -1.31), where m_c is the effective mass. For $m_c=1.31\pm0.24$ GeV (determined from ν -induced dimuon production [38]) this contributes ±0.003 to the total uncertainty $\Delta\sin^2\theta_W \sim \pm0.004$. This would require a high-energy neutrino beam for improvement. (The experimental uncertainty is also ±0.003). The CCFR group quotes $s_W^2=0.2236\pm0.0041$ for $(m_t, M_H)=(175, 150)$ GeV with very little sensitivity to (m_t, M_H) . Combining all of the precise deep-inelastic measurements, one obtains $s_W^2=0.2260\pm0.0039$.

The laboratory cross section for $\nu_{\mu}e \to \nu_{\mu}e$ or $\overline{\nu}_{\mu}e \to \overline{\nu}_{\mu}e$ elastic scattering is

$$\begin{split} \frac{d\sigma_{\nu_{\mu},\nu_{\mu}}}{dy} &= \frac{G_F^2 m_e E_{\nu}}{2\pi} \\ &\times \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2 (1-y)^2 \right. \\ &\left. - (g_V^{\nu e^2} - g_A^{\nu e^2}) \frac{y m_e}{E_{\nu}} \right] \,, \end{split} \tag{10.17}$$

where the upper (lower) sign refers to $\nu_{\mu}(\overline{\nu}_{\mu})$, and $y \equiv E_e/E_{\nu}$ (which runs from 0 to $(1 + m_e/2E_{\nu})^{-1}$) is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_{\nu} \gg m_e$ this yields a total cross section

$$\sigma = \frac{G_F^2 \ m_e \ E_{\nu}}{2\pi} \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3} (g_V^{\nu e} \mp g_A^{\nu e})^2 \right] \ . \tag{10.18}$$

The most accurate leptonic measurements [39-41] of $\sin^2\theta_W$ are from the ratio $R \equiv \sigma_{\nu\mu e}/\sigma_{\overline{\nu}\mu e}$ in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2\theta_W$. The most precise experiment (CHARM II) [41] determined not only $\sin^2\theta_W$ but g_{VA}^{ν} as well. The cross sections for $\nu_e e$ and $\overline{\nu}_e e$ may be obtained from

Eq. (10.17) by replacing $g_{V,A}^{\nu e}$ by $g_{V,A}^{\nu e}+1$, where the 1 is due to the charged-current contribution.

The SLAC polarized-electron experiment [42] measured the parity-violating asymmetry

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} \,, \tag{10.19}$$

where $\sigma_{R,L}$ is the cross section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N\to e{\rm X}$. In the quark parton model

$$\frac{A}{Q^2} = a_1 + a_2 \, \frac{1 - (1 - y)^2}{1 + (1 - y)^2} \,, \tag{10.20}$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar targets, one has, neglecting the s-quark and antiquarks,

$$a_1 = rac{3G_F}{5\sqrt{2}\pilpha} \left(C_{1u} - rac{1}{2}C_{1d}
ight) pprox rac{3G_F}{5\sqrt{2}\pilpha} \left(-rac{3}{4} + rac{5}{3}\sin^2 heta_W
ight) \,, \ (10.21a)$$

 $a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(C_{2u} - \frac{1}{2}C_{2d} \right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha} \left(\sin^2\theta_W - \frac{1}{4} \right) . \quad (10.21b)$

There are now precise experiments measuring atomic parity violation [43] in cesium (at the 0.4% level) [44], thallium [45], lead [46], and bismuth [47]. The uncertainties associated with atomic wave functions are quite small for cesium, for which they are $\sim 1\%$ [48]. The theoretical uncertainties are 3% for thallium [49] but larger for the other atoms. For heavy atoms one determines the "weak charge"

$$Q_W = -2 \left[C_{1u} \left(2Z + N \right) + C_{1d} (Z + 2N) \right]$$

$$\approx Z (1 - 4 \sin^2 \theta_W) - N . \tag{10.22}$$

The recent Boulder experiment in cesium also observed the parity-violating weak corrections to the nuclear electromagnetic vertex (the anapole moment [50]).

In the future it should be possible to reduce the theoretical wave function uncertainties by taking the ratios of parity violation in different isotopes [43,51]. There would still be some residual uncertainties from differences in the neutron charge radii, however [52].

The forward-backward asymmetry for $e^+e^- \to \ell^+\ell^-$, $\ell=\mu$ or τ , is defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B} \,, \tag{10.23}$$

where $\sigma_F(\sigma_B)$ is the cross section for ℓ^- to travel forward (backward) with respect to the e^- direction. A_{FB} and R, the total cross section relative to pure QED, are given by

$$R=F_1, \qquad (10.24)$$

$$A_{FB} = 3F_2/4F_1 , \qquad (10.25)$$

where

$$F_1 = 1 - 2\chi_0 \; g_V^e \; g_V^\ell \; \cos \delta_R + \chi_0^2 \left(g_V^{e2} + g_A^{e2} \right) \left(g_V^{\ell2} + g_A^{\ell2} \right), \eqno(10.26a)$$

$$F_2 = -2\chi_0 g_A^e g_A^{\ell} \cos \delta_R + 4\chi_0^2 g_A^e g_A^{\ell} g_V^{\ell} g_V^{\ell} , \qquad (10.26b)$$

$$\tan \delta_R = \frac{M_Z \Gamma_Z}{M_Z^2 - s} , \qquad (10.27)$$

$$\chi_0 = \frac{G_F}{2\sqrt{2}\pi\alpha} \frac{sM_Z^2}{\left[(M_Z^2 - s)^2 + M_Z^2\Gamma_Z^2\right]^{1/2}} , \qquad (10.28)$$

and \sqrt{s} is the CM energy. Eq. (10.26) is valid at tree level. If the data is radiatively corrected for QED effects (as described above), then the remaining electroweak corrections can be incorporated [53,54] (in an approximation adequate for existing PEP, PETRA, and TRISTAN data, which are well below the Z pole) by replacing χ_0 by $\chi(s) \equiv (1+\rho_t)\chi_0(s)\alpha/\alpha(s)$, where $\alpha(s)$ is the running QED coupling, and evaluating g_V in the $\overline{\rm MS}$ scheme. Formulas for $e^+e^-\to {\rm hadrons}$ may be found in Ref. 55.

At LEP and SLC, there are high-precision measurements of various Z pole observables [56-61]. These include the Z mass and total width, Γ_Z , and partial widths $\Gamma(f\overline{f})$ for $Z \to f\overline{f}$ where fermion f = e, μ , τ , hadrons, b, or c. The data is consistent with lepton-family universality, $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-) = \Gamma(\tau^+\tau^-)$, so one may work with an average width $\Gamma(\ell^+\ell^-)$. It is convenient to use the variables M_Z , Γ_Z , $R_\ell \equiv \Gamma(\mathrm{had})/\Gamma(\ell^+\ell^-)$, $\sigma_{\mathrm{had}} \equiv 12\pi\Gamma(e^+e^-)\Gamma(\mathrm{had})/M_Z^2 \Gamma_Z^2$, $R_b \equiv \Gamma(b\bar{b})/\Gamma(\text{had})$, and $R_c \equiv \Gamma(c\bar{c})/\Gamma(\text{had})$, most of which are weakly correlated experimentally. ($\Gamma(had)$ is the partial width into hadrons.) The largest correlation coefficient of -0.20 occurs between R_b and R_c . R_ℓ is insensitive to m_t except for the $Z \to b\bar{b}$ vertex and final state corrections and the implicit dependence through $\sin^2 \theta_W$. Thus it is especially useful for constraining α_s . The width for invisible decays [57], $\Gamma(\text{inv}) = \Gamma_Z - 3\Gamma(\ell^+\ell^-) - \Gamma(\text{had}) = 500.1 \pm 1.8 \text{ MeV},$ can be used to determine the number of neutrino flavors much lighter than $M_Z/2$, $N_{
u}=\Gamma({
m inv})/\Gamma^{
m theory}(
u\overline{
u})=2.990\pm0.011$ for $(m_t, M_H) = (175 \pm 5 \text{ GeV}, M_Z).$

There are also measurements of various Z pole asymmetries. These include the polarization or left-right asymmetry

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R} \,, \tag{10.29}$$

where $\sigma_L(\sigma_R)$ is the cross section for a left- (right)-handed incident electron. A_{LR} has been measured precisely by the SLD collaboration at the SLC [59], and has the advantages of being extremely sensitive to $\sin^2\theta_W$ and that systematic uncertainties largely cancel. In addition, the SLD collaboration has extracted the final-state couplings A_b , A_c , A_τ , and A_μ from left-right forward-backward asymmetries [57,60], using

$$A_{LR}^{FB}(f) = \frac{\sigma_{LF}^{f} - \sigma_{LB}^{f} - \sigma_{RF}^{f} + \sigma_{RB}^{f}}{\sigma_{LF}^{f} + \sigma_{LB}^{f} + \sigma_{RF}^{f} + \sigma_{RB}^{f}} = \frac{3}{4}A_{f} , \qquad (10.30)$$

where, for example, σ_{LF} is the cross section for a left-handed incident electron to produce a fermion f traveling in the forward hemisphere. Similarly, A_{τ} is measured at LEP [57] through the negative total τ polarization, \mathcal{P}_{τ} , and A_{ε} is extracted from the angular distribution of \mathcal{P}_{τ} . An equation such as (10.30) assumes that initial state QED corrections, photon exchange, $\gamma-Z$ interference, the tiny electroweak boxes, and corrections for $\sqrt{s} \neq M_Z$ are removed from the data, leaving the pure electroweak asymmetries. This allows the use of effective tree-level expressions,

$$A_{LR} = A_e P_e , \qquad (10.31)$$

$$A_{FB} = \frac{3}{4} A_f \frac{A_e + P_e}{1 + P_o A_e} \,, \tag{10.32}$$

where

$$A_f \equiv \frac{2\bar{g}_Y^f \bar{g}_A^f}{\bar{g}_Y^{f2} + \bar{g}_A^{f2}} , \qquad (10.33)$$

and

$$\bar{g}_V^f = \sqrt{\rho_f} \left(t_{3L}^{(f)} - 2q_f \kappa_f \sin^2 \theta_W \right) ,$$
 (10.33b)

$$\overline{g}_A^f = \sqrt{\rho_f} \, t_{3L}^{(f)} \ . \tag{10.33c}$$

 P_e is the initial e^- polarization, so that the second equality in Eq. (10.30) is reproduced for $P_e=1$, and the Z pole forward-backward asymmetries at LEP ($P_e=0$) are given by $A_{FB}^{(0,f)}=\frac{3}{4}A_eA_f$ where $f=e,\ \mu,\ \tau,\ b,\ c,\ s,\$ and $q,\$ and where $A_{FB}^{(0,q)}$ refers to the hadronic charge asymmetry. The initial state coupling, A_e , is also determined through the left-right charge asymmetry [61] and in polarized Bhabba scattering [60] at the SLC.

The electroweak-radiative corrections have been absorbed into corrections $\rho_f - 1$ and $\kappa_f - 1$, which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is given by $\rho_f \sim 1 + \rho_t$, $\kappa_f \sim 1 + \rho_t/\tan^2\theta_W$, while in $\overline{\rm MS}$, $\widehat{\rho}_f \sim \widehat{\kappa}_f \sim 1$, for $f \neq b$ ($\widehat{\rho}_b \sim 1 - \frac{4}{3}\rho_t$, $\widehat{\kappa}_b \sim 1 + \frac{2}{3}\rho_t$). In the $\overline{\rm MS}$ scheme the normalization is changed according to $G_F M_Z^2/2\sqrt{2}\pi \to \widehat{\alpha}/4\widehat{s}_Z^2\widehat{c}_Z^2$.

(If one continues to normalize amplitudes by $G_FM_Z^2/2\sqrt{2}\pi$, as in the 1996 edition of this Review, then $\hat{\rho}_f$ contains an additional factor of $\hat{\rho}$.) In practice, additional bosonic and fermionic loops, vertex corrections, leading higher order contributions, etc., must be included. For example, in the $\overline{\rm MS}$ scheme one has, for $(m_t,M_H)=(175~{\rm GeV},M_Z)$, $\hat{\rho}_\ell=0.9978,\,\hat{\kappa}_\ell=1.0013,\,\hat{\rho}_b=0.9868~{\rm and}\,\hat{\kappa}_b=1.0067.$ It is convenient to define an effective angle $\overline{s}_f^2\equiv\sin^2\overline{\theta}_{Wf}\equiv\hat{\kappa}_f\widehat{s}_Z^2=\kappa_fs_W^2$, in terms of which \overline{g}_V^f and \overline{g}_A^f are given by $\sqrt{\rho_f}$ times their tree-level formulae. Because \overline{g}_V^ℓ is very small, not only $A_{LR}^0=A_e$, $A_{FB}^{(0,\ell)}$, and \mathcal{P}_τ , but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, $A_{FB}^{(0,e)}$, and the hadronic asymmetries are mainly sensitive to \overline{s}_L^g . One finds that $\hat{\kappa}_f$ $(f\neq b)$ is almost independent of (m_t,M_H) , so that one can write

$$\bar{s}_{\ell}^2 \sim \hat{s}_{Z}^2 + 0.00029$$
 (10.34)

Thus, the asymmetries determine values of $\overline{\mathfrak{d}}_{\ell}^2$ and $\widehat{\mathfrak{d}}_{Z}^2$ almost independent of m_t , while the κ 's for the other schemes are m_t dependent.

10.4. W and Z decays

The partial decay width for gauge bosons to decay into massless fermions $f_1\overline{f}_2$ is

$$\Gamma(W^{+} \to e^{+}\nu_{e}) = \frac{G_{F}M_{W}^{3}}{6\sqrt{2}\pi} \approx 226.5 \pm 0.3 \text{ MeV} , \qquad (10.35a)$$

$$\Gamma(W^{+} \to u_{i}\overline{d}_{j}) = \frac{CG_{F}M_{W}^{3}}{6\sqrt{2}\pi} |V_{ij}|^{2} \approx (707 \pm 1)|V_{ij}|^{2} \text{ MeV} , \qquad (10.35b)$$

$$\Gamma(Z \to \psi_{i}\overline{\psi}_{i}) = \frac{CG_{F}M_{Z}^{3}}{6\sqrt{2}\pi} \left[g_{V}^{i2} + g_{A}^{i2}\right] \qquad (10.35c)$$

$$\approx \begin{cases} 167.25 \pm 0.08 & \text{MeV } (\nu \overline{\nu}), 84.01 \pm 0.05 & \text{MeV } (e^+e^-), \\ 300.3 \pm 0.2 & \text{MeV } (u\overline{u}), 383.1 \pm 0.2 & \text{MeV } (d\overline{d}), \\ 376.0 \mp 0.1 & \text{MeV } (b\overline{b}), \end{cases}$$

where the numerical values are for $(m_t, M_H) = (175 \pm 5 \text{ GeV}, M_Z)$. For leptons C=1, while for quarks $C=3(1+\alpha_s(M_V)/\pi)$ $+1.409\alpha_s^2/\pi^2-12.77\alpha_s^3/\pi^3$), where the 3 is due to color and the factor in parentheses represents the universal part of the QCD corrections [62] for massless quarks [63]. The $Z \to f\overline{f}$ widths contain a number of additional corrections: universal (non-singlet) top-mass contributions [64]; fermion mass effects and further QCD corrections proportional to m_q^2 [65] (m_q is the running quark mass evaluated at the Z scale) which are different for vector and axial-vector partial widths; and singlet contributions starting from two-loop order which are large, strongly top-mass dependent, family universal, and flavor non-universal [66]. All QCD effects are known and included up to three loop order. The QED factor $1 + 3\alpha q_f^2/4\pi$, as well as two-loop $\alpha\alpha_s$ and α^2 corrections [67,68] are also included. Working in the on-shell scheme, i.e., expressing the widths in terms of $G_F M_{WZ}^3$ incorporates the largest radiative corrections from the running QED coupling [18,69]. Electroweak corrections to the Z widths are then incorporated by replacing $g_{V,A}^{i2}$ by $\overline{g}_{V,A}^{i2}$. Hence, in the on-shell scheme the Z widths are proportional to $\rho_i \sim 1 + \rho_t$. The $\overline{\rm MS}$ normalization (see the end of the previous section) accounts also for the leading electroweak corrections [22]. There is additional (negative) quadratic m_t dependence in the $Z \to b\bar{b}$ vertex corrections [70] which causes $\Gamma(b\overline{b})$ to decrease with m_t . The dominant effect is to multiply $\Gamma(b\overline{b})$ by the vertex correction $1 + \delta \rho_{b\bar{b}}$, where $\delta \rho_{b\bar{b}} \sim 10^{-2} (-\frac{1}{2} \frac{m_t^2}{M_Z^2} + \frac{1}{5})$. In practice, the corrections are included in ρ_b and κ_b , as discussed before.

$$\Gamma_Z \approx 2.496 \pm 0.001 \text{ GeV}$$
 , (10.36)
 $\Gamma_W \approx 2.093 \pm 0.002 \text{ GeV}$. (10.37)

We have assumed $\alpha_s=0.120$. An uncertainty in α_s of ± 0.003 introduces an additional uncertainty of 0.1% in the hadronic widths, corresponding to ± 1.6 MeV in Γ_Z . These predictions are to be compared with the experimental results $\Gamma_Z=2.4948\pm 0.0025$ GeV and $\Gamma_W=2.062\pm 0.059$ GeV.

For 3 fermion families the total widths are predicted to be

10.5. Experimental results

Table 10.3: Principal LEP and other recent observables, compared with the Standard Model predictions for M_Z = 91.1867 \pm 0.0020 GeV, $M_H=M_Z$, and the global best fit values $m_t=173\pm4$ GeV, $\alpha_s=0.1214\pm0.0031$, and $\widehat{\alpha}(M_Z)^{-1} = 127.90 \pm 0.07$. The LEP averages of the ALEPH, DELPHI, L3, and OPAL results include common systematic errors and correlations [57]. $\bar{s}_{\ell}^2(A_{FB}^{(0,q)})$ is the effective angle extracted from the hadronic charge asymmetry. The values of $\Gamma(\ell^+\ell^-)$, $\Gamma(\text{had})$, and $\Gamma(\text{inv})$ are not independent of Γ_Z , R_ℓ , and $\sigma_{\rm had}$. The first M_W value is from CDF, UA2, and DØ [71] while the second includes the measurements at LEP [57]. M_W and M_Z are correlated, but the effect is negligible due to the tiny M_Z error. The four values of A_ℓ are (i) from A_{LR} for hadronic final states [59]; (ii) the combined value from SLD including leptonic asymmetries; (iii) from the total τ polarization; and (iv) from the angular distribution of the τ polarization. The two values of s_W^2 from deep-inelastic scattering are from CCFR [36] and the global average, respectively. Similarly, the $g_{VA}^{\nu e}$ are from CHARM II [41] and the world average. The second errors in Q_W are theoretical [48,49]. Older low-energy results are not listed but are included in the fits. In the Standard Model predictions, the uncertainty is from M_Z , m_t , $\Delta \alpha(M_Z)$ and α_s . In parentheses we show the shift in the predictions when M_H is changed to 300 GeV which is its 90% CL upper limit. The errors in Γ_Z , $\Gamma(\text{had})$, R_ℓ , and σ_{had} are completely dominated by the uncertainty in α_s .

The values of the principal Z pole observables are listed in Table 10.3, along with the Standard Model predictions for $M_Z=91.1867\pm0.0020,\ m_t=173\pm4$ GeV, $M_H=M_Z$ and $\alpha_s=0.1214\pm0.0031.$ Note, that the values of the Z pole observables (as well as M_W) differ from those in the Particle Listings because they include recent preliminary results [57,58,59,71]. The values and predictions of M_W [57,71], the Q_W for cesium [44] and thallium [45], and recent results from deep inelastic [32–36] and $\nu_\mu e$ scattering [39–41] are also listed. The agreement is excellent. Even the largest discrepancies, A_{LR}^0 , $A_{FB}^{(0,b)}$, and $A_{FB}^{(0,\tau)}$, deviate by only 2.4 σ , 1.9 σ and 1.7 σ , respectively.

Other observables like $R_b = \Gamma(b\bar{b})/\Gamma(\text{had})$ and $R_c = \Gamma(c\bar{c})/\Gamma(\text{had})$ which showed significant deviations in the past, are now in perfect (R_c) or at least better agreement. In particular, R_b whose measured value deviated as much as 3.7 σ from the Standard Model prediction is now only 1.3 σ high. Many types of new physics could contribute to R_b (the implications of this possibility for the value of $\alpha_s(M_Z)$ extracted from the fits are discussed below) and A_b and as a consequence to $A_{FB}^{(0,b)} = \frac{3}{4}A_eA_b$. Indeed, A_b can be extracted from $A_{FB}^{(0,b)}$ when A_e is taken from leptonic asymmetries (using lepton universality), and combined with the measurement at the SLC. The result, $A_b = 0.877 \pm 0.023$, is 2.5 σ below the Standard Model prediction. (Alternatively, one can use $A_{\ell} = 0.1469 \pm 0.0013$ from the global fit and obtain $A_b = 0.894 \pm 0.021$ which is 1.9 σ low.) However, this deviation of about 6% cannot arise from new physics radiative corrections since a 30% correction to $\hat{\kappa}_b$ would be necessary to account for the central value of A_b . Only a new type of physics which couples at the tree level preferentially to the third generation, and which does not contradict R_b (including the off-peak R_b measurements by DELPHI [72]), can conceivably account for a low A_b [73].

The left-right asymmetry, $A_{LR}^0=0.1550\pm0.0034$ [59], based on all hadronic data from 1992–1996 has moved closer to the Standard Model expectation of 0.1469 ± 0.0013 than previous values. However, because of the smaller error A_{LR}^0 is still $2.4~\sigma$ above the Standard Model prediction. There is also an experimental difference of $\sim 1.9~\sigma$ between the SLD value of $A_\ell(\text{SLD})=0.1547\pm00032$ from all A_{LR} and $A_{LR}^{FB}(\ell)$ data on one hand, and the LEP value $A_\ell(\text{LEP})=0.1461\pm0.0033$ obtained from $A_{FB}^{(0,\ell)}$, $A_\tau(\mathcal{P}_\tau)$ on the other hand, in both cases assuming lepton-family universality.

Despite these discrepancies the χ^2 value of the fit for the Standard Model is excellent. It is 25 for 30 d.o.f. when fitting to the independent observables in Table 10.3, and 181 for 209 d.o.f. when the older neutral current observables are included. The probability of a larger χ^2 is 0.73 and 0.92 for the two cases, respectively. (The low χ^2 for the older data is likely due to overly conservative estimates of systematic errors.)

With the latest value of $A_{FB}^{(0,\tau)}$ the data is now in reasonable agreement with lepton-family universality, which will be assumed. The observables in Table 10.3 (including correlations on the LEP lineshape and LEP/SLD heavy flavor observables), as well as all low-energy neutral-current data [16,17], are used in the global fits described below. The parameter $\sin^2\theta_W$ can be determined from Z pole observables, M_W , and from a variety of neutral-current processes spanning a very wide Q^2 range. The results [16], shown in Table 10.4, are in impressive agreement with each other, indicating the quantitative success of the Standard Model. The one discrepancy is the value $\hat{s}_Z^2 = 0.23023 \pm 0.00043$ from $A_\ell(\text{SLD})$ which is 2.3 σ below the value 0.23124 \pm 0.00017 from the global fit to all data and 2.6 σ below the value 0.23144 \pm 0.00019 obtained from all data other than $A_\ell(\text{SLD})$.

The data allow a simultaneous determination of $\sin^2\theta_W$, m_t , and the strong coupling $\alpha_s(M_Z)$. The latter is determined mainly from R_ℓ , Γ_Z , and $\sigma_{\rm had}$, and is only weakly correlated with the other variables. The global fit to all data, including the CDF/DØ value, $m_t=175\pm5$ GeV, yields

$$\begin{split} \widehat{s}_Z^2 &= 0.23124 \pm 0.00017 \, (+0.00024) \; , \\ m_t &= 173 \pm 4 \, (+5) \; \mathrm{GeV} \; , \\ \alpha_s(M_Z) &= 0.1214 \pm 0.0031 \, (+0.0018) \; , \\ M_H &= M_Z \; . \end{split} \tag{10.38}$$

In parentheses we show the effect of changing M_H to 300 GeV which is the conservative 90% CL upper limit (see below). In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The \hat{s}_{Z}^{2} error reflects the error on $\bar{s}_{f}^{2} \sim \pm 0.00023$ from the Z pole asymmetries. In the on-shell scheme one has $s_W^2 = 0.22304 \pm 0.00044$, the larger error due to the stronger sensitivity to mt. The extracted value of α_s is based on a formula with negligible theoretical uncertainty (± 0.0005 in α_s) if one assumes the exact validity of the Standard Model. It is in excellent agreement with other precise values [74], such as 0.122 ± 0.005 from τ decays, 0.121 ± 0.005 from jet-event shapes in e^+e^- annihilation, and the very recent result [75], 0.119 ± 0.002 (exp) ± 0.004 (scale), from deep-inelastic scattering. It is slightly higher than the values from lattice calculations of the b ar b $(0.1174 \pm 0.0024 \ [76])$ and $c\bar{c} \ (0.116 \pm 0.003 \ [77])$ spectra, and from decays of heavy quarkonia $(0.112 \pm 0.006 [74])$. For more details, see our Section 9 on "Quantum Chromodynamics" in this Review. The average $\alpha_s(M_Z)$ obtained from Section 9 when ignoring the precision measurements discussed in this Section is 0.1178 ± 0.0023 . We use this value as an external constraint for the second fit in Table 10.5. The resulting value,

$$\alpha_s = 0.1191 \pm 0.0018 \,(+0.0006)$$
, (10.39)

can be regarded as the present world average.

Table 10.4: Values obtained for s_W^2 (on-shell) and $\hat{s}_Z^2(\overline{MS})$ from various reactions assuming the global best fit values (for $M_H = M_Z$) $m_t = 173 \pm 4$ GeV and $\alpha_s = 0.1214 \pm 0.0031$.

$\operatorname{SLAC}eD$	0.213 ± 0	.019	0.222	±0.018
All data	0.2230 ± 0	.0004	0.23124	± 0.00017

The value of R_b is 1.3 σ above the Standard Model expectation. If this is not just a fluctuation but is due to a new physics contribution to the $Z \to b\bar{b}$ vertex (many types would couple preferentially to the third family), the value of $\alpha_s(M_Z)$ extracted from the hadronic Z width would be reduced [17]. Allowing for this possibility one obtains $\alpha_s(M_Z)=0.1166\pm0.0048$ (+0.0007). Similar remarks apply in principle for R_c and the other quark and lepton flavors, and one should keep in mind that the Z lineshape value of α_s is very sensitive to many types of new physics.

The data indicate a preference for a small Higgs mass. There is a strong correlation between the quadratic m_t and logarithmic M_H terms in $\widehat{\rho}$ in all of the indirect data except for the $Z \to b \overline{b}$ vertex. Therefore, observables (other than R_b) which favor m_t values higher than the Tevatron range favor lower values of M_H . This effect is enhanced by R_b , which has little direct M_H dependence but favors the lower end of the Tevatron m_t range. M_W has additional M_H dependence through $\Delta \widehat{\tau}_W$ which is not coupled to m_t^2 effects. The strongest individual pulls towards smaller M_H are from M_W , A_{LR}^0 , and $A_{FB}^{(0,\ell)}$ (when combined

with M_Z), as well as R_b . The difference in χ^2 for the global fit is $\Delta\chi^2=\chi^2(M_H=1000~{\rm GeV})-\chi^2(M_H=77~{\rm GeV})=16.6$. Hence, the data favor a small value of M_H , as in supersymmetric extensions of the Standard Model, and m_t on the lower side of the Tevatron range. If one allows M_H as a free fit parameter and does not include any constraints from direct Higgs searches, one obtains $M_H = 69^{+85}_{-43}$ GeV, i.e., the central value below the direct lower bound, $M_H \ge 77$ GeV (95% CL) [78]. Including the results of the direct searches as an extra contribution to the likelihood function drives the best fit value to the present kinematic reach ($M_H \sim 83$ GeV), and we obtain the upper limit $M_H < 236$ (287) GeV at 90 (95)% CL. The extraction of M_H from the precision data depends strongly on the value used for $\alpha(M_Z)$. The value derived by Martin and Zeppenfeld [11] relying on the predictions of perturbative QCD down to smaller values of \sqrt{s} is higher and has a smaller stated error. Using this value would give a best fit at $M_H = 140$ GeV, and an upper limit $M_H < 300$ (361) GeV at 90 (95)% CL. Clearly, a consensus on the applicability of perturbative QCD in e^+e^- annihilation is highly desirable.

The most deviating observable, A_{LR} , has a strong impact on the Higgs mass limits as well [17,79]. The Introduction to this *Review* suggests an unbiased treatment of deviating observables r through the introduction of scale factors S_r . It is instructive to study the impact of this more conservative procedure on M_H . For the case of a fit to the Standard Model, we define

$$S_r = \max(\sqrt{\chi_r^2}, 1)$$
, (10.40)

where χ_r^2 is the χ^2 contribution of observable r to a global fit in which M_H is allowed as a free fit parameter (with no direct constraints included). We then repeat the fit with all errors multiplied by S_r , and proceed iteratively until the procedure has converged. This way we obtain

$$\begin{split} S_{A_{LR}^0} &= 2.76, \qquad S_{A_{FB}^{(0,b)}} = 2.05, \qquad S_{A_{FB}^{(0,\tau)}} = 1.83, \\ S_{A_{LR}^{FB}(\tau)} &= 1.45, \qquad S_{A_{LR}^{FB}(\mu)} = 1.34, \qquad S_{R_b} = 1.33, \end{split}$$

as well as $S_{A_{\bf e}(\mathcal{P}_{\bf r})}=1.02,$ and $S_{\bf r}=1$ for all other observables. The result of the global fit is

$$\begin{split} \widehat{s}_Z^2 &= 0.23141 \pm 0.00031 \;, \\ m_t &= 174 \pm 5 \; \mathrm{GeV} \;, \\ \alpha_s(M_Z) &= 0.1222 \pm 0.0034 \;, \\ M_H &= 122^{+134}_{-77} \; \mathrm{GeV} \;, \end{split} \eqno(10.41)$$

where the larger errors compared to Eq. (10.38) are from M_H rather than the S_r . Since the central value of M_H is much larger than the present direct lower bound, and $\log(M_H)$ is approximately normal distributed, it is justified to include the error due to M_H (with all correlations properly taken into account) in a Gaussian way in the uncertainties of the other parameters. For comparison with other fits we also list the results for fixed M_H in Table 10.5. Including the direct constraint we obtain an upper limit $M_H < 329$ (408) GeV at 90 (95)% CL, which is higher by $\mathcal{O}(100 \text{ GeV})$ than the one without scale factors. It is in good agreement with the bound we obtained above by switching to the higher $\alpha(M_Z)$. Indeed, both analyses decrease the impact of A_{LR} on the Higgs mass limit.

A few comments are in order: (i) The procedure used here is not unambiguous. It depends on whether results from different experiments (e.g., the various experimental groups at LEP or the Tevatron) are combined or used as individual pieces of input. We use combined result, primarily in order to avoid insurmountable complications with cross correlations between different experimental groups on top of the correlations between the observables. Even the result on a single observable quoted by an individual group, is in general a combination of various channels, with different types of systematic errors (which are the prime reason for the introduction of scale factors in the first place). Thus, ideally, one would prefer to define the S_r at this level. In practice, however, this is virtually impossible to achieve. In the case of M_W we use the individual

determinations, since they are uncorrelated and are based on entirely different processes. (ii) None of the definitions of scale factors in the Introduction to this Review is directly applicable to our case. However, we have tried to work as closely as possible in spirit to the definitions given there. One major difference is that central values of fit parameters (in particular of M_H) change upon introducing S_r ; on the other hand, central values of measurements remain unchanged. (iii) The procedure used here relies on the validity of the Standard Model, since in the presence of new physics, some discrepancies will be shifted into new physics parameters. When fits to new types of physics are to be compared to Standard Model fits as is done in Section 10.5 one has to refrain from using scale factors.

One can also carry out a fit to the indirect data alone, i.e., without including the value $m_t=175\pm 5$ GeV observed directly by CDF and DØ. (The indirect prediction is for the $\overline{\rm MS}$ mass which is in the end converted to the pole mass using an BLM optimized [80] version of the two-loop perturbative QCD formula [81]; this should correspond approximately to the kinematic mass extracted from the collider events.) One obtains $m_t=170\pm 7$ (+14) GeV, with little change in the $\sin^2\theta_W$ and α_s values, in remarkable agreement with the direct CDF/DØ value. The results of fits to various combinations of the data are shown in Table 10.5 and the relation between \widehat{s}_Z^2 and m_t for various observables in Fig. 10.1.

Table 10.5: Values of \widehat{s}_Z^2 and s_W^2 (in parentheses), α_s , and m_t for various combinations of observables. The central values and uncertainties are for $M_H=M_Z$ while the third numbers show the shift (positive unless specified) from changing M_H to 300 GeV.

Data	$\widehat{s}_{Z}^{2} \ (s_{W}^{2})$	$\alpha_s (M_Z)$	m _t [GeV]
All indirect $+ m_t$	0.23124(17)(24) ±0.0004 (+0.0007))	0.1214(31)(18)	173(4)(5)

$A_{FB}^{(0,b)} + M_Z \tag{0.2261}$	0.23209(45) ±0.0018 (-0.0009))	0.1200 (fixed)	147(17)(21)
$M_W + M_Z \tag{0.2221}$	0.23101(43)(22) ±0.0015)	0.1200 (fixed)	181(12)(12)

Using $\alpha(M_Z)$ and \widehat{s}_Z^2 as inputs, one can predict $\alpha_s(M_Z)$ assuming grand unification. One predicts [82] $\alpha_s(M_Z) = 0.130 \pm 0.001 \pm 0.01$ for the simplest theories based on the minimal supersymmetric extension of the Standard Model, where the first (second) uncertainty is from the inputs (thresholds). This is consistent with the experimental $\alpha_s(M_Z) = 0.1216 \pm 0.0031 \pm 0.0003$ from the Z lineshape (with the second error corresponding to $M_H < 150$ GeV, as is appropriate to the lower M_H range appropriate for supersymmetry) and with the world average 0.119 ± 0.002 . Nonsupersymmetric unified theories predict the low value $\alpha_s(M_Z) = 0.073 \pm 0.001 \pm 0.001$. See also the note on "Low-Energy Supersymmetry" in the Particle Listings.

One can also determine the radiative correction parameters Δr : including the CDF and DØ data, one obtains $\Delta r = 0.0355 \pm$

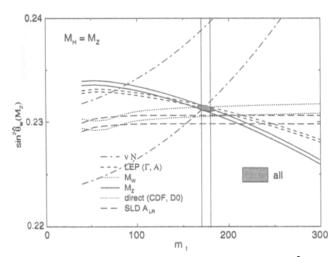

Figure 10.1: One-standard-deviation uncertainties in $\sin^2 \hat{\theta}_W$ as a function of m_t , the direct CDF and DØ range 175 \pm 5 GeV, and the 90% CL region in $\sin^2 \hat{\theta}_W - m_t$ allowed by all data, assuming $M_H = M_Z$.

0.0014 (+0.0021) and $\Delta \hat{\tau}_W = 0.0697 \pm 0.0005$ (+0.0001), in excellent agreement with the predictions 0.0349 \pm 0.0020 and 0.0698 \pm 0.0007. M_W measurements [57,71] (when combined with M_Z) are equivalent to measurements of $\Delta r = 0.0325 \pm 0.0045$.

Table 10.6: Values of the model-independent neutral-current parameters, compared with the Standard Model predictions for $M_Z = 91.1867 \pm 0.0020$ GeV, $M_H = M_Z$, and the global best fit values $m_t = 173 \pm 4$ GeV, $\alpha_s = 0.1214 \pm 0.0031$, and $\widehat{\alpha}(M_Z)^{-1} = 127.90 \pm 0.07$. There is a second $g_{V,A}^{V}$ solution, given approximately by $g_V^{Ve} \leftrightarrow g_A^{Ve}$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z. θ_i , i = L or R, is defined as $\tan^{-1}[\epsilon_i(u)/\epsilon_i(d)]$.

Quantity	Experimental Value	Standard Model Prediction	c	orrelation

Most of the parameters relevant to ν -hadron, νe , e-hadron, and e^+e^- processes are determined uniquely and precisely from the data in "model independent" fits (i.e., fits which allow for an arbitrary electroweak gauge theory). The values for the parameters defined in Eqs. (10.12)–(10.14) are given in Table 10.6 along with the predictions of the Standard Model. The agreement is excellent. The low-energy e^+e^- results are difficult to present in a model-independent way because Z propagator effects are non-negligible at TRISTAN, PETRA, and PEP energies. However, assuming $e^-\mu^-\tau$ universality, the lepton asymmetries imply [55] $4(g_A^e)^2=0.99\pm0.05$, in good agreement with the Standard Model prediction $\simeq 1$.

The results presented here are generally in reasonable agreement with the ones obtained by the LEP Electroweak Working Group [57]. We obtain slightly higher values for α_s and significantly lower best fit values for M_H . We could trace the differences to be due to (i) the inclusion of recent higher order radiative corrections, in particular, $\mathcal{O}(\alpha^2 m_t^2)$ [26] and $\mathcal{O}(\alpha \alpha_s)$ vertex [68] corrections, as well as the leading $\mathcal{O}(\alpha_s^4)$ contribution to hadronic Z decays; (ii) the use of a slightly higher value of $\alpha(M_Z)$ [9]; (iii) a more complete set of low energy data (which is not very important for Standard Model fits, but is for physics beyond the Standard Model); and (iv) scheme dependences. Taking into account these differences, the agreement is excellent.

10.6. Constraints on new physics

The Z pole, W mass, and neutral-current data can be used to search for and set limits on deviations from the Standard Model. In particular, the combination of these indirect data with the direct CDF and DØ value for m_t allows stringent limits on new physics. We will mainly discuss the effects of exotic particles (with heavy masses $M_{\text{new}} \gg M_Z$ in an expansion in M_Z/M_{new}) on the gauge boson self-energies. (Brief remarks are made on new physics which is not of this type.) Most of the effects on precision measurements can be described by three gauge self-energy parameters S, T, and U. We will define these, as well as related parameters, such as ρ_0 , ϵ_i , and $\hat{\epsilon}_i$, to arise from new physics only. I.e., they are equal to zero ($\rho_0 = 1$) exactly in the Standard Model, and do not include any contributions from m_t or M_H , which are treated seperately. Our treatment differs from most of the original papers. We also allow a $Zb\bar{b}$ vertex correction parameter γ_b .

Many extensions of the Standard Model are described by the ρ_0 parameter:

$$\rho_0 \equiv M_W^2 / (M_Z^2 \, \hat{c}_Z^2 \, \hat{\rho}) \,, \tag{10.42}$$

which describes new sources of SU(2) breaking that cannot be accounted for by Higgs doublets or m_t effects. In the presence of $\rho_0 \neq 1$, Eq. (10.42) generalizes Eq. (10.9b), while Eq. (10.9a) remains unchanged. Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect the radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (10.12)–(10.14), (10.28), and Γ_Z in Eq. (10.35). There is now enough data to determine ρ_0 , $\sin^2\theta_W$, m_t , and α_s simultaneously. In particular, the direct CDF and $D\emptyset$ events and R_b yield m_t independent of ρ_0 , the asymmetries yield \widehat{s}_Z^2 , R_t gives α_s , and M_Z and the widths constrain ρ_0 . From the global fit,

$$\begin{array}{ll} \rho_0 = 0.9998 \pm 0.0008 \, (+0.0014) \; , & (10.43) \\ \widehat{s}_Z^2 = 0.23126 \pm 0.00019 \, (+0.00010) \; , & (10.44) \\ \alpha_s = 0.1219 \pm 0.0034 \, (-0.0009) \; , & (10.45) \\ m_t = 174 \pm 5 \; \text{GeV} \; , & (10.46) \end{array}$$

where the central values are for $M_H=M_Z$ and in parentheses we show the effect of changing M_H to 300 GeV. (As in the case $\rho_0=1$, the best fit value for M_H is below its direct lower limit.) The allowed regions in the $\rho_0-\widehat{s}_Z^2$ plane are shown in Fig. 10.2:

The result in Eq. (10.43) is in remarkable agreement with the Standard Model expectation, $\rho_0=1$. It can be used to constrain higher-dimensional Higgs representations to have vacuum expectation values of less than a few percent of those of the doublets. Indeed, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin > 1/2 with significant vacuum expectation values. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters which one may conveniently choose to be α , G_F , M_Z , and M_W , since M_W and M_Z are directly measurable. Then \hat{s}_Z^2 and ρ_0 can be considered dependent parameters.

Eq. (10.43) can also be used to constrain other types of new physics. For example, nondegenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W . A nondegenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a

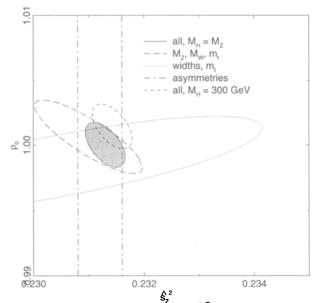

Figure 10.2: The allowed regions in $\sin^2 \hat{\theta}_W - \rho_0$ at 90% CL. m_t is a free parameter and $M_H = M_Z$ is assumed except for the dashed contour for all data which is for $M_H = 300$ GeV. The horizontal (width) band uses the experimental value of M_Z in Eq. (10.35).

positive contribution to ρ_t of [83]

$$\frac{CG_F}{8\sqrt{2}\pi^2}\Delta m^2 , \qquad (10.47)$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2m_2^2}{m_1^2 - m_2^2} \ln \frac{m_1}{m_2} \ge (m_1 - m_2)^2 , \qquad (10.48)$$

and C=1 (3) for color singlets (triplets). Thus, in the presence of such multiplets, one has

$$\frac{3G_F}{8\sqrt{2}\pi^2}\sum_i \frac{C_i}{3} \Delta m_i^2 = \rho_0 - 1 , \qquad (10.49)$$

where the sum includes fourth-family quark or lepton doublets, $\binom{t'}{b'}$ or $\binom{E^0}{E^-}$, and scalar doublets such as $\binom{\tilde{t}}{b}$ in supersymmetry (in the absence of L-R mixing). This implies

$$\sum_{i} \frac{C_{i}}{3} \Delta m_{i}^{2} < (49 \text{ GeV})^{2} \text{ and } (83 \text{ GeV})^{2}$$
 (10.50)

for $M_H = M_Z$ and 300 GeV, respectively, at 90% CL.

Nondegenerate multiplets usually imply $\rho_0 > 1$. Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally lead to $\rho_0 > 1$ [84]. On the other hand, additional Higgs doublets which participate in spontaneous symmetry breaking [85], heavy lepton doublets involving Majorana neutrinos [86], and the vacuum expectation values of Higgs triplets or higher-dimensional representations can contribute to ρ_0 with either sign. Allowing for the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) affects the determination of ρ_0 from the data, at present leading to a smaller value.

A number of authors [87–92] have considered the general effects on neutral current and Z and W pole observables of various types of heavy (i.e., $M_{\rm new}\gg M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to nondegenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators. The effects of one degenerate chiral doublet are small, but in technicolor

theories there may be many chiral doublets and therefore significant effects [87].

Such effects can be described by just three parameters, S, T, and U at the (electroweak) one loop level. (Three additional parameters are needed if the new physics scale is comparable to M_Z [93].) T is proportional to the difference between the W and Z self-energies at $Q^2=0$ (i.e., vector SU(2)-breaking), while S (S+U) is associated with the difference between the Z (W) self-energy at $Q^2=M_{Z,W}^2$ and $Q^2=0$ (axial SU(2)-breaking). In the $\overline{\rm MS}$ scheme [20]

$$\begin{split} \alpha(M_Z)T &\equiv \frac{\Pi^{\text{new}}_{WW}(0)}{M_W^2} - \frac{\Pi^{\text{new}}_{ZZ}(0)}{M_Z^2} \;, \\ \frac{\alpha(M_Z)}{4\widehat{s}_Z^2\widehat{c}_Z^2}S &\equiv \frac{\Pi^{\text{new}}_{ZZ}(M_Z^2) - \Pi^{\text{new}}_{ZZ}(0)}{M_Z^2} \;, \\ \frac{\alpha(M_Z)}{4\widehat{s}_Z^2}(S+U) &\equiv \frac{\Pi^{\text{new}}_{WW}(M_W^2) - \Pi^{\text{new}}_{WW}(0)}{M_W^2} \;, \end{split} \tag{10.51}$$

where Π^{new}_{WW} and Π^{new}_{ZZ} are, respectively, the contributions of the new physics to the W and Z self-energies. S, T, and U are defined with a factor of α removed, so that they are expected to be of order unity in the presence of new physics. They are related to other parameters $(\hat{\epsilon}_i, h_i, S_i)$ defined in [20,88,89] by

$$\begin{split} T &= h_V = \hat{\epsilon}_1/\alpha \;, \\ S &= h_{AZ} = S_Z = 4 \hat{s}_Z^2 \hat{\epsilon}_3/\alpha \;, \\ U &= h_{AW} - h_{AZ} = S_W - S_Z = -4 \hat{s}_Z^2 \hat{\epsilon}_2/\alpha \;. \end{split} \tag{10.52}$$

A heavy nondegenerate multiplet of fermions or scalars contributes positively to T as

$$\rho_0 = \frac{1}{1 - \alpha T} \simeq 1 + \alpha T \; , \tag{10.53}$$

where ρ_0 is given in Eq. (10.49). The effects of nonstandard Higgs representations cannot be separated from heavy nondegenerate multiplets unless the new physics has other consequences, such as vertex corrections. Most of the original papers defined T to include the effects of loops only. However, we will redefine T to include all new sources of SU(2) breaking, including nonstandard Higgs, so that T and ρ_0 are equivalent by Eq. (10.53).

A multiplet of heavy degenerate chiral fermions yields

$$S = C \sum_{i} (t_{3L}(i) - t_{3R}(i))^{2} / 3\pi , \qquad (10.54)$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left-(right-) handed component of fermion i and C is the number of colors. For example, a heavy degenerate ordinary or mirror family would contribute $2/3\pi$ to S. In technicolor models with QCD-like dynamics, one expects [87] $S \sim 0.45$ for an isodoublet of technifermions, assuming $N_{TC}=4$ technicolors, while $S\sim 1.62$ for a full technique ration with $N_{TC} = 4$; T is harder to estimate because it is model dependent. In these examples one has $S \geq 0$. However, the QCD-like models are excluded on other grounds (flavor-changing neutral currents, and too-light quarks and pseudo-Goldstone bosons [94]). In particular, these estimates do not apply to models of walking technicolor [94], for which S can be smaller or even negative [95]. Other situations in which S < 0, such as loops involving scalars or Majorana particles, are also possible [96]. Supersymmetric extensions of the Standard Model generally give very small effects [97]. Most simple types of new physics yield U = 0, although there are counter-examples, such as the effects of anomalous triple-gauge vertices [89].

The Standard Model expressions for observables are replaced by

$$\begin{split} M_Z^2 &= M_{Z0}^2 \frac{1 - \alpha T}{1 - G_F M_{Z0}^2 S / 2\sqrt{2}\pi} \;, \\ M_W^2 &= M_{W0}^2 \frac{1}{1 - G_F M_{W0}^2 (S + U) / 2\sqrt{2}\pi} \;, \end{split} \tag{10.55}$$

where M_{Z0} and M_{W0} are the Standard Model expressions (as functions of m_t and M_H) in the $\overline{\rm MS}$ scheme. Furthermore,

$$\begin{split} \Gamma_{Z} &= \frac{1}{1 - \alpha T} M_{Z}^{3} \beta_{Z} \; , \\ \Gamma_{W} &= M_{W}^{3} \beta_{W} \; , \\ A_{i} &= \frac{1}{1 - \alpha T} A_{i0} \; , \end{split} \tag{10.56}$$

where β_Z and β_W are the Standard Model expressions for the reduced widths Γ_{Z0}/M_{Z0}^3 and Γ_{W0}/M_{W0}^3 , M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral current amplitude (in the Standard Model).

The $Z \to b\bar{b}$ vertex is sensitive to certain types of new physics which primarily couple to heavy families. It is useful to introduce an additional parameter γ_b by [98]

$$\Gamma(Z \to b\bar{b}) = \Gamma^0(Z \to b\bar{b})(1 + \gamma_b) , \qquad (10.57)$$

where Γ^0 is the Standard Model expression (or the expression modified by S, T, and U). Experimentally, R_b is 1.3 σ above the Standard Model expectations, favoring a positive γ_b . Extended technicolor interactions generally yield negative values of γ_b of a few percent [99], although it is possible to obtain a positive γ_b in models for which the extended technicolor group does not commute with the electroweak gauge group [100] or for which diagonal interactions related to the extended technicolor dominate [101]. Topcolor and topcolor-assisted technicolor models do not generally give a significant contribution to γ_b because the extended technicolor contribution to m_t is small [102]. Supersymmetry can yield (typically small) contributions of either sign [103,104].

The data allow a simultaneous determination of \widehat{s}_Z^2 (e.g., from the Z pole asymmetries), S (from M_Z), U (from M_W), T (e.g., from the Z decay widths), α_s (from R_ℓ), m_t (from CDF and DØ), and γ_b (from R_b) with little correlation among the Standard Model parameters:

$$S = -0.16 \pm 0.14 (-0.10) ,$$

$$T = -0.21 \pm 0.16 (+0.10) ,$$

$$U = 0.25 \pm 0.24 (+0.01) ,$$

$$\gamma_b = 0.007 \pm 0.005 ,$$

$$(10.58)$$

and $\widehat{s}_Z^2 = 0.23118 \pm 0.00023$, $\alpha_s = 0.1191 \pm 0.0051$, $m_t = 175 \pm 5$ GeV, where the uncertainties are from the inputs. The central values assume $M_H = M_Z$, and in parentheses we show the change for $M_H = 300$ GeV. The parameters in Eq. (10.58) which by definition are due to new physics only, are all consistent with the Standard Model values of zero near the 1σ level, although at present there is a slight tendency for negative S and T, and positive U and γ_b . With the latest value of R_b , the extracted $\alpha_s = 0.1191 \pm 0.0051$ is now in perfect agreement with other determinations, even in the presence of the large class of new physics allowed in this fit. Its error is slightly higher than in Eq. (10.38) for the Standard Model, but the central value is independent of M_H . Using Eq. (10.53) the value of ρ_0 corresponding to T is 0.9984 \pm 0.0012 (+0.0008). The values of the $\widehat{\epsilon}$ parameters defined in Eq. (10.52) are

$$\widehat{\epsilon}_3 = -0.0013 \pm 0.0012 \ (-0.0009) \ ,$$

$$\widehat{\epsilon}_1 = -0.0016 \pm 0.0012 \ (+0.0008) \ ,$$

$$\widehat{\epsilon}_2 = -0.0022 \pm 0.0021 \ (-0.0001) \ .$$
(10.59)

There is a strong correlation between γ_b and the predicted α_s (the correlation coefficient is -0.69), just as in the model with S=T=U=0 [17]. For $\gamma_b=0$ one obtains $\alpha_s=0.1239\pm0.0037$, with little change in the other parameters. The largest correlation coefficient (+0.73) is between S and T. The allowed region in S-T is shown in Fig. 10.3. From Eq. (10.58) one obtains S<0.03 (0.08) and T<0.09 (0.15) at 90 (95)% CL for $M_H=M_Z$ (S) and 300 GeV (T). If one fixes $M_H=600$ GeV and requires the constraint $S\geq0$ (as is appropriate in QCD-like technicolor models) then S<0.12 (0.15). Allowing arbitrary S, an extra generation of ordinary fermions is now excluded at the 99.2% CL. This is in agreement with a fit to the

number of light neutrinos, $N_{\nu}=2.993\pm0.011$. The favored value of S is problematic for simple technicolor models with many techni-doublets and QCD-like dynamics, as is the value of γ_b . Although S is consistent with zero, the electroweak asymmetries, especially the SLD left-right asymmetry, favor S<0. The simplest origin of S<0 would probably be an additional heavy Z' boson [84], which could mimic S<0. Similarly, there is a slight indication of negative T, while, as discussed above, nondegenerate scalar or fermion multiplets generally predict T>0.

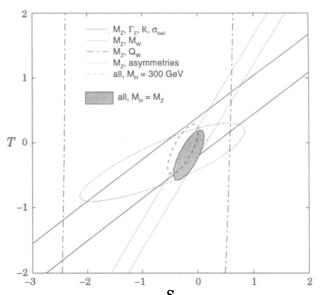

Figure 10.3: 90% CL limits on S and T from various inputs. S and T represent the contributions of new physics only. (Uncertainties from m_t are included in the errors.) The contours assume $M_H = M_Z$ except for the dashed contour for all data which is for $M_H = 300$ GeV. The fit to M_W and M_Z assumes U = 0, while U is arbitrary in the other fits.

There is no simple parametrization that is powerful enough to describe the effects of every type of new physics on every possible observable. The S, T, and U formalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons [84] or mixing with exotic fermions [105] cannot be fully parametrized in the S, T, and U framework. It is convenient to treat these types of new physics by parametrizations that are specialized to that particular class of theories (e.g., extra Z' bosons), or to consider specific models (which might contain, e.g., Z' bosons and exotic fermions with correlated parameters). Constraints on various types of new physics are reviewed in [17,106,107]. Fits to models with technicolor, extended technicolor, and supersymmetry are described, respectively, in [100], [108], and [109]. An alternate formalism [110] defines parameters, ϵ_1 , ϵ_2 , ϵ_3 , ϵ_b in terms of the specific observables M_W/M_Z , $\Gamma_{\ell\ell}$, $A_{FB}^{(0,\ell)}$, and R_b . The definitions coincide with those for $\hat{\epsilon}_i$ in Eqs. (10.51) and (10.52) for physics which affects gauge self-energies only, but the ϵ 's now parametrize arbitrary types of new physics. However, the ϵ 's are not related to other observables unless additional model-dependent assumptions are made. Another approach [111-113] parametrizes new physics in terms of gaugeinvariant sets of operators. It is especially powerful in studying the effects of new physics on nonabelian gauge vertices. The most general approach introduces deviation vectors [106]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its Standard Model prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

11. THE CABIBBO-KOBAYASHI-MASKAWA MIXING MATRIX

Revised 1997 by F.J. Gilman (Carnegie-Mellon University), K. Kleinknecht and B. Renk (Johannes-Gutenberg Universität Mainz).

In the Standard Model with $SU(2) \times U(1)$ as the gauge group of electroweak interactions, both the quarks and leptons are assigned to be left-handed doublets and right-handed singlets. The quark mass eigenstates are not the same as the weak eigenstates, and the matrix relating these bases was defined for six quarks and given an explicit parametrization by Kobayashi and Maskawa [1] in 1973. It generalizes the four-quark case, where the matrix is parametrized by a single angle, the Cabibbo angle [2].

By convention, the mixing is often expressed in terms of a 3×3 unitary matrix V operating on the charge -e/3 quarks (d, s, and b):

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} . \tag{11.1}$$

The values of individual matrix elements can in principle all be determined from weak decays of the relevant quarks, or, in some cases, from deep inelastic neutrino scattering. Using the constraints discussed below together with unitarity, and assuming only three generations, the 90% confidence limits on the magnitude of the elements of the complete matrix are:

$$\begin{pmatrix} 0.9745 \text{ to } 0.9760 & 0.217 & \text{to } 0.224 & 0.0018 \text{ to } 0.0045 \\ 0.217 & \text{to } 0.224 & 0.9737 \text{ to } 0.9753 & 0.036 & \text{to } 0.042 \\ 0.004 & \text{to } 0.013 & 0.035 & \text{to } 0.042 & 0.9991 \text{ to } 0.9994 \end{pmatrix} . \quad (11.2)$$

The ranges shown are for the individual matrix elements. The constraints of unitarity connect different elements, so choosing a specific value for one element restricts the range of others.

There are several parametrizations of the Cabibbo-Kobayashi-Maskawa matrix. We advocate a "standard" parametrization [3] of V that utilizes angles θ_{12} , θ_{23} , θ_{13} , and a phase, δ_{13} :

$$V = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{13}} \\ -s_{12}c_{23}-c_{12}s_{23}s_{13}e^{i\delta_{13}} & c_{12}c_{23}-s_{12}s_{23}s_{13}e^{i\delta_{13}} & s_{23}c_{13} \\ s_{12}s_{23}-c_{12}c_{23}s_{13}e^{i\delta_{13}} & -c_{12}s_{23}-s_{12}c_{23}s_{13}e^{i\delta_{13}} & c_{23}c_{13} \end{pmatrix}$$

$$(11.3)$$

with $c_{ij}=\cos\theta_{ij}$ and $s_{ij}=\sin\theta_{ij}$ for the "generation" labels i,j=1,2,3. This has distinct advantages of interpretation, for the rotation angles are defined and labeled in a way which relate to the mixing of two specific generations and if one of these angles vanishes, so does the mixing between those two generations; in the limit $\theta_{23}=\theta_{13}=0$ the third generation decouples, and the situation reduces to the usual Cabibbo mixing of the first two generations with θ_{12} identified with the Cabibbo angle [2]. The real angles θ_{12} , θ_{23} , θ_{13} can all be made to lie in the first quadrant by an appropriate redefinition of quark field phases.

The matrix elements in the first row and third column, which can be directly measured in decay processes, are all of a simple form, and as c_{13} is known to deviate from unity only in the sixth decimal place, $V_{ud}=c_{12},\,V_{us}=s_{12},\,V_{ub}=s_{13}\,\,e^{\delta_{13}},\,V_{cb}=s_{23},\,{\rm and}\,\,V_{tb}=c_{23}$ to an excellent approximation. The phase δ_{13} lies in the range $0\leq\delta_{13}<2\pi$, with non-zero values generally breaking CP invariance for the weak interactions. The generalization to the n generation case contains n(n-1)/2 angles and (n-1)(n-2)/2 phases. The range of matrix elements in Eq. (11.2) corresponds to 90% CL limits on the sines of the angles of $s_{12}=0.217$ to $0.222,s_{23}=0.036$ to $0.042,\,{\rm and}\,\,s_{13}=0.0018$ to 0.0044.

Kobayashi and Maskawa [1] originally chose a parametrization involving the four angles, θ_1 , θ_2 , θ_3 , δ :

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} c_1 & -s_1 c_3 & -s_1 s_3 \\ s_1 c_2 & c_1 c_2 c_3 -s_2 s_3 e^{i\delta} & c_1 c_2 s_3 + s_2 c_3 e^{i\delta} \\ s_1 s_2 & c_1 s_2 c_3 + c_2 s_3 e^{i\delta} & c_1 s_2 s_3 - c_2 c_3 e^{i\delta} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} , \qquad (11.4)$$

where $c_i=\cos\theta_i$ and $s_i=\sin\theta_i$ for i=1,2,3. In the limit $\theta_2=\theta_3=0$, this reduces to the usual Cabibbo mixing with θ_1 identified (up to a sign) with the Cabibbo angle [2]. Several different forms of the Kobayashi-Maskawa parametrization are found in the literature. Since all these parametrizations are referred to as "the" Kobayashi-Maskawa form, some care about which one is being used is needed when the quadrant in which δ lies is under discussion.

A popular approximation that emphasizes the hierarchy in the size of the angles, $s_{12}\gg s_{23}\gg s_{13}$, is due to Wolfenstein [4], where one sets $\lambda\equiv s_{12}$, the sine of the Cabibbo angle, and then writes the other elements in terms of powers of λ :

$$V = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} .$$
 (11.5)

with A, ρ , and η real numbers that were intended to be of order unity. No physics can depend on which of the above parametrizations (or any other) is used as long as a single one is used consistently and care is taken to be sure that no other choice of phases is in conflict.

Our present knowledge of the matrix elements comes from the following sources:

(1) $|V_{ud}|$ - Analyses have been performed comparing nuclear beta decays that proceed through a vector current to muon decay. Radiative corrections are essential to extracting the value of the matrix element. They already include [5] effects of order $Z\alpha^2$, and most of the theoretical argument centers on the nuclear mismatch and structure-dependent radiative corrections [6,7]. New data have been obtained on superallowed $0^+ \to 0^+$ beta decays [8]. Taking the complete data set for nine decays, the values obtained in analyses by two groups are:

$$ft = 3146.0 \pm 3.2$$
 (Ref. 8)
 $ft = 3150.8 \pm 2.8$ (Ref. 9) . (11.6)

Averaging these results (essentially for $|V_{ud}|^{-2}$), but keeping the same error bar, we obtain $|V_{ud}| = 0.9735 \pm 0.0005$. It has been argued [10] that the change in charge-symmetry-violation for quarks inside nucleons that are in nuclear matter results in a further increase of the ft value by 0.075 to 0.2%, leading to a systematic underestimate of $|V_{ud}|$. While more work needs to be done to clarify the structure-dependent effects, for now we add linearly a further $0.1 \pm 0.1\%$ to the ft values coming from nuclear decays, obtaining a value:

$$|V_{nd}| = 0.9740 \pm 0.0010 . (11.7)$$

(2) $|V_{us}|$ - Analysis of K_{e3} decays yields [11]

$$|V_{us}| = 0.2196 \pm 0.0023 . (11.8)$$

With isospin violation taken into account in K^+ and K^0 decays, the extracted values of $|V_{us}|$ are in agreement at the 1% level. A reanalysis [7] obtains essentially the same value, but quotes a somewhat smaller error which is only statistical. The analysis [12] of hyperon decay data has larger theoretical uncertainties because of first order SU(3) symmetry breaking effects in the axial-vector couplings. This has been redone incorporating second order SU(3) symmetry breaking corrections in models [13] applied to the WA2 data [14] to give a value of $|V_{us}| = 0.2176 \pm 0.0026$ with the "best-fit" model, which is consistent with Eq. (11.8). Since the values obtained in the models differ outside the errors and generally do not give good fits, we retain the value in Eq. (11.8) for $|V_{us}|$.

(3) $|V_{cd}|$ – The magnitude of $|V_{cd}|$ may be deduced from neutrino and antineutrino production of charm off valence d quarks. The dimuon production cross sections of the CDHS group [15] yield $\overline{B}_c |V_{cd}|^2 = 0.41 \pm 0.07 \times 10^{-2}$, where \overline{B}_c is the semileptonic branching fraction of the charmed hadrons produced. The corresponding value from a more recent Tevatron experiment [16], where a next-to-leading-order

QCD analysis has been carried out, is $0.534 \pm 0.021^{+0.025}_{-0.081} \times 10^{-2}$, where the last error is from the scale uncertainty. Assuming a similar scale error for the CDHS result and averaging these two results gives $0.49 \pm 0.05 \times 10^{-2}$. Supplementing this with data [17] on the mix of charmed particle species produced by neutrinos and PDG values for their semileptonic branching fractions to give [16] $\overline{B}_c = 0.099 \pm 0.012$, then yields

$$|V_{cd}| = 0.224 \pm 0.016 \tag{11.9}$$

(4) $|V_{cs}|$ – Values of $|V_{cs}|$ from neutrino production of charm are dependent on assumptions about the strange quark density in the parton-sea. The most conservative assumption, that the strange-quark sea does not exceed the value corresponding to an SU(3) symmetric sea, leads to a lower bound [15], $|V_{cs}| > 0.59$. It is more advantageous to proceed analogously to the method used for extracting $|V_{us}|$ from K_{e3} decay; namely, we compare the experimental value for the width of D_{e3} decay with the expression [18] that follows from the standard weak interaction amplitude:

$$\Gamma(D \to \overline{K}e^+\nu_e) = |f_+^D(0)|^2 |V_{cs}|^2 (1.54 \times 10^{11} \text{ s}^{-1}).$$
 (11.10)

Here $f_+^D(q^2)$, with $q=p_D-p_K$, is the form factor relevant to D_{e3} decay; its variation has been taken into account with the parametrization $f_+^D(t)/f_+^D(0)=M^2/(M^2-t)$ and $M=2.1~{\rm GeV}/c^2$, a form and mass consistent with direct measurements [19]. Combining data on branching ratios for D_{e3} decays with accurate values for the D lifetimes [19] yields a value of $(0.818\pm0.041)\times10^{11}~{\rm s}^{-1}$ for $\Gamma(D\to \overline{K}e^+\nu_e)$. Therefore

$$|f_{+}^{D}(0)|^{2} |V_{cs}|^{2} = 0.531 \pm 0.027$$
 (11.11)

A very conservative assumption is that $|f_+^D(0)| < 1$, from which it follows that $|V_{cs}| > 0.62$. Calculations of the form factor either performed [20,21] directly at $q^2 = 0$, or done [22] at the maximum value of $q^2 = (m_D - m_K)^2$ and interpreted at $q^2 = 0$ using the measured q^2 dependence, gives the value $f_+^D(0) = 0.7 \pm 0.1$. It follows that

$$|V_{cs}| = 1.04 \pm 0.16 . (11.12)$$

The constraint of unitarity when there are only three generations gives a much tighter bound (see below).

(5) $|V_{cb}|$ – The heavy quark effective theory [24](HQET) provides a nearly model-independent treatment of B semileptonic decays to charmed mesons, assuming that both the b and c quarks are heavy enough for the theory to apply. From measurements of the exclusive decay $B \to \overline{D}^*\ell^+\nu_\ell$, the value $|V_{cb}| = 0.0387 \pm 0.0021$ has been extracted [25] using corrections based on the HQET. Exclusive $B \to \overline{D}\ell^+\nu_\ell$ decays give a consistent but less precise result. Analysis of inclusive decays, where the measured semileptonic bottom hadron partial width is assumed to be that of a b quark decaying through the usual V - A interaction, depends on going from the quark to hadron level. This is also understood within the context of the HQET [26], and the results for $|V_{cb}|$ are again consistent with those from exclusive decays. Combining all these results [25]:

$$|V_{cb}| = 0.0395 \pm 0.0017 , \qquad (11.13)$$

which is now the third most accurately measured CKM matrix element.

(6) $|V_{ub}|$ – The decay $b \to u\ell\bar{\nu}$ and its charge conjugate can be observed from the semileptonic decay of B mesons produced on the $\Upsilon(4S)$ $(b\bar{b})$ resonance by measuring the lepton energy spectrum above the endpoint of the $b \to c\ell\bar{\nu}_\ell$ spectrum. There the $b \to u\ell\bar{\nu}_\ell$ decay rate can be obtained by subtracting the background from nonresonant e^+e^- reactions. This continuum background is determined from auxiliary measurements off the $\Upsilon(4S)$. The interpretation of the result in terms of $|V_{ub}/V_{cb}|$ depends fairly strongly on the theoretical model used to generate the lepton energy spectrum, especially for $b \to u$ transitions [21,22,27]. Combining the experimental and theoretical uncertainties, we quote

$$|V_{ub}/V_{cb}| = 0.08 \pm 0.02 . {(11.14)}$$

This result is supported by the first exclusive determinations of $|V_{ub}|$ from the decays $B\to\pi\ell\nu_\ell$ and $B\to\rho\ell\nu_\ell$ by the CLEO experiment [28] to obtain $|V_{ub}|=3.3\pm0.4\pm0.7\times10^{-3}$, where the first error is experimental and the second reflects systematic uncertainty from different theoretical models of the exclusive decays. While this result is consistent with Eq. (11.14) and has a similar error bar, given the theoretical model dependence of both results we do not combine them, and retain the inclusive result for V_{ub} .

(7) V_{tb} – The discovery of the top quark by the CDF and DØ collaborations utilized in part the semileptonic decays of t to b. One can set a (still rather crude) limit on the fraction of decays of the form $t \to b \ \ell^+ \ \nu_\ell$, as opposed to semileptonic t decays that involve s or d quarks, of Ref. 29

$$\frac{|V_{tb}|^2}{|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2} = 0.99 \pm 0.29 . \tag{11.15}$$

For many of these CKM matrix elements, the primary source of error is no longer statistical, but rather theoretical. This arises from explicit model dependence in interpreting data or in the use of specific hadronic matrix elements to relate experimental measurements to weak transitions of quarks. This is even more the case in extracting CKM matrix elements from loop diagrams discussed below. Such errors are generally not Gaussian. We have taken a " 1σ " range to correspond to a 68% likelihood that the true value lies within " $\pm 1\sigma$ " of the central value.

The results for three generations of quarks, from Eqs. (11.7), (11.8), (11.9), (11.12), (11.13), (11.14), and (11.15) plus unitarity, are summarized in the matrix in Eq. (11.2). The ranges given there are different from those given in Eqs. (11.7)–(11.15) because of the inclusion of unitarity, but are consistent with the one-standard-deviation errors on the input matrix elements. Note in particular that the unitarity constraint has pushed $|V_{ud}|$ about one standard deviation higher than given in Eq. (11.7).

The data do not preclude there being more than three generations. Moreover, the entries deduced from unitarity might be altered when the CKM matrix is expanded to accommodate more generations. Conversely, the known entries restrict the possible values of additional elements if the matrix is expanded to account for additional generations. For example, unitarity and the known elements of the first row require that any additional element in the first row have a magnitude $|V_{ub}t| < 0.08$. When there are more than three generations, the allowed ranges (at 90% CL) of the matrix elements connecting the first three generations are

where we have used unitarity (for the expanded matrix) and the same measurements of the magnitudes of the CKM matrix elements.

Further information, particularly on CKM matrix elements involving the top quark, can be obtained from flavor-changing processes that occur at the one-loop level. We have not used this information in the discussion above since the derivation of values for V_{td} and V_{ts} in this manner from, for example, B mixing or $b \to s \gamma$, require an additional assumption that the top-quark loop, rather than new physics, gives the dominant contribution to the process in question. Conversely, the agreement of CKM matrix elements extracted from loop diagrams with the values based on direct measurements and three generations can be used to place restrictions on new physics.

The measured value [25] of $\Delta M_{B_d}=0.472\pm0.018~{\rm ps}^{-1}$ from $B_d^0-\overline{B}_d^0$ mixing can be turned in this way into information on $|V_{tb}^*V_{td}|$, assuming that the dominant contribution to the mass difference arises from the matrix element between a B_d and a \overline{B}_d of an operator that corresponds to a box diagram with W bosons and top quarks as sides. Using the characteristic hadronic matrix element that then occurs, $\widehat{B}_{B_d}f_{B_d}^2=(1.4\pm0.1)(175\pm25~{\rm MeV})^2$ from lattice QCD calculations [30], which we regard as having become the most

B = (1.0)

reliable source of such matrix elements, next-to-leading-order QCD corrections ($\eta_{\rm QCD}=0.55$) [31], and the running top-quark mass, $\overline{m}_t(m_t)=166\pm 5$ GeV, as input,

$$|V_{tb}^* \cdot V_{td}| = 0.0084 \pm 0.0018$$
 , (11.17)

where the uncertainty comes primarily from that in the hadronic matrix elements, whose estimated errors are combined linearly.

In the ratio of B_s to B_d mass differences, many common factors (such as the QCD correction and dependence on the top-quark mass) cancel, and we have

$$\frac{\Delta M_{B_s}}{\Delta M_{B_d}} = \frac{M_{B_s}}{M_{B_d}} \frac{\widehat{B}_{B_s} f_{B_s}^2}{\widehat{B}_{B_d} f_{B_d}^2} \frac{|V_{tb}^* \cdot V_{ts}|^2}{|V_{tb}^* \cdot V_{td}|^2} \,. \tag{11.18}$$

With the experimentally measured masses [19], $\widehat{B}_{B_s}/\widehat{B}_{B_d}=1.01\pm0.04$ and $f_{B_s}/f_{B_d}=1.15\pm0.05$ from lattice QCD [30], and the improved experimental lower limit [25] at 95% CL of $\Delta M_{B_s}>10.2~{\rm ps}^{-1}$,

$$|V_{td}|/|V_{ts}| < 0.27 . (11.19)$$

Since with three generations, $|V_{ts}| \approx |V_{cb}|$, this result converts to $|V_{td}| < 0.011$, which is a significant constraint by itself (see Fig. 11.2).

The CLEO observation [32] of $b\to s\gamma$ can be translated [33] similarly into $|V_{ts}|/|V_{cb}|=1.1\pm0.43$, where the large uncertainty is again dominantly theoretical. In $K^+\to\pi^+\nu\bar{\nu}$ there are significant contributions from loop-diagrams involving both charm and top quarks. Experiment is just beginning to probe the level predicted in the Standard Model [34]. All these additional indirect constraints are consistent with the matrix elements obtained from the direct measurements plus unitarity, assuming three generations; with the recent results on B mixing and theoretical improvements in lattice calculations, adding the indirect constraints to the fit reduces the range allowed for $|V_{td}|$.

Direct and indirect information on the CKM matrix is neatly summarized in terms of the "unitarity triangle." The name arises since unitarity of the 3×3 CKM matrix applied to the first and third columns yields

$$V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0. (11.20)$$

The unitarity triangle is just a geometrical presentation of this equation in the complex plane [35]. We can always choose to orient the triangle so that V_{cd} V_{cb}^* lies along the horizontal; in the parametrization we have chosen, V_{cb} is real, and V_{cd} is real to a very good approximation in any case. Setting cosines of small angles to unity, Eq. (11.20) becomes

$$V_{ub}^* + V_{td} = s_{12} \ V_{cb}^* \ ,$$
 (11.21)

which is shown as the unitarity triangle in Fig. 11.1(a). Rescaling the triangle by a factor $[1/|s_{12}|V_{cb}|]$ so that the base is of unit length, the coordinates of the vertices become

$$A\big({\rm Re}(V_{ub})/|s_{12}\ V_{cb}|\ ,\ -{\rm Im}(V_{ub})/|s_{12}\ V_{cb}|\big)$$
 , $B(1,0)$, $C(0,0)$.
 (11.22

In the Wolfenstein parametrization [4], the coordinates of the vertex A of the unitarity triangle are simply (ρ, η) , as shown in Fig. 11.1(b).

CP-violating processes will involve the phase in the CKM matrix, assuming that the observed CP violation is solely related to a nonzero value of this phase. This allows additional constraints to be brought to bear. More specifically, a necessary and sufficient condition for CP violation with three generations can be formulated in a parametrization-independent manner in terms of the non-vanishing of the determinant of the commutator of the mass matrices for the charge 2e/3 and charge -e/3 quarks [36]. CP violating amplitudes or differences of rates are all proportional to the CKM factor in this quantity. This is the product of factors $s_{12}s_{13}s_{23}c_{12}c_{13}^2c_{23}s_{613}$ in the parametrization adopted above, and is $s_1^2s_2s_3c_1c_2c_3s_6$ in that of

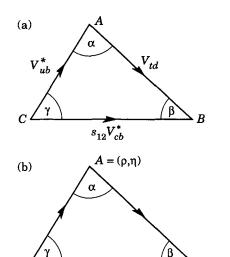

Figure 11.1: (a) Representation in the complex plane of the triangle formed by the CKM matrix elements V_{ub}^* , V_{td} , and s_{12} V_{cb}^* . (b) Rescaled triangle with vertices $A(\rho, \eta)$, B(1, 0), and C(0, 0).

C = (0.0)

Ref. 1. With the approximation of setting cosines to unity, this is just twice the area of the unitarity triangle.

While hadronic matrix elements whose values are imprecisely known generally enter the calculations, the constraints from CP violation in the neutral kaon system, taken together with the restrictions on the magnitudes of the CKM matrix elements shown above, are tight enough to restrict considerably the range of angles and the phase of the CKM matrix. For example, the constraint obtained from the CP-violating parameter ϵ in the neutral K system corresponds to the vertex A of the unitarity triangle lying on a hyperbola for fixed values of the hadronic matrix elements [37,38]. The constraints on the vertex of the unitarity triangle that follow from $|V_{ub}|$, B mixing, and ϵ are shown in Fig. 11.2. The improved limit in Eq. (11.19) that arises from the ratio of B_s to B_d mixing eliminates a significant region for the vertex A of the unitarity triangle, otherwise allowed by direct measurements of the CKM matrix elements. This limit is more robust theoretically since it depends on ratios (rather than absolute values) of hadronic matrix elements and is independent of the top mass or QCD corrections (which cancel in the ratio). Ultimately in the Standard Model, the CP-violating process $K_L \to \pi^0 \nu \overline{\nu}$ offers high precision in measuring the imaginary part of $V_{td} \cdot V_{ts}^*$ to yield Im V_{td} , the altitude of the unitarity triangle. However, the experimental upper limit is presently many orders of magnitude away from the requisite sensitivity.

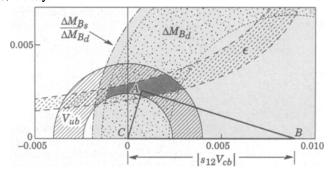

Figure 11.2: Constraints on the position of the vertex, A, of the unitarity triangle following from $|V_{ub}|$, B-mixing, and ϵ . A possible unitarity triangle is shown with A in the preferred region.

For CP-violating asymmetries of neutral B mesons decaying to CP eigenstates, there is a direct relationship between the magnitude

of the asymmetry in a given decay and $\sin 2\phi$, where $\phi = \alpha$, β , γ is an appropriate angle of the unitarity triangle [35]. The combination of all the direct and indirect information can be used to find the implications for future measurements of CP violation in the B system. (See Sec. 12 on CP Violation and the review on "CP Violation in B Decay – Standard Model Predictions" in the B Listings.)

12. CP VIOLATION

Revised August 1997 by L. Wolfenstein (Carnegie-Mellon Univ.)

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$. Larger CP-violation effects are anticipated in B^0 decays.

12.1. CP violation in Kaon decay

CP violation has been observed in the semi-leptonic decays $K_L^0 \to \pi^\mp \ell^\pm \nu$ and in the nonleptonic decay $K_L^0 \to 2\pi$. The experimental numbers that have been measured are

$$\delta = \frac{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) - \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) + \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}$$
(12.1a)

$$\begin{split} \eta_{+-} &= A(K_L^0 \to \pi^+ \pi^-) / A(K_S^0 \to \pi^+ \pi^-) \\ &= |\eta_{+-}| \ e^{i\phi_{+-}} \\ \eta_{00} &= A(K_L^0 \to \pi^0 \pi^0) / A(K_S^0 \to \pi^0 \pi^0) \end{split} \tag{12.1b}$$

$$= |\eta_{00}| e^{i\phi_{00}} . (12.1c)$$

Thus there are five real numbers, three magnitudes, and two phases. The present data gives $|\eta_{+-}| \approx |\eta_{00}| = 2.28 \times 10^{-3}$, $\phi_{+-} \approx \phi_{00} = 44^{\circ}$, and $\delta = 3.3 \times 10^{-3}$.

CP violation can occur either in the $K^0-\overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the $K^0-\overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle$$
, $|K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle$. (12.2)

If CP invariance held, we would have q=p so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in $K^0-\overline{K}^0$ mixing is then given by the parameter $\widetilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1+\tilde{\epsilon})}{(1-\tilde{\epsilon})} \ . \tag{12.3}$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi\pi(I)) = A_I e^{i\delta_I}$$
, $A(\overline{K}^0 \to \pi\pi(I)) = A_I^* e^{i\delta_I}$, (12.4)

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP-violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon', \quad (12.5a)$$

One can then show [1]

$$\epsilon = \tilde{\epsilon} + i \text{ (Im } A_0/\text{Re } A_0), \qquad (12.5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2/\text{Re } A_0) \text{ (Im } A_2/\text{Re } A_2 - \text{Im } A_0/\text{Re } A_0) ,$$

$$(12.5c)$$

$$\delta = 2\text{Re } \epsilon/(1 + |\epsilon|^2) \approx 2\text{Re } \epsilon .$$

$$(12.5d)$$

In Eq. (12.5c) small corrections of order $\epsilon' \times \text{Re } (A_2/A_0)$ are neglected and Eq. (12.5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities Im A_0 , Im A_2 , and Im ϵ depend on the choice of phase convention since one can change the phases of K^0 and \overline{K}^0 by a transformation of the strange quark state $|s\rangle \rightarrow |s\rangle e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set Im A_0 or Im ϵ to zero, but none of these is zero may be the usual phase conventions in the Standard Model. The choice Im $A_0 = 0$ is called the Wu-Yang phase convention [2] in which case $\epsilon = \epsilon$. The value of ϵ' is independent of phase convention and a nonzero value would demonstrate CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that

direct CP violation is essentially zero and that CP violation occurs only in the mixing matrix is referred to as the superweak theory [3].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi(\epsilon) \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} = 43.49 \pm 0.08^{\circ}$$
 (12.6a)

while Eq. (12.5c) gives

$$\phi(\epsilon') = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 48 \pm 4^{\circ} ,$$
 (12.6b)

where the numerical value is based on an analysis of $\pi-\pi$ scattering [4]. The approximation in Eq. (12.6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree as indicated by the small value of ϵ' and of η_{+-0} , the CP violation parameter in the decay $K_S \to \pi^+\pi^-\pi^0$ [5], although limits on η_{000} are still poor. The relation in Eq. (12.6a) is exact in the superweak theory so this is sometimes called the superweak phase. The most important point for the analysis is that $\cos[\phi(\epsilon') - \phi(\epsilon)] \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$, which is very close to unity, is given to a good approximation by

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}\left(\epsilon'/\epsilon\right) \approx 1 - 6\epsilon'/\epsilon$$
 (12.7)

The values of ϕ_{+-} and $\phi_{00}-\phi_{+-}$ are used to set limits on CPT violation. [See Tests of Conservation Laws.]

In the Standard Model, CP violation arises as a result of a single phase entering the CKM matrix (Sec. 11). As a result in what is now the standard phase convention, two elements have large phases, $V_{ub} \sim e^{-i\gamma}$, $V_{td} \sim e^{-i\beta}$. Because these elements have small magnitudes and involve the third generation, CP violation in the K^0 system is small. In general a nonzero value for ϵ'/ϵ is expected but uncertainties in evaluating hadronic matrix elements make the prediction uncertain. Most theoretical calculations [6] give a value between zero and 10^{-3} , but somewhat larger values or small negative values may be possible. On the other hand, large effects are expected in the B^0 system, which is a major motivation for B factories.

12.2. CP violation in B decay

CP violation in the B^0 system can be observed by comparing B^0 and \overline{B}^0 decays [7]. For a final CP eigenstate a, the decay rate has a time dependence given by

$$\Gamma_a \sim e^{-\Gamma t} \left(\left[1 + |\lambda_a|^2 \right] \pm \left[1 - |\lambda_a|^2 \right] \cos(\Delta M t) \right.$$

$$\mp \operatorname{Im} \lambda_a \sin(\Delta M t) \right) \tag{12.8}$$

where the top sign is for B^0 and the bottom for $\overline{B}{}^0$ and

$$\lambda_a = (q_B/p_B) \ \overline{A}_a/A_a \ . \tag{12.9}$$

The quantities p_B and q_B come from the analogue for B^0 of Eq. (12.2), and $A_a(\overline{A}_a)$ is the decay amplitude to state a for $B^0(\overline{B}^0)$. However, for B^0 the eigenstates are expected to have a negligible lifetime difference and are only distinguished by the mass difference ΔM ; also as a consequence $|q_B/p_B| \approx 1$ so that $\tilde{\epsilon}_B$ is purely imaginary.

If only one quark weak transition contributes to the decay, $|\overline{A}_a/A_a|=1$ so that $|\lambda_a|=1$ and the $\cos(\Delta Mt)$ term vanishes. In this case, the difference between B^0 and \overline{B}^0 decays is given by the $\sin(\Delta Mt)$ term with the asymmetry coefficient

$$a_{a} = \frac{\Gamma_{a}(t) - \overline{\Gamma}_{a}(t)}{(\Gamma_{a}(t) + \overline{\Gamma}_{a}(t))\sin(\Delta M t)} = \eta_{a}\sin(2(\phi_{M} + \phi_{D})), \quad (12.10)$$

where $2\phi_M$ is the phase of the $B^0-\overline{B}^0$ mixing, ϕ_D is the weak phase of the decay transition, and η_a is the CP eigenvalue of a.

For $B^0(\overline{B}^0) \to \psi K_S$ from the transition $b \to c\overline{c}s$, one finds in the Standard Model that the asymmetry is given directly in terms of a CKM phase with no hadronic uncertainty:

$$a_{\psi K_S} = -\sin 2\beta \ . \tag{12.11}$$

From the constraints on the CKM matrix (Sec. 11) $\sin 2\beta$ is predicted to be between 0.3 and 0.9. A significantly different value could be a sign of new physics.

A second decay of interest is B^0 $(\overline B{}^0)\to \pi^+\pi^-$ from the transition $b\to u\overline u d$ with

$$a_{\pi\pi} = \sin 2(\beta + \gamma) \ . \tag{12.12}$$

While either of these asymmetries could be ascribed to $B^0-\overline{B}^0$ mixing $(q_B/p_B \text{ or } \widetilde{\epsilon}_B)$, the difference between the two asymmetries is evidence for direct CP violation. From Eq. (12.9) it is seen that this corresponds to a phase difference between $A_{\psi K_S}$ and $A_{\pi^+\pi^-}$. Thus this is analogous to ϵ' . In the standard phase convention, 2β in Eqs. (12.11) and (12.12) arises from $B^0-\overline{B}^0$ mixing whereas the γ in Eq. (12.12) comes from V_{ub} in the transition $b \to u\overline{u}d$. The result in Eq. (12.12) may have a sizeable correction due to what is called a penguin diagram. This is a one-loop graph producing $b \to d$ + gluon with a W and a quark, predominantly the t quark, in the loop. This leads to an amplitude proportional to $V_{tb}^*V_{td}$, which has a weak phase different from that of the original tree amplitude proportional to $V_{ub}V_{ud}^*$. There are several methods to approximately determine this correction using additional measurements [8].

CP violation in the decay amplitude is also revealed by the $\cos(\Delta Mt)$ term in Eq. (12.8) or by a difference in rates of B^+ and B^- to charge-conjugate states. These effects, however, require two contributing amplitudes to the decay (such as a tree amplitude plus a penguin) and also require final-state interaction phases. Predicted effects are very uncertain and are generally small [9].

In the case of the B_s system, the mass difference ΔM is much larger than for B^0 and has not yet been measured. As a result, it will be difficult to isolate the $\sin(\Delta Mt)$ term to measure asymmetries. Furthermore, in the Standard Model with the standard phase convention, ϕ_M is very small so that decays due to $b \to c\overline{c}s$, yielding $B_s \to \psi \eta^i$, would have zero asymmetry. Decays due to $b \to u\overline{u}d$, yielding $B_s \to \rho^0 K_S$, would have an asymmetry $\sin 2\gamma$ in the tree approximation. The width difference $\Delta\Gamma$ is also expected to be much larger for B_s so that $\Delta\Gamma/\Gamma$ might be a large as 0.15. In this case, there might be a possibility of detecting CP violation as in the case of K^0 by observing the B_s states with different lifetimes decaying into the same CP eigenstate [10].

For further details, see the notes on CP violation in the K_L^0 , K_S^0 , and B^0 Particle Listings of this Review.

13. QUARK MODEL

Revised April 1998 by C. Amsler (Univ. of Zürich) and C.G. Wohl (LBNL).

13.1. Quantum numbers of the quarks

Each quark has spin 1/2 and baryon number 1/3. Table 13.1 gives the additive quantum numbers (other than baryon number) of the three generations of quarks. Our convention is that the *flavor* of a quark (I_s , S, C, B, or T) has the same sign as its *charge*. With this convention, any flavor carried by a *charged* meson has the same sign as its charge; e.g., the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm and strangeness of the D_s^- are each -1.

By convention, each quark is assigned positive parity. Then each antiquark has negative parity.

Table 13.1: Additive quantum numbers of the quarks.

Property Quark	d	น	8	с	ь	t
Q - electric charge	$-\frac{1}{3}$	+2/3	- 1 3	+3	-13	$+\frac{2}{3}$
l _s – isospin z-component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	-1	0	0	0
C – charm	0	0	0	+1	0	0
B - bottomness	0	0	0	0	-1	0
T - topness	0	0	0	0	0	+1

13.2. Mesons: $q\overline{q}$ states

Nearly all known mesons are bound states of a quark q and an antiquark \overline{q}' (the flavors of q and q' may be different). If the orbital angular momentum of the $q\overline{q}'$ state is L, then the parity P is $(-1)^{L+1}$. A state $q\overline{q}$ of a quark and its own antiquark is also an eigenstate of charge conjugation, with $C=(-1)^{L+S}$, where the spin S is 0 or 1. The L=0 states are the pseudoscalars, $J^P=0^-$, and the vectors, $J^P=1^-$. Assignments for many of the known mesons are given in Table 13.2. States in the "normal" spin-parity series, $P=(-1)^J$, must, according to the above, have S=1 and hence CP=+1. Thus mesons with normal spin-parity and CP=-1 are forbidden in the $q\overline{q}'$ model. The $J^{PC}=0^{--}$ state is forbidden as well. Mesons with such J^{PC} may exist, but would lie outside the $q\overline{q}'$ model.

The nine possible $q\bar{q}'$ combinations containing u, d, and s quarks group themselves into an octet and a singlet:

$$\mathbf{3} \otimes \overline{\mathbf{3}} = \mathbf{8} \oplus \mathbf{1} \tag{13.1}$$

States with the same IJ^P and additive quantum numbers can mix. (If they are eigenstates of charge conjugation, they must also have the same value of C.) Thus the I=0 member of the ground-state pseudoscalar octet mixes with the corresponding pseudoscalar singlet to produce the η and η' . These appear as members of a nonet, which is shown as the middle plane in Fig. 13.1(a). Similarly, the ground-state vector nonet appears as the middle plane in Fig. 13.1(b).

A fourth quark such as charm can be included in this scheme by extending the symmetry to SU(4), as shown in Fig. 13.1. Bottom extends the symmetry to SU(5); to draw the multiplets would require four dimensions.

For the pseudoscalar mesons, the Gell-Mann-Okubo formula is

$$m_{\eta}^2 = \frac{1}{3}(4m_K^2 - m_{\pi}^2) , \qquad (13.2)$$

assuming no octet-singlet mixing. However, the octet η_8 and singlet η_1 mix because of SU(3) breaking. In general, the mixing angle is

mass dependent and becomes complex for resonances of finite width. Neglecting this, the physical states η and η' are given in terms of a mixing angle θ_P by

$$\eta = \eta_8 \cos \theta_P - \eta_1 \sin \theta_P \tag{13.3a}$$

$$\eta' = \eta_8 \sin \theta_P + \eta_1 \cos \theta_P . \tag{13.3b}$$

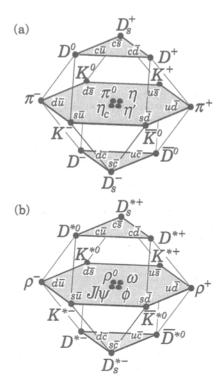

Figure 13.1: SU(4) 16-plets for the (a) pseudoscalar and (b) vector mesons made of u, d, s, and c quarks. The nonets of light mesons occupy the central planes, to which the $c\overline{c}$ states have been added. The neutral mesons at the centers of these planes are mixtures of $u\overline{u}$, $d\overline{d}$, $s\overline{s}$, and $c\overline{c}$ states.

These combinations diagonalize the mass-squared matrix

$$M^2 = \begin{pmatrix} M_{11}^2 & M_{18}^2 \\ M_{18}^2 & M_{88}^2 \end{pmatrix} , (13.4)$$

where $M_{88}^2 = \frac{1}{3}(4m_K^2 - m_\pi^2)$. It follows that

$$\tan^2 \theta_P = \frac{M_{88}^2 - m_{\eta}^2}{m_{\eta'}^2 - M_{88}^2} \,. \tag{13.5}$$

The sign of θ_P is meaningful in the quark model. If

$$\eta_1 = (u\overline{u} + d\overline{d} + s\overline{s})/\sqrt{3} \tag{13.6a}$$

$$\eta_8 = (u\overline{u} + d\overline{d} - 2s\overline{s})/\sqrt{6} , \qquad (13.6b)$$

then the matrix element M_{18}^2 , which is due mostly to the strange quark mass, is negative. From the relation

$$an heta_P = rac{M_{88}^2 - m_\eta^2}{M_{18}^2} \; , ag{13.7}$$

we find that $\theta_P < 0$. However, caution is suggested in the use of the η - η' mixing-angle formulas, as they are extremely sensitive to SU(3)

Table 13.2: Suggested $q\bar{q}$ quark-model assignments for most of the known mesons. Some assignments, especially for the 0⁺⁺ multiplet and for some of the higher multiplets, are controversial. Mesons in bold face are included in the Meson Summary Table. Of the light mesons in the Summary Table, the $f_0(1500)$, $f_1(1510)$, $f_1(1710)$, $f_2(2300)$, $f_2(2340)$, and one of the two peaks in the $\eta(1440)$ entry are not in this table. Within the $q\bar{q}$ model, it is especially hard to find a place for the first three of these f mesons and for one of the $\eta(1440)$ peaks. See the "Note on Non- $q\bar{q}$ Mesons" at the end of the Meson Listings.

^{*} See our scalar minireview in the Particle Listings. The candidates for the I=1 states are $a_0(980)$ and $a_0(1450)$, while for I=0 they are: $f_0(400-1200)$, $f_0(980)$, and $f_0(1370)$. The light scalars are problematic, since there may be two poles for one $q\overline{q}$ state and $a_0(980)$, $f_0(980)$ may be $K\overline{K}$ bound states.

If we allow $M_{88}^2=\frac{1}{3}(4m_K^2-m_\pi^2)$ $(1+\Delta),$ the mixing angle is determined by

$$\tan^2\theta_P = 0.0319(1+17\Delta) \tag{13.8}$$

$$\theta_P = -10.1^{\circ}(1 + 8.5\Delta) \tag{13.9}$$

to first order in Δ . A small breaking of the Gell-Mann-Okubo relation can produce a major modification of θ_P .

For the vector mesons, $\pi \to \rho, \ K \to K^*, \ \eta \to \phi, \ {\rm and} \ \eta' \to \omega, \ {\rm so}$ that

$$\phi = \omega_8 \cos \theta_V - \omega_1 \sin \theta_V \tag{13.10}$$

$$\omega = \omega_8 \sin \theta_V + \omega_1 \cos \theta_V . \tag{13.11}$$

For "ideal" mixing, $\phi=s\bar{s}$, so $\tan\theta_V=1/\sqrt{2}$ and $\theta_V=35.3^\circ$. Experimentally, θ_V is near 35°, the sign being determined by a formula like that for $\tan\theta_P$. Following this procedure we find the mixing angles given in Table 13.3.

Table 13.3: Singlet-octet mixing angles for several nonets, neglecting possible mass dependence and imaginary parts. The sign conventions are given in the text. The values of $\theta_{\rm quad}$ are obtained from the equations in the text, while those for $\theta_{\rm lin}$ are obtained by replacing m^2 by m throughout. Of the two isosinglets in a nonet, the mostly octet one is listed first.

J^{PC}	Nonet members	$\theta_{ ext{quad}}$	$ heta_{ m lin}$
0-+	π, K, η, η'	-10°	-23°
1	$ ho,K^*(892),\phi,\omega$	39°	36°
2++	$a_2(1320), K_2^*(1430), f_2^l(1525), f_2(1270)$	28°	26°
3	$\rho_3(1690), K_3^*(1780), \phi_3(1850), \omega_3(1670)$	29°	28°

[†] The K_{1A} and K_{1B} are nearly equal (45°) mixes of the $K_1(1270)$ and $K_1(1400)$.

[‡]The $K^*(1410)$ could be replaced by the $K^*(1680)$ as the 2 3S_1 state.

In the quark model, the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the *i*-th quark. This provides an alternative characterization of mixing. For example, defining

$$\operatorname{Amp}\left[P \to \gamma(k_1) \ \gamma(k_2)\right] = M \epsilon^{\mu\nu\alpha\beta} \ \epsilon_{1\mu}^* \ k_{1\nu} \ \epsilon_{2\alpha}^* \ k_{2\beta} \ , \tag{13.12}$$

where $\epsilon_{i\lambda}$ is the λ component of the polarization vector of the i^{th} photon, one finds

$$\frac{M(\eta \to \gamma \gamma)}{M(\pi^0 \to \gamma \gamma)} = \frac{1}{\sqrt{3}} (\cos \theta_P - 2\sqrt{2} \sin \theta_P)$$

$$= \frac{1.73 \pm 0.18}{\sqrt{3}}$$
(13.13a)

$$= \frac{1762332}{\sqrt{3}}$$

$$\frac{M(\eta' \to \gamma\gamma)}{M(\pi^0 \to \gamma\gamma)} = 2\sqrt{2/3} \left(\cos\theta_P + \frac{\sin\theta_P}{2\sqrt{2}}\right)$$

$$= 2\sqrt{2/3} \left(0.78 \pm 0.04\right),$$

$$(13.13a)$$

where the numbers with errors are experimental. These data favor $\theta_P \approx -20^\circ$, which is compatible with the quadratic mass mixing formula with about 12% SU(3) breaking in M_{88}^2 .

13.3. Baryons: qqq states

All the established baryons are apparently 3-quark (qqq) states, and each such state is an SU(3) color singlet, a completely antisymmetric state of the three possible colors. Since the quarks are fermions, the state function for any baryon must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus the state function may be written as

$$|qqq\rangle_A = |\operatorname{color}\rangle_A \times |\operatorname{space}, \operatorname{spin}, \operatorname{flavor}\rangle_S,$$
 (13.14)

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two of the equal-mass quarks. Note the contrast with the state function for the three nucleons in 3H or 3He :

$$|NNN\rangle_A = |\text{space, spin, isospin}\rangle_A$$
. (13.15)

This difference has major implications for internal structure, magnetic moments, etc. (For a nice discussion, see Ref. 1.)

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor SU(3), which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \tag{13.16}$$

(see Sec. 34, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The 1 is a uds state (Λ_1) and the octet contains a similar state (Λ_8). If these have the same spin and parity they can mix. An example is the mainly octet D_{03} $\Lambda(1690)$ and mainly singlet D_{03} $\Lambda(1520)$. In the ground state multiplet, the SU(3) flavor singlet Λ is forbidden by Fermi statistics. The mixing formalism is the same as for η - η' or ϕ - ω (see above), except that for baryons the mass M instead of M^2 is used. Section 33, on "SU(3) Isoscalar Factors and Representation Matrices", shows how relative decay rates in, say, $10 \to 8 \otimes 8$ decays may be calculated. A summary of results of fits to the observed baryon masses and decay rates for the best-known SU(3) multiplets is given in Appendix II of our 1982 edition [2].

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). Figures 13.2(a) and 13.2(b) show the (badly broken) SU(4) baryon multiplets that have as their "ground floors" the SU(3) octet that contains the nucleons and the SU(3) decuplet that contains the $\Delta(1232)$. All the particles in a given SU(4) multiplet have the same spin and parity. The only charmed baryons that have been discovered each contain one charmed quark. These belong to the first floor of the multiplet shown in Fig. 13.2(a); for details, see the "Note on Charmed Baryons" in the Baryon Particle Listings. The addition of a b quark extends the flavor symmetry to SU(5); it would require four dimensions to draw the multiplets.

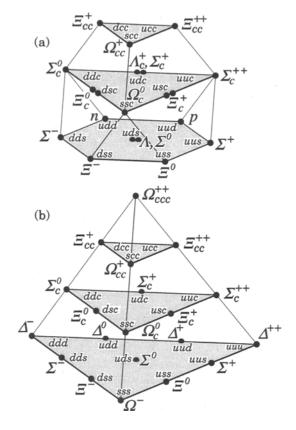

Figure 13.2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

For the "ordinary" baryons, flavor and spin may be combined in an approximate flavor-spin SU(6) in which the six basic states are $d\uparrow$, $d\downarrow$, \cdots , $s\downarrow$ (\uparrow , \downarrow = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A . \tag{13.17}$$

These SU(6) multiplets decompose into flavor SU(3) multiplets as follows:

$$\mathbf{56} = {}^{4}\mathbf{10} \oplus {}^{2}\mathbf{8} \tag{13.18a}$$

$$70 = {}^{2}10 \oplus {}^{4}8 \oplus {}^{2}8 \oplus {}^{2}1 \tag{13.18b}$$

$$20 = {}^{2}8 \oplus {}^{4}1 , \qquad (13.18c)$$

where the superscript (2S+1) gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P=1/2^+$ octet containing the nucleon and the $J^P=3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The 70 and 20 require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in SU(6) \otimes O(3) supermultiplets. Physical baryons with the same quantum numbers do not belong to a single supermultiplet, since SU(6) is broken by spin-dependent interactions, differences in quark masses, etc. Nevertheless, the SU(6) \otimes O(3) basis provides a suitable framework for describing baryon state functions.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of supermultiplets, specified by (D, L_N^P) , where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to N=12 are given in Ref. 3. The N=0 band,

which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The N=1 band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The N=2 band contains five supermultiplets: $(56,0_2^+)$, $(70,0_2^+)$, $(56,2_2^+)$, $(70,2_2^+)$, and $(20,1_2^+)$. Baryons belonging to the $(20,1_2^+)$ supermultiplet are not ever likely to be observed, since a coupling from the ground-state baryons requires a two-quark excitation. Selection rules are similarly responsible for the fact that many other baryon resonances have not been observed [4].

In Table 13.4, quark-model assignments are given for many of the established baryons whose $SU(6)\otimes O(3)$ compositions are relatively unmixed. We note that the unestablished resonances $\varSigma(1480)$, $\varSigma(1560)$, $\varSigma(1580)$, $\varSigma(1770)$, and $\varSigma(1620)$ in our Baryon Particle Listings are too low in mass to be accommodated in most quark models [4,5].

Table 13.4: Quark-model assignments for many of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for some states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses.

The quark model for baryons is extensively reviewed in Ref. 6 and 7.

13.4. Dynamics

Many specific quark models exist, but most contain the same basic set of dynamical ingredients. These include:

- i) A confining interaction, which is generally spin-independent.
- ii) A spin-dependent interaction, modeled after the effects of gluon exchange in QCD. For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\overrightarrow{\sigma} \lambda_a)_i (\overrightarrow{\sigma} \lambda_a)_j , \qquad (13.19)$$

where M is a constant with units of energy, λ_a $(a=1,\dots,8,)$ is the set of SU(3) unitary spin matrices, defined in Sec. 33, on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small.

- iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets.
- iv) In the case of isoscalar mesons, an interaction for mixing $q\overline{q}$ configurations of different flavors (e.g., $u\overline{u} \leftrightarrow d\overline{d} \leftrightarrow s\overline{s}$), in a manner which is generally chosen to be flavor independent.

These four ingredients provide the basic mechanisms that determine the hadron spectrum.

14. EXPERIMENTAL TESTS OF GRAVITATIONAL THEORY

Revised April 1998 by T. Damour (IHES, Bures-sur-Yvette, France).

Einstein's General Relativity, the current "standard" theory of gravitation, describes gravity as a universal deformation of the Minkowski metric:

$$g_{\mu\nu}(x^{\lambda}) = \eta_{\mu\nu} + h_{\mu\nu}(x^{\lambda})$$
, where $\eta_{\mu\nu} = \text{diag}(-1, +1, +1, +1)$. (14.1)

Alternatively, it can be defined as the unique, consistent, local theory of a massless spin-2 field $h_{\mu\nu}$, whose source must then be the total, conserved energy-momentum tensor [1]. General Relativity is classically defined by two postulates. One postulate states that the Lagrangian density describing the propagation and self-interaction of the gravitational field is

$$\mathcal{L}_{\rm Ein}[g_{\mu\nu}] = \frac{c^4}{16\pi G_N} \sqrt{g} g^{\mu\nu} R_{\mu\nu}(g) , \qquad (14.2)$$

$$R_{\mu\nu}(g) = \partial_{\alpha}\Gamma^{\alpha}_{\mu\nu} - \partial_{\nu}\Gamma^{\alpha}_{\mu\alpha} + \Gamma^{\beta}_{\alpha\beta}\Gamma^{\alpha}_{\mu\nu} - \Gamma^{\beta}_{\nu\alpha}\Gamma^{\alpha}_{\mu\beta} , \qquad (14.3)$$

$$\Gamma^{\lambda}_{\mu\nu} = \frac{1}{2} g^{\lambda\sigma} (\partial_{\mu} g_{\nu\sigma} + \partial_{\nu} g_{\mu\sigma} - \partial_{\sigma} g_{\mu\nu}) , \qquad (14.4)$$

where G_N is Newton's constant, $g=-\det(g_{\mu\nu})$, and $g^{\mu\nu}$ is the matrix inverse of $g_{\mu\nu}$. A second postulate states that $g_{\mu\nu}$ couples universally, and minimally, to all the fields of the Standard Model by replacing everywhere the Minkowski metric $\eta_{\mu\nu}$. Schematically (suppressing matrix indices and labels for the various gauge fields and fermions and for the Higgs doublet),

$$\mathcal{L}_{\text{SM}}[\psi, A_{\mu}, H, g_{\mu\nu}] = -\frac{1}{4} \sum \sqrt{g} g^{\mu\alpha} g^{\nu\beta} F^{a}_{\mu\nu} F^{a}_{\alpha\beta} - \sum \sqrt{g} \overline{\psi} \gamma^{\mu} D_{\mu} \psi - \frac{1}{2} \sqrt{g} g^{\mu\nu} \overline{D_{\mu} H} D_{\nu} H - \sqrt{g} V(H) - \sum \lambda \sqrt{g} \overline{\psi} H \psi ,$$
 (14.5)

where $\gamma^{\mu}\gamma^{\nu} + \gamma^{\nu}\gamma^{\mu} = 2g^{\mu\nu}$, and where the covariant derivative D_{μ} contains, besides the usual gauge field terms, a (spin dependent) gravitational contribution $\Gamma_{\mu}(x)$ [2]. From the total action $S_{\text{tot}}[g_{\mu\nu}, \psi, A_{\mu}, H] = c^{-1} \int d^4x (\mathcal{L}_{\text{Ein}} + \mathcal{L}_{\text{SM}})$ follow Einstein's field equations,

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} = \frac{8\pi G_N}{c^4} T_{\mu\nu} . \qquad (14.6)$$

Here $R=g^{\mu\nu}R_{\mu\nu}$, $T_{\mu\nu}=g_{\mu\alpha}g_{\nu\beta}T^{\alpha\beta}$, and $T^{\mu\nu}=(2/\sqrt{g})\delta \mathcal{L}_{\rm SM}/\delta g_{\mu\nu}$ is the (symmetric) energy-momentum tensor of the Standard Model matter. The theory is invariant under arbitrary coordinate transformations: $x'^{\mu}=f^{\mu}(x^{\nu})$. To solve the field equations Eq. (14.6) one needs to fix this coordinate gauge freedom. E.g. the "harmonic gauge" (which is the analogue of the Lorentz gauge, $\partial_{\mu}A^{\mu}=0$, in electromagnetism) corresponds to imposing the condition $\partial_{\nu}(\sqrt{g}g^{\mu\nu})=0$.

In this Review, we only consider the classical limit of gravitation (i.e. classical matter and classical gravity). Considering quantum matter in a classical gravitational background already poses interesting challenges, notably the possibility that the zero-point fluctuations of the matter fields generate a nonvanishing vacuum energy density $\rho_{\rm vac}$, corresponding to a term $-\sqrt{g}$ $\rho_{\rm vac}$ in $\mathcal{L}_{\rm SM}$ [3]. This is equivalent to adding a "cosmological constant" term $+\Lambda g_{\mu\nu}$ on the left-hand side of Einstein's equations Eq. (14.6), with $\Lambda = 8\pi G_N \, \rho_{\rm vac}/c^4$. Cosmological observations set bounds on Λ (see "Astrophysical Constants," Sec. 2 of this Review) which, when translated in particle physics units, appear suspiciously small: $\rho_{\rm vac} \lesssim 10^{-46}~{\rm GeV}^4$. This bound shows that $\rho_{\rm vac}$, even if it is not strictly zero, has a negligible effect on the tests discussed below. Quantizing the gravitational field itself poses a very difficult challenge because of the perturbative non-renormalizability of Einstein's Lagrangian. Supergravity and superstring theory offer promising avenues toward solving this challenge.

14.1. Experimental tests of the coupling between matter and gravity

The universality of the coupling between $g_{\mu\nu}$ and the Standard Model matter postulated in Eq. (14.5) ("Equivalence Principle") has many observable consequences. First, it predicts that the outcome of a local non-gravitational experiment, referred to local standards, does not depend on where, when, and in which locally inertial frame, the experiment is performed. This means, for instance, that local experiments should neither feel the cosmological evolution of the universe (constancy of the "constants"), nor exhibit preferred directions in spacetime (isotropy of space, local Lorentz invariance). These predictions are consistent with many experiments and observations. The best limit on a possible time variation of the basic coupling constants concerns the fine-structure constant $\alpha_{\rm em}$ and has been obtained by analyzing a natural fission reactor phenomenon which took place at Oklo, Gabon, two billion years ago [4]

$$-6.7 \times 10^{-17} \rm{yr}^{-1} < \frac{\dot{\alpha}_{\rm em}}{\alpha_{\rm em}} < 5.0 \times 10^{-17} \rm{yr}^{-1} \ . \eqno(14.7)$$

The highest precision tests of the isotropy of space have been performed by looking to possible quadrupolar shifts of nuclear energy levels [5]. The (null) results can be interpreted as testing the fact that the various pieces in the matter Lagrangian Eq. (14.5) are indeed coupled to one and the same external metric $g_{\mu\nu}$ to the 10^{-27} level.

The universal coupling to $g_{\mu\nu}$ postulated in Eq. (14.5) implies that two (electrically neutral) test bodies dropped at the same location and with the same velocity in an external gravitational field fall in the same way, independently of their masses and compositions. The universality of the acceleration of free fall has been verified at the 10^{-12} level both for laboratory bodies [6],

$$\left(\frac{\Delta a}{a}\right)_{\text{BeCu}} = (-1.9 \pm 2.5) \times 10^{-12} ,$$
 (14.8)

and for the gravitational accelerations of the Moon and the Earth toward the Sun [7],

$$\left(\frac{\Delta a}{a}\right)_{\text{MoonFarth}} = (-3.2 \pm 4.6) \times 10^{-13} \ .$$
 (14.9)

Finally, Eq. (14.5) also implies that two identically constructed clocks located at two different positions in a static external Newtonian potential $U(\boldsymbol{x}) = \sum G_N m/r$ exhibit, when intercompared by means of electromagnetic signals, the (apparent) difference in clock rate,

$$\frac{\tau_1}{\tau_2} = \frac{\nu_2}{\nu_1} = 1 + \frac{1}{c^2} [U(\boldsymbol{x}_1) - U(\boldsymbol{x}_2)] + O\left(\frac{1}{c^4}\right) , \qquad (14.10)$$

independently of their nature and constitution. This universal gravitational redshift of clock rates has been verified at the 10^{-4} level by comparing a hydrogen-maser clock flying on a rocket up to an altitude $\sim 10,000$ km to a similar clock on the ground [8]. For more details and references on experimental gravity see, e.g., Refs. 9 and 10.

14.2. Tests of the dynamics of the gravitational field in the weak field regime

The effect on matter of one-graviton exchange, i.e. the interaction Lagrangian obtained when solving Einstein's field equations Eq. (14.6) written in, say, the harmonic gauge at first order in $h_{\mu\nu}$,

$$\Box h_{\mu\nu} = -\frac{16\pi G_N}{c^4} (T_{\mu\nu} - \frac{1}{2}T\eta_{\mu\nu}) + O(h^2) + O(hT) , \qquad (14.11)$$

reads $-(8\pi G_N/c^4)T^{\mu\nu}\Box^{-1}(T_{\mu\nu}-\frac{1}{2}T\eta_{\mu\nu})$. For a system of N moving point masses, with free Lagrangian $L^{(1)}=\sum_{A=1}^N-m_Ac^2\sqrt{1-v_A^2/c^2}$, this interaction, expanded to order v^2/c^2 , reads (with $r_{AB}\equiv |x_A-x_B|$, $n_{AB}\equiv (x_A-x_B)/r_{AB}$)

$$\begin{split} L^{(2)} = & \frac{1}{2} \sum_{A \neq B} \frac{G_N \, m_A \, m_B}{r_{AB}} \left[1 + \frac{3}{2c^2} (v_A^2 + v_B^2) - \frac{7}{2c^2} (v_A \cdot v_B) \right. \\ & \left. - \frac{1}{2c^2} (n_{AB} \cdot v_A) (n_{AB} \cdot v_B) + O\left(\frac{1}{c^4}\right) \right] \,. \end{split} \tag{14.12}$$

The two-body interactions Eq. (14.12) exhibit v^2/c^2 corrections to Newton's 1/r potential induced by spin-2 exchange. Consistency at the "post-Newtonian" level $v^2/c^2 \sim G_N \, m/rc^2$ requires that one also considers the three-body interactions induced by some of the three-graviton vertices and other nonlinearities (terms $O(h^2)$ and O(hT) in Eq. (14.11)),

$$L^{(3)} = -\sum_{B \neq A \neq C} \frac{G_N^2 \, m_A \, m_B \, m_C}{r_{AB} \, r_{AC} \, c^2} + O\left(\frac{1}{c^4}\right) . \tag{14.13}$$

All currently performed gravitational experiments in the solar system, including perihelion advances of planetary orbits, the bending and delay of electromagnetic signals passing near the Sun, and very accurate ranging data to the Moon obtained by laser echoes, are compatible with the post-Newtonian results Eqs. (14.11)–(14.13).

Similarly to what is done in discussions of precision electroweak experiments (see Section 10 in this Review), it is useful to quantify the significance of precision gravitational experiments by parameterizing plausible deviations from General Relativity. Endowing the spin-2 excitations with a (Pauli-Fierz) mass term is excluded both for phenomenological (discontinuities in observable predictions [11]) and theoretical (no energy lower bound [12]) reasons. Therefore, deviations from Einstein's pure spin-2 theory are defined by adding new, bosonic, ultra light or massless, macroscopically coupled fields. The addition of a vector (spin 1) field necessarily leads to violations of the universality of free fall and is constrained by "fifth force" experiments. See Refs. [6,13] for compilations of constraints. The addition of a scalar (spin 0) field is the most studied type of deviation from General Relativity, being motivated by many attempts to unify gravity with the Standard Model (Kaluza-Klein program, supergravity, string theory). The technically simplest class of tensor-scalar (spin 2 \oplus spin 0) theories consists in adding a massless scalar field φ coupled to the trace of the energy-momentum tensor $T=g_{\mu\nu}T^{\mu\nu}$ [14]. The most general such theory contains an arbitrary function $a(\varphi)$ of the scalar field, and can be defined by the Lagrangian

$$\mathcal{L}_{\text{tot}}[g_{\mu\nu}, \varphi, \psi, A_{\mu}, H] = \frac{c^4}{16\pi G} \sqrt{g} (R(g) - 2g^{\mu\nu} \partial_{\mu} \varphi \partial_{\nu} \varphi) + \mathcal{L}_{\text{SM}}[\psi, A_{\mu}, H, \tilde{g}_{\mu\nu}], \qquad (14.14)$$

where G is a "bare" Newton constant, and where the Standard Model matter is coupled not to the "Einstein" (pure spin-2) metric $g_{\mu\nu}$, but to the conformally related ("Jordan-Fierz") metric $\widetilde{g}_{\mu\nu}=\exp(2a(\varphi))g_{\mu\nu}$. The scalar field equation $\Box_g\varphi=-(4\pi G/c^4)\alpha(\varphi)T$ displays $\alpha(\varphi)\equiv\partial a(\varphi)/\partial\varphi$ as the basic (field-dependent) coupling between φ and matter [15]. The one-parameter Jordan-Fierz-Brans-Dicke theory [14] is the special case $a(\varphi)=\alpha_0\varphi$ leading to a field-independent coupling $\alpha(\varphi)=\alpha_0$.

In the weak field, slow motion, limit appropriate to describing gravitational experiments in the solar system, the addition of φ modifies Einstein's predictions only through the appearance of two "post-Einstein" dimensionless parameters: $\bar{\gamma} = -2\alpha_0^2/(1+\alpha_0^2)$ and $\overline{\beta} = +\frac{1}{2}\beta_0\alpha_0^2/(1+\alpha_0^2)^2$, where $\alpha_0 \equiv \alpha(\varphi_0)$, $\beta_0 \equiv \partial\alpha(\varphi_0)/\partial\varphi_0$, φ_0 denoting the vacuum expectation value of φ . These parameters show up also naturally (in the form $\gamma_{PPN} = 1 + \overline{\gamma}$, $\beta_{PPN} = 1 + \overline{\beta}$) in phenomenological discussions of possible deviations from General Relativity [16,9]. The parameter $\overline{\gamma}$ measures the admixture of spin 0 to Einstein's graviton, and contributes an extra term $+ \bar{\gamma}(v_A - v_B)^2/c^2$ in the square brackets of the two-body Lagrangian Eq. (14.12). The parameter $\overline{\beta}$ modifies the three-body interaction Eq. (14.13) by a factor $1 + 2\overline{\beta}$. Moreover, the combination $\eta \equiv 4\overline{\beta} - \overline{\gamma}$ parameterizes the lowest order effect of the self-gravity of orbiting masses by modifying the Newtonian interaction energy terms in Eq. (14.12) into $G_{AB}m_Am_B/r_{AB}$, with a body-dependent gravitational "constant" $G_{AB} = G_N[1 + \eta(E_A^{\sf grav}/m_Ac^2 + E_B^{\sf grav}/m_Bc^2) + O(1/c^4)],$ where $G_N = G \exp[2a(\varphi_0)](1 + \alpha_0^2)$ and where $E_A^{\sf grav}$ denotes the gravitational binding energy of body A.

The best current limits on the post-Einstein parameters $\overline{\gamma}$ and $\overline{\beta}$ are (at the 68% confidence level): (i) $|\overline{\gamma}| < 2 \times 10^{-3}$ [17] deduced from the Viking mission measurement of the gravitational time delay [18] of radar signals passing near the Sun (with similar limits coming from Very Long Baseline Interferometry (VLBI) measurements of the deflection of radio waves by the Sun [19]), and (ii) $4\overline{\beta} - \overline{\gamma} = -0.0007 \pm 0.0010$ [7] from Lunar Laser Ranging measurements of a possible polarization of the Moon toward the Sun [20]. More stringent limits on $\overline{\gamma}$ are obtained in models (e.g., string-inspired ones [21]) where scalar couplings violate the Equivalence Principle.

14.3. Tests of the dynamics of the gravitational field in the radiative and/or strong field regimes

The discovery of pulsars (i.e. rotating neutron stars emitting a beam of radio noise) in gravitationally bound orbits [22,23] has opened up an entirely new testing ground for relativistic gravity, giving us an experimental handle on the regime of radiative and/or strong gravitational fields. In these systems, the finite velocity of propagation of the gravitational interaction between the pulsar and its companion generates damping-like terms at order $(v/c)^5$ in the equations of motion [24]. These damping forces are the local counterparts of the gravitational radiation emitted at infinity by the system ("gravitational radiation reaction"). They cause the binary orbit to shrink and its orbital period Pb to decrease. The remarkable stability of the pulsar clock has allowed Taylor and collaborators to measure the corresponding very small orbital period decay $\dot{P}_b \equiv dP_b/dt \sim (v/c)^5 \sim 10^{-12}$ [23,25], thereby giving us a direct experimental confirmation of the propagation properties of the gravitational field. In addition, the surface gravitational potential of a neutron star $h_{00}(R) \simeq 2Gm/c^2R \simeq 0.4$ being a factor $\sim 10^8$ higher than the surface potential of the Earth, and a mere factor 2.5 below the black hole limit $(h_{00} = 1)$, pulsar data are sensitive probes of the strong-gravitational-field regime.

Binary pulsar timing data record the times of arrival of successive electromagnetic pulses emitted by a pulsar orbiting around the center of mass of a binary system. After correcting for the Earth motion around the Sun and for the dispersion due to propagation in the interstellar plasma, the time of arrival of the Nth pulse t_N can be described by a generic, parameterized "timing formula [26]" whose functional form is common to the whole class of tensor-scalar gravitation theories:

$$t_N - t_0 = F[T_N(\nu_p, \dot{\nu}_p, \ddot{\nu}_p); \{p^K\}; \{p^{PK}\}].$$
 (14.15)

Here, T_N is the pulsar proper time corresponding to the Nth turn given by $N/2\pi = \nu_p T_N + \frac{1}{2}\dot{\nu}_p T_N^2 + \frac{1}{6}\ddot{\nu}_p T_N^3$ (with $\nu_p \equiv 1/P_p$ the spin frequency of the pulsar, etc.), $\{p^K\} = \{P_b, T_0, e, \omega_0, x\}$ is the set of "Keplerian" parameters (notably, orbital period P_b , eccentricity e and projected semi-major axis $x = a \sin i/c$), and $\{p^{PK}\} = \{k, \gamma_{\text{timing}}, \dot{P}_b, r, s, \delta_\theta, \dot{e}, \dot{x}\}$ denotes the set of (separately

measurable) "post-Keplerian" parameters. Most important among these are: the fractional periastron advance per orbit $k \equiv \dot{\omega} P_b/2\pi$, a dimensionful time-dilation parameter $\gamma_{\rm timing}$, the orbital period derivative \dot{P}_b , and the "range" and "shape" parameters of the gravitational time delay caused by the companion, r and s.

Without assuming any specific theory of gravity, one can phenomenologically analyze the data from any binary pulsar by least-squares fitting the observed sequence of pulse arrival times to the timing formula Eq. (14.15). This fit yields the "measured" values of the parameters $\{\nu_p,\dot{\nu}_p,\ddot{\nu}_p\}$, $\{p^K\}$, $\{p^{PK}\}$. Now, each specific relativistic theory of gravity predicts that, for instance, k, γ_{timing} , \dot{P}_b , r and s (to quote parameters that have been successfully measured from some binary pulsar data) are some theory-dependent functions of the Keplerian parameters and of the (unknown) masses m_1 , m_2 of the pulsar and its companion. For instance, in General Relativity, one finds (with $M \equiv m_1 + m_2$, $n \equiv 2\pi/P_b$)

$$\begin{split} k^{\text{GR}}(m_1, m_2) &= 3(1 - e^2)^{-1} (G_N M n/c^3)^{2/3} , \\ \gamma^{\text{GR}}_{\text{timing}}(m_1, m_2) &= e n^{-1} (G_N M n/c^3)^{2/3} m_2 (m_1 + 2m_2)/M^2 , \\ \dot{P}_b^{\text{GR}}(m_1, m_2) &= - (192 \pi/5 c^5) (1 - e^2)^{-7/2} \left(1 + \frac{73}{24} e^2 + \frac{37}{96} e^4\right) \\ &\qquad \times (G_N M n/c^3)^{5/3} m_1 m_2/M^2 , \\ r(m_1, m_2) &= G_N m_2/c^3 , \\ s(m_1, m_2) &= n x (G_N M n/c^3)^{-1/3} M/m_2 . \end{split}$$
(14.16)

In tensor-scalar theories, each of the functions $k^{\text{theory}}(m_1, m_2)$, $\gamma_{\text{timing}}^{\text{theory}}(m_1, m_2)$, $\dot{P}_b^{\text{theory}}(m_1, m_2)$, etc is modified by quasi-static strong field effects (associated with the self-gravities of the pulsar and its companion), while the particular function $\dot{P}_b^{\text{theory}}(m_1, m_2)$ is further modified by radiative effects (associated with the spin 0 propagator) [15,27].

Let us summarize the current experimental situation. In the first discovered binary pulsar PSR1913 + 16 [22,23], it has been possible to measure with accuracy the three post-Keplerian parameters k, $\gamma_{\rm timing}$ and \dot{P}_b . The three equations $k^{\rm measured} = k^{\rm theory}(m_1,m_2)$, $\gamma_{\rm timing}^{\rm measured} = \gamma_{\rm timing}^{\rm theory}(m_1,m_2)$, $\dot{P}_b^{\rm measured} = \dot{P}_b^{\rm theory}(m_1,m_2)$ determine, for each given theory, three curves in the two-dimensional mass plane. This yields one (combined radiative/strong-field) test of the specified theory, according to whether the three curves meet at one point, as they should. After subtracting a small ($\sim 10^{-14}$ level in $\dot{P}_b^{\rm obs} = (-2.422 \pm 0.006) \times 10^{-12}$), but significant, Newtonian perturbing effect caused by the Galaxy [28], one finds that General Relativity passes this $(k - \gamma_{\rm timing} - \dot{P}_b)_{1913+16}$ test with complete success at the 10^{-3} level [23,25]

$$\begin{bmatrix} \dot{P}_b^{\rm obs} - \dot{P}_b^{\rm galactic} \\ \dot{P}_b^{\rm GR}[k^{\rm obs}, \gamma_{\rm timing}^{\rm obs}] \end{bmatrix}_{1913+16} = 1.0032 \pm 0.0023 (\rm obs) \pm 0.0026 (\rm galactic) \\ = 1.0032 \pm 0.0035 \ . \tag{14.17}$$

Here $\dot{P}_b^{\rm GR}[k^{\rm obs},\gamma_{\rm timing}^{\rm obs}]$ is the result of inserting in $\dot{P}_b^{\rm GR}(m_1,m_2)$ the values of the masses predicted by the two equations $k^{\rm obs}=k^{\rm GR}(m_1,m_2)$, $\gamma_{\rm timing}^{\rm obs}=\gamma_{\rm timing}^{\rm GR}(m_1,m_2)$. This experimental evidence for the reality of gravitational radiation damping forces at the 0.3% level is illustrated in Fig. 14.1, which shows actual orbital phase data (after subtraction of a linear drift).

The discovery of the binary pulsar PSR1534 + 12 [29] has allowed one to measure the four post-Keplerian parameters k, γ_{timing} , r and s, and thereby to obtain two (four observables minus two masses) tests of strong field gravity, without mixing of radiative effects [30]. General Relativity passes these tests within the measurement accuracy [30,23]. The most precise of these new, pure, strong-field tests is the one obtained by combining the measurements of k, γ , and s. Using the data reported in [31], one finds agreement at the 1% level:

$$\left[\frac{s^{\text{obs}}}{s^{\text{GR}}[k^{\text{obs}}, \gamma_{\text{timing}}^{\text{obs}}]}\right]_{1534+12} = 1.010 \pm 0.008 \ . \tag{14.18}$$

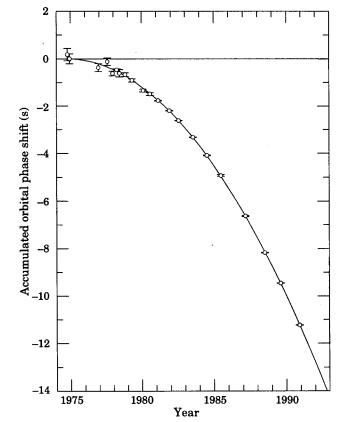

Figure 14.1: Accumulated shift of the times of periastron passage in the PSR 1913+16 system, relative to an assumed orbit with a constant period. The parabolic curve represents the general relativistic prediction, modified by Galactic effects, for orbital period decay from gravitational radiation damping forces. (Figure obtained with permission from Ref. 23.)

Recently, it has been possible to measure the orbital period change of PSR1534 + 12. General Relativity passes the corresponding $(k - \gamma_{\text{timing}} - \dot{P}_b)_{1534+12}$ test with success at the 15% level [32].

Several other binary pulsar systems, of a nonsymmetric type (nearly circular systems made of a neutron star and a white dwarf), can also be used to test relativistic gravity [33,34]. The constraints on tensor-scalar theories provided by three binary-pulsar "experiments" have been analyzed in [27] and shown to exclude a large portion of the parameter space allowed by solar-system tests.

The tests considered above have examined the gravitational interaction on scales between a few centimeters and a few astronomical units. Millimeter scale tests of Newtonian gravity have been reported in Ref. 35. On the other hand, the general relativistic action on light and matter of an external gravitational field on a length scale ~ 100 kpc has been verified to $\sim 30\%$ in some gravitational lensing systems (see, e.g., [36]). Some tests on cosmological scales are also available. In particular, Big Bang Nucleosynthesis (see Section 15 of this Review) has been used to set significant constraints on the variability of the gravitational "constant" [37].

14.4. Conclusions

All present experimental tests are compatible with the predictions of the current "standard" theory of gravitation: Einstein's General Relativity. The universality of the coupling between matter and gravity (Equivalence Principle) has been verified at the 10^{-12} level. Solar system experiments have tested the weak-field predictions of Einstein's theory at the 10^{-3} level. The propagation properties of relativistic gravity, as well as several of its strong-field aspects, have been verified at the 10^{-3} level in binary pulsar experiments. Several important new developments in experimental gravitation are expected in the near future. The approved NASA Gravity Probe B mission

(a space gyroscope experiment; due for launch in 2000) will directly measure the gravitational spin-orbit and spin-spin couplings, thereby measuring the weak-field post-Einstein parameter $\overline{\gamma}$ to the 10^{-5} level (an improvement by two orders of magnitude). The planned NASA-ESA MiniSTEP mission (a satellite test of the Equivalence Principle) should test the universality of acceleration of free fall down to the 10^{-18} level (an improvement by six orders of magnitude). Finally, the various kilometer-size laser interferometers under construction (notably LIGO in the USA and VIRGO in Europe) should, soon after 2000, directly detect gravitational waves arriving on Earth. As the sources of these waves are expected to be extremely relativistic objects with strong internal gravitational fields (e.g., coalescing binary neutron stars, or neutron stars plunging into large black holes), their detection will allow one to experimentally probe gravity in highly dynamical circumstances.

15. BIG-BANG COSMOLOGY

Revised April 1998 by K.A. Olive (University of Minnesota).

At early times, and today on a sufficiently large scale, our Universe is very nearly homogeneous and isotropic. The most general space-time metric for a homogeneous, isotropic space is the Friedmann-Robertson-Walker metric (with c=1) [1,2,3]:

$$ds^{2} = dt^{2} - R^{2}(t) \left[\frac{dr^{2}}{1 - \kappa r^{2}} + r^{2} (d\theta^{2} + \sin^{2}\theta \, d\phi^{2}) \right] . \tag{15.1}$$

R(t) is a scale factor for distances in comoving coordinates. With appropriate rescaling of the corrdinates, κ can be chosen to be +1, -1, or 0, corresponding to closed, open, or spatially flat geometries. Einstein's equations lead to the Friedmann equation

$$H^2 \equiv \left(\frac{\dot{R}}{R}\right)^2 = \frac{8\pi G_N \rho}{3} - \frac{\kappa}{R^2} + \frac{\Lambda}{3} ,$$
 (15.2)

as well as to

$$\frac{\ddot{R}}{R} = \frac{\Lambda}{3} - \frac{4\pi G_N}{3} \ (\rho + 3p) \ , \tag{15.3}$$

where H(t) is the Hubble parameter, ρ is the total mass-energy density, p is the isotropic pressure, and Λ is the cosmological constant. (For limits on Λ , see the Table of Astrophysical Constants; we will assume here $\Lambda=0$.) The Friedmann equation serves to define the density parameter Ω_0 (subscript 0 indicates present-day values):

$$\kappa/R_0^2 = H_0^2(\Omega_0 - 1)$$
, $\Omega_0 = \rho_0/\rho_c$; (15.4)

and the critical density is defined as

$$\rho_{\rm c} \equiv \frac{3H^2}{8\pi G_N} = 1.88 \times 10^{-29} \, h^2 \, {\rm g \, cm}^{-3} \, , \tag{15.5}$$

with

$$H_0 = 100 h_0 \text{ km s}^{-1} \text{ Mpc}^{-1} = h_0/(9.78 \text{ Gyr})$$
. (15.6)

Observational bounds give $0.4 < h_0 < 1$. The three curvature signatures $\kappa = +1, -1$, and 0 correspond to $\Omega_0 > 1$, < 1, and = 1. Knowledge of Ω_0 is even poorer than that of h_0 . Luminous matter (stars and associated material) contribute $\Omega_{lum} \leq 0.01$. There is no lack of evidence for copious amounts of dark matter: rotation curves of spiral galaxies, virial estimates of cluster masses, gravitational lensing by clusters and individual galaxies, and so on. The minimum amount of dark matter required to explain the flat rotation curves of spiral galaxies only amounts to $\Omega_0 \sim 0.1$, while estimates for Ω_0 based upon cluster virial masses suggests $\Omega_0\,\sim\,0.2-0.4.$ The highest estimates for the mass density come from studies of the peculiar motions of galaxies (including our own); estimates for Ω_0 obtained by relating peculiar velocity measurements to the distribution galaxies within a few hundred Mpc approach unity. A conservative range for the mass density is: $0.1 \le \Omega_0 \le 2$. The excess of Ω_0 over Ω_{lum} leads to the inference that most of the matter in the Universe is nonluminous dark matter.

In an expanding universe, the wavelength of light emitted from a distant source is shifted towards the red. The redshift z is defined such that 1+z is the ratio of the detected wavelength (λ) to emitted (laboratory) wavelength (λ_e) of some electromagnetic spectral feature. It follows from the metric given in Eq. (15.1) that

$$1 + z = \lambda/\lambda_{\rm e} = R_0/R_{\rm e} \tag{15.7}$$

where $R_{\rm e}$ is the value of the scale factor at the time the light was emitted. For light emitted in the not too distant past, one can expand $R_{\rm e}$ and write $R_{\rm e} \simeq R_0 + (t_{\rm e} - t_0) \dot{R}_0$. For small (compared to H_0^{-1}) $\Delta t = (t_{\rm e} - t_0)$, Eq. (15.7) takes the form of Hubble's law

$$z \approx \Delta t \frac{\dot{R}_0}{R_0} \approx \ell H_0 , \qquad (15.8)$$

where ℓ is the distance to the source.

Energy conservation implies that

$$\dot{\rho} = -3(\dot{R}/R)(\rho + p) ,$$
 (15.9)

so that for a matter-dominated (p=0) universe $\rho \propto R^{-3}$, while for a radiation-dominated $(p=\rho/3)$ universe $\rho \propto R^{-4}$. Thus the less singular curvature term κ/R^2 in the Friedmann equation can be neglected at early times when R is small. If the Universe expands adiabatically, the entropy per comoving volume $(\equiv R^3 s)$ is constant, where the entropy density is $s=(\rho+p)/T$ and T is temperature. The energy density of radiation can be expressed (with $\hbar=c=1$) as

$$\rho_{\tau} = \frac{\pi^2}{30} N(T)(kT)^4 , \qquad (15.10)$$

where N(T) counts the effectively massless degrees of freedom of bosons and fermions:

$$N(T) = \sum_{R} g_{B} + \frac{7}{8} \sum_{F} g_{F} . \qquad (15.11)$$

For example, for $m_{\mu} > kT > m_e$, $N(T) = g_{\gamma} + 7/8 (g_e + 3g_{\nu}) = 2 + 7/8 [4 + 3(2)] = 43/4$. For $m_{\pi} > kT > m_{\mu}$, N(T) = 57/4. At temperatures less than about 1 MeV, neutrinos have decoupled from the thermal background, i.e., the weak interaction rates are no longer fast enough compared with the expansion rate to keep neutrinos in equilibrium with the remaining thermal bath consisting of γ, e^{\pm} . Furthermore, at temperatures $kT < m_e$, by entropy conservation, the ratio of the neutrino temperature to the photon temperature is given by $(T_{\nu}/T_{\gamma})^3 = g_{\gamma}/(g_{\gamma} + \frac{7}{8}g_e) = 4/11$.

In the early Universe when $\rho \approx \rho_r$, then $\dot{R} \propto 1/R$, so that $R \propto t^{1/2}$ and $Ht \to 1/2$ as $t \to 0$. The time-temperature relationship at very early times can then be found from the above equations:

$$t = \frac{2.42}{\sqrt{N(T)}} \left(\frac{1 \text{ MeV}}{kT}\right)^2 \text{ sec} .$$
 (15.12)

At later times, since the energy density in radiation falls off as R^{-4} and the energy density in non-relativistic matter falls off as R^{-3} , the Universe eventually became matter dominated. The epoch of matter-radiation density equality is determined by equating the matter density at $t_{\rm eq}$, $\rho_m = \Omega_0 \rho_c (R_0/R_{\rm eq})^3$ to the radiation density, $\rho_r = (\pi^2/30)[2 + (21/4)(4/11)^{4/3}](kT_0)^4(R_0/R_{\rm eq})^4$ where T_0 is the present temperature of the microwave background (see below). Solving for $(R_0/R_{\rm eq}) = 1 + z_{\rm eq}$ gives

$$\begin{split} z_{\rm eq} + 1 &= \Omega_0 h_0^2 / 4.2 \times 10^{-5} = 2.4 \times 10^4 \, \Omega_0 h_0^2 \; ; \\ kT_{\rm eq} &= 5.6 \, \Omega_0 h_0^2 \, {\rm eV} \; ; \\ t_{\rm eq} &\approx 0.39 (\Omega_0 H_0^2)^{-1/2} (1 + z_{\rm eq})^{-3/2} \\ &= 3.2 \times 10^{10} (\Omega_0 h_0^2)^{-2} \, {\rm sec} \; . \end{split} \tag{15.13}$$

Prior to this epoch the density was dominated by radiation (relativistic particles; see Eq. (15.10)), and at later epochs matter density dominated. Atoms formed at $z\approx 1300$, and by $z_{\rm dec}\approx 1100$ the free electron density was low enough that space became essentially transparent to photons and matter and radiation were decoupled. These are the photons observed in the microwave background today.

The age of the Universe today, t_0 , is related to both the Hubble parameter and the value of Ω_0 (still assuming that $\Lambda=0$). In the Standard Model, $t_0\gg t_{\rm eq}$ and we can write

$$t_0 = H_0^{-1} \int_0^1 \left(1 - \Omega_0 + \Omega_0 x^{-1} \right)^{-1/2} dx . \tag{15.14}$$

Constraints on t_0 yield constraints on the combination $\Omega_0 h_0^2$. For example, $t_0 \geq 13 \times 10^9$ yr implies that $\Omega_0 h_0^2 \leq 0.25$ for $h_0 \geq 0.5$, or $\Omega_0 h_0^2 \leq 0.45$ for $h_0 \geq 0.4$, while $t_0 \geq 10 \times 10^9$ yr implies that $\Omega_0 h_0^2 \leq 0.8$ for $h_0 \geq 0.5$, or $\Omega_0 h_0^2 \leq 1.1$ for $h_0 \geq 0.4$.

The present temperature of the microwave background is $T_0=2.728\pm0.002$ K as measured by COBE [4], and the number density of photons $n_{\gamma}=(2\zeta(3)/\pi^2)(kT_0)^3\approx412$ cm⁻³. The energy density in photons (for which $g_{\gamma}=2$) is $\rho_{\gamma}=(\pi^2/15)(kT_0)^4$. At the present epoch, $\rho_{\gamma}=4.66\times10^{-34}$ g cm⁻³ = 0.262 eV cm⁻³. For nonrelativistic matter (such as baryons) today, the energy density is $\rho_B=m_Bn_B$ with $n_B\propto R^{-3}$, so that for most of the history of the Universe n_B/s is constant. Today, the entropy density is related to the photon density by $s=(4/3)(\pi^2/30)[2+(21/4)(4/11)](kT_0)^3=7.0\,n_{\gamma}$. Big Bang nucleosynthesis calculations limit $\eta=n_B/n_{\gamma}$ to $2.8\times10^{-10}\leq\eta\leq4.0\times10^{-10}$. The parameter η is also related to the portion of Ω in baryons

$$\Omega_B = 3.67 \times 10^7 \eta \ h_0^{-2} \ (T_0/2.728 \ \text{K})^3 \ ,$$
 (15.15)

so that 0.010 < $\Omega_B \ h_0^2 <$ 0.015, and hence the Universe cannot be closed by baryons.

16. BIG-BANG NUCLEOSYNTHESIS

Revised July 1997 by K.A. Olive (Univ. of Minnesota) and D.N. Schramm (deceased).

Among the successes of the standard big-bang model is the agreement between the predictions of big-bang nucleosynthesis (BBN) for the abundances of the light elements, D, $^3{\rm He},\,^4{\rm He},\,$ and $^7{\rm Li},\,$ and the primordial abundances inferred from observational data (see [1–3] for a more complete discussion). These abundances span some nine orders of magnitude: $^4{\rm He}$ has an abundance by number relative to hydrogen of about 0.08 (accounting for about 25% of the baryonic mass), while $^7{\rm Li},\,$ the least abundant of the elements with a big-bang origin, has a abundance by number relative to hydrogen of about $\sim 10^{-10}$.

16.1. Big-bang nucleosynthesis theory

The BBN theory matches the observationally determined abundances with a single well-defined parameter, the baryon-to-photon ratio, η . All the light-element abundances can be explained with η in the range $(1.5-6.3)\times 10^{-10}$, or $\eta_{10}\equiv \eta\times 10^{10}=1.5-6.3$. Equivalently, this range can be expressed as the allowed range for the baryon mass density, $\rho_B=1.0-4.3\times 10^{-31}$ g cm⁻³, and can be converted to the fraction, Ω , of the critical density, ρ_c .

The synthesis of the light elements was affected by conditions in the early Universe at temperatures $T\lesssim 1$ MeV, corresponding to an age as early as 1 s. At somewhat higher temperatures, weak-interaction rates were in equilibrium, thus fixing the ratio of the neutron and proton number densities. At $T\gg 1$ MeV, $n/p\approx 1$, since the ratio was given approximately by the Saha relation, $n/p\approx e^{-Q/T}$, where Q is the neutron-proton mass difference. As the temperature fell, the Universe approached the point ("freeze-out") where the weak-interaction rates were no longer fast enough to maintain equilibrium. The final abundance of ⁴He is very sensitive to the n/p ratio at freeze-out.

The nucleosynthesis chain begins with the formation of deuterium in the process $pn \to D\gamma$. However, photo-dissociation by the high number density of photons $(n_\gamma/n_B=\eta^{-1}\sim 10^{10})$ delays production of deuterium (and other complex nuclei) well past the point where T reaches the binding energy of deuterium, $E_B=2.2$ MeV. (The average photon energy in a blackbody is $\overline{E}_\gamma\approx 2.7$ T.) When the quantity $\eta^{-1}\exp(-E_B/T)$ reaches about 1 (at $T\approx 0.1$ MeV), the photo-dissociation rate finally falls below the nuclear production rate.

The 25% fraction of mass in ⁴He due to BBN is easily estimated by counting the number of neutrons present when nucleosynthesis begins. When the weak-interaction rates freeze-out at about $T \approx 0.8$ MeV, the n-to-p ratio is about 1/6. When free-neutron decays prior to deuterium formation are taken into account, the ratio drops to $n/p \lesssim 1/7$. Then simple counting yields a primordial ⁴He mass fraction

$$Y_p = \frac{2(n/p)}{1 + n/p} \lesssim 0.25 . {(16.1)}$$

In the Standard Model, the ⁴He mass fraction depends primarily on the baryon-to-photon ratio η , as it is this quantity that determines when nucleosynthesis via deuterium production may begin. But because the n/p ratio depends only weakly on η , the ⁴He mass fraction is relatively flat as a function of η . The effect of the uncertainty in the neutron half-life, $\tau_n=887\pm2$ s, is now small. Lesser amounts of the other light elements are produced: D and ³He at the level of a few times 10^{-5} by number relative to H, and ⁷Li/H at the level of about 10^{-10} , when η is in the range $1-10\times10^{-10}$.

When we go beyond the Standard Model, the ⁴He abundance is very sensitive to changes in the expansion rate, which can be related to the effective number of neutrino flavors. This will be discussed below.

The calculated abundances of the light elements are shown in Fig. 16.1 as a function of η_{10} . The curves for the ⁴He mass fraction, Y_p , bracket the range based on the uncertainty of the neutron mean-life, $\tau_n = 887 \pm 2$ s. The spread in the ⁷Li curves is due to the 1σ uncertainties in nuclear cross sections leading to ⁷Li and ⁷Be which subsequently decays to ⁷Li [4–6]. The uncertainties in the D and ³He

predictions are small and have been neglected here. The boxes show the observed abundances with their range of uncertainty, discussed below. Since the observational boxes line up on top of each other, there is an overall agreement between theory and observations for η_{10} in the range 1.5–6.3.

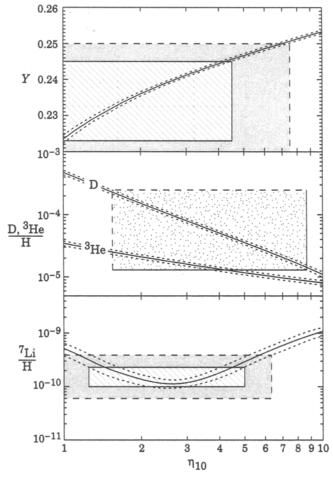

Figure 16.1: The abundances of D, ³He, ⁴He and ⁷Li as predicted by the standard model of big-bang nucleosynthesis. Also shown by a series of boxes is the comparison between these predictions and the observational determination of the light element abundances. See text for details.

16.2. Observations

Because stars produce helium as well as heavier elements, one must search for primordial helium in regions where stellar processing has been minimal, *i.e.*, in regions where abundances of elements such as carbon, nitrogen and oxygen are very low. There are extensive compilations of observed abundances of ⁴He, N, and O in many different extra-galactic regions of ionized H [7-9]. Extrapolating the ⁴He abundances from the data leads to a observational estimate for Y_p of [10-12]

$$Y_p = 0.234 \pm 0.002 \pm 0.005$$
. (16.2)

(Here and elsewhere, the first error is the statistical standard deviation, and the second systematic.) The large box in Fig. 16.1 bracketing the 4 He curves covers the range 0.223 to 0.245, where the half height is given as twice the errors when added in quadrature. There has been some debate on the size of systematic errors [4] and the dashed box is obtained using a larger error, allowing Y_p to take a maximal value of 0.250.

Observations for deuterium and ³He abundances currently present certain difficulties. All deuterium is primordial [13], but some of the primordial deuterium has been destroyed. Thus, as can be seen in the figure, the present deuterium abundance gives us an absolute upper limit to η . However, to get more information requires either an understanding of galactic chemical evolution of deuterium or a direct measurement of primordial deuterium. Even more problematical is ${}^3\text{He}$: Not only is primordial ${}^3\text{He}$ destroyed in stars but it is very likely that at least some low-mass stars are net producers of ${}^3\text{He}$. Neither the galactic chemical evolution of ${}^3\text{He}$ nor the production of ${}^3\text{He}$ in stars is well understood with standard models and observations presenting an inconsistent picture.

It appears that D/H has decreased over the age of the galaxy. Samples obtained deep inside meteorites provide measurements of the true (pre)-solar system abundance of ³He, while measurements on meteoritic near-surface samples, the solar wind, and lunar soil samples also contain ³He converted from deuterium in the early pre-main-sequence stage of the sun. The best current values are [14]

$$\left(\frac{D + {}^{3}\text{He}}{H}\right)_{\odot} = (4.1 \pm 1.0) \times 10^{-5} ,$$

$$\left(\frac{{}^{3}\text{He}}{H}\right)_{\odot} = (1.5 \pm 0.3) \times 10^{-5} . \tag{16.3}$$

The difference between these is the pre-solar D abundance. There has also been a recent measurement of HD in the atmosphere of Jupiter [15] yielding a value D/H = $(5 \pm 2) \times 10^{-5}$. This would be an important measurement if it can be acertained that isotopic fractionation of deuterium did not occur, however, this point is debatable at the present time.

The present interstellar-medium abundance of D/H is [16]

$$D/H = 1.60 \pm 0.09^{+0.05}_{-0.10} \times 10^{-5}$$
. (16.4)

It is this lowest value of D/H that provides the most robust upper bound on η , since D is only destroyed. It is shown (decreased by twice the errors added in quadrature) as the lower right corner of the D and ³He box in Fig. 16.1. Thus, with confidence we can be sure that $\eta_{10} < 9$ And correspondingly $\Omega_B h^2 < 0.033$

Deuterium has also been detected in high-redshift, low-metallicity quasar absorption systems [17-19]. These measured abundances should represent the primordial value, but they are at present not consistent: Two [17,18] give a relatively high value for D/H $\approx 2 \times 10^{-4}$ while the other [19] gives D/H $\approx 2.3 \pm 0.3 \times 10^{-5}$. Although it appears that the quality of the low D/H data is better than those showing high D/H, the latter can be used at the very least as an upper limit to primordial D/H and this is shown by the dashed box in Fig. 16.1. As one can see, the corresponding value of Y_p (at the same value of η as inferred by the observation of a high D/H) is in excellent agreement with the data. 7Li is also acceptable at this value as well. However, due to the still somewhat preliminary status of this observation, it is premature to use it to fix the primordial abundance. A high value for the D abundance would require an even greater degree of D destruction over the age of the galaxy. The lower measurement for D/H requires that systematics work coherently for both ⁴He and ⁷Li to give an overlap with this data. Eventually, the primordial D/H issue will hopefully be resolved and give a correspondingly narrow allowed range in η and perhaps change the nature of the ³He and ⁷Li (see below) arguments which are currently dominated by galactic and/or stellar evolution issuses.

Finally, we turn to ^7Li . In old, hot, population-II stars, ^7Li is found to have a very nearly uniform abundance. For stars with a surface temperature T > 5500 K and a metallicity less than about 1/20th solar (so that effects such as stellar convection may not be important), the abundances show little or no dispersion beyond that consistent with the errors of individual measurements. Much data has been obtained recently from a variety of sources, and the best estimate for the mean ^7Li abundance and its statistical uncertainty in halo stars is [20](the estimate of the systematic uncertainty discussed below is our own)

$$\text{Li/H} = (1.6 \pm 0.1^{+0.4}_{-0.3}^{+1.6}_{-0.5}) \times 10^{-10}$$
. (16.5)

The first error is statistical, and the second is a systematic uncertainty that covers the range of abundances derived by various methods. The

box in Fig. 16.1 corresponds to these errors (as before, with a half height of $2\sigma_{\rm stat} + \sigma_{\rm syst}$). The third set of errors in Eq. (16.5) accounts for the possibility that as much as half of the primordial ⁷Li has been destroyed in stars, and that as much as 30% of the observed ⁷Li was produced in cosmic ray collisions rather than in the Big Bang. These uncertainties are shown by the dashed box in Fig. 16.1. Observations of ⁶Li, Be, and B help constrain the degree to which these effects play a role [21–23].

16.3. A consistent value for η

For the Standard Model of BBN to be deemed successful, theory and observation of the light element abundances must agree using a single value of η . We summarize the constraints on η from each of the light elements. From the ⁴He mass fraction, $Y_p < (0.245-0.250)$, we have $\eta_{10} < (4.5-7.6)$ as a 2σ upper limit (the highest values use possible systematic errors up to their extreme range). Because of the sensitivity to the assumed upper limit on Y_p and Li/H, the upper limit on η from D/H, is still of value. From D/H $> 1.3 \times 10^{-5}$, we have $\eta_{10} \lesssim 9$.

The lower limit on η_{10} can be obtained from either D/H or ⁷Li. From the high D/H measurement in quasar absorption systems, we obtain $\eta_{10} > 1.5$. ⁷Li allows a broad range for η_{10} consistent with the other elements. When uncertainties in the reaction rates and systematic uncertainties in the observed abundances are both taken into account, ⁷Li allows values of η_{10} between (1.0-6.3).

The determination of η depends on our certainty that the observations of the light elements abundances can be translated into primordial abundances. This is perhaps more straightforward for ⁴He and ⁷Li, where the element abundances are determined in primitive low metallicity environments. If it turns out that a consistent value for D/H can be obtained from quasar absorption systems, then because of the slope of D/H with respect to η , D/H will be the best isotopic ratio for the determination of η . Until then, the use of the D and ³He abundance determinations is necessarily complicated by the evolution of the abundances of these elements over the star forming history of the galaxy. Uncertainties in the ³He evolution are compounded by uncertainties of stellar production/destruction mechanisms. The resulting overall consistent range for η_{10} is extended to (1.5-6.3) when systematic errors are pushed to their limits. These bounds on η_{10} constrain the fraction of critical density in baryons, Ω_B , to be

$$0.005 < \Omega_B h_0^2 < 0.024 \tag{16.6}$$

for a Hubble parameter, h_0 , between 0.4 and 1.0. The corresponding range for Ω_B is 0.005–0.15.

Perhaps the best test of BBN will come when anisotropies in the microwave background check the determination of Ω_B . At present, other measurements (such as of hot x-ray gas in clusters of galaxies, Lyman- α clouds, or microwave anisotropies) of Ω_B give considerably larger uncertainties than those from BBN, but they are consistent with the BBN range.

16.4. Beyond the Standard Model

Limits on particle physics beyond the Standard Model come mainly from the observational bounds on the ⁴He abundance. As discussed earlier, the neutron-to-proton ratio is fixed by its equilibrium value at the freeze-out of the weak-interaction rates at a temperature $T_f \sim 1$ MeV, with corrections for free neutron decay. Furthermore, freeze-out is determined by the competition between the weak-interaction rates and the expansion rate of the Universe,

$$G_F^2 T_f^5 \sim \Gamma_{wk}(T_f) = H(T_f) \sim \sqrt{G_N N} T_f^2$$
, (16.7)

where N counts the total (equivalent) number of relativistic particle species. The presence of additional neutrino flavors (or of any other relativistic species) at the time of nucleosynthesis increases the energy density of the Universe and hence the expansion rate, leading to a larger value of T_f , n/p, and ultimately Y_p . It is clear that just as one can place limits [25] on N, any changes in the weak or gravitational coupling constants can be similarly constrained.

In the Standard Model, the number of particle species can be written as $N=5.5+\frac{7}{4}N_{\nu}$; 5.5 accounts for photons and e^{\pm} , and N_{ν} is the number of (massless) neutrino flavors. The helium curves in Fig. 16.1 were computed assuming $N_{\nu}=3$, and the computed ⁴He abundance scales roughly as $\Delta Y_{\rm BBN}\approx 0.012-0.014$ ΔN_{ν} . Clearly the central value for N_{ν} from BBN will depend on η . If the best value for the observed primordial ⁴He abundance is 0.234, then, for $\eta_{10}\sim 1.8$, the central value for N_{ν} is 3. By means of a likelihood analysis on η and N_{ν} based on ⁴He and ⁷Li [24,26], (see also [27]), it was found that the 95% CL ranges are $1.6 \leq N_{\nu} \leq 4.0$, and $1.3 \leq \eta_{10} \leq 5.0$.

The limits on N_{ν} can be translated into limits on other types of particles or particle masses that would affect the expansion rate of the Universe just prior to nucleosynthesis. In some cases, it is the interaction strengths of new particles which are constrained. Particles with less than full weak strength interactions contribute less to the energy density than particles that remain in equilibrium up to the time of nucleosynthesis [28].

We close with a simple example. Suppose there exist three righthanded neutrinos with only right-handed interactions of strength $G_R < G_F$. The standard left-handed neutrinos are no longer in equilibrium at temperatures below ~ 1 MeV. Particles with weaker interactions decouple at higher temperatures, and their number density $(\propto T^3)$ relative to neutrinos is reduced by the annihilations of particles more massive than 1 MeV. If we use the upper bound N_{ν} < 4.0, then the three right-handed neutrinos must have a temperature $3(T_{\nu_R}/T_{\nu_L})^4 < 1$. Since the temperature of the decoupled ν_R 's is determined by entropy conservation, $T_{\nu_R}/T_{\nu_L} = [(43/4)/N(T_f)]^{1/3} < 0.76$, where T_f is the freeze-out temperature of the ν_R 's. Thus $N(T_f) > 24$ and decoupling must have occurred at $T_f > 140$ MeV. Finally, the decoupling temperature is related to G_R by $(G_R/G_F)^2 \sim (T_f/3 \text{ MeV})^{-3}$, where 3 MeV corresponds to the decoupling temperature for ν_L . This yields a limit $G_R \lesssim 10^{-2} G_F$. These limits are strongly dependent on the assumed upper limit to N_{ν} ; for N_{ν} < 3.5, the limit on G_R strengthened to G_R < 0.002 G_F , since T_f is constrained to be larger than the temperature corresponding to the QCD transition in the early Universe.

17. THE HUBBLE CONSTANT

Revised August 1997 by C.J. Hogan (University of Washington).

In a uniform expanding universe, the position r and velocity v of any particle relative to another obey Hubble's relation $v = H_0 r$, where H_0 is Hubble's constant.* As cosmological distances are measured in Mpc, the natural unit for H_0 is km s⁻¹ Mpc⁻¹, which has the dimensions of inverse time: $[100 \text{ km s}^{-1} \text{ Mpc}^{-1}]^{-1} = 9.78 \times 10^9 \text{ yr.}$

The real universe is nonuniform on small scales, and its motion obeys the Hubble relation only as a large scale average. As typical non-Hubble motions ("peculiar velocities") are less than about 500 km s⁻¹, on scales more than about 5,000 km s⁻¹ the deviations from Hubble flow are less than about 10%, so the notion of a global Hubble constant is well defined. The value of H_0 averaged over the local 15,000 km s⁻¹ volume is known to lie within 10% of its global value even if H_0 itself is not known this precisely [1-3].

Measurement of H_0 thus entails measuring large absolute distances. Traditionally, certain astronomical systems ("Standard Candles") are used to measure relative distance, and are tied to an absolute trigonometric parallax scale by a series of distance ratios (or "distance ladder") [4–9]. Several relatively new techniques now allow direct absolute calibration using physical models.

Table 17.1 lists several candles and calibrators with a typical range of distance accessible to each. The ranges are not precisely defined; the near end suffers from small numbers of accessible objects and the far end from faint signal. The precision quoted is in units of astronomical "distance modulus," given by $\mu=5\log_{10}(distance\ in\ parsecs)-5.0$; a ±0.1 magnitude error in magnitude or distance modulus corresponds to a 5% error in distance. In the case of distance ratios the precision is estimated by cross-checking indicators on a galaxy-by-galaxy basis. Some options often used for verification and absolute calibration are listed. The Hubble relation itself is included, as it is the most precise indication of relative distance for large distances, and is used to verify the standardization of several candles.

Table 17.1: Selected extragalactic distance indicators.

Technique	Range of distance	Accuracy (1σ)	Verification/calibration
Cepheids	<lmc 25="" mpc<="" td="" to=""><td>0.15 mag</td><td>LMC/parallax</td></lmc>	0.15 mag	LMC/parallax
SNIa	4 Mpc to > 2 Gpc	0.2 mag	Hubble/Cepheid
EPM/SNII	LMC to 200 Mpc	0.4 mag	Hubble/Cepheid
PNLF	LMC to 20 Mpc	0.1 mag	SBF/Cepheid
SBF	1 Mpc to 100 Mpc	0.1 mag	PNLF/Cepheid
TF	1 Mpc to 100 Mpc	0.3 mag	Hubble/Cepheid
BCG	50 Mpc to 1 Gpc	0.3 mag	Hubble/SBF
GCLF	1 Mpc to 100 Mpc	0.4 mag	SBF/MWG
SZ	100 Mpc to > 1 Gpc	0.4 mag	Hubble/Model
$_{ m GL}$	∼5 Gpc	0.4 mag	Model
Hubble	20 Mpc to ≳1Gpc	500 km s ⁻¹ ÷ H_0D	BCG, SNeIa/ H_0

MWG = Milky Way Galaxy †Extracted from [4-9].

17.1. Calibration of Cepheid variables

Using stars as standard candles and the Earth's orbit as a baseline, distances in the nearby Galaxy are tied directly to trigonometric parallax measurements. With the release in 1997 of the first results of the Hipparcos satellite, the range, precision, and size of calibrating samples have greatly improved. The early recalibrations of the absolute scale of the Galaxy indicate an increase in the distance scale for Cepheid variables which propagates to all larger scale measurements, reducing previous measurements of H_0 by 0.1 to 0.2 mag [10,11]. (Note that the RRLyrae distance scale, used to calibrate the distances to old globular clusters within the Galaxy, has also increased [12], which increases the stellar brightness and decreases

their estimated age, possibly reconciling the cosmic age and Hubble parameter for a wider range of cosmological models [11,13].) The revised distance scale however would also increase the distance to the Large Magellanic Cloud (LMC) which is constrained by geometrical arguments from SN 1987A [14]. Another promising method is based on detailed knowledge of orbits of gas in N4258 precisely constrained by observations of maser gas emission. This has the potential to calibrate the Cepheid scale independently [23].

The best studied and most trusted of the absolute calibrators, Cepheids are bright stars undergoing overstable oscillations driven by the variation of helium opacity with temperature. The period of oscillation is tightly correlated with the absolute brightness of the star, though this "period-luminosity relation" [15] may vary with metallicity [16,17]. With Hubble Space Telescope (HST), Cepheids are now measured in over a dozen galaxies out to 25 Mpc ($\mu=32$) allowing direct absolute calibration of many other indicators to better than 10% accuracy [18–22].

17.2. Type Ia supernovae (SNIa)

A SNIa occurs when a degenerate dwarf, of the order of a solar mass and of CNO composition, undergoes explosive detonation or deflagration by nuclear burning to iron-group elements (Ni, Co, Fe). Their uniformity arises because the degenerate material only becomes unstable when it is gravitationally compressed to where the electrons become close to relativistic, which requires approximately a Chandrasekhar mass (1.4 solar masses). Theoretical models of the explosion predict approximately the right peak brightness, but cannot give a precise calibration. SNIa are very bright, so their brightness distribution can be studied using the distant Hubble flow as a reference. Indeed, the Hubble diagram of distant SNIa shows that they can yield remarkably precise relative distances; even though they display large variations in brightness, with detailed knowledge of the shape of the light curve and colors, the relative intrinsic brightness of a single SNIa can be predicted to $\Delta m \simeq 0.2$ mag and its distance estimated to $\simeq 10\%$ accuracy [24-26]. Distant SNIa constrain the global deviations from a linear Hubble law including those from cosmic deceleration [27-28].

17.3. Type II supernovae (SNII)

A SNII occurs when a massive star has accumulated 1.4 solar masses of iron group elements in its core; there is then no source of nuclear energy and the core collapses by the Chandrasekhar instability. The collapse to a neutron star releases a large gravitational binding energy, some of which powers an explosion. The large variety of envelopes around collapsing cores means that SNII are not at all uniform in their properties. However, their distances can be calibrated absolutely by the fairly reliable "expanding photosphere method" (EPM). In principle the spectral temperature and absolute flux yield the source angular size; spectral lines yield the expansion velocity, which combined with elapsed time gives a physical size; and the two sizes yield a distance. Models of real photospheres are not so simple but yield individual distances accurate to about 20% [29]. This is in principle an independent absolute distance, but is verified by comparison with Cepheids in several cases, the distant Hubble diagram and Tully-Fisher distance ratios in several others, and by multiple-epoch fits of the same object.

17.4. Planetary nebula luminosity function (PNLF)

A planetary nebula (PN) forms when the gaseous envelope is ejected from a low-mass star as its core collapses to a white dwarf. We see bright fluorescent radiation from the ejected gas shell, excited by UV light from the hot proto-white dwarf. The line radiation makes PN's easy to find and measure even in far-away galaxies; a bright galaxy can have tens of thousands, of which hundreds are bright enough to use to construct a PNLF. It is found empirically that the range of PN brightnesses has a sharp upper cutoff possibly as a consequence of the very narrow range in core masses that result from normal stellar evolution. The cutoff appears to provide a good empirical standard candle [30], verified by comparison with SBF distance ratios.

17.5. Surface brightness fluctuations (SBF)

In images of galaxies, individual stars are generally too crowded to resolve. However, with modern linear detectors, it is still possible to measure the moments of the distribution of stellar brightness in a population (in particular, the brightness-weighted average stellar brightness) from surface brightness fluctuations. Stellar populations in elliptical galaxies appear to be universal enough for this to be one of the most precise standard candles, as verified by comparison with PNLF and Cepheids, although absolute calibration must be done on the bulge components of spiral galaxies. With HST data it can now be applied into the far Hubble flow [31–32].

17.6. Tully-Fisher (TF) and diameter-dispersion $(D_n-\sigma)$

The TF relation refers to a correlation of the properties of whole spiral galaxies, between rotational velocity and total luminosity. In rough terms, the relation can be understood as a relation between mass and luminosity, but given the variation in structural properties and stellar populations the narrow relation is a surprisingly good relative distance indicator. The TF distance ratios and precision have been verified by cross-checking against all of the above methods, and against the Hubble flow, particularly galaxy cluster averages, which permit greater precision. HST has permitted absolute calibration of TF in a larger, more representative, and more distant sample, including galaxies in the Virgo and Fornax clusters [33]. For elliptical galaxies, a similar relation (" D_n - σ ") is particularly useful for verifying distance ratios of galaxy clusters, whose cores contain almost no spirals.

17.7. Brightest cluster galaxies (BCG)

As a result of agglomeration, rich clusters of galaxies have accumulated the largest and brightest galaxies in the universe in their centers, which are remarkably homogenous. They provide a check on the approach to uniform Hubble flow on large scales [2-3] and are now tied to an absolute scale via SBF [34].

17.8. Globular cluster luminosity function (GCLF)

Many galaxies have systems of globular clusters orbiting them, each of which contain hundreds of thousands of stars and hence is visible at large distances. Empirically it appears that similar galaxies have similar distributions of globular cluster luminosity [35]

17.9. Sunyaev-Zeldovich effect (SZ)

The electron density and temperature of the hot plasma in a cluster of galaxies can be measured in two ways which depend differently on distance: the thermal x-ray emission, which is mostly bremsstrahlung by hot electrons, and the Sunyaev-Zeldovich effect on the microwave background, caused by Compton scattering off the same electrons. This provides in principle an absolute calibration. Although the model has other unconstrained parameters, such as the gas geometry, which limit the precision and reliability of distances, in the handful of cases which have been studied most recently the distances are broadly in accord with those obtained by the other techniques. [36–38]

17.10. Gravitational lenses (GL)

The time delay δt between different images of a high redshift gravitationally lensed quasar is $\delta t = C\delta\theta^2/H_0\approx 1$ yr for image separations $\delta\theta$ of the order of arcseconds, with a numerical factor C typically of order unity determined by the specific lens geometry (the angular distribution of the lensing matter) and background cosmology. Variability of the double quasar 0957+561 has permitted measurements of δt from time series correlation, 417 ± 3 days [39-40], with well controlled theoretical errors in deriving constraints on H_0 [41]; measurements of other lens systems are also improving [42]. It is an amazing sanity check that this technique, which relies on no other intermediate steps for its calibration, gives estimates on the scale of the Hubble length which are consistent with local measures of H_0 .

Table 17.2: Some recent estimates of Hubble's constant

Technique	Calibration*	Ties to Hubble flow	Result* $(\text{km s}^{-1} \text{ Mpc}^{-1})$	Ref.
EPM	EPM model, Cepheids	Direct EPM Hubble Diagram + Flow model or TF	73 ± 6 ± 7	[29,19]
SNeIa	Host galaxy Cepheids	Direct SNIa Hubble Diagram	63 ± 3.4 58 ± 8	[25] [21]
Clusters	Virgo mean (M100 Cepheids) + local + M101 Cepheids	Virgo infall model Virgo/Coma ratio Cluster TF + LS flow model fit	$81 \pm 11^{\dagger}$ $73-77 \pm 10^{\dagger}$ $82 \pm 11^{\dagger}$	[19] [19] [19]
	M96 Cepheids	LeoI to Virgo and Coma	69 ± 8	[22]
Field TF	Local Cepheids	Field TF Hubble Diagram + Malmquist bias correction	80 ± 10	[43]
BCG	SBF, Cepheids	BCG	82 ± 8	[34]
SZ	SZ model + X-ray maps + SZ maps	Single cluster velocities A478,A2142,A2256 Coma	54 ± 14 74 ± 29	[38] [37]
GL	Lens model, time delay	Direct, Q0957+561	63 ± 12	[40]

^{*} For all methods except SZ and GL, add a common multiplicative error of ± 0.15 mag or 7% in H_0 for absolute calibration of Cepheids. These values assume the pre-Hipparcos calibration of the Cepheid PL relation.

[†] Plus Virgo depth uncertainty (scales with M100/Virgo ratio).

17.11. Estimates of H_0

The central idea is to find "landmark" systems whose distance is given by more than one technique. The number of techniques and the range of each has now increased enough for reliable overlapping calibration at each stage of the distance scale. The reason for the diversity of estimates of the Hubble constant lies in the many different ways to combine these techniques to obtain an absolute distance calibration in the Hubble flow. There is now broad agreement within the errors among a wide variety of semi-independent ladders with different systematics. As examples, we cite a variety of (somewhat arbitrarily chosen) independent methods, which illustrate some of the choices and tradeoffs, summarized in Table 17.2. Note that most of the quoted values depend in common on the absolute Cepheid calibration.

- 1. Expanding photosphere method (EPM) distances give an absolute calibration to objects in the distant Hubble flow. A small sample of these direct distances with small flow corrections gives $H_0=73\pm6$ (statistical) ±7 (systematic).The distance estimates and limits on the systematic error component are verified by Cepheid distances in three cases, where the Cepheid/EPM distances come out to 1.02 ± 0.08 (LMC), $1.01^{+0.23}_{-0.17}$ (M101) and 1.13 ± 0.28 (M100).
- 2. With HST, it is now possible to calibrate SNIa directly with Cepheid distances to host galaxies. The light from brighter SNIa decays more slowly than from faint ones, so the best fits to the distant Hubble diagram include information about the light curve shape rather than simply assuming uniformity.
- 3. The distance to Virgo or any other local cluster is tied to H_0 via the distant Hubble diagram for TF or D_n - σ distances for galaxies in distant clusters. This can be done with a large scale flow model fit to many clusters or using the distance ratio to a fiducial reference such as the Coma cluster.
- 4. TF comparison with distant field galaxies in the Hubble flow (after corrections for Malmquist bias in the samples, which is worse than in cluster samples) yield $H_0 = 80 \pm 10 \; \mathrm{km \; s^{-1} \; Mpc^{-1}}$.
- 5. The distant BCG sample is now calibrated with SBF directly.
- Recent SZ and GL estimates lie squarely in the range of the other techniques and are completely independent of them, although errors are not yet well constrained with such small samples.

The central values by most reliably calibrated methods lie in the range $H_0=60$ to $80~{\rm km~s^{-1}~Mpc^{-1}}$, and indeed this corresponds roughly with the range of estimates expected from the internally estimated errors. Thus systematic errors are at least not overwhelming, although there are still discrepencies which are not understood.

18. DARK MATTER

Revised Oct. 1997 by M. Srednicki (University of California, Santa Barbara).

There is strong evidence from a variety of different observations for a large amount of dark matter in the universe [1]. The phrase "dark matter" means matter whose existence has been inferred only through its gravitational effects. There is also extensive circumstantial evidence that at least some of this dark matter is nonbaryonic: that is, composed of elementary particles other than protons, neutrons, and electrons. These particles must have survived from the Big Bang, and therefore must either be stable or have lifetimes in excess of the current age of the universe.

The abundance of dark matter is usually quoted in terms of its mass density $\rho_{\rm dm}$ in units of the critical density, $\Omega_{\rm dm}=\rho_{\rm dm}/\rho_{\rm c}$; the critical density $\rho_{\rm c}$ is defined in Eq. (15.5) (in Section 15 on "Big-Bang Cosmology" in this *Review*). The total amount of visible matter (that is, matter whose existence is inferred from its emission or absorption of photons) is roughly $\Omega_{\rm vis}\simeq 0.005$, with an uncertainty of at least a factor of two.

The strongest evidence for dark matter is from the rotation curves of spiral galaxies [1,2]. In these observations, the circular velocity v_c of hydrogen clouds surrounding the galaxy is measured (via Doppler shift) as a function of radius r. If there were no dark matter, at large rwe would find $v_c^2 \simeq G_N M_{\rm vis}/r$, since the visible mass $M_{\rm vis}$ of a spiral galaxy is concentrated at its center. However, observations of many spiral galaxies instead find a velocity v_c which is independent of r at large r, with a typical value $v_c \sim 200 \, \mathrm{km \ s^{-1}}$. Such a "flat rotation curve" implies that the total mass within radius r grows linearly with $r,\,M_{
m tot}(r)\simeq G_N^{-1}v_{
m c}^2r.\,$ A self-gravitating ball of ideal gas at a uniform temperature of $kT = \frac{1}{2}m_{\rm dm}v_{\rm c}^2$ would have this mass profile; here $m_{
m dm}$ is the mass of one dark matter particle. The rotation curves are measured out to some tens of kiloparsecs, implying a total mass within this radius which is typically about ten times the visible mass. This would imply $\Omega_{\rm dm} \gtrsim 10\,\Omega_{\rm vis}\,\simeq\,0.05.$ In our own galaxy, estimates of the local density of dark matter typically give $ho_{
m dm} \simeq 0.3\,{
m GeV}~{
m cm}^{-3},$ but this result depends sensitively on how the halo of dark matter is

Other indications of the presence of dark matter come from observations of the motion of galaxies and hot gas in clusters of galaxies [3]. The overall result is that $\Omega_{dm}\sim 0.2$. Studies of large-scale velocity fields result in $\Omega_{dm}\gtrsim 0.3$ [4]. However, these methods of determining Ω_{dm} require some astrophysical assumptions about how galaxies form.

None of these observations give us any direct indication of the nature of the dark matter. If it is baryonic, the forms it can take are severely restricted, since most forms of ordinary matter readily emit and absorb photons in at least one observable frequency band [5]. Possible exceptions include remnants (white dwarfs, neutron stars, black holes) of an early generation of massive stars, or smaller objects which never initiated nuclear burning (and would therefore have masses less than about $0.1\,M_\odot$). These massive compact halo objects are collectively called machos. Results from one of the ongoing searches for machos via gravitational lensing effects [6] indicate that a significant fraction (roughly 20% to 60%, depending on the details of the model of the galaxy which is assumed) of the mass of our galaxy's halo is composed of machos.

There are, also, several indirect arguments which argue for a substantial amount of nonbaryonic dark matter. First, nucleosynthesis gives the limits $0.010 \le \Omega_{\rm b} h_0^2 \le 0.016$ for the total mass of baryons; h_0 is defined in Eq. (15.6) (in Section 15 on "Big-Bang Cosmology" in this Review). The upper limit on $\Omega_{\rm b}$ is substantially below the value $\Omega_{\rm dm} \gtrsim 0.3$ given by large scale measurements, even if h_0 is near the lower end of its optimistically allowed range, $0.4 \le h_0 \le 1.0$. A second, purely theoretical argument is that inflationary models (widely regarded as providing explanations of a number of otherwise puzzling paradoxes) generically predict $\Omega_{\rm total} = 1$. Finally, it is difficult to construct a model of galaxy formation without nonbaryonic dark matter that predicts sufficiently small fluctuations in the cosmic microwave background radiation [7].

For purposes of galaxy formation models, nonbaryonic dark matter is classified as "hot" or "cold," depending on whether the dark matter particles were relativistic or nonrelativistic at the time when the horizon of the universe enclosed enough matter to form a galaxy. If the dark matter particles are in thermal equilibrium with the baryons and radiation, then only the mass of a dark matter particle is relevant to knowing whether the dark matter is hot or cold, with the dividing line being $m_{\rm dm} \sim 1 \, {\rm keV}$. In addition, specifying a model requires giving the power spectrum of initial density fluctuations. Inflationary models generically predict a power spectrum which is nearly scale invariant. Given this, models with only cold dark matter are much more successful than models with only hot dark matter at reproducing the observed structure of our universe, but there are still serious discrepancies [8]. Some of the suggestions proposed to alleviate these include a nonzero value of the cosmological constant A [9], significant deviations from scale invariance in the spectrum of initial fluctuations [10], and a mixture of both hot and cold dark matter [11]. Another class of models uses mass fluctuations due to topological defects [12].

The best candidate for hot dark matter is one of the three neutrinos, endowed with a Majorana mass m_{ν} . Such a neutrino would contribute $\Omega_{\nu} = 0.56\,G_N\,T_0^3\,H_0^{-2}m_{\nu} = m_{\nu}/(92\,h_0^2\,\mathrm{eV})$, where T_0 is the present temperature of the cosmic microwave background radiation. There is another constraint on neutrinos (or any light fermions) if they are to comprise the halos of dwarf galaxies: the Fermi-Dirac distribution in phase space restricts the number of neutrinos that can be put into a halo [13], and this implies a lower limit on the neutrino mass of $m_{\nu} \gtrsim 80\,\mathrm{eV}$.

There are no presently known particles which could be cold dark matter. However, many proposed extensions of the Standard Model predict a stable (or sufficiently long-lived) particle. The key question then becomes the predicted value of $\Omega_{\rm dm}$.

If the particle is its own antiparticle (or there are particles and antiparticles present in equal numbers), and these particles were in thermal equilibrium with radiation at least until they became nonrelativistic, then their relic abundance is determined by their annihilation cross section $\sigma_{\rm ann}\colon\Omega_{\rm dm}\sim G_N^{3/2}T_0^3H_0^{-2}\langle\sigma_{\rm ann}v_{\rm rel}\rangle^{-1}$. Here $v_{\rm rel}$ is the relative velocity of the two incoming dark matter particles, and the angle brackets denote an averaging over a thermal distribution of velocities for each at the freezeout temperature $T_{\rm fr}$ when the dark matter particles go out of thermal equilibrium with radiation; typically $T_{\rm fr}\simeq\frac{1}{20}m_{\rm dm}$. One then finds (putting in appropriate numerical factors) that $\Omega_{\rm dm}h_0^2\simeq 3\times 10^{-27}\,{\rm cm}^3\,{\rm s}^{-1}/\langle\sigma_{\rm ann}v_{\rm rel}\rangle$. The value of $\langle\sigma_{\rm ann}v_{\rm rel}\rangle$ needed for $\Omega_{\rm dm}\simeq 1$ is remarkably close to what one would expect for a weakly interacting massive particle (wimp) with a mass of $m_{\rm dm}=100\,{\rm GeV}$: $\langle\sigma_{\rm ann}v_{\rm rel}\rangle\sim\alpha^2/8\pi m_{\rm dm}^2\sim 3\times 10^{-27}\,{\rm cm}^3\,{\rm s}^{-1}$.

If the dark matter particle is not its own antiparticle, and the number of particles minus antiparticles is conserved, then an initial asymmetry in the abundances of particles and antiparticles will be preserved, and can give relic abundances much larger than those predicted above.

If the dark matter particles were never in thermal equilibrium with radiation, then their abundance today must be calculated in some other way, and will in general depend on the precise initial conditions which are assumed.

The two best known and most studied cold dark matter candidates are the neutralino and the axion. The neutralino is predicted by supersymmetric extensions of the Standard Model [14,15]. It qualifies as a wimp, with a theoretically expected mass in the range of tens to hundreds of GeV. The axion is predicted by extensions of the Standard Model which resolve the strong CP problem [16]. Its mass must be approximately $10^{-5}\,\mathrm{eV}$ if it is to be a significant component of the dark matter. Axions can occur in the early universe form of a Bose condensate which never comes into thermal equilibrium. The axions in this condensate are always nonrelativistic, and can be a significant component of the dark matter if the axion mass is approximately $10^{-5}\,\mathrm{eV}$.

There are prospects for direct experimental detection of both these candidates (and other wimp candidates as well). Wimps will scatter off nuclei at a calculable rate, and produce observable nuclear recoils [15,17]. This technique has been used to show that all the dark matter cannot consist of massive Dirac neutrinos or scalar neutrinos (predicted by supersymmetric models) with masses in the range of $10~{\rm GeV} \lesssim m_{\rm dm} \lesssim 4~{\rm TeV}$ [18]. The neutralino is harder to detect because its scattering cross section with nuclei is considerably smaller. Condensed axions can be detected by axion to photon conversion in an inhomogeneous magnetic field, and limits on the allowed axion-photon coupling (for certain ranges of the axion mass) have been set [16]. Both types of detection experiments are continuing.

Wimp candidates can have indirect signatures as well, via presentday annihilations into particles which can be detected as cosmic rays [15]. The most promising possibility arises from the fact that wimps collect at the centers of the sun and the earth, thus greatly increasing their annihilation rate, and producing high energy neutrinos which can escape and arrive at the earth's surface in potentially observable numbers.

19. COSMIC BACKGROUND RADIATION

Revised April 1998 by G.F. Smoot (LBNL) and D. Scott (University of British Columbia).

19.1. Introduction

The observed cosmic microwave background (CMB) radiation provides strong evidence for the hot big bang. The success of primordial nucleosynthesis calculations (see Sec. 16, "Big-bang nucleosynthesis") requires a cosmic background radiation (CBR) characterized by a temperature $kT \sim 1\,\mathrm{MeV}$ at a redshift of $z \simeq 10^9$. In their pioneering work, Gamow, Alpher, and Herman [1] realized this and predicted the existence of a faint residual relic, primordial radiation, with a present temperature of a few degrees. The observed CMB is interpreted as the current manifestation of the required CBR.

The CMB was serendipitously discovered by Penzias and Wilson [2] in 1965. Its spectrum is well characterized by a $2.73\pm0.01\,\mathrm{K}$ black-body (Planckian) spectrum over more than three decades in frequency (see Fig. 19.1). A non-interacting Planckian distribution of temperature T_i at redshift z_i transforms with the universal expansion to another Planckian distribution at redshift z_r with temperature $T_r/(1+z_r)=T_i/(1+z_i)$. Hence thermal equilibrium, once established (e.g. at the nucleosynthesis epoch), is preserved by the expansion, in spite of the fact that photons decoupled from matter at early times. Because there are about 10^9 photons per nucleon, the transition from the ionized primordial plasma to neutral atoms at $z\sim1000$ does not significantly alter the CBR spectrum [3].

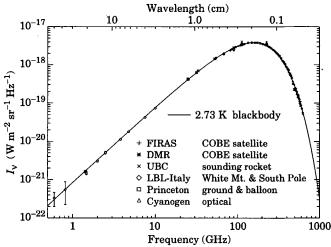

Figure 19.1: Precise measurements of the CMB spectrum. The line represents a 2.73 K blackbody, which describes the spectrum very well, especially around the peak of intensity. The spectrum is less well constrained at 10 cm and longer wavelengths. (References for this figure are at the end of this section under "CMB Spectrum References.")

19.2. The CMB frequency spectrum

The remarkable precision with which the CMB spectrum is fitted by a Planckian distribution provides limits on possible energy releases in the early Universe, at roughly the fractional level of 10^{-4} of the CBR energy, for redshifts $\lesssim 10^7$ (corresponding to epochs $\gtrsim 1\,\text{year}$). The following three important classes of theoretical spectral distortions (see Fig. 19.2) generally correspond to energy releases at different epochs. The distortion results from the CBR photon interactions with a hot electron gas at temperature T_e .

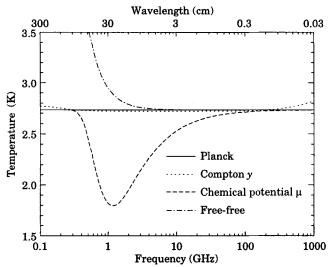

Figure 19.2: The shapes of expected, but so far unobserved, CMB distortions, resulting from energy-releasing processes at different epochs.

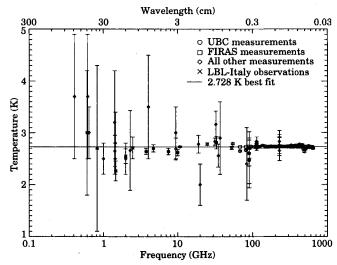

Figure 19.3: Observed thermodynamic temperature as a function frequency.

19.2.1. Compton distortion: Late energy release $(z \lesssim 10^5)$. Compton scattering $(\gamma e \to \gamma' e')$ of the CBR photons by a hot electron gas creates spectral distortions by transfering energy from the electrons to the photons. Compton scattering cannot achieve thermal equilibrium for y < 1, where

$$y = \int_0^z \frac{kT_e(z') - kT_{\gamma}(z')}{m_e c^2} \sigma_T n_e(z') c \frac{dt}{dz'} dz', \qquad (19.1)$$

is the integral of the number of interactions, $\sigma_T n_e(z) c dt$, times the mean-fractional photon-energy change per collision [4]. For $T_e \gg T_\gamma$ y is also proportional to the integral of the electron pressure $n_e k T_e$ along the line of sight. For standard thermal histories y < 1 for epochs later than $z \simeq 10^5$.

The resulting CMB distortion is a temperature decrement

$$\Delta T_{\rm RJ} = -2y \, T_{\gamma} \tag{19.2}$$

in the Rayleigh-Jeans $(h\nu/kT\ll 1)$ portion of the spectrum, and a rapid rise in temperature in the Wien $(h\nu/kT\gg 1)$ region, *i.e.* photons are shifted from low to high frequencies. The magnitude of the distortion is related to the total energy transfer [4] ΔE by

$$\Delta E/E_{\rm CBR} = e^{4y} - 1 \simeq 4y \ . \tag{19.3}$$

A prime candidate for producing a Comptonized spectrum is a hot intergalactic medium. A hot $(T_c>10^5\,\mathrm{K})$ medium in clusters of galaxies can and does produce a partially Comptonized spectrum as seen through the cluster, known as the Sunyaev-Zel'dovich effect. Based upon X-ray data, the predicted large angular scale total combined effect of the hot intracluster medium should produce $y\lesssim 10^{-6}$ [5].

19.2.2. Bose-Einstein or chemical potential distortion: Early energy release ($z \sim 10^5-10^7$). After many Compton scatterings (y > 1), the photons and electrons will reach statistical (not thermodynamic) equilibrium, because Compton scattering conserves photon number. This equilibrium is described by the Bose-Einstein distribution with non-zero chemical potential:

$$n = \frac{1}{e^{x+\mu_0}-1} \,, \tag{19.4}$$

where $x \equiv h\nu/kT$ and $\mu_0 \simeq 1.4~\Delta E/E_{\rm CBR}$, with μ_0 being the dimensionless chemical potential that is required.

The collisions of electrons with nuclei in the plasma produce free-free (thermal bremsstrahlung) radiation: $eZ \rightarrow eZ\gamma$. Free-free emission thermalizes the spectrum to the plasma temperature at long wavelengths. Including this effect, the chemical potential becomes frequency-dependent,

$$\mu(x) = \mu_0 e^{-2x_b/x} , \qquad (19.5)$$

where x_b is the transition frequency at which Compton scattering of photons to higher frequencies is balanced by free-free creation of new photons. The resulting spectrum has a sharp drop in brightness temperature at centimeter wavelengths [6]. The minimum wavelength is determined by Ω_B .

The equilibrium Bose-Einstein distribution results from the oldest non-equilibrium processes ($10^5 < z < 10^7$), such as the decay of relic particles or primordial inhomogeneities. Note that free-free emission (thermal bremsstrahlung) and radiative-Compton scattering effectively erase any distortions [7] to a Planckian spectrum for epochs earlier than $z \sim 10^7$.

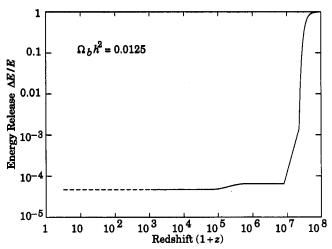

Figure 19.4: Upper Limits (95% CL) on fractional energy $(\Delta E/E_{\rm CBR})$ releases from processes at different epochs as set by resulting lack of CMB spectral distortions. These can be translated into constraints on the mass, lifetime and photon branching ratio of unstable relic particles, with some additional dependence on cosmological parameters such as Ω_B [9,10].

19.2.3. Free-free distortion: Very late energy release $(z \ll 10^3)$. Free-free emission can create rather than erase spectral distortion in the late Universe, for recent reionization $(z < 10^3)$ and from a warm intergalactic medium. The distortion arises because of the lack of Comptonization at recent epochs. The effect on the present-day CMB spectrum is described by

$$\Delta T_{ff} = T_{\gamma} Y_{ff}/x^2, \tag{19.6}$$

where T_{γ} is the undistorted photon temperature, x is the dimensionless frequency, and Y_{ff}/x^2 is the optical depth to free-free emission:

$$Y_{ff} = \int_0^z \frac{T_e(z') - T_{\gamma}(z')}{T_e(z')} \frac{8\pi e^6 h^2 n_e^2 g}{3m_e (kT_{\gamma})^3 \sqrt{6\pi m_e kT_e}} \frac{dt}{dz'} dz' . \quad (19.7)$$

Here h is Planck's constant, n_c is the electron density and g is the Gaunt factor [8].

19.2.4. Spectrum summary: The CMB spectrum is consistent with a blackbody spectrum over more than three decades of frequency around the peak. A least-squares fit to all CMB measurements yields:

$$\begin{split} T_{\gamma} &= 2.728 \pm 0.002 \text{ K} &\quad (1\sigma \text{ error}) \\ n_{\gamma} &= (2\zeta(3)/\pi^2)T_{\gamma}^3 \simeq 412 \text{ cm}^{-3} \\ \rho_{\gamma} &= (\pi^2/15)T_{\gamma}^4 \simeq 4.68 \times 10^{-34} \text{ g cm}^{-3} \simeq 0.262 \text{ eV cm}^{-3} \\ |y| &< 1.2 \times 10^{-5} &\quad (95\% \text{ CL}) \\ |\mu_{0}| &< 9 \times 10^{-5} &\quad (95\% \text{ CL}) \\ |Y_{ff}| &< 1.9 \times 10^{-5} &\quad (95\% \text{ CL}) \end{split}$$

The limits here [11] correspond to limits [11–13] on energetic processes $\Delta E/E_{\rm CBR} < 2 \times 10^{-4}$ occurring between redshifts 10^3 and 5×10^6 (see Fig. 19.4). The best-fit temperature from the COBE FIRAS experiment is $T_{\gamma} = 2.728 \pm 0.002$ K [11].

19.3. Deviations from isotropy

Penzias and Wilson reported that the CMB was isotropic and unpolarized to the 10% level. Current observations show that the CMB is unpolarized at the 10^{-5} level but has a dipole anisotropy at the 10^{-3} level, with smaller-scale anisotropies at the 10^{-5} level. Standard theories predict anisotropies in linear polarization well below currently achievable levels, but temperature anisotropies of roughly the amplitude now being detected.

It is customary to express the CMB temperature anisotropies on the sky in a spherical harmonic expansion,

$$\frac{\Delta T}{T}(\theta,\phi) = \sum_{\ell m} a_{\ell m} Y_{\ell m}(\theta,\phi) , \qquad (19.8)$$

and to discuss the various multipole amplitudes. The power at a given angular scale is roughly $\ell \sum_m |a_{\ell m}|^2/4\pi$, with $\ell \sim 1/\theta$.

19.3.1. The dipole: The largest anisotropy is in the $\ell=1$ (dipole) first spherical harmonic, with amplitude at the level of $\Delta T/T=1.23\times 10^{-3}$. The dipole is interpreted as the result of the Doppler shift caused by the solar system motion relative to the nearly isotropic blackbody field. The motion of the observer (receiver) with velocity $\beta=v/c$ relative to an isotropic Planckian radiation field of temperature T_0 produces a Doppler-shifted temperature

$$T(\theta) = T_0 (1 - \beta^2)^{1/2} / (1 - \beta \cos \theta)$$

= $T_0 \left(1 + \beta \cos \theta + (\beta^2/2) \cos 2\theta + O(\beta^3) \right)$. (19.9)

The implied velocity [11,14] for the solar-system barycenter is $\beta=0.001236\pm0.000002$ (68% CL) or $v=371\pm0.5~{\rm km\,s^{-1}}$, assuming a value $T_0=2.728\pm0.002~{\rm K}$, towards $(\alpha,\delta)=(11.20^{\rm h}\pm0.01^{\rm h},-7.22^{\rm o}\pm0.08^{\rm o})$, or $(\ell,b)=(264.31^{\rm o}\pm0.17^{\rm o},48.05^{\rm o}\pm0.10^{\rm o})$. Such a solar-system velocity implies a velocity for the Galaxy and the Local Group of galaxies relative to the CMB. The derived velocity is $v_{\rm LG}=627\pm22~{\rm km\,s^{-1}}$

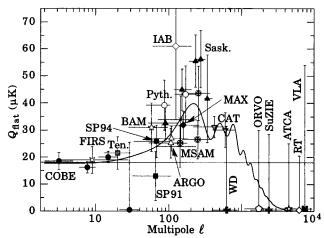

Figure 19.5: Current status of CMB anisotropy observations, adapted from Scott, Silk, & White (1995) [18]. This is a representation of the results from COBE, together with a wide range of ground- and balloon-based experiments which have operated in the last few years. Plotted are the quadrupole amplitudes for a flat (unprocessed scale-invariant spectrum of primordial perturbations, i.e., a horizontal line) anisotropy spectrum that would give the observed results for each experiment. In other words each point is the normalization of a flat spectrum derived from the individual experiments. The vertical error bars represent estimates of 68% CL, while the upper limits are at 95% CL. Horizontal bars indicate the range of ℓ values sampled. The curve indicates the expected spectrum for a standard CDM model ($\Omega_0 = 1, \Omega_B = 0.05, h = 0.5$), although true comparison with models should involve convolution of this curve with each experimental filter function. The dashed line is the best fitted flat spectrum derived from the COBE data alone [24]. (References for this figure are at the end of this section under "CMB Anisotropy References.")

toward $(\ell, b) = (276^{\circ} \pm 3^{\circ}, 30^{\circ} \pm 3^{\circ})$, where most of the error comes from uncertainty in the velocity of the solar system relative to the Local Group.

The Doppler effect of this velocity and of the velocity of the Earth around the Sun, as well as any velocity of the receiver relative to the Earth, is normally removed for the purposes of CMB anisotropy study. The resulting high degree of CMB isotropy is the strongest evidence for the validity of the Robertson-Walker metric.

19.3.2. The quadrupole: The rms quadrupole anisotropy amplitude is defined through $Q_{\rm rms}^2/T_\gamma^2=\sum_m|a_{2m}|^2/4\pi$. The current estimate of its value is $4\,\mu{\rm K}\leq Q_{\rm rms}\leq 28\,\mu{\rm K}$ for a 95% confidence interval [15]. The uncertainty here includes both statistical errors and systematic errors, which are dominated by the effects of galactic emission modelling. This level of quadrupole anisotropy allows one to set general limits on anisotropic expansion, shear, and vorticity; all such dimensionless quantities are constrained to be less than about 10^{-5} .

. For specific homogeneous cosmologies, fits to the whole anisotropy pattern allow stringent limits to be placed on, for example, the global rotation at the level of about 10^{-7} of the expansion rate [16].

19.3.3. Smaller angular scales: The COBE-discovered [17] higher-order $(\ell > 2)$ anisotropy is interpreted as being the result of perturbations in the energy density of the early Universe, manifesting themselves at the epoch of the CMB's last scattering. Hence the detection of these anisotropies has provided evidence for the existence of primordial density perturbations which grew through gravitational instability to form all the structure we observe today.

In the standard scenario the last scattering takes place at a redshift of approximately 1100, at which epoch the large number of photons was no longer able to keep the hydrogen sufficiently ionized. The optical thickness of the cosmic photosphere is roughly $\Delta z \sim 100$ or about 5 arcminutes, so that features smaller than this size are damped.

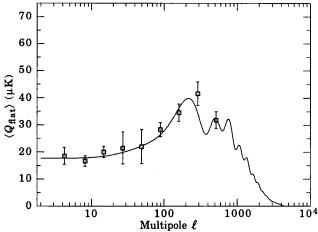

Figure 19.6: This is a binned version of the previous figure. To obtain this figure we took all reported detections, split the multipole range into equal logarithmic 'bins,' and calculated the weighted average in each bin. Although this is not a statistically rigorous procedure, the resulting figure gives a visual indication of the current consensus. It is also worth mentioning that there is no strong indication for excess scatter (above Gaussian) within each bin.

Anisotropies are observed on angular scales larger than this damping scale (see Fig. 19.5 and 19.6), and are consistent with those expected from an initially scale-invariant power spectrum (flat = independent of scale) of potential and thus metric fluctuations. It is believed that the large scale structure in the Universe developed through the process of gravitational instability, where small primordial perturbations in energy density were amplified by gravity over the course of time. The initial spectrum of density perturbations can evolve significantly in the epoch z>1100 for causally connected regions (angles $\lesssim 1^{\circ}~\Omega_{\rm tot}^{1/2}$). The primary mode of evolution is through adiabatic (acoustic) oscillations, leading to a series of peaks that encode information about the perturbations and geometry of the Universe, as well as information on $\Omega_0,~\Omega_B,~\Omega_\Lambda$ (cosmological constant), and H_0 [18]. The location of the first acoustic peak is predicted to be at $\ell \sim 220~\Omega_{\rm tot}^{-1/2}$ or $\theta \sim 0.3^{\circ}~\Omega_{\rm tot}^{1/2}$ and its amplitude is a calculable function of the parameters.

Theoretical models generally predict a power spectrum in spherical harmonic amplitudes, since the models lead to primordial fluctuations and thus $a_{\ell m}$ that are Gaussian random fields, and hence the power spectrum in ℓ is sufficient to characterize the results. The power at each ℓ is $(2\ell+1)C_\ell/(4\pi)$, where $C_\ell \equiv \langle |a_{\ell m}|^2 \rangle$ and a statistically isotropic sky means that all m's are equivalent. For an idealized full-sky observation, the variance of each measured C_ℓ is $[2/(2\ell+1)]C_\ell^2$. This sampling variance (known as cosmic variance) comes about because each C_ℓ is chi-squared distributed with $(2\ell+1)$ degrees of freedom for our observable volume of the Universe [19].

Thomson scattering of the anisotropic radiation field also generates linear polarization at the roughly 5% level [20]. Although difficult to detect, the polarization signal should act as a strong confirmation of the general paradigm.

Figure 19.7 shows the theoretically predicted anisotropy power spectrum for a sample of models, plotted as $\ell(\ell+1)C_\ell$ versus ℓ which is the power per logarithmic interval in ℓ or, equivalently, the two-dimensional power spectrum. If the initial power spectrum of perturbations is the result of quantum mechanical fluctuations produced and amplified during inflation, then the shape of the anisotropy spectrum is coupled to the ratio of contributions from density (scalar) and gravitational wave (tensor) perturbations [21]. If the energy scale of inflation at the appropriate epoch is at the level of $\simeq 10^{16}\,\mathrm{GeV}$, then detection of the effect of gravitons is possible, as well as partial reconstruction of the inflaton potential. If the energy scale is $\lesssim 10^{14}\,\mathrm{GeV}$, then density fluctuations dominate and less constraint is possible.

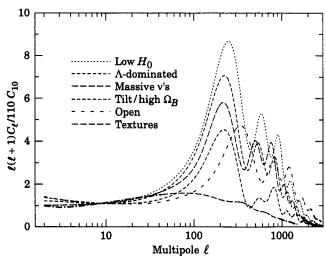

Figure 19.7: Examples of theoretically predicted $\ell(\ell+1)C_\ell$ or CMB anisotropy power spectra [22]. The plot indicates that precise measurements of the CMB anisotropy power spectrum could distinguish between models which are currently favored from galaxy clustering and other considerations. The textures model is from Ref. 23.

Fits to data over smaller angular scales are often quoted as the expected value of the quadrupole $\langle Q \rangle$ for some specific theory, e.g. a model with power-law initial conditions (primordial density perturbation power spectrum $P(k) \propto k^n$). The full 4-year COBE DMR data give $\langle Q \rangle = 15.3^{+3.7}_{-2.8}~\mu \text{K}$, after projecting out the slope dependence, while the best-fit slope is $n=1.2\pm0.3$, and for a pure n=1 (scale-invariant potential perturbation) spectrum $\langle Q \rangle$ (n=1) = $18\pm1.6~\mu \text{K}$ [15,24]. The conventional notation is such that $\langle Q \rangle^2/T_\gamma^2 = 5C_2/4\pi$, and an alternative convention is to plot the "band-power" $\sqrt{\ell(2\ell+1)C_\ell/4\pi}$). The fluctuations measured by other experiments can also be quoted in terms of Q_{flat} , the equivalent value of the quadrupole for a flat (n=1) spectrum, as presented in Fig. 19.5.

It now seems clear that there is more power at sub-degree scales than at COBE scales, which provides some model-dependent information on cosmological parameters [18,25], for example Ω_B . In terms of such parameters, fits to the COBE data alone yield $\Omega_0 > 0.34$ at 95% CL [26] and $\Omega_{\rm tot} < 1.5$ also at 95% CL [27], for inflationary models. Only somewhat weak conclusions can be drawn based on the current smaller angular scale data (see Fig. 19.5). A sample preliminary fit [28] finds Ω_0 $h^{1/2} \simeq 0.55 \pm 0.10$ ($\equiv 68\%$ CL).

However, new data are being acquired at an increasing rate, with a large number of improved ground- and balloon-based experiments being developed. It appears that we are not far from being able to distinguish crudely between currently favored models, and to begin a more precise determination of cosmological parameters. A vigorous suborbital and interferometric program could map out the CMB anisotropy power spectrum to about 10% accuracy and determine several parameters at the 10 to 20% level in the next few years.

There are also now two approved satellite missions: the NASA Millimetre Anisotropy Probe (MAP), scheduled for launch in 2000; and the ESA Planck Surveyor, expected to launch around 2004. The improved sensitivity, freedom from earth-based systematics, and all-sky coverage allow a simultaneous determination of many of the cosmological parameters to unprecedented precision: for example, Ω_0 and n to about 1%, Ω_B and H_0 at the level of a few percent [29].

Furthermore, detailed measurement of the polarization signal provides more precise information on the physical parameters. In particular it allows a clear distinction of any gravity wave contribution, which is crucial to probing the $\sim 10^{16}~{\rm GeV}$ energy range. The fulfillment of this promise may await an even more sensitive generation of satellites.

20. COSMIC RAYS

Written 1995 by T.K. Gaisser and T. Stanev (Bartol Research Inst., Univ. of Delaware).

20.1. Primary spectra

The cosmic radiation incident at the top of the terrestrial atmosphere includes all stable charged particles and nuclei with lifetimes of order 10^6 years or longer. Technically, "primary" cosmic rays are those particles accelerated at astrophysical sources and "secondaries" are those particles produced in interaction of the primaries with interstellar gas. Thus electrons, protons and helium, as well as carbon, oxygen, iron, and other nuclei synthesized in stars, are primaries. Nuclei such as lithium, beryllium, and boron (which are not abundant end-products of stellar nucleosynthesis) are secondaries. Antiprotons and positrons are partly, if not entirely, secondaries, but the fraction of these particles that may be primary is a question of current interest.

Apart from particles associated with solar flares, the cosmic radiation comes from outside the solar system. The incoming charged particles are "modulated" by the solar wind, the expanding magnetized plasma generated by the Sun, which decelerates and partially excludes the lower energy galactic cosmic rays from the inner solar system. There is a significant anticorrelation between solar activity (which has an eleven-year cycle) and the intensity of the cosmic rays with energies below about 10 GeV. In addition, the lower-energy cosmic rays are affected by the geomagnetic field, which they must penetrate to reach the top of the atmosphere. Thus the intensity of any component of the cosmic radiation in the GeV range depends both on the location and time.

There are four different ways to describe the spectra of the components of the cosmic radiation: (1) By particles per unit rigidity. Propagation (and probably also acceleration) through cosmic magnetic fields depends on gyroradius or magnetic rigidity, R, which is gyroradius multiplied by the magnetic field strength:

$$R = \frac{p c}{Z e} = r_L B . \qquad (20.1)$$

(2) By particles per energy-per-nucleon. Fragmentation of nuclei propagating through the interstellar gas depends on energy per nucleon, since that quantity is approximately conserved when a nucleus breaks up on interaction with the gas. (3) By nucleons per energy-per-nucleon. Production of secondary cosmic rays in the atmosphere depends on the intensity of nucleons per energy-per-nucleon, approximately independently of whether the incident nucleons are free protons or bound in nuclei. (4) By particles per energy-per-nucleus. Air shower experiments that use the atmosphere as a calorimeter generally measure a quantity that is related to total energy per particle.

The units of differential intensity I are $[cm^{-2}s^{-1}sr^{-1}\mathcal{E}^{-1}]$, where \mathcal{E} represents the units of one of the four variables listed above.

The intensity of primary nucleons in the energy range from several GeV to somewhat beyond 100 TeV is given approximately by

$$I_N(E) \approx 1.8 E^{-\alpha} \frac{\text{nucleons}}{\text{cm}^2 \text{ s sr GeV}},$$
 (20.2)

where E is the energy-per-nucleon (including rest mass energy) and $\alpha \ (\equiv \gamma+1)=2.7$ is the differential spectral index of the cosmic ray flux and γ is the integral spectral index. About 79% of the primary nucleons are free protons and about 70% of the rest are nucleons bound in helium nuclei. The fractions of the primary nuclei are nearly constant over this energy range (possibly with small but interesting variations). Fractions of both primary and secondary incident nuclei are listed in Table 20.1. Figure 20.1 [1] shows the major components as a function of energy at a particular epoch of the solar cycle.

The spectrum of electrons and positrons incident at the top of the atmosphere is steeper than the spectra of protons and nuclei, as shown in Fig. 20.2 [2]. The positron fraction is about 10% in the region in which it is measured (< 20 GeV), but it is not yet fully understood [5].

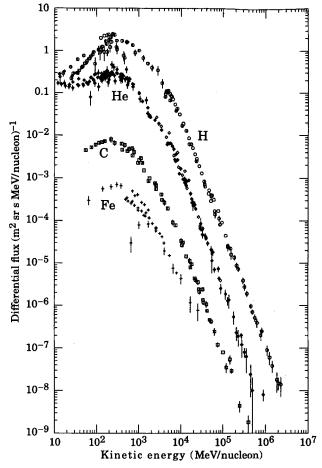

Figure 20.1: Major components of the primary cosmic radiation (from Ref. 1).

Table 20.1: Relative abundances F of cosmic-ray nuclei at 10.6 GeV/nucleon normalized to oxygen (\equiv 1) [3]. The oxygen flux at kinetic energy of 10.6 GeV/nucleon is 3.26×10^{-6} cm⁻² s⁻¹ sr⁻¹ (GeV/nucleon)⁻¹. Abundances of hydrogen and helium are from Ref. 4.

\boldsymbol{Z}	Element	F	\boldsymbol{z}	Element	F
1	H	730	13-14	Al-Si	0.19
2	${ m He}$	34	15-16	P-S	0.03
3-5	Li-B	0.40	17-18	Cl-Ar	0.01
6-8	C-O	2.20	19–2 0	K-Ca	0.02
9–10	F-Ne	0.30	21-25	Sc-Mn	0.05
11-12	Na-Mg	0.22	26-28	Fe-Ni	0.12

Above 10 GeV the fraction of antiprotons to protons is about 10^{-4} , and there is evidence for the kinematic suppression at lower energy expected for secondary antiprotons [5]. There is at this time no evidence for a significant primary component of antiprotons.

20.2. Cosmic rays in the atmosphere

Figure 20.3 shows the vertical fluxes of the major cosmic ray components in the atmosphere in the energy region where the particles are most numerous (except for electrons, which are most numerous near their critical energy, which is about 81 MeV in air). Except for protons and electrons near the top of the atmosphere, all particles are produced in interactions of the primary cosmic rays in the air. Muons

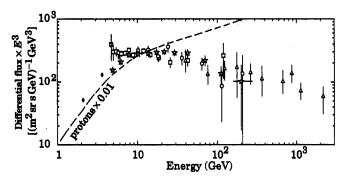

Figure 20.2: Differential spectrum of electrons plus positrons multiplied by E^3 (from Ref. 2).

and neutrinos are products of the decay of charged mesons, while electrons and photons originate in decays of neutral mesons.

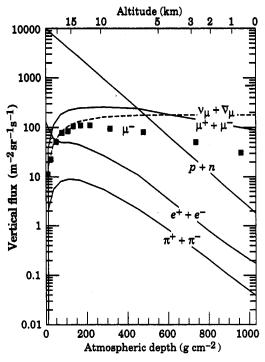

Figure 20.3: Vertical fluxes of cosmic rays in the atmosphere with E>1 GeV estimated from the nucleon flux of Eq. (20.2). The points show measurements of negative muons with $E_{\mu}>1$ GeV [7].

Most measurements are made at ground level or near the top of the atmosphere, but there are also measurements of muons and electrons from airplanes and balloons. Fig. 20.3 includes a recent measurement of negative muons [7]. Since $\mu^+(\mu^-)$ are produced in association with $\nu_{\mu}(\mathcal{P}_{\mu})$, the measurement of muons near the maximum of the intensity curve for the parent pions serves to calibrate the atmospheric ν_{μ} beam [6]. Because muons typically lose almost two GeV in passing through the atmosphere, the comparison near the production altitude is important for the sub-GeV range of $\nu_{\mu}(\mathcal{P}_{\mu})$ energies.

The flux of cosmic rays through the atmosphere is described by a set of coupled cascade equations with boundary conditions at the top of the atmosphere to match the primary spectrum. Numerical or Monte Carlo calculations are needed to account accurately for decay and energy-loss processes, and for the energy-dependences of the cross sections and of the primary spectral index γ . Approximate analytic solutions are, however, useful in limited regions of energy [8]. For example, the vertical intensity of nucleons at depth X (g cm⁻²) in the

atmosphere is given by

$$I_N(E,X) \approx I_N(E,0) e^{-X/\Lambda}$$
, (20.3)

where Λ is the attenuation length of nucleons in air.

The corresponding expression for the vertical intensity of charged pions with energy $E_\pi \ll \epsilon_\pi = 115$ GeV is

$$I_{\pi}(E_{\pi}, X) \approx \frac{Z_{N\pi}}{\lambda_N} I_N(E_{\pi}, 0) e^{-X/\Lambda} \frac{X E_{\pi}}{\epsilon_{\pi}}$$
 (20.4)

This expression has a maximum at $t=\Lambda\approx 120~{\rm g~cm^{-2}}$, which corresponds to an altitude of 15 kilometers. The quantity $Z_{N\pi}$ is the spectrum-weighted moment of the inclusive distribution of charged pions in interactions of nucleons with nuclei of the atmosphere. The intensity of low-energy pions is much less than that of nucleons because $Z_{N\pi}\approx 0.079$ is small and because most pions with energy much less than the critical energy ϵ_π decay rather than interact.

20.3. Cosmic rays at the surface

20.3.1. Muons: Muons are the most numerous charged particles at sea level (see Fig. 20.3). Most muons are produced high in the atmosphere (typically 15 km) and lose about 2 GeV to ionization before reaching the ground. Their energy and angular distribution reflect a convolution of production spectrum, energy loss in the atmosphere, and decay. For example, $E_{\mu} = 2.4$ GeV muons have a decay length of 15 km, which is reduced to 8.7 km by energy loss. The mean energy of muons at the ground is ≈ 4 GeV. The energy spectrum is almost flat below 1 GeV, steepens gradually to reflect the primary spectrum in the 10-100 GeV range, and steepens further at higher energies because pions with $E_{\pi} > \epsilon_{\pi} \approx 115$ GeV tend to interact in the atmosphere before they decay. Asymptotically $(E_{\mu} \gg 1 \text{ TeV})$, the energy spectrum of atmospheric muons is one power steeper than the primary spectrum. The integral intensity of vertical muons above 1 GeV/c at sea level is $\approx 70 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ [9,10]. Experimentalists are familiar with this number in the form $I \approx 1 \text{ cm}^{-2} \text{ min}^{-1}$ for horizontal detectors.

The overall angular distribution of muons at the ground is $\propto \cos^2 \theta$, which is characteristic of muons with $E_{\mu} \sim 3$ GeV. At lower energy the angular distribution becomes increasingly steeper, while at higher energy it flattens and approaches a $\sec \theta$ distribution for $E_{\mu} \gg \epsilon_{\pi}$ and $\theta < 70^{\circ}$.

Figure 20.4 shows the muon energy spectrum at sea level for two angles. At large angles low energy muons decay before reaching the surface and high energy pions decay before they interact, thus the average muon energy increases. An approximate extrapolation formula valid when muon decay is negligible $(E_{\mu}>100/\cos\theta~{\rm GeV})$ and the curvature of the Earth can be neglected $(\theta<70^{\circ})$ is

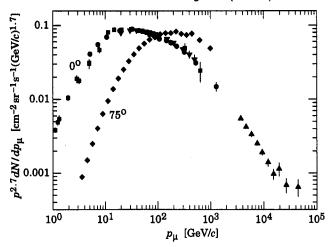

Figure 20.4: Spectrum of muons at $\theta = 0^{\circ}$ (\blacksquare [12], \bullet [13], \blacktriangledown [14], \blacktriangle [15]), and $\theta = 75^{\circ}$ \blacklozenge [16]).

$$\frac{dN_{\mu}}{dE_{\mu}} \approx \frac{0.14 \, E^{-2.7}}{\text{cm}^2 \, \text{s sr GeV}} \times \left\{ \frac{1}{1 + \frac{1.1E_{\mu} \cos \theta}{115 \, \text{GeV}}} + \frac{0.054}{1 + \frac{1.1E_{\mu} \cos \theta}{850 \, \text{GeV}}} \right\} , \quad (20.5)$$

where the two terms give the contribution of pions and charged kaons. Eq. (20.5) neglects a small contribution from charm and heavier flavors which is negligible except at very high energy [17].

The muon charge ratio reflects the excess of π^+ over π^- in the forward fragmentation region of proton initiated interactions together with the fact that there are more protons than neutrons in the primary spectrum. The charge ratio is between 1.2 and 1.3 from 250 MeV up to 100 GeV [9].

20.3.2. Electromagnetic component: At the ground, this component consists of electrons, positrons, and photons primarily from electromagnetic cascades initiated by decay of neutral and charged mesons. Muon decay is the dominant source of low-energy electrons at sea level. Decay of neutral pions is more important at high altitude or when the energy threshold is high. Knock-on electrons also make a small contribution at low energy [11]. The integral vertical intensity of electrons plus positrons is very approximately 30, 6, and 0.2 m⁻²s⁻¹sr⁻¹ above 10, 100, and 1000 MeV respectively [10,18], but the exact numbers depend sensitively on altitude, and the angular dependence is complex because of the different altitude dependence of the different sources of electrons [11,18,19]. The ratio of photons to electrons plus positrons is approximately 1.3 above a GeV and 1.7 below the critical energy [19].

20.3.3. **Protons**: Nucleons above 1 GeV/c at ground level are degraded remnants of the primary cosmic radiation. The intensity is approximately represented by Eq. (20.3) with the replacement $t \to t/\cos\theta$ for $\theta < 70^\circ$ and an attenuation length $\Lambda = 123$ g cm⁻². At sea level, about 1/3 of the nucleons in the vertical direction are neutrons (up from $\approx 10\%$ at the top of the atmosphere as the n/p ratio approaches equilibrium). The integral intensity of vertical protons above 1 GeV/c at sea level is $\approx 0.9 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ [10,20].

20.4. Cosmic rays underground

Only muons and neutrinos penetrate to significant depths underground. The muons produce tertiary fluxes of photons, electrons, and hadrons.

20.4.1. Muons: As discussed in Section 23.9 of this *Review*, muons lose energy by ionization and by radiative processes: bremsstrahlung, direct production of e^+e^- pairs, and photonuclear interactions. The total muon energy loss may be expressed as a function of the amount of matter traversed as

$$-\frac{dE_{\mu}}{dX} = a + b E_{\mu} , \qquad (20.6)$$

where a is the ionization loss and b is the fractional energy loss by the three radiation processes. Both are slowly varying functions of energy. The quantity $\epsilon \equiv a/b$ (≈ 500 GeV in standard rock) defines a critical energy below which continuous ionization loss is more important the radiative losses. Table 20.2 shows a and b values for standard rock as a function of muon energy. The second column of Table 20.2 shows the muon range in standard rock (A = 22, Z = 11, $\rho = 2.65$ g cm⁻³). These parameters are quite sensitive to the chemical composition of the rock, which must be evaluated for each experimental location.

The intensity of muons underground can be estimated from the muon intensity in the atmosphere and their rate of energy loss. To the extent that the mild energy dependence of a and b can be neglected, Eq. (20.6) can be integrated to provide the following relation between the energy $E_{\mu,0}$ of a muon at production in the atmosphere and its average energy E_{μ} after traversing a thickness X of rock (or ice or water):

$$E_{\mu} = (E_{\mu,0} + \epsilon) e^{-bX} - \epsilon . \qquad (20.7)$$

Table 20.2: Average muon range R and energy loss parameters calculated for standard rock. Range is given in km-water-equivalent, or 10^5 g cm⁻².

E_{μ} GeV	R km.w.e.	$^{a}_{\rm MeVg^{-1}cm^{2}}$		b _{brems} 10 ⁻⁶ g		
10	0.05	2.15	0.73	0.74	0.45	1.91
100	0.41	2.40	1.15	1.56	0.41	3.12
1000	2.42	2.58	1.47	2.10	0.44	4.01
10000	6.30	2.76	1.64	2.27	0.50	4.40

Especially at high energy, however, fluctuations are important and an accurate calculation requires a simulation that accounts for stochastic energy-loss processes [21].

Fig. 20.5 shows the vertical muon intensity versus depth. In constructing this "depth-intensity curve," each group has taken account of the angular distribution of the muons in the atmosphere, the map of the overburden at each detector, and the properties of the local medium in connecting measurements at various slant depths and zenith angles to the vertical intensity. Use of data from a range of angles allows a fixed detector to cover a wide range of depths. The flat portion of the curve is due to muons produced locally by charged-current interactions of ν_{μ} .

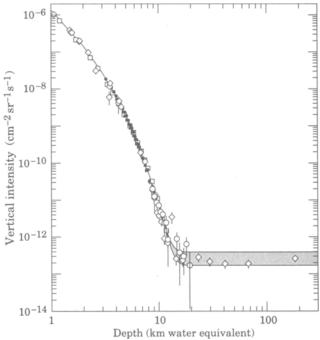

Figure 20.5: Vertical muon intensity vs. depth (1 km.w.e. = 10^5 g cm⁻² of standard rock). The experimental data are from: \Diamond : the compilations of Crouch [29], \Box : Baksan [30], \bigcirc : LVD [31], \bullet : MACRO [32], \blacksquare : Frejus [33]. The shaded area at large depths represents neutrino induced muons of energy above 2 GeV. The upper line is for horizontal neutrino-induced muons, the lower one for vertically upward muons.

The energy spectrum of atmospheric muons underground can be estimated from Eq. (20.7). The muon energy spectrum at slant depth X is

$$\frac{dN_{\mu}(X)}{dE_{\mu}} = \frac{dN_{\mu}}{dE_{\mu,0}} e^{bX} , \qquad (20.8)$$

where $E_{\mu,0}$ is the solution of Eq. (20.7). For $X \ll b^{-1} \approx 2.5$ km water equivalent, $E_{\mu,0} \approx E_{\mu}(X) + aX$. Thus at shallow depths the differential muon energy spectrum is approximately constant for $E_{\mu} < aX$ and steepens to reflect the surface muon spectrum for

 $E_{\mu} > aX$. For $X \gg b^{-1}$ the differential spectrum underground is again constant for small muon energies but steepens to reflect the surface muon spectrum for $E_{\mu} > \epsilon \approx 0.5$ TeV. In this regime the shape is independent of depth although the intensity decreases exponentially with depth.

20.4.2. Neutrinos: Because neutrinos have small interaction cross sections, measurements of atmospheric neutrinos require a deep detector to avoid backgrounds. There are two types of measurements: contained (or semi-contained) events, in which the vertex is determined to originate inside the detector, and neutrino-induced muons. The latter are muons that enter the detector from zenith angles so large (e.g., nearly horizontal or upward) that they cannot be muons produced in the atmosphere. In neither case is the neutrino flux measured directly. What is measured is a convolution of the neutrino flux and cross section with the properties of the detector (which includes the surrounding medium in the case of entering muons).

Contained events reflect the neutrinos in the GeV region where the product of increasing cross section and decreasing flux is maximum. In this energy region the neutrino flux and its angular distribution depend on the geomagnetic location of the detector and to a lesser extent on the phase of the solar cycle. Naively, we expect $\nu_{\mu}/\nu_{e}=2$ from counting the neutrinos of the two flavors coming from the chain of pion and muon decay. This ratio is only slightly modified by the details of the decay kinematics. Experimental measurements have also to account for the ratio of $\overline{\nu}/\nu$, which have cross sections different by a factor of 3 in this energy range. In addition, detectors will generally have different efficiencies for detecting muon neutrinos and electron neutrinos. Even after correcting for these and other effects, some detectors [22,23] infer a ν_{μ}/ν_{e} ratio lower by $\approx 4\sigma$ from the expected value. (See Tables in the Particle Listings of this Review.) This effect is sometimes cited as possible evidence of neutrino oscillations and is a subject of current investigation. Figure 20.6 shows the data of Refs. 22,23 for the distributions of visible energy in electron-like and muon-like charged-current events, which appear to be nearly equal in number. Corrections for detection efficiencies and backgrounds are insufficient to account for the difference from the expected value of two.

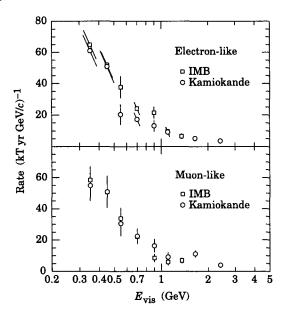

Figure 20.6: Contained neutrino interactions from IMB [23](\square) and Kamiokande [22].

Muons that enter the detector from outside after production in charged-current interactions of neutrinos naturally reflect a higher energy portion of the neutrino spectrum than contained events because the muon range increases with energy as well as the cross section. The relevant energy range is $\sim 10 < E_{\nu} < 1000$ GeV, depending somewhat on angle. Like muons (see Eq. (20.5)), high energy neutrinos show

a "secant theta" effect which causes the flux of horizontal neutrino induced muons to be approximately a factor two higher than the vertically upward flux. The upper and lower edges of the horizontal shaded region in Fig. 20.5 correspond to horizontal and vertical intensities of neutrino-induced muons. Table 20.3 gives the measured fluxes of neutrino induced muons.

Table 20.3: Measured fluxes $(10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1})$ of neutrino-induced muons as a function of the minimum muon energy E_{μ} .

$E_{\mu} >$	1 GeV	1 GeV	1 GeV	2 GeV	3 GeV
Ref.	CWI [24]	Baksan [25]	MACRO [26]	IMB [27]	Kam [28]
F_{μ}	2.17±0.21	2.77 ± 0.17	2.48 ± 0.27	2.26 ± 0.11	2.04±0.13

20.5. Air showers

So far we have discussed inclusive or uncorrelated fluxes of various components of the cosmic radiation. An air shower is caused by a single cosmic ray with energy high enough for its cascade to be detectable at the ground. The shower has a hadronic core, which acts as a collimated source of electromagnetic subshowers, generated mostly from $\pi^0 \to \gamma \gamma$. The resulting electrons and positrons are the most numerous particles in the shower. The number of muons, produced by decays of charged mesons, is an order of magnitude lower.

Air showers spread over a large area on the ground, and arrays of detectors operated for long times are useful for studying cosmic rays with primary energy $E_0>100~{\rm TeV}$, where the low flux makes measurements with small detectors in balloons and satellites difficult.

Greisen [46] gives the following approximate expressions for the numbers and lateral distributions of particles in showers at ground level. The total number of muons N_{μ} with energies above 1 GeV is

$$N_{\mu}(> 1 \text{ GeV}) \approx 0.95 \times 10^5 \left(\frac{N_e}{10^6}\right)^{3/4} ,$$
 (20.9)

where N_e is the total number of charged particles in the shower (not just e^{\pm}). The number of muons per square meter, ρ_{μ} , as a function of the lateral distance r (in meters) from the center of the shower is

$$\rho_{\mu} = \frac{1.25 \, N_{\mu}}{2\pi \, \Gamma(1.25)} \left(\frac{1}{320}\right)^{1.25} \, r^{-0.75} \, \left(1 + \frac{r}{320}\right)^{-2.5} \, , \qquad (20.10)$$

where Γ is the gamma function. The number density of charged particles is

$$\rho_e = C_1(s, d, C_2) x^{(s-2)} (1+x)^{(s-4.5)} (1+C_2 x^d) . \tag{20.11}$$

Here s, d, and C_2 are parameters in terms of which the overall normalization constant $C_1(s, d, C_2)$ is given by

$$\begin{split} C_1(s,d,C_2) &= \frac{N_e}{2\pi r_1^2} [\, B(s,4.5-2s) \\ &\quad + C_2 \, B(s+d,\,4.5-d-2s)]^{-1} \,\,, \end{split} \tag{20.12}$$

where B(m,n) is the beta function. The values of the parameters depend on shower size (N_e) , depth in the atmosphere, identity of the primary nucleus, etc. For showers with $N_e \approx 10^6$ at sea level, Greisen uses s=1.25, d=1, and $C_2=0.088$. Finally, x is r/r_1 , where r_1 is the Molière radius, which depends on the density of the atmosphere and hence on the altitude at which showers are detected. At sea level $r_1 \approx 78$ m. It increases with altitude.

The lateral spread of a shower is determined largely by Coulomb scattering of the many low-energy electrons and is characterized by the Moliere radius. The lateral spread of the muons (ρ_{μ}) is larger and depends on the transverse momenta of the muons at production as well as multiple scattering.

There are large fluctuations in development from shower to shower, even for showers of the same energy and primary mass—especially for small showers, which are usually well past maximum development when observed at the ground. Thus the shower size N_e and primary energy E_0 are only related in an average sense, and even this relation depends on depth in the atmosphere. One estimate of the relation is [35]

$$E_0 \sim 3.9 \times 10^6 \text{ GeV } (N_e/10^6)^{0.9}$$
 (20.13)

for vertical showers with $10^{14} < E < 10^{17}$ eV at 920 g cm⁻² (965 m above sea level). Because of fluctuations, N_e as a function of E_0 is not the inverse of Eq. (20.13). As E_0 increases the shower maximum (on average) moves down into the atmosphere and the relation between N_e and E_0 changes. At the maximum of shower development, there are approximately 2/3 particles per GeV of primary energy.

Detailed simulations and cross-calibrations between different types of detectors are necessary to establish the primary energy spectrum from air-shower experiments [35,36]. Figure 20.7 shows the "all-particle" spectrum. In establishing this spectrum, efforts have been made to minimize the dependence of the analysis on the primary composition. In the energy range above 10^{17} eV, the Fly's Eye technique [48] is particularly useful because it can establish the primary energy in a model-independent way by observing most of the longitudinal development of each shower, from which E_0 is obtained by integrating the energy deposition in the atmosphere.

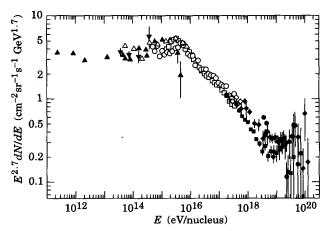

Figure 20.7: The all-particle spectrum: \blacktriangle [37], \blacktriangledown [38], \triangle [39], \Box [40], \bigcirc [35], \blacksquare [48], \spadesuit [42], \spadesuit [43].

In Fig. 20.7 the differential energy spectrum has been multiplied by $E^{2.7}$ in order to display the features of the steep spectrum that are otherwise difficult to discern. The steepening that occurs between 10^{15} and 10^{16} eV is known as the *knee* of the spectrum. The feature between 10^{18} and 10^{19} eV is called the *ankle* of the spectrum. Both these features are the subject of intense interest at present [44].

The ankle has the classical characteristic shape [45] of a higher energy population of particles overtaking a lower energy population. A possible interpretation is that the higher energy population represents cosmic rays of extragalactic origin. If this is the case and if the cosmic rays are cosmological in origin, then there should be a cutoff around 5×10^{19} eV, resulting from interactions with the microwave background [46,47]. It is therefore of special interest that several events have been assigned energies above 10^{20} eV [48,49,50].

If the cosmic ray spectrum below 10^{18} eV is of galactic origin, the knee could reflect the fact that some (but not all) cosmic accelerators have reached their maximum energy. Some types of expanding supernova remnants, for example, are estimated not to be able to accelerate particles above energies in the range of 10^{15} eV total energy per particle. Effects of propagation and confinement in the galaxy [51] also need to be considered.

21. ACCELERATOR PHYSICS OF COLLIDERS

Written November 1997 by K. Desler and D.A. Edwards (DESY).

21.1. Introduction

This article is intended to be a mini-introduction to accelerator physics, with emphasis on colliders. Essential data are summarized in the "Tables of Collider Parameters" (Sec. 22). Luminosity is the quantity of most immediate interest for HEP, and so we begin with its definition and a discussion of the various factors involved. Then we talk about some of the underlying beam dynamics. Finally, we comment on present limitations and possible future directions.

The focus is on colliders because they provide the highest c.m. energy, and so the longest potential discovery reach. All present-day colliders are synchrotrons with the exception of the SLAC Linear Collider. In the pursuit of higher c.m. energy with electrons, synchrotron radiation presents a formidable barrier to energy beyond LEP. The LHC will be the first proton collider in which synchrotron radiation has significant design impact.

21.2. Luminosity

The event rate R in a collider is proportional to the interaction cross section σ_{int} and the factor of proportionality is called the *luminosity*:

$$R = \mathcal{L}\sigma_{\text{int}} \quad . \tag{21.1}$$

If two bunches containing n_1 and n_2 particles collide with frequency f, then the luminosity is

$$\mathscr{L} = f \frac{n_1 n_2}{4\pi \sigma_x \sigma_y} \tag{21.2}$$

where σ_x and σ_y characterize the Gaussian transverse beam profiles in the horizontal (bend) and vertical directions. Though the initial distribution at the source may be far from Gaussian, by the time the beam reaches high energy the normal form is a very good approximation thanks to the central limit theorem of probability and diminished importance of space charge effects.

Luminosity is normally expressed in units of $\rm cm^{-2}s^{-1}$, and tends to be a large number; the highest instantaneous luminosity achieved to date is about $4.5\times 10^{32}~\rm cm^{-2}s^{-1}$ at CESR, and for protons, $2.3\times 10^{32}~\rm cm^{-2}s^{-1}$ at the now-decommissioned ISR. The critical quantity for HEP is the integrated luminosity, often stated in $\rm pb^{-1}$. For example, during the most-recent two-year Tevatron run, an integrated luminosity of 150 $\rm pb^{-1}$ was obtained.

The beam size can be expressed in terms of two quantities, one termed the transverse emittance, ϵ and the other, the amplitude function, β . The transverse emittance is a beam quality concept reflecting the process of bunch preparation, extending all the way back to the source for hadrons and, in the case of electrons, mostly dependent on synchrotron radiation. The amplitude function is a beam optics quantity and is determined by the accelerator magnet configuration.

The transverse emittance is a measure of the phase space area associated with either of the two transverse degrees of freedom, x and y. These coordinates represent the position of a particle with reference to some ideal design trajectory. Think of x as the "horizontal" displacement (in the bend plane for the case of a synchrotron), and y as the "vertical" displacement. The conjugate coordinates are the transverse momenta, which at constant energy are proportional to the angles of particle motion with respect to the design trajectory, x' and y'. Various conventions are in use to characterize the boundary of phase space. Beam sizes are usually given as the standard deviations characterizing Gaussian beam profiles in the two transverse degrees of freedom. In each degree of freedom, the one- σ contour in displacement and angle is frequently used and we will follow this choice.

Suppose that at some location in the collider, the phase space boundary appears as an upright ellipse where the coordinates are the displacement x (using the horizontal plane for instance) and the angle x' with respect to the beam axis. The choice of an elliptical

contour will be justified under Beam Dynamics below. If σ and σ' are the ellipse semi-axes in the x and x' directions respectively, then the emittance may be defined by $\epsilon \equiv \pi \sigma \sigma'$. Transverse emittance is often stated in units of mm-mrad.

The aspect ratio, σ/σ' , is the so-called *amplitude function*, β , and its value depends on position within the focusing structure. When expressed in terms of σ and β the transverse emittance becomes

$$\epsilon = \pi \frac{\sigma^2}{\beta} \ . \tag{21.3}$$

Of particular significance is the value of the amplitude function at the interaction point, β^* . To achieve high luminosity, one wants β^* to be as small as possible; how small depends on the capability of the hardware to make a near-focus at the interaction point. For example, in the HERA proton ring, β^* at one of the major detectors is 1 m while elsewhere in the synchrotron typical values of the amplitude function lie in the range 30–100 m.

Eq. (21.2) can now be recast in terms of emittances and amplitude functions as

$$\mathscr{L} = f \frac{n_1 n_2}{4\sqrt{\epsilon_x \beta_x^* \epsilon_y \beta_y^*}} \ . \tag{21.4}$$

Thus, to achieve high luminosity, all one has to do is make high population bunches of low emittance to collide at high frequency at locations where the beam optics provides as low values of the amplitude functions as possible.

Depending on the particular facility, there are other ways of stating the expression for the luminosity. In a multibunch collider, the various bunch populations will differ, in a facility such as HERA, the electron and proton bunches may differ in emittance, the variation of the beam size in the neighborhood of the interaction point may be significant, and so on.

21.3. Beam dynamics

A major concern of beam dynamics is stability: conservation of adequate beam properties over a sufficiently long time scale. Several time scales are involved, and the approximations used in writing the equations of motion reflect the time scale under consideration. For example, when, in Sec. 21.3.1 below, we write the equations for transverse stability no terms associated with phase stability or synchrotron radiation appear; the time scale associated with the last two processes is much longer than that demanded by the need for transverse stability.

21.3.1. Betatron oscillations: Present-day high-energy accelerators employ alternating gradient focusing provided by quadrupole magnetic fields [1]. The equations of motion of a particle undergoing oscillations with respect to the design trajectory are

$$x'' + K_x(s) x = 0$$
 , $y'' + K_y(s) y = 0$, (21.5)

with

$$x' \equiv dx/ds$$
, $y' \equiv dy/ds$ (21.6)

$$K_x \equiv B'/(B\rho) + \rho^{-2} \ , \ K_y \equiv -B'/(B\rho)$$
 (21.7)

$$B' \equiv \partial B_u / \partial x \quad . \tag{21.8}$$

The independent variable s is path length along the design trajectory. This motion is called a betatron oscillation because it was initially studied in the context of that type of accelerator. The functions K_x and K_y reflect the transverse focussing—primarily due to quadrupole fields except for the radius of curvature, ρ , term in K_x for a synchrotron—so each equation of motion resembles that for a harmonic oscillator but with spring constants that are a function of position. No terms relating to synchrotron oscillations appear, because their time scale is much longer and in this approximation play no role.

These equations have the form of Hill's equation and so the solution in one plane may be written as

$$x(s) = A\sqrt{\beta(s)} \cos(\psi(s) + \delta), \tag{21.9}$$

where A and δ are constants of integration and the phase advances according to $d\psi/ds=1/\beta$. The dimension of A is the square root of length, reflecting the fact that the oscillation amplitude is modulated by the square root of the amplitude function. In addition to describing the envelope of the oscillation, β also plays the role of an 'instantaneous' λ . The wavelength of a betatron oscillation may be some tens of meters, and so typically values of the amplitude function are of the order of meters rather than on the order of the beam size. The beam optics arrangement generally has some periodicity and the amplitude function is chosen to reflect that periodicity. As noted above, at the interaction point a small value of the amplitude function is desired, and so the focussing optics is tailored in the neighborhood to provide a suitable β^* .

The number of betatron oscillations per turn in a synchrotron is called the *tune* and is given by

$$\nu = \frac{1}{2\pi} \oint \frac{ds}{\beta} \ . \tag{21.10}$$

Expressing the integration constant A in the solution above in terms of x, x' yields the Courant-Snyder invariant

$$A^2 = \gamma(s) x(s)^2 + 2\alpha(s) x(s) x'(s) + \beta(s) x'(s)^2$$

where

$$\alpha \equiv -\beta'/2, \ \gamma \equiv \frac{1+\alpha^2}{\beta}$$
 (21.11)

(The Courant-Snyder parameters α , β and γ employ three Greek letters which have other meanings and the significance at hand must often be recognized from context.) Because β is a function of position in the focusing structure, this ellipse changes orientation and aspect ratio from location to location but the area πA^2 remains the same.

As noted above the transverse emittance is a measure of the area in x, x' (or y, y') phase space occupied by an ensemble of particles. The definition used in Eq. (21.3) is the area that encloses 39% of a Gaussian beam.

For electron synchrotrons the equilibrium emittance results from the balance between synchrotron radiation damping and excitation from quantum fluctuations in the radiation rate. The equilibrium is reached in a time small compared with the storage time.

For present-day hadron synchrotrons, synchrotron radiation does not play a similar role in determining the transverse emittance. Rather the emittance during storage reflects the source properties and the abuse suffered by the particles throughout acceleration and storage. Nevertheless it is useful to argue as follows: Though x' and x can serve as canonically conjugate variables at constant energy this definition of the emittance would not be an adiabatic invariant when the energy changes during the acceleration cycle. However, $\gamma(v/c)x'$, where here γ is the Lorentz factor, is proportional to the transverse momentum and so qualifies as a variable conjugate to x. So often one sees a normalized emittance defined according to

$$\epsilon_N = \gamma \frac{v}{c} \epsilon. \tag{21.12}$$

21.3.2. Phase stability: The particles in a circular collider also undergo synchrotron oscillations. This is usually referred to as motion in the longitudinal degree-of-freedom because particles arrive at a particular position along the accelerator earlier or later than an ideal reference particle. This circumstance results in a finite bunch length, which is related to an energy spread.

For dynamical variables in longitudinal phase space, let us take ΔE and Δt , where these are the energy and time differences from that of the ideal particle. A positive Δt means a particle is behind the ideal particle. The equation of motion is the same as that for a physical pendulum and therefore is nonlinear. But for small oscillations, it reduces to a simple harmonic oscillator:

$$\frac{d^2\Delta t}{dn^2} = -(2\pi\nu_s)^2\Delta t \tag{21.13}$$

where the independent variable n is the turn number and ν_s is the number of synchrotron oscillations per turn, analogous to the betatron oscillation tune defined earlier.

In the high-energy limit, where $v/c \approx 1$,

$$\nu_s = \left[\frac{h\eta \, eV \, \cos\phi_s}{2\pi E}\right]^{1/2} \quad . \tag{21.14}$$

There are four as yet undefined quantities in this expression: the harmonic number h, the slip factor η , the maximum energy eV gain per turn from the acceleration system, and the synchronous phase ϕ_s . The frequency of the RF system is normally a relatively high multiple, h, of the orbit frequency. The slip factor relates the fractional change in the orbit period τ to changes in energy according to

$$\frac{\Delta \tau}{\tau} = \eta \frac{\Delta E}{E} \ . \tag{21.15}$$

At sufficiently high energy, the slip factor just reflects the relationship between path length and energy, since the speed is a constant; η is positive for all the synchrotrons in the tables.

The synchronous phase is a measure of how far up on the RF wave the average particle must ride in order to maintain constant energy in the face of synchrotron radiation. That is, $\sin \phi_s$ is the ratio of the energy loss per turn to the maximum energy per turn that can be provided by the acceleration system. For hadron colliders built to date, $\sin \phi_s$ is effectively zero. This is not the case for electron storage rings; for example, the electron ring of HERA runs at a synchronous phase of 45°.

Now if one has a synchrotron oscillation with amplitudes $\widehat{\Delta t}$ and $\widehat{\Delta E}$,

$$\Delta t = \widehat{\Delta t} \sin(2\pi \nu_s n) , \qquad \Delta E = \widehat{\Delta E} \cos(2\pi \nu_s n)$$
 (21.16)

then the amplitudes are related according to

$$\widehat{\Delta E} = \frac{2\pi\nu_s E}{n\tau} \widehat{\Delta t} . \qquad (21.17)$$

The longitudinal emittance ϵ_{ℓ} may be defined as the phase space area bounded by particles with amplitudes $\widehat{\Delta t}$ and $\widehat{\Delta E}$. In general, the longitudinal emittance for a given amplitude is found by numerical integrations. For $\sin\phi_s=0$, an analytical expression is as follows:

$$\epsilon_{\ell} = \left[\frac{2\pi^3 EeVh}{\tau^2 \eta}\right]^{1/2} (\widehat{\Delta t})^2 \tag{21.18}$$

Again, a Gaussian is a reasonable representation of the longitudinal profile of a well-behaved beam bunch; if $\sigma_{\Delta t}$ is the standard deviation of the time distribution, then the bunch length can be characterized by

$$\ell = c \, \sigma_{\Delta t} \ . \tag{21.19}$$

In the electron case the longitudinal emittance is determined by the synchrotron radiation process just as in the transverse degrees of freedom. For the hadron case the history of acceleration plays a role and because energy and time are conjugate coordinates, the longitudinal emittance is a quasi-invariant.

For HEP bunch length is a significant quantity because if the bunch length becomes larger than β^* the luminosity is adversely affected. This is because β grows parabolically as one proceeds from the IP and so the beam size increases thus lowering the contribution to the luminosity from such locations.

21.3.3. Synchrotron radiation [2]: A relativistic particle undergoing centripetal acceleration radiates at a rate given by the Larmor formula multiplied by the 4th power of the Lorentz factor:

$$P = \frac{1}{6\pi\epsilon_0} \frac{e^2 a^2}{c^3} \gamma^4. \tag{21.20}$$

Here, $a=v^2/\rho$ is the centripetal acceleration of a particle with speed v undergoing deflection with radius of curvature ρ . In a synchrotron

that has a constant radius of curvature within bending magnets, the energy lost due to synchrotron radiation per turn is the above multiplied by the time spent in bending magnets, $2\pi\rho/v$. Expressed in familiar units, this result may be written

$$W = 8.85 \times 10^{-5} \frac{E^4}{\rho}$$
 MeV per turn (21.21)

for electrons at sufficiently high energy that $v \approx c$. The energy E is in GeV and ρ is in kilometers.

The characteristic time for synchrotron radiation processes is the time during which the energy must be replenished by the acceleration system. If f_0 is the orbit frequency, then the characteristic time is given by

$$\tau_0 = \frac{E}{f_0 W} \ . \tag{21.22}$$

Oscillations in each of the three degrees of freedom either damp or antidamp depending on the design of the accelerator. For a simple separated function alternating gradient synchrotron, all three modes damp. The damping time constants are related by Robinson's Theorem [3], which, expressed in terms of τ_0 , is

$$\frac{1}{\tau_x} + \frac{1}{\tau_y} + \frac{1}{\tau_s} = 2\frac{1}{\tau_0} . {(21.23)}$$

Even though all three modes may damp, the emittances do not tend toward zero. Statistical fluctuations in the radiation rate excite synchrotron oscillations and radial betatron oscillations. Thus there is an equilibrium emittance at which the damping and excitation are in balance. The vertical emittance is non-zero due to horizontal-vertical coupling.

The radiation rate for protons is of course down by a factor of the fourth power of the mass ratio, and is given by

$$W = 7.8 \times 10^{-3} \frac{E^4}{\rho}$$
 keV per turn (21.24)

where E is now in TeV and ρ in km. As noted in the Introduction, the LHC will the first proton facility in which synchrotron radiation plays a significant role.

21.3.4. Beam-beam tune shift: In a bunch-bunch collision the particles of one bunch see the other bunch as a nonlinear lens. Therefore the focussing properties of the ring are changed in a way that depends on the transverse oscillation amplitude. And so there is a spread in the frequency of betatron oscillations.

There is an extensive literature on the subject of how large this tune spread can be. In practice, the limiting value is hard to predict. It is consistently larger for electrons because of the beneficial effects of damping from synchrotron radiation.

In order that contributions to the total tune spread arise only at the detector locations, the beams in a multibunch collider are kept apart elsewhere by a variety of techniques. For equal energy particles of opposite charge circulating in the same vacuum chamber, electrostatic separators may be used assisted by a crossing angle if appropriate. For particles of equal energy and of the same charge, a crossing angle is needed not only for tune spread reasons but to steer the particles into two separate beam pipes. In HERA, because of the large ratio of proton to electron energy, separation can be achieved by bending magnets.

21.3.5. Luminosity lifetime: In electron synchrotrons the luminosity degrades during the store primarily due to particles leaving the phase stable region in longitudinal phase space as a result of quantum fluctuations in the radiation rate and bremsstrahlung. For hadron colliders the luminosity deteriorates due to emittance dilution resulting from a variety of processes. In practice, stores are intentionally terminated when the luminosity drops to the point where a refill will improve the integrated luminosity.

21.4. Status and prospects

Present facilities represent a balance between available technology and the desires of High Energy Physics. For forty-five years, beam optics has exploited the invention of alternating gradient focussing. This principle is employed in all colliders both linear and circular. Superconducting technology has grown dramatically in importance during the last two decades. Superconducting magnets are vital to the Tevatron, HERA, and to the future LHC. Superconducting accelerating structures are necessary to CESR, LEP, HERA, Jefferson Laboratory and other facilities requiring high-gradient long pulse length RF systems. Present room temperature accelerating structures produce very short pulses, but with gradients well in excess of the superconducting variety [7].

At present, the next potential facilities are perceived to include the LHC and an electron linear collider. The LHC is an approved project that will represent a major step forward in superconducting magnet technology. No linear collider project has been approved as yet, and the conventional and superconducting approaches compete for prominence. Of perhaps more immediate impact are the B and τ "factories" that are designed to go beyond the $10^{33}~\rm cm^{-2}s^{-1}$ level in luminosity.

In addition to the possibilities of the preceding paragraph, there are other synchrotron-based collider studies underway. Despite formidable R&D challenges a muon-muon collider may become feasible. Proponents of a very large hadron collider at higher energy than the cancelled SSC project are exploring low-cost magnets and tunnels for a facility on the 100 TeV c.m. energy scale.

Ideas abound in accelerator R&D for the long term. Approaches such as wakefield accelerators, plasma-laser combinations, and related investigations may if successful deliver gradients far higher than anything realized today. These studies could potentially lead to a new vision for HEP facilities.

HIGH-ENERGY COLLIDER PARAMETERS: e^+e^- Colliders (I)

The numbers here were received from representatives of the colliders in 1998 (contact C.G. Wohl, LBNL). Many of the numbers of course change with time, and only the latest values (or estimates) are given here; those in brackets are for coming upgrades. Quantities are, where appropriate, r.m.s. H and V indicate horizontal and vertical directions. Parameters for the defunct SPEAR, DORIS, PETRA, PEP, and TRISTAN colliders may be found in our 1996 edition (Phys. Rev. **D54**, 1 July 1996, Part I).

23. PASSAGE OF PARTICLES THROUGH MATTER

Revised May 1998 by D.E. Groom (LBNL).

23.1. Notation

Table 23.1: Summary of variables used in this section. The kinematic variables β and γ have their usual meanings.

Symbol	Definition	Units or Value
α	Fine structure constant	1/137.035 989 5(61)
M	Incident particle mass	${ m MeV}/c^2$
\boldsymbol{E}	Incident particle energy γMc^2	MeV
T	Kinetic energy	MeV
m_ec^2	Electron mass $\times c^2$	0.510 999 06(15) MeV
r_e	Classical electron radius $e^2/4\pi\epsilon_0 m_e c^2$	2.817 940 92(38) fm
N_A	Avogadro's number	$6.0221367(36)\times10^{23}\mathrm{mol}^{-1}$
ze	Charge of incident particle	• •
\boldsymbol{z}	Atomic number of medium	
\boldsymbol{A}	Atomic mass of medium	$g mol^{-1}$
K/A	$4\pi N_A r_e^2 m_e c^2/A$	0.307075 MeV g^{-1} cm ² for $A = 1$ g mol ⁻¹
I	Mean excitation energy	eV
δ	Density effect correction to ion	ization energy loss
$\hbar\omega_p$	Plasma energy $\sqrt{4\pi N_e r_e^3} \ m_e c^2/\alpha$	$28.816\sqrt{ ho\langle Z/A\rangle} \text{ eV}^{(a)}$
N_c	Electron density	(units of r_e) ⁻³
w_j	Weight fraction of the jth elem	ent in a compound or mixture
n_{j}	∝ number of jth kind of atoms	
X_0	Radiation length	g cm ⁻²
_	$4\alpha re^2 N_A/A$	$(716.408 \text{ g cm}^{-2})^{-1}$ for $A = 1 \text{ g mol}^{-1}$
E_c	Critical energy	MeV
E_s	Scale energy $\sqrt{4\pi/\alpha} \ m_e c^2$	21.2052 MeV
R_{M}	Molière radius	$ m MeV~g^{-1}~cm^2$

⁽a) For ρ in g cm⁻³.

23.2. Ionization energy loss by heavy particles [1-5]

Moderately relativistic charged particles other than electrons lose energy in matter primarily by ionization. The mean rate of energy loss (or stopping power) is given by the Bethe-Bloch equation,

$$-\frac{dE}{dx} = Kz^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 T_{\text{max}}}{I^2} - \beta^2 - \frac{\delta}{2} \right] . \tag{23.1}$$

Here $T_{\rm max}$ is the maximum kinetic energy which can be imparted to a free electron in a single collision, and the other variables are defined in Table 23.1. The units are chosen so that dx is measured in mass per unit area, e.g., in g cm⁻².

In this form, the Bethe-Bloch equation describes the energy loss of pions in a material such as copper to about 1% accuracy for energies between about 6 MeV and 6 GeV. At lower energies corrections for tightly-bound atomic electrons and other effects must be made, and at higher energies radiative effects begin to be important. These limits of validity depend on both the effective atomic number of the absorber and the mass of the slowing particle. Low-energy effects will be discussed in Sec. 23.2.2.

The function as computed for pions on copper is shown by the solid curve in Fig. 23.1, and for pions on other materials in Fig. 23.2. A minor dependence on M at the highest energies is introduced through $T_{\rm max}$, but for all practical purposes in high-energy physics dE/dx in a given material is a function only of β . Except in hydrogen, particles of the same velocity have very similar rates of energy loss in different materials; there is a slow decrease in the rate of energy loss with increasing Z. The qualitative difference in stopping power behavior at high energies between a gas (He) and the other materials shown in Fig. 23.2 is due to the density-effect correction, δ , discussed below.

The stopping power functions are characterized by broad minima whose position drops from $\beta \gamma = 3.5$ to 3.0 as Z goes from 7 to 100.

In practical cases, most relativistic particles (e.g., cosmic-ray muons) have energy loss rates close to the minimum, and are said to be minimum ionizing particles, or mip's.

Eq. (23.1) may be integrated to find the total range R for a particle which loses energy only through ionization. Since dE/dx depends only on β , R/M is a function of E/M or pc/M. In practice, range is a useful concept only for low-energy hadrons ($R \lesssim \lambda_I$, where λ_I is the nuclear interaction length), and for muons below a few hundred GeV (above which radiative effects dominate). R/M as a function of $\beta\gamma = pc/M$ is shown for a variety of materials in Fig. 23.3.

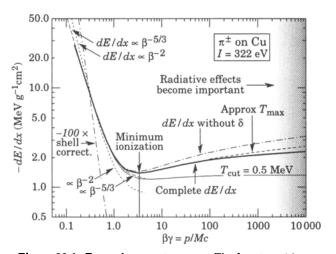

Figure 23.1: Energy loss rate in copper. The function without the density-effect correction, δ , is also shown, as is the loss rate excluding energy transfers with T>0.5 MeV. The shell correction is indicated. The conventional β^{-2} low-energy approximation is compared with $\beta^{-5/3}$.

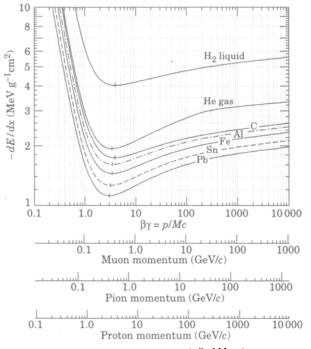

Figure 23.2: Energy loss rate in liquid (bubble chamber) hydrogen, gaseous helium, carbon, aluminum, tin, and lead.

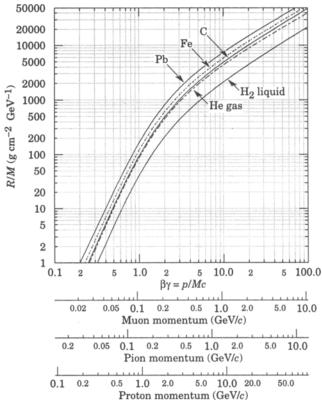

Figure 23.3: Range of heavy charged particles in liquid (bubble chamber) hydrogen, helium gas, carbon, iron, and lead. For example: For a K^+ whose momentum is 700 MeV/c, $\beta\gamma=1.42$. For lead we read $R/M\approx396$, and so the range is 195 g cm⁻².

For a particle with mass M and momentum $M\beta\gamma c$, T_{\max} is given by

$$T_{\rm max} = \frac{2m_e c^2 \, \beta^2 \gamma^2}{1 + 2\gamma m_e/M + (m_e/M)^2} \; . \tag{23.2}$$

It is usual [1,2] to make the "low-energy" approximation $T_{\rm max}=2m_ec^2\,\beta^2\gamma^2$, valid for $2\gamma m_e/M\ll 1$; this, in fact, is done implicitly in many standard references. For a pion in copper, the error thus introduced into dE/dx is greater than 6% at 100 GeV. The correct expression should be used.

At energies of order 100 GeV, the maximum 4-momentum transfer to the electron can exceed 1 GeV/c, where structure effects significantly modify the cross sections. This problem has been investigated by J.D. Jackson [6], who concluded that for hadrons (but not for large nuclei) corrections to dE/dx are negligible below energies where radiative effects dominate. While the cross section for rare hard collisions is modified, the average stopping power, dominated by many softer collisions, is almost unchanged.

The mean excitation energy I is $(10\pm 1~{\rm eV})\times Z$ for elements heavier than sulphur. The values adopted by the ICRU for the chemical elements [7] are now in wide use; these are shown in Fig. 23.4. Machine-readable versions can also be found [8]. Given the availability of these constants and their variation with atomic structure, there seems little point to depending upon approximate formulae, as was done in the past.

Ionization losses by electrons and positrons [7,9,10] are not discussed here. Above the critical energy, which is a few tens of MeV in most materials (see Fig. 23.7, bremsstrahlung is the dominant source of energy loss. This important case is discussed below. The contributions of various electron energy-loss processes in lead are shown in Fig. 24.4.

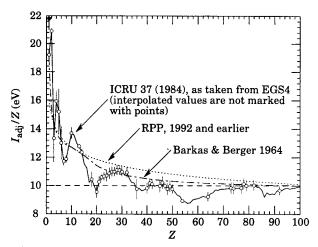

Figure 23.4: Excitation energies (divided by Z) as adopted by the ICRU [7]. Those based on measurement are shown by points with error flags; the interpolated values are simply joined. The solid point is for liquid H_2 ; the open point at 19.2 is for H_2 gas. Also shown are curves based on two approximate formulae.

23.2.1. The density effect: As the particle energy increases, its electric field flattens and extends, so that the distant-collision contribution to Eq. (23.1) increases as $\ln \beta \gamma$. However, real media become polarized, limiting the field extension and effectively truncating this part of the logarithmic rise [4,11-14]. At very high energies,

$$\delta/2 \to \ln(\hbar\omega_p/I) + \ln\beta\gamma - 1/2$$
, (23.3)

where $\delta/2$ is the density effect correction introduced in Eq. (23.1) and $\hbar\omega_p$ is the plasma energy defined in Table 23.1. A comparison with Eq. (23.1) shows that |dE/dx| then grows as $\ln\beta\gamma$ rather than $\ln\beta^2\gamma^2$, and that the mean excitation energy I is replaced by the plasma energy $\hbar\omega_p$. The stopping power as calculated with and without the density effect correction is shown in Fig. 23.1. Since the plasma frequency scales as the square root of the electron density, the correction is much larger for a liquid or solid than for a gas, as is illustrated by the examples in Fig. 23.2.

The density effect correction is usually computed using Sternheimer's parameterization [11]:

iner's parameterization [11]:
$$\delta = \begin{cases} 2(\ln 10)x - \overline{C} & \text{if } x \geq x_1; \\ 2(\ln 10)x - \overline{C} + a(x_1 - x)^k & \text{if } x_0 \leq x < x_1; \\ 0 & \text{if } x < x_0 \text{ (nonconductors)}; \\ \delta_0 10^{2(x-x_0)} & \text{if } x < x_0 \text{ (conductors)} \end{cases}$$

Here $x = \log_{10} \eta = \log_{10}(p/Mc)$. \overline{C} (the negative of the C used in Ref. 11) is obtained by equating the high-energy case of Eq. (23.4) with the limit given in Eq. (23.3). The other parameters are adjusted to give a best fit to the results of detailed calculations for momenta below $Mc\exp(x_1)$. Parameters for elements and nearly 200 compounds and mixtures of interest are published in a variety of places, notably in Ref. 14. A recipe for finding the coefficients for nontabulated materials given by Sternheimer and Peierls [13] is summarized in Ref. 10.

The remaining relativistic rise can be attributed to large energy transfers to a few electrons. If these escape or are otherwise accounted for separately, the energy deposited in an absorbing layer (in contrast to the energy lost by the particle) approaches a constant value, the Fermi plateau (see Sec. 23.2.5 below). The curve in Fig. 23.1 labeled " $T_{\rm cut}=0.5$ MeV" illustrates this behavior. At extreme energies (e.g., > 321 GeV for muons in iron), radiative effects are more important than ionization losses. These are especially relevant for high-energy muons, as discussed in Sec. 23.6.

23.2.2. Energy loss at low energies: A shell correction C/Z is often included in the square brackets of Eq. (23.1) [3,5,7] to correct for atomic binding having been neglected in calculating some of the contributions to Eq. (23.1). We show the Barkas form [3] in Fig. 23.1. For copper it contributes about 1% at $\beta\gamma=0.3$ (kinetic energy 6 MeV for a pion), and the correction decreases very rapidly with energy.

Eq. (23.1) is based on a first-order Born approximation. Higher-order corrections, again important only at lower energy, are normally included by adding a term $z^2L_2(\beta)$ inside the square brackets.

An additional "Barkas correction" $zL_1(\beta)$ makes the stopping power for a negative particle somewhat larger than for a positive particle with the same mass and velocity. In a 1956 paper, Barkas et al. noted that negative pions had a longer range than positive pions [15]. The effect has been measured for a number of negative/positive particle pairs, most recently for antiprotons at the CERN LEAR facility [16].

A detailed discussion of low-energy corrections to the Bethe formula is given in ICRU Report 49 [5]. When the corrections are properly included, the accuracy of the Bethe-Bloch treatment is accurate to about 1% down to $\beta \approx 0.05$, or about 1 MeV for protons.

For $0.01 < \beta < 0.05$, there is no satisfactory theory. For protons, one usually relies on the empirical fitting formulae developed by Andersen and Ziegler [5,17]. For particles moving more slowly than $\approx 0.01c$ (more or less the velocity of the outer atomic electrons), Lindhard has been quite successful in describing electronic stopping power, which is proportional to β [18,19]. Finally, we note that at low energies, e.g., for protons of less than several hundred eV, non-ionizing nuclear recoil energy loss dominates the total energy loss [5,19,20].

As shown in ICRU49 [5] (using data taken from Ref. 17), the nuclear plus electronic proton stopping power in copper is 113 MeV cm² g $^{-1}$ at $T=10~{\rm keV}$, rises to a maximum of 210 MeV cm² g $^{-1}$ at 100–150 keV, then falls to 120 MeV cm² g $^{-1}$ at 1 MeV. Above 0.5–1.0 MeV the corrected Bethe-Block theory is adequate.

23.2.3. Fluctuations in energy loss: The quantity $(dE/dx)\delta x$ is the mean energy loss via interaction with electrons in a layer of the medium with thickness δx . For finite δx , there are fluctuations in the actual energy loss. The distribution is skewed toward high values (the Landau tail) [1,21]. Only for a thick layer $[(dE/dx)\delta x\gg T_{\rm max}]$ is the distribution nearly Gaussian. The large fluctuations in the energy loss are due to the small number of collisions involving large energy transfers. The fluctuations are smaller for the so-called restricted energy loss rate, as discussed in Sec. 23.2.5 below.

23.2.4. Energy loss in mixtures and compounds: A mixture or compound can be thought of as made up of thin layers of pure elements in the right proportion (Bragg additivity). In this case,

$$\frac{dE}{dx} = \sum w_j \left. \frac{dE}{dx} \right|_j , \qquad (23.5)$$

where $dE/dx|_j$ is the mean rate of energy loss (in MeV g cm⁻²) in the jth element. Eq. (23.1) can be inserted into Eq. (23.5) to find expressions for $\langle Z/A \rangle$, $\langle I \rangle$, and $\langle \delta \rangle$; for example, $\langle Z/A \rangle = \sum w_j Z_j/A_j = \sum n_j Z_j/\sum n_j A_j$. However, $\langle I \rangle$ as defined this way is an underestimate, because in a compound electrons are more tightly bound than in the free elements, and $\langle \delta \rangle$ as calculated this way has little relevance, because it is the electron density which matters. If possible, one uses the tables given in Refs. 14 and 10, which include effective excitation energies and interpolation coefficients for calculating the density effect correction for the chemical elements and nearly 200 mixtures and compounds. If a compound or mixture is not found, then one uses the recipe for δ given in Ref. 13 (or Ref. 22), and calculates $\langle I \rangle$ according to the discussion in Ref. 9. (Note the "13%" rule!)

23.2.5. Restricted energy loss rates for relativistic ionizing particles: Fluctuations in energy loss are due mainly to the production of a few high-energy knock-on electrons. Practical detectors often measure the energy deposited, not the energy lost. When energy is carried off by energetic knock-on electrons, it is more appropriate to consider the mean energy loss excluding energy transfers greater than

some cutoff Tcut. The restricted energy loss rate is

$$-\frac{dE}{dx}\Big|_{T < T_{\text{cut}}} = Kz^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 T_{\text{upper}}}{I^2} - \frac{\beta^2}{2} \left(1 + \frac{T_{\text{upper}}}{T_{\text{max}}} \right) - \frac{\delta}{2} \right]$$
(23.6)

where $T_{\rm upper} = {\rm MIN}(T_{\rm cut},T_{\rm max})$. This form agrees with the equation given in previous editions of this Review [23] for $T_{\rm cut} \ll T_{\rm max}$ but smoothly joins the normal Bethe-Bloch function (Eq. (23.1)) for $T_{\rm cut} > T_{\rm max}$.

23.2.6. Energetic knock-on electrons (δ rays): The distribution of secondary electrons with kinetic energies $T \gg I$ is given by [1]

$$\frac{d^2N}{dTdx} = \frac{1}{2} K z^2 \frac{Z}{A} \frac{1}{\beta^2} \frac{F(T)}{T^2}$$
 (23.7)

for $I \ll T \leq T_{\rm max}$, where $T_{\rm max}$ is given by Eq. (23.2). The factor F is spin-dependent, but is about unity for $T \ll T_{\rm max}$. For spin-0 particles $F(T) = (1-\beta^2T/T_{\rm max})$; forms for spins 1/2 and 1 are also given by Rossi [1]. When Eq. (23.7) is integrated from $T_{\rm cut}$ to $T_{\rm max}$, one obtains the difference between Eq. (23.1) and Eq. (23.6). For incident electrons, the indistinguishability of projectile and target means that the range of T extends only to half the kinetic energy of the incident particle. Additional formulae are given in Ref. 24. Equation (23.7) is inaccurate for T close to I: for $2I \lesssim T \lesssim 10I$, the $1/T^2$ dependence above becomes approximately $T^{-\eta}$, with $3 \lesssim \eta \lesssim 5$ [25].

23.2.7. Ionization yields: Physicists frequently relate total energy loss to the number of ion pairs produced near the particle's track. This relation becomes complicated for relativistic particles due to the wandering of energetic knock-on electrons whose ranges exceed the dimensions of the fiducial volume. For a qualitative appraisal of the nonlocality of energy deposition in various media by such modestly energetic knock-on electrons, see Ref. 26. The mean local energy dissipation per local ion pair produced, W, while essentially constant for relativistic particles, increases at slow particle speeds [27]. For gases, W can be surprisingly sensitive to trace amounts of various contaminants [27]. Furthermore, ionization yields in practical cases may be greatly influenced by such factors as subsequent recombination [28].

23.3. Multiple scattering through small angles

A charged particle traversing a medium is deflected by many small-angle scatters. Most of this deflection is due to Coulomb scattering from nuclei, and hence the effect is called multiple Coulomb scattering. (However, for hadronic projectiles, the strong interactions also contribute to multiple scattering.) The Coulomb scattering distribution is well represented by the theory of Molière [29]. It is roughly Gaussian for small deflection angles, but at larger angles (greater than a few θ_0 , defined below) it behaves like Rutherford scattering, having larger tails than does a Gaussian distribution.

If we define

$$\theta_0 = \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{2}} \theta_{\text{space}}^{\text{rms}}$$
 (23.8)

then it is sufficient for many applications to use a Gaussian approximation for the central 98% of the projected angular distribution, with a width given by [30,31]

a width given by [30,31]
$$\theta_0 = \frac{13.6 \text{ MeV}}{\beta cp} z \sqrt{x/X_0} \left[1 + 0.038 \ln(x/X_0) \right]. \tag{23.9}$$

Here p, βc , and z are the momentum, velocity, and charge number of the incident particle, and x/X_0 is the thickness of the scattering medium in radiation lengths (defined below). This value of θ_0 is from a fit to Molière distribution [29] for singly charged particles with $\beta=1$ for all Z, and is accurate to 11% or better for $10^{-3} < x/X_0 < 100$.

Eq. (23.9) describes scattering from a single material, while the usual problem involves the multiple scattering of a particle traversing many different layers and mixtures. Since it is from a fit to a Molière distribution, it is incorrect to add the individual θ_0 contributions in quadrature; the result is systematically too small. It is much more accurate to apply Eq. (23.9) once, after finding x and X_0 for the combined scatterer.

Lynch and Dahl have extended this phenomenological approach, fitting Gaussian distributions to a variable fraction of the Molière distribution for arbitrary scatterers [31], and achieve accuracies of 2% or better.

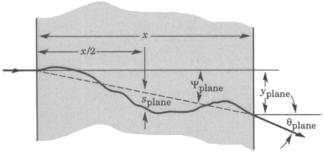

Figure 23.5: Quantities used to describe multiple Coulomb scattering. The particle is incident in the plane of the figure.

The nonprojected (space) and projected (plane) angular distributions are given approximately by [29]

$$\frac{1}{2\pi\,\theta_0^2}\,\exp\left(-\frac{\theta_{\rm space}^2}{2\theta_0^2}\right)\,d\Omega\;,\tag{23.10}$$

$$\frac{1}{\sqrt{2\pi}\,\theta_0}\,\exp\left(-\frac{\theta_{\rm plane}^2}{2\theta_0^2}\right)\,d\theta_{\rm plane}\;, \tag{23.11}$$

where θ is the deflection angle. In this approximation, $\theta_{\mathrm{space}}^2 \approx (\theta_{\mathrm{plane},x}^2 + \theta_{\mathrm{plane},y}^2)$, where the x and y axes are orthogonal to the direction of motion, and $d\Omega \approx d\theta_{\mathrm{plane},x} \, d\theta_{\mathrm{plane},y}$. Deflections into $\theta_{\mathrm{plane},x}$ and $\theta_{\mathrm{plane},y}$ are independent and identically distributed.

Figure 23.5 shows these and other quantities sometimes used to describe multiple Coulomb scattering. They are

$$\psi_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} \theta_0$$
, (23.12)

$$y_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x \theta_{\text{plane}}^{\text{rms}} = \frac{1}{\sqrt{3}} x \theta_0$$
, (23.13)

$$s_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x \theta_{\text{plane}}^{\text{rms}} = \frac{1}{4\sqrt{3}} x \theta_0. \qquad (23.14)$$

All the quantitative estimates in this section apply only in the limit of small $\theta_{\mathrm{plane}}^{\mathrm{rms}}$ and in the absence of large-angle scatters. The random variables $s,\ \psi,\ y,$ and θ in a given plane are distributed in a correlated fashion (see Sec. 28.1 of this *Review* for the definition of the correlation coefficient). Obviously, $y \approx x\psi$. In addition, y and θ have the correlation coefficient $\rho_{y\theta} = \sqrt{3}/2 \approx 0.87$. For Monte Carlo generation of a joint $(y_{\mathrm{plane}},\theta_{\mathrm{plane}})$ distribution, or for other calculations, it may be most convenient to work with independent Gaussian random-variables (z_1,z_2) with mean zero and variance one, and then set

$$y_{\text{plane}} = z_1 x \,\theta_0 (1 - \rho_{y\theta}^2)^{1/2} / \sqrt{3} + z_2 \,\rho_{y\theta} x \,\theta_0 / \sqrt{3}$$
$$= z_1 x \,\theta_0 / \sqrt{12} + z_2 x \,\theta_0 / 2 ; \qquad (23.15)$$

$$\theta_{\text{plane}} = z_2 \, \theta_0 \, . \tag{23.16}$$

Note that the second term for $y_{\rm plane}$ equals $x\,\theta_{\rm plane}/2$ and represents the displacement that would have occurred had the deflection $\theta_{\rm plane}$ all occurred at the single point x/2.

For heavy ions the multiple Coulomb scattering has been measured and compared with various theoretical distributions [32].

23.4. Radiation length and associated quantities

In dealing with electrons and photons at high energies, it is convenient to measure the thickness of the material in units of the radiation length X_0 . This is the mean distance over which a high-energy electron loses all but 1/e of its energy by bremsstrahlung, and is the appropriate scale length for describing high-energy electromagnetic cascades. X_0 has been calculated and tabulated by Y.S. Tsai [33]:

$$\frac{1}{X_0} = 4\alpha r_e^2 \frac{N_A}{A} \left\{ Z^2 \left[L_{\rm rad} - f(Z) \right] + Z L'_{\rm rad} \right\}. \tag{23.17}$$

For A=1 g mol⁻¹, $4\alpha re^2N_A/A=(716.408 \text{ g cm}^{-2})^{-1}$. $L_{\rm rad}$ and $L'_{\rm rad}$ are given in Table 23.2. The function f(Z) is an infinite sum, but for elements up to uranium can be represented to 4-place accuracy by $f(Z)=a^2[(1+a^2)^{-1}+0.20206$

$$-0.0369 a^2 + 0.0083 a^4 - 0.002 a^6$$
 (23.18)

where $a = \alpha Z$ [34].

Table 23.2: Tsai's L_{rad} and L'_{rad} , for use in calculating the radiation length in an element using Eq. (23.17).

Element	\boldsymbol{z}	$L_{ m rad}$	$L'_{ m rad}$
H	1	5.31	6.144
\mathbf{He}	2	4.79	5.621
Li	3	4.74	5.805
Be	4	4.71	5.924
Others	> 4	$\ln(184.15Z^{-1/3})$	$\ln(1194 Z^{-2/3})$

Although it is easy to use Eq. (23.17) to calculate X_0 , the functional dependence on Z is somewhat hidden. Dahl provides a compact fit to the data [35]:

$$X_0 = \frac{716.4 \text{ g cm}^{-2} A}{Z(Z+1) \ln(287/\sqrt{Z})}$$
 (23.19)

Results obtained with this formula agree with Tsai's values to better than 2.5% for all elements except helium, where the result is about 5% low.

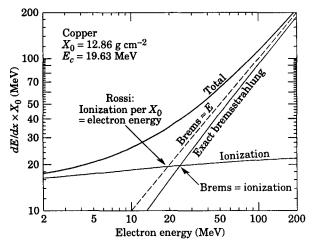

Figure 23.6: Two definitions of the critical energy E_c .

The radiation length in a mixture or compound may be approximated by

$$1/X_0 = \sum w_j/X_j \,\,, \tag{23.20}$$

where w_j and X_j are the fraction by weight and the radiation length for the jth element.

An electron loses energy by bremsstrahlung at a rate nearly proportional to its energy, while the ionization loss rate varies only logarithmically with the electron energy. The critical energy E_c is sometimes defined as the energy at which the two loss rates are equal [36]. Berger and Seltzer [36] also give the approximation $E_c = (800 \text{ MeV})/(Z+1.2)$. This formula has been widely quoted, and has been given in previous editions of this Review [23]. Among alternate definitions is that of Rossi [1], who defines the critical energy as the energy at which the ionization loss per radiation length is equal to the electron energy. Equivalently, it is the same as the first definition with the approximation $|dE/dx|_{\text{brems}} \approx E/X_0$. These definitions are illustrated in the case of copper in Fig. 23.6.

The accuracy of approximate forms for E_c has been limited by the failure to distinguish between gases and solid or liquids, where there

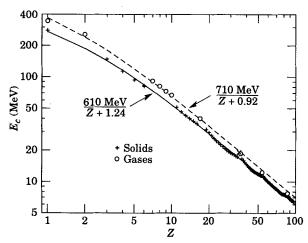

Figure 23.7: Electron critical energy for the chemical elements, using Rossi's definition [1]. The fits shown are for solids and liquids (solid line) and gases (dashed line). The rms deviation is 2.2% for the solids and 4.0% for the gases. (Computed with code supplied by A. Fassó.)

is a substantial difference in ionization at the relevant energy because of the density effect. We distinguish these two cases in Fig. 23.7. Fits were also made with functions of the form $a/(Z+b)^{\alpha}$, but α was essentially unity.

The transverse development of electromagnetic showers in different materials scales fairly accurately with the *Molière radius* R_M , given by [37,38]

$$R_M = X_0 E_s / E_c , (23.21)$$

where $E_s \approx 21$ MeV (see Table 23.1), and the Rossi definition of E_c is used

In a material containing a weight fraction w_j of the element with critical energy E_{cj} and radiation length X_j , the Molière radius is given by

$$\frac{1}{R_M} = \frac{1}{E_s} \sum \frac{w_j E_{cj}}{X_j} . {23.22}$$

For very high-energy photons, the total e^+e^- pair-production cross section is approximately

$$\sigma = \frac{7}{9}(A/X_0N_A) , \qquad (23.23)$$

where A is the atomic weight of the material and N_A is Avogadro's number. Equation Eq. (23.23) is accurate to within a few percent down to energies as low as 1 GeV. The cross section decreases at lower energies, as shown in Fig. 24.4 of this *Review*. As the energy decreases, a number of other processes become important, as is shown in Fig. 24.3 of this *Review*.

23.5. Electromagnetic cascades

When a high-energy electron or photon is incident on a thick absorber, it initiates an electromagnetic cascade as pair production and bremsstrahlung generate more electrons and photons with lower energy. The longitudinal development is governed by the high-energy part of the cascade, and therefore scales as the radiation length in the material. Electron energies eventually fall below the critical energy, and then dissipate their energy by ionization and excitation rather than by the generation of more shower particles. In describing shower behavior, it is therefore convenient to introduce the scale variables

$$t = x/X_0$$

$$y = E/E_c , \qquad (23.24)$$

so that distance is measured in units of radiation length and energy in units of critical energy.

Longitudinal profiles for an EGS4 [22] simulation of a 30 GeV electron-induced cascade in iron are shown in Fig. 23.8. The number of particles crossing a plane (very close to Rossi's II function [1]) is sensitive to the cutoff energy, here chosen as a total energy of

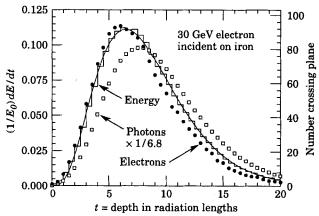

Figure 23.8: An EGS4 simulation of a 30 GeV electron-induced cascade in iron. The histogram shows fractional energy deposition per radiation length, and the curve is a gamma-function fit to the distribution. Circles indicate the number of electrons with total energy greater than 1.5 MeV crossing planes at $X_0/2$ intervals (scale on right) and the squares the number of photons with $E \geq 1.5$ MeV crossing the planes (scaled down to have same area as the electron distribution).

1.5 MeV for both electrons and photons. The electron number falls off more quickly than energy deposition. This is because, with increasing depth, a larger fraction of the cascade energy is carried by photons. Exactly what a calorimeter measures depends on the device, but it is not likely to be exactly any of the profiles shown. In gas counters it may be very close to the electron number, but in glass Čerenkov detectors and other devices with "thick" sensitive regions it is closer to the energy deposition (total track length). In such detectors the signal is proportional to the "detectable" track length T_d , which is in general less than the total track length T_d . Practical devices are sensitive to electrons with energy above some detection threshold E_d , and $T_d = T F(E_d/E_c)$. An analytic form for $F(E_d/E_c)$ obtained by Rossi [1] is given by Fabjan [39]; see also Amaldi [40].

The mean longitudinal profile of the energy deposition in an electromagnetic cascade is reasonably well described by a gamma distribution [41]:

$$\frac{dE}{dt} = E_0 b \frac{(bt)^{a-1} e^{-bt}}{\Gamma(a)}$$
 (23.25)

The maximum $t_{\rm max}$ occurs at (a-1)/b. We have made fits to shower profiles in elements ranging from carbon to uranium, at energies from 1 GeV to 100 GeV. The energy deposition profiles are well described by Eq. (23.25) with

$$t_{\text{max}} = (a-1)/b = 1.0 \times (\ln y + C_j)$$
, $j = e, \gamma$, (23.26)

where $C_e=-0.5$ for electron-induced cascades and $C_{\gamma}=+0.5$ for photon-induced cascades. To use Eq. (23.25), one finds (a-1)/b from Eq. (23.26) and Eq. (23.24), then finds a either by assuming $b\approx 0.5$ or by finding a more accurate value from Fig. 23.9. The results are very similar for the electron number profiles, but there is some dependence on the atomic number of the medium. A similar form for the electron number maximum was obtained by Rossi in the context of his "Approximation B," [1] (see Fabjan's review in Ref. 39), but with $C_e=-1.0$ and $C_{\gamma}=-0.5$; we regard this as superseded by the EGS4 result.

The "shower length" $X_s = X_0/b$ is less conveniently parameterized, since b depends upon both Z and incident energy, as shown in Fig. 23.9. As a corollary of this Z dependence, the number of electrons crossing a plane near shower maximum is underestimated using Rossi's approximation for carbon and seriously overestimated for uranium. Essentially the same b values are obtained for incident electrons and photons. For many purposes it is sufficient to take $b \approx 0.5$.

The gamma distribution is very flat near the origin, while the EGS4 cascade (or a real cascade) increases more rapidly. As a result Eq. (23.25) fails badly for about the first two radiation lengths; it was necessary to exclude this region in making fits.

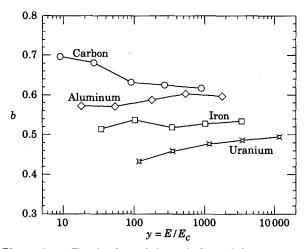

Figure 23.9: Fitted values of the scale factor b for energy deposition profiles obtained with EGS4 for a variety of elements for incident electrons with $1 \le E_0 \le 100$ GeV. Values obtained for incident photons are essentially the same.

Because fluctuations are important, Eq. (23.25) should be used only in applications where average behavior is adequate. Grindhammer et al. have developed fast simulation algorithms in which the variance and correlation of a and b are obtained by fitting Eq. (23.25) to individually simulated cascades, then generating profiles for cascades using a and b chosen from the correlated distributions [42].

Measurements of the lateral distribution in electromagnetic cascades are shown in Refs. 37 and 38. On the average, only 10% of the energy lies outside the cylinder with radius R_M . About 99% is contained inside of $3.5R_M$, but at this radius and beyond composition effects become important and the scaling with R_M fails. The distributions are characterized by a narrow core, and broaden as the shower develops. They are often represented as the sum of two Gaussians, and Grindhammer [42] describes them with the function

$$f(r) = \frac{2r R^2}{(r^2 + R^2)^2} , \qquad (23.27)$$

where R is a phenomenological function of x/X_0 and $\ln E$.

23.6. Muon energy loss at high energy

At sufficiently high energies, radiative processes become more important than ionization for all charged particles. For muons and pions in materials such as iron, this "critical energy" occurs at several hundred GeV. Radiative effects dominate the energy loss of energetic muons found in cosmic rays or produced at the newest accelerators. These processes are characterized by small cross sections, hard spectra, large energy fluctuations, and the associated generation of electromagnetic and (in the case of photonuclear interactions) hadronic showers [45–53]. As a consequence, at these energies the treatment of energy loss as a uniform and continuous process is for many purposes inadequate.

It is convenient to write the average rate of muon energy loss as [43]

$$-dE/dx = a(E) + b(E)E. (23.28)$$

Here a(E) is the ionization energy loss given by Eq. (23.1), and b(E) is the sum of e^+e^- pair production, bremsstrahlung, and photonuclear contributions. To the approximation that these slowly-varying functions are constant, the mean range x_0 of a muon with initial energy E_0 is given by

$$x_0 \approx (1/b) \ln(1 + E_0/E_{\mu c})$$
, (23.29)

where $E_{\mu c}=a/b$. Figure 23.10 shows contributions to b(E) for iron. Since $a(E)\approx 0.002$ GeV g⁻¹ cm², b(E)E dominates the energy loss above several hundred GeV, where b(E) is nearly constant. The rate of energy loss for muons in hydrogen, uranium, and iron is shown in Fig. 23.11 [44].

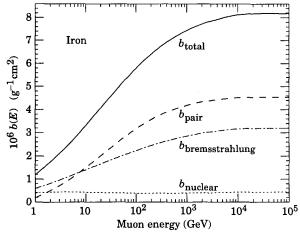

Figure 23.10: Contributions to the fractional energy loss by muons in iron due to e^+e^- pair production, bremsstrahlung, and photonuclear interactions, as obtained from Lohmann *et al.* [44].

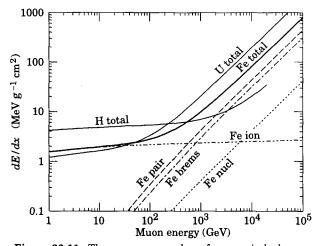

Figure 23.11: The average energy loss of a muon in hydrogen, iron, and uranium as a function of muon energy. Contributions to dE/dx in iron from ionization and the processes shown in Fig. 23.10 are also shown.

The "muon critical energy" $E_{\mu c}$ can be defined more exactly as the energy at which radiative and ionization losses are equal, and can be found by solving $E_{\mu c} = a(E_{\mu c})/b(E_{\mu c})$. This definition corresponds to the solid-line intersection in Fig. 23.6, and is different from the Rossi definition we used for electrons. It serves the same function: below $E_{\mu c}$ ionization losses dominate, and above $E_{\mu c}$ dominate. The dependence of $E_{\mu c}$ on atomic number Z is shown in Fig. 23.12.

The radiative cross sections are expressed as functions of the fractional energy loss ν . The bremsstrahlung cross section goes roughly as $1/\nu$ over most of the range, while for the pair production case the distribution goes as ν^{-3} to ν^{-2} (see Ref. 55). "Hard" losses are therefore more probable in bremsstrahlung, and in fact energy losses due to pair production may very nearly be treated as continuous. The calculated momentum distribution of an incident 1 TeV/c muon beam after it crosses 3 m of iron is shown in Fig. 23.13. The most probable loss is 9 GeV, or 3.8 MeV g⁻¹cm². The full width at half maximum is 7 GeV/c, or 0.7%. The radiative tail is almost entirely due to bremsstrahlung; this includes most of the 10% that lost more than 2.8% of their energy. Most of the 3.3% that lost more than 10% of their incident energy experienced photonuclear interactions, which are concentrated in rare, relatively hard collisions. The latter can exceed nominal detector resolution [56], necessitating the reconstruction of lost energy. Electromagnetic and hadronic cascades in detector materials can obscure muon tracks in detector planes and reduce tracking efficiency [57].

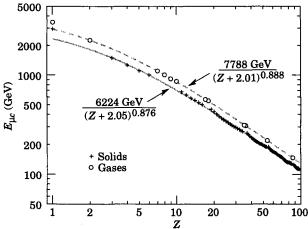

Figure 23.12: Muon critical energy for the chemical elements, defined as the energy at which radiative and ionization energy loss rates are equal. The equality comes at a higher energy for gases than for solids or liquids with the same atomic number because of a smaller density effect reduction of the ionization losses. The fits shown in the figure exclude hydrogen. Alkali metals fall 3-4% above the fitted function for alkali metals, while most other solids are within 2% of the function. Among the gases the worst fit is for neon (1.4% high). (Courtesy of N.V. Mokhov and S.I. Striganov.)

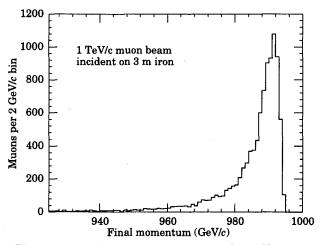

Figure 23.13: The momentum distribution of 1 TeV/c muons after traversing 3 m of iron, as obtained with Van Ginniken's TRAMU muon transport code [55].

23.7. Čerenkov and transition radiation [4,58,59]

A charged particle radiates if its velocity is greater than the local phase velocity of light (Čerenkov radiation) or if it crosses suddenly from one medium to another with different optical properties (transition radiation). Neither process is important for energy loss, but both are used in high-energy physics detectors.

<u>Čerenkov Radiation</u>. The half-angle θ_c of the Čerenkov cone for a particle with velocity β_c in a medium with index of refraction n is

$$\theta_c = \arccos(1/n\beta)$$
 $\approx \sqrt{2(1-1/n\beta)}$ for small θ_c , e.g. in gases. (23.30)

The threshold velocity β_t is 1/n, and $\gamma_t = 1/(1 - \beta_t^2)^{1/2}$. Therefore, $\beta_t \gamma_t = 1/(2\delta + \delta^2)^{1/2}$, where $\delta = n - 1$. Values of δ for various commonly used gases are given as a function of pressure and wavelength in Ref. 60. For values at atmospheric pressure, see Table 6.1. Data for other commonly used materials are given in Ref. 61.

The number of photons produced per unit path length of a particle with charge ze and per unit energy interval of the photons is

$$\frac{d^2 N}{dE dx} = \frac{\alpha z^2}{\hbar c} \sin^2 \theta_c = \frac{\alpha^2 z^2}{r_e m_e c^2} \left(1 - \frac{1}{\beta^2 n^2(E)} \right)$$

$$\approx 370 \sin^2 \theta_c(E) \text{ eV}^{-1} \text{cm}^{-1} \qquad (z = 1) , \qquad (23.31)$$

or, equivalently,

$$\frac{d^2N}{dxd\lambda} = \frac{2\pi\alpha z^2}{\lambda^2} \left(1 - \frac{1}{\beta^2 n^2(\lambda)}\right) . \tag{23.32}$$

The index of refraction is a function of photon energy E, as is the sensitivity of the transducer used to detect the light. For practical use, Eq. (23.31) must be multiplied by the the transducer response function and integrated over the region for which $\beta n(E) > 1$. Further details are given in the discussion of Čerenkov detectors in the Detectors section (Sec. 25 of this *Review*).

<u>Transition Radiation</u>. The energy radiated when a particle with charge ze crosses the boundary between vacuum and a medium with plasma frequency ω_p is

$$I = \alpha z^2 \gamma \hbar \omega_p / 3 , \qquad (23.33)$$

where

$$\begin{split} \hbar\omega_p &= \sqrt{4\pi N_e r_e^3} \ m_e c^2/\alpha \\ &= \sqrt{4\pi N_e a_\infty^3} \ 2\times 13.6 \ \text{eV} \ . \end{split} \tag{23.34}$$

Here N_e is the electron density in the medium, r_e is the classical electron radius, and a_{∞} is the Bohr radius. For styrene and similar materials, $\sqrt{4\pi N_e a_{\infty}^3} \approx 0.8$, so that $\hbar \omega_p \approx 20$ eV. The typical emission angle is $1/\gamma$.

The radiation spectrum is logarithmically divergent at low energies and decreases rapidly for $\hbar\omega/\gamma\hbar\omega_p>1$. About half the energy is emitted in the range $0.1 \le \hbar\omega/\gamma\hbar\omega_p \le 1$. For a particle with $\gamma=10^3$, the radiated photons are in the soft x-ray range 2 to 20 eV. The γ dependence of the emitted energy thus comes from the hardening of the spectrum rather than from an increased quantum yield. For a typical radiated photon energy of $\gamma\hbar\omega_p/4$, the quantum yield is

$$N_{\gamma} \approx \frac{1}{2} \frac{\alpha z^2 \gamma \hbar \omega_p}{3} / \frac{\gamma \hbar \omega_p}{4}$$

 $\approx \frac{2}{3} \alpha z^2 \approx 0.5\% \times z^2$. (23.35)

More precisely, the number of photons with energy $\hbar\omega > \hbar\omega_0$ is given by [4]

$$N_{\gamma}(\hbar\omega > \hbar\omega_0) = \frac{\alpha z^2}{\pi} \left[\left(\ln \frac{\gamma \hbar\omega_p}{\hbar\omega_0} - 1 \right)^2 + \frac{\pi^2}{12} \right] , \qquad (23.36)$$

within corrections of order $(\hbar\omega_0/\gamma\hbar\omega_p)^2$. The number of photons above a fixed energy $\hbar\omega_0\ll\gamma\hbar\omega_p$ thus grows as $(\ln\gamma)^2$, but the number above a fixed fraction of $\gamma\hbar\omega_p$ (as in the example above) is constant. For example, for $\hbar\omega>\gamma\hbar\omega_p/10$, $N_\gamma=2.519\,\alpha z^2/\pi=0.59\%\times z^2$.

The yield can be increased by using a stack of plastic foils with gaps between. However, interference can be important, and the soft x rays are readily absorbed in the foils. The first problem can be overcome by choosing thicknesses and spacings large compared to the "formation length" $D = \gamma c/\omega_p$, which in practical situations is tens of μ m. Other practical problems are discussed in Sec. 25.

24. PHOTON AND ELECTRON INTERACTIONS WITH MATTER

Revised April 1998 by D.E. Groom (LBNL).

Photon Attenuation Length

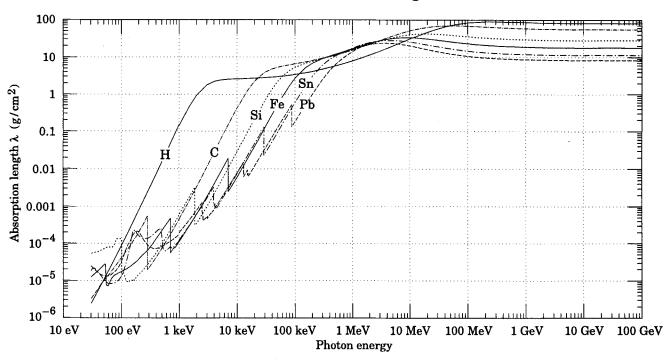

Figure 24.1: The photon mass attenuation length (or mean free path) $\lambda = 1/(\mu/\rho)$ for various elemental absorbers as a function of photon energy. The mass attenuation coefficient is μ/ρ , where ρ is the density. The intensity I remaining after traversal of thickness t (in mass/unit area) is given by $I = I_0 \exp(-t/\lambda)$. The accuracy is a few percent. For a chemical compound or mixture, $1/\lambda_{\text{eff}} \approx \sum_{\text{elements}} w_Z/\lambda_Z$, where w_Z is the proportion by weight of the element with atomic number Z. The processes responsible for attenuation are given in Fig. 24.4. Since coherent processes are included, not all these processes result in energy deposition.

The data for 30 eV < E < 1 keV are obtained from http://www-cxro.lbl.gov/optical_constants (courtesy of Eric M. Gullikson, LBNL). The data for 1 keV < E < 100 GeV are from http://physics.nist.gov/PhysRefData, through the courtesy of John H. Hubbell (NIST).

Photon Pair Conversion Probability

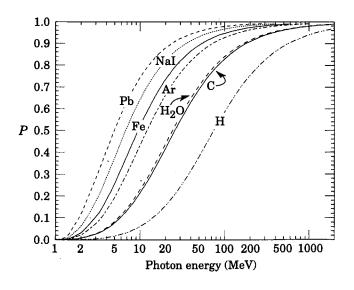

Figure 24.2: Probability P that a photon interaction will result in conversion to an e^+e^- pair. Except for a few-percent contribution from photonuclear absorption around 10 or 20 MeV, essentially all other interactions in this energy range result in Compton scattering off an atomic electron. For a photon attenuation length λ (Fig. 24.1), the probability that a given photon will produce an electron pair (without first Compton scattering) in thickness t of absorber is $P[1-\exp(-t/\lambda)]$.

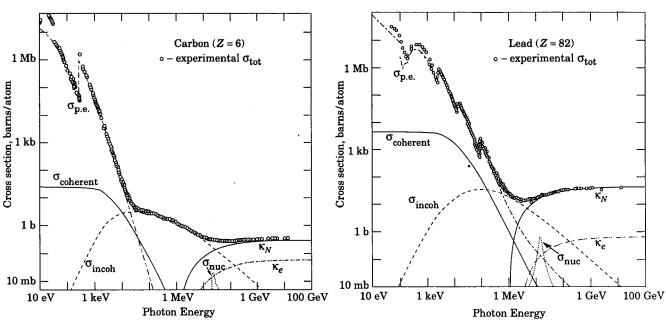

Figure 24.3: Photon total cross sections as a function of energy in carbon and lead, showing the contributions of different processes:

 $\sigma_{p.e.}$ = Atomic photo-effect (electron ejection, photon absorption)

 $\sigma_{\mathrm{coherent}} = \mathrm{Coherent}$ scattering (Rayleigh scattering—atom neither ionized nor excited)

 $\sigma_{\mathrm{incoherent}} = \mathrm{Incoherent}$ scattering (Compton scattering off an electron)

 κ_n = Pair production, nuclear field

 κ_e = Pair production, electron field

 $\sigma_{\rm nuc}$ = Photonuclear absorption (nuclear absorption, usually followed by emission of a neutron or other particle)

From Hubbell, Gimm, and Øverbø, J. Phys. Chem. Ref. Data 9, 1023 (80). Data for these and other elements, compounds, and mixtures may be obtained from http://physics.nist.gov/PhysRefData. The photon total cross section is assumed approximately flat for at least two decades beyond the energy range shown. Figures courtesy J.H. Hubbell (NIST).

Fractional Energy Loss for Electrons and Positrons in Lead

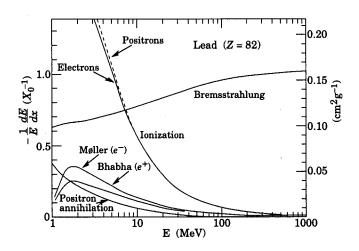

Figure 24.4: Fractional energy loss per radiation length in lead as a function of electron or positron energy. Electron (positron) scattering is considered as ionization when the energy loss per collision is below 0.255 MeV, and as Moller (Bhabha) scattering when it is above. Adapted from Fig. 3.2 from Messel and Crawford, Electron-Photon Shower Distribution Function Tables for Lead, Copper, and Air Absorbers, Pergamon Press, 1970. Messel and Crawford use $X_0(Pb) = 5.82 \text{ g/cm}^2$, but we have modified the figures to reflect the value given in the Table of Atomic and Nuclear Properties of Materials, namely $X_0(Pb)$ $= 6.4 \text{ g/cm}^2$. The development of electron-photon cascades is approximately independent of absorber when the results are expressed in terms of inverse radiation lengths (i.e., scale on left of plot).

25. PARTICLE DETECTORS

Revised 1997 (see the various sections for authors).

In this section we give various parameters for common detector components. The quoted numbers are usually based on typical devices, and should be regarded only as rough approximations for new designs. A more detailed discussion of detectors can be found in Ref. 1. In Table 25.1 are given typical spatial and temporal resolutions of common detectors.

Table 25.1: Typical detector characteristics.

Detector Type	Accuracy (rms)	Resolution Time	Dead Time
Bubble chamber	10 to 150 μm	1 ms	50 ms
Streamer chamber	$300~\mu\mathrm{m}$	$2~\mu s$	100 ms
Proportional chamber	$\geq 300~\mu\mathrm{m}^{b,c}$	50 ns	200 ns
Drift chamber	50 to 300 μm	2 ns^d	100 ns
Scintillator		150 ps	10 ns
Emulsion	$1~\mu\mathrm{m}$		_
Silicon strip	$\frac{\text{pitch }^e}{3 \text{ to } 7}$	f	f
Silicon pixel	$2 \mu m^g$	f	f

- ^a Multiple pulsing time.
- ^b 300 μ m is for 1 mm pitch.
- ^c Delay line cathode readout can give $\pm 150~\mu m$ parallel to anode wire.
- d For two chambers.
- ^e The highest resolution ("7") is obtained for small-pitch detectors ($\lesssim 25 \ \mu m$) with pulse-height-weighted center finding.
- f Limited at present by properties of the readout electronics. (Time resolution of ≤ 15 ns is planned for the SDC silicon tracker.)
- g Analog readout of 34 μm pitch, monolithic pixel detectors.

25.1. Organic scintillators

Written October 1995 by K.F. Johnson (FSU).

Organic scintillators are broadly classed into three types, crystalline, liquid, and plastic, all of which utilize the ionization produced by charged particles (see the section on "Passage of particles through matter" (Sec. 23.2) of this *Review*) to generate optical photons, usually in the blue to green wavelength regions [2]. Plastic scintillators are by far the most widely used and we address them primarily; however, most of the discussion will also have validity for liquid scintillators with obvious caveats. Crystal organic scintillators are practically unused in high-energy physics.

Densities range from 1.03 to 1.20 g cm⁻³. Typical photon yields are about 1 photon per 100 eV of energy deposit [3]. A one-cm-thick scintillator traversed by a minimum-ionizing particle will therefore yield $\approx 2\times 10^4$ photons. The resulting photoelectron signal will depend on the collection and transport efficiency of the optical package and the quantum efficiency of the photodetector.

Plastic scintillators do not respond linearly to the ionization density. Very dense ionization columns emit less light than expected on the basis of dE/dx for minimum-ionizing particles. A widely used semi-empirical model by Birks posits that recombination and quenching effects between the excited molecules reduce the light yield [9]. These effects are more pronounced the greater the density of the excited molecules. Birks' formula is

$$\frac{d\mathcal{L}}{dx} = \mathcal{L}_0 \frac{dE/dx}{1 + k_B dE/dx} , \qquad (25.1)$$

where \mathscr{L} is the luminescence, \mathscr{L}_0 is the luminescence at low specific ionization density, and k_B is Birks' constant, which must be determined for each scintillator by measurement.

Decay times are in the ns range; risetimes are much faster. The combination of high light yield and fast response time allows the possibility of sub-ns timing resolution [4]. The fraction of light emitted during the decay "tail" can depend on the exciting particle. This allows pulse shape discrimination as a technique to carry out particle identification. Because of the hydrogen content (carbon to hydrogen ratio ≈ 1) plastic scintillator is sensitive to proton recoils from neutrons. Ease of fabrication into desired shapes and low cost has made plastic scintillators a common detector component. Recently, plastic scintillators in the form of scintillating fibers have found widespread use in tracking and calorimetry [5].

25.1.1. Scintillation mechanism:

Scintillation: A charged particle traversing matter leaves behind it a wake of excited molecules. Certain types of molecules, however, will release a small fraction ($\approx 3\%$) of this energy as optical photons. This process, scintillation, is especially marked in those organic substances which contain aromatic rings, such as polystyrene, polyvinyltoluene, and napthalene. Liquids which scintillate include toluene and xylene.

Fluorescence: In fluorescence, the initial excitation takes place via the absorption of a photon, and de-excitation by emission of a longer wavelength photon. Fluors are used as "waveshifters" to shift scintillation light to a more convenient wavelength. Occurring in complex molecules, the absorption and emission are spread out over a wide band of photon energies, and have some overlap, that is, there is some fraction of the emitted light which can be re-absorbed [6]. This "self-absorption" is undesirable for detector applications because it causes a shortened attenuation length. The wavelength difference between the major absorption and emission peaks is called the Stokes' shift. It is usually the case that the greater the Stokes' shift, the smaller the self absorption—thus, a large Stokes' shift is a desirable property for a fluor.

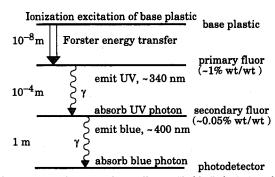

Figure 25.1: Cartoon of scintillation "ladder" depicting the operating mechanism of plastic scintillator. Approximate fluor concentrations and energy transfer distances for the separate sub-processes are shown.

Scintillators: The plastic scintillators used in high-energy physics are binary or ternary solutions of selected fluors in a plastic base containing aromatic rings. (See the appendix in Ref. 7 for a comprehensive list of plastic scintillator components.) Virtually all plastic scintillators contain as a base either polyvinyltoluene, polystyrene, or acrylic, whereby polyvinyltoluene-based scintillator can be up to 50% brighter than the others. Acrylic is non-aromatic and has therefore a very low scintillation efficiency. It becomes an acceptable scintillator when napthalene, a highly aromatic compound, is dissolved into the acrylic at 5% to 20% weight fraction. Thus, in "acrylic" scintillator the active component is napthalene. The fluors must satisfy additional conditions besides being fluorescent. They must be sufficiently stable, soluble, chemically inert, fast, radiation tolerant, and efficient.

The plastic base is the ionization-sensitive (i.e., the scintillator) portion of the plastic scintillator (see Fig. 25.1). In the absence of fluors the base would emit UV photons with short attenuation length (several mm). Longer attenuation lengths are obtained by dissolving a "primary" fluor in high concentration (1% by weight) into the

base, which is selected to efficiently reradiate absorbed energy at wavelengths where the base is more transparent.

The primary fluor has a second important function. The decay time of the scintillator base material can be quite long—in pure polystyrene it is 16 ns, for example. The addition of the primary fluor in high concentration can shorten the decay time by an order of magnitude and increase the total light yield. At the concentrations used (1% and greater), the average distance between a fluor molecule and an excited base unit is around 100 Å, much less than a wavelength of light. At these distances the predominant mode of energy transfer from base to fluor is not the radiation of a photon, but a resonant dipole-dipole interaction, first described by Foerster, which strongly couples the base and fluor [8]. The strong coupling sharply increases the speed and the light yield of the plastic scintillators.

Unfortunately, a fluor which fulfills other requirements is usually not completely adequate with respect to emission wavelength or attenuation length, so it is necessary to add yet another waveshifter (the "secondary" fluor), at fractional percent levels, and ocassionally a third (not shown in Fig. 25.1).

External wavelength shifters: Light emitted from a plastic scintillator may be absorbed in a (nonscintillating) base doped with a waveshifting fluor. Such wavelength shifters are widely used to aid light collection in complex geometries. The wavelength shifter must be insensitive to ionizing radiation and Čerenkov light. A typical wavelength shifter uses an acrylic base (without napthalene!) because of its good optical qualities, a single fluor to shift the light emerging from the plastic scintillator to the blue-green, and contains ultra-violet absorbing additives to deaden response to Čerenkov light.

25.1.2. Caveats and cautions: Plastic scintillators are reliable, robust, and convenient. However, they possess quirks to which the experimenter must be alert.

Aging and Handling: Plastic scintillators are subject to aging which diminishes the light yield. Exposure to solvent vapors, high temperatures, mechanical flexing, irradiation, or rough handling will aggravate the process. A particularly fragile region is the surface which can "craze"—develop microcracks—which rapidly destroy the capability of plastic scintillators to transmit light by total internal reflection. Crazing is particularly likely where oils, solvents, or fingerprints have contacted the surface.

Attenuation length: The Stokes' shift is not the only factor determining attenuation length. Others are the concentration of fluors (the higher the concentration of a fluor, the greater will be its self-absorption); the optical clarity and uniformity of the bulk material; the quality of the surface; and absorption by additives, such as stabilizers, which may be present.

<u>Afterglow</u>: Plastic scintillators have a long-lived luminescence which does not follow a simple exponential decay. Intensities at the 10^{-4} level of the initial fluorescence can persist for hundreds of ns [10].

Atmospheric quenching: Plastic scintillators will decrease their light yield with increasing partial pressure of oxygen. This can be a 10% effect in an artificial atmosphere [11]. It is not excluded that other gasses may have similar quenching effects.

<u>Magnetic field</u>: The light yield of plastic scintillators may be changed by a magnetic field. The effect is very nonlinear and apparently not all types of plastic scintillators are so affected. Increases of $\approx 3\%$ at 0.45 T have been reported [12]. Data are sketchy and mechanisms are not understood.

Radiation damage: Irradiation of plastic scintillators creates color centers which absorb light more strongly in the UV and blue than at longer wavelengths. This poorly understood effect appears as a reduction both of light yield and attenuation length. Radiation damage depends not only on the integrated dose, but on the dose rate, atmosphere, and temperature, before, during and after irradiation, as well as the materials properties of the base such as glass transition temperature, polymer chain length, etc. Annealing also occurs,

accelerated by the diffusion of atmospheric oxygen and elevated temperatures. The phenomena are complex, unpredictable, and not well understood [13]. Since color centers are less intrusive at longer wavelengths, the most reliable method of mitigating radiation damage is to shift emissions at every step to the longest practical wavelengths, e.g., utilize fluors with large Stokes' shifts.

25.2. Inorganic scintillators

Written October 1995 by C.L. Woody (BNL).

Table 25.2 gives a partial list of commonly-used inorganic scintillators in high-energy and nuclear physics [14-21]. These scintillating crystals are generally used where high density and good energy resolution are required. In a crystal which contains nearly all of the energy deposited by an incident particle, the energy resolution is determined largely, but not totally, by the light output. The table gives the light output of the various materials relative to NaI, which has an intrinsic light output of about 40000 photons per MeV of energy deposit. The detected signal is usually quoted in terms of photoelectrons per MeV produced by a given photodetector. The relationship between photons/MeV produced and p.e.'s/MeV detected involves factors for light collection efficiency (typically 10-50%, depending on geometry) and the quantum efficiency of the detector ($\sim 15-20\%$ for photomultiplier tubes and $\sim 70\%$ for silicon photodiodes for visible wavelengths). The quantum efficiency of the detector is usually highly wavelength dependent and should be matched to the particular crystal of interest to give the highest quantum yield at the wavelength corresponding to the peak of the scintillation emission. The comparison of the light output given in Table 25.2 is for a standard photomultiplier tube with a bialkali photocathode. Results with photodiodes can be significantly different; e.g., the CsI(Tl) response relative to NaI(Tl) is 1.4 rather than 0.40 [21]. For scintillators which emit in the UV, a detector with a quartz window should be used.

25.3. Čerenkov detectors

Written October 1993 by D.G. Coyne (UCSC).

Čerenkov detectors utilize one or more of the properties of Čerenkov radiation discussed in the Passages of Particles through Matter section (Sec. 23 of this Review): the existence of a threshold for radiation; the dependence of the Čerenkov cone half-angle θ_c on the velocity of the particle; the dependence of the number of emitted photons on the particle's velocity. The presence of the refractive index n in the relations allows tuning these quantities for a particular experimental application (e.g., using pressurized gas and/or various liquids as radiators).

The number of photoelectrons (p.e.'s) detected in a given device or channel is

$$N_{\rm p.e.} = L \frac{\alpha^2 z^2}{r_e \, m_e c^2} \int \epsilon_{\rm coll}(E) \, \epsilon_{\rm det}(E) \sin^2 \theta_c(E) dE \,, \qquad (25.2)$$

where L is the path length in the radiator, $\epsilon_{\rm coll}$ is the efficiency for collecting the Čerenkov light, $\epsilon_{\rm det}$ is the quantum efficiency of the transducer (photomultiplier or equivalent), and $\alpha^2/(r_e\,m_ec^2)=370~{\rm cm}^{-1}{\rm eV}^{-1}$. The quantities $\epsilon_{\rm coll}$, $\epsilon_{\rm det}$, and θ_c are all functions of the photon energy E, although in typical detectors θ_c (or, equivalently, the index of refraction) is nearly constant over the useful range of photocathode sensitivity. In this case,

$$N_{\rm p.e.} \approx L N_0 \left\langle \sin^2 \theta_c \right\rangle$$
 (25.3)

with

$$N_0 = \frac{\alpha^2 z^2}{r_e \, m_e c^2} \int \epsilon_{\rm coll} \, \epsilon_{\rm det} dE \ . \tag{25.4}$$

We take z=1, the usual case in high-energy physics, in the following discussion.

Threshold Čerenkov detectors make a simple yes/no decision based on whether the particle is above/below the Čerenkov threshold velocity

^{*} For standard photomultiplier tube with a bialkali photocathode. See Ref. 21 for photodiode results.

f =fast component, s =slow component

 $eta_t=1/n$. Careful designs give $\langle\epsilon_{\rm coll}\rangle\gtrsim90\%$. For a photomultiplier with a typical bialkali cathode, $\int\epsilon_{\rm det}dEpprox0.27$, so that

$$N_{\rm p.e.}/L \approx 90~{\rm cm}^{-1}~\left<\sin^2\theta_c\right>~(i.e.,~N_0=90~{\rm cm}^{-1})$$
 . (25.5)

Suppose, for example, that n is chosen so that the threshold for species a is p_t ; that is, at this momentum species a has velocity $\beta_a = 1/n$. A second, lighter, species b with the same momentum has velocity β_b , so $\cos \theta_c = \beta_a/\beta_b$, and

$$\frac{N_{\rm p.e.}}{L} \approx 90 \text{ cm}^{-1} \frac{m_a^2 - m_b^2}{p_t^2 + m_a^2} . \tag{25.6}$$

For K/π separation at p=1 GeV/c, $N_{\rm p.e.}/L\approx 16$ cm⁻¹ for π 's and (by design) 0 for K's.

For limited path lengths $N_{\rm p.e.}$ can be small, and some minimum number is required to trigger external electronics. The overall efficiency of the device is controlled by Poisson fluctuations, which can be especially critical for separation of species where one particle type is dominant [22].

A related class of detectors uses the number of observed photoelectrons (or the calibrated pulse height) to discriminate between species or to set probabilities for each particle species [23].

<u>Differential Čerenkov detectors</u> exploit the dependence of θ_c on β , using optical focusing and/or geometrical masking to select particles having velocities in a specified region. With careful design, a velocity resolution of $\sigma_{\beta}/\beta \approx 10^{-4}$ - 10^{-5} can be obtained [22,24].

Ring-Imaging Čerenkov detectors use all three properties of Čerenkov radiation in both small-aperture and 4π geometries. They are

principally used as hypothesis-testing rather than yes/no devices; that is, the probability of various identification possibilities is established from θ_c and $N_{\rm p.e.}$ for a particle of known momentum. In most cases the optics map the Čerenkov cone onto a circle at the photodetector, often with distortions which must be understood.

The 4π devices [25,26] typically have both liquid (C_6F_{14} , n=1.276) and gas (C_5F_{12} , n=1.0017) radiators, the light from the latter being focused by mirrors. They achieve 3 σ separation of $e/\pi/K/p$ over wide ranges, as shown in Table 25.3. Great attention to detail, especially with the minimization of UV-absorbing impurities, is required to get $\langle \epsilon_{\rm coll} \rangle \gtrsim 50\%$.

Table 25.3: Momentum range for 3σ separation in the SLD ring-imaging Čerenkov detector.

Particle pair	Mom. range for 3 σ separation
e/π	$p \lesssim 5 \text{ GeV}/c$
π/K	$0.23 \lesssim p \lesssim 20 \text{ GeV}/c$
K/p	$0.82 \lesssim p \lesssim 30 $

The phototransducer is typically a TPC/wire-chamber combination sensitive to single photoelectrons and having charge division or pads. This construction permits three-dimensional reconstruction of photoelectron origins, which is important for transforming the Čerenkov cone into a ring. Single photoelectrons are generated by doping the TPC gas (for instance, ethane/methane in some proportion) with $\sim 0.05\%$ TMAE [tetrakis(dimethylamino)ethylene] [27], leading to photon absorption lengths along the Čerenkov cone of ~ 30 mm. The readout wires must be equipped with special structures (blinds or wire gates) to prevent photon feedback from avalanches generating cross-talk photoelectrons in the TPC. Drift-gas purity must be maintained to assure mean drift lengths of the order of meters without recombination (i.e., lifetimes of $\gtrsim 100~\mu s$ at typical drift velocities of $\gtrsim 4~cm/\mu s$). The net $(\epsilon_{\rm det})$'s reach 30%, with the limitation being the TMAE quantum efficiency.

Photon energy cutoffs are set by the TMAE $(E>5.4~{\rm eV})$, the UV transparency of fused silica glass $(E<7.4~{\rm eV})$, and the ${\rm C_6F_{14}}$ $(E<7.1~{\rm eV})$. With effort one gets $50\leq N_0\leq 100$ for complete rings using liquid or gas. This includes losses due to electrostatic shielding wires and window/mirror reflections, but not gross losses caused by total internal reflection or inadequate coverage by the TPC's.

Such numbers allow determination of ring radii to $\sim 0.5\%$ (liquid) and $\sim 2\%$ (gas), leading to the particle species separations quoted above. Since the separation efficiencies may have "holes" as a function of p, detailed calculations are necessary.

25.4. Transition radiation detectors (TRD's)

Revised February 1998 by D. Froidevaux (CERN).

It is clear from the discussion in the Passages of Particles Through Matter section (Sec. 23 of this *Review*) that transition radiation (TR) only becomes useful for particle detectors when the signal can be observed as x rays emitted along the particle direction for Lorentz factors γ larger than 1000. In practice, TRD's are therefore used to provide electron/pion separation for 0.5 GeV/ $c \lesssim p \lesssim 100$ GeV/c. The charged-particle momenta have usually been measured elsewhere in the detector in the past [28].

Since soft x rays, in the useful energy range between 2 and 20 keV, are radiated with about 1% probability per boundary crossing, practical detectors use radiators with several hundred interfaces, e.g. foils or fibres of low-Z materials such as polypropylene (or, more rarely, lithium) in a gas. Absorption inside the radiator itself and in the inactive material of the x-ray detector is important and limits the usefulness of the softer x rays, but interference effects are even larger, and saturate the x-ray yield for electron energies above a few GeV [29,30].

A classical detector is composed of several similar modules, each consisting of a radiator and an x-ray detector, which is usually a wire chamber operated with a xenon-rich mixture, in order efficiently

to absorb the x rays. Since transition-radiation photons are mostly emitted at very small angles with respect to the charged-particle direction, the x-ray detector most often detects the sum of the ionization loss (dE/dx) of the charged particle in the gas and energy deposition of the x rays. The discrimination between electrons and pions can be based on the charges measured in each detection module, on the number of energy clusters observed above an optimal threshold (usually in the 5 to 7 keV region), or on more sophisticated methods analysing the pulse shape as a function of time. Once properly calibrated and optimized, most of these methods yield very similar results.

More recent development work has aimed at increasing the intrinsic quality of the TRD-performance by increasing the probability per detection module of observing a signal from TR-photons produced by electrons. This has been achieved experimentally by distributing small-diameter straw-tube detectors uniformly throughout the radiator material [31]. This method has thereby also cured one of the major drawbacks of more classical TRD's, that is, their need to rely on another detector to measure the charged-particle trajectory. For example, in the straw tracker proposed for one of the LHC experiments [32], charged particles cross about 40 straw tubes embedded in the radiator material. Dedicated R&D work and detailed simulations have shown that the combination of charged-track measurement and particle identification in the same detector will provide a very powerful tool even at the highest LHC luminosity.

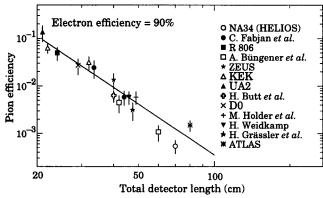

Figure 25.2: Pion efficiency measured (or predicted) for different TRDs as a function of the detector length for a fixed electron efficiency of 90%. The experimental data are directly taken or extrapolated from references [33-45] (top to bottom).

The major factor in the performance of any TRD is its overall length. This is illustrated in Fig. 25.2, which shows, for a variety of detectors, the measured (or predicted) pion efficiency at a fixed electron efficiency of 90% as a function of the overall detector length. The experimental data cover too wide a range of particle energies (from a few GeV to 40 GeV) to allow for a quantitative fit to a universal curve. Fig. 25.2 shows that an order of magnitude in rejection power against pions is gained each time the detector length is increased by \sim 20 cm.

25.5. Silicon photodiodes and particle detectors

Written October 1993 by H.F.W. Sadrozinski (UCSC) and H.G. Spieler (LBNL).

Silicon detectors are p-n junction diodes operated at reverse bias. This forms a sensitive region depleted of mobile charge and sets up an electric field that sweeps charge liberated by radiation to the electrodes. The thickness of the depleted region is

$$W = \sqrt{\frac{2\epsilon \left(V + V_{bi}\right)}{ne}} = \sqrt{2\rho\mu\epsilon(V + V_{bi})}, \qquad (25.7)$$

where V = external bias voltage

 $V_{bi}=$ "built-in" voltage ($\approx 0.8~{
m V}$ for resistivities typically used in detectors

n =doping concentration

e = electron charge

 $\epsilon = \text{dielectric constant} = 11.9 \ \epsilon_0 \approx 1 \ \text{pF/cm}$

 $\rho = \text{resistivity (typically 1-10 k}\Omega \text{ cm)}$

 $\mu = \text{charge carrier mobility}$

= 1350 cm² V⁻¹ s⁻¹ for electrons (n-type material)

= $450 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ for holes (p-type material)

or

$$W = 0.5 \ \mu \text{m} \times \sqrt{\rho (V + V_{bi})}$$
 for n-type material, (25.8)

and

$$W = 0.3 \ \mu \text{m} \times \sqrt{\rho(V + V_{bi})}$$
 for p-type material, (25.9)

where V is in volts and ρ is in Ω cm.

The corresponding capacitance per unit area is

$$C = \frac{\epsilon}{W} \approx 1 \,[\text{pF/cm}] \,\frac{1}{W} \,. \tag{25.10}$$

In strip detectors the capacitance is dominated by the strip-to-strip fringing capacitance of $\sim 1\text{--}1.5~\mathrm{pF}~\mathrm{cm}^{-1}$ of strip length at a strip pitch of 25–50 $\mu\mathrm{m}$.

About 3.6 eV is required to create an electron-hole pair. For minimum-ionizing particles, the most probable charge deposition in a 300 μ m thick silicon detector is about 4 fC (25000 electrons). Readily available photodiodes have quantum efficiences > 70% for wavelengths between 600 nm and 1 μ m. UV extended photodiodes have useful efficiency down to 200 nm. In applications in which photodiodes detect light from scintillators, care must be taken so that signal from the scintillator is larger than that produced by particles going through the photodiode.

Collection time decreases with increased depletion voltage, and can be reduced further by operating the detector with "overbias," i.e., a bias voltage exceeding the value required to fully deplete the device. The collection time is limited by velocity saturation at high fields; at an average field of 10^4 V/cm, the collection times is about 15 ps/ μ m for electrons and 30 ps/ μ m for holes. In typical strip detectors of 300 μ m thickness, electrons are collected within about 8 ns, and holes within about 25 ns.

Position resolution is limited by transverse diffusion during charge collection (typically 5 μ m for 300 μ m thickness) and by knock-on electrons. Resolutions of 3–4 μ m (rms) have been obtained in beam tests. In magnetic fields, the Lorentz drift can increase the spatial spread appreciably (see "Hall effect" in semiconductor textbooks).

Radiation damage occurs through two basic mechanisms:

- Bulk damage due to displacement of atoms from their lattice sites.
 This leads to increased leakage current, carrier trapping, and changes in doping concentration. Displacement damage depends on the nonionizing energy loss, i.e., particle type and energy. The dose should be specified as a fluence of particles of a specific type and energy.
- 2. Surface damage due to charge build-up in surface layers, which leads to increased surface leakage currents. In strip detectors the inter-strip isolation is affected. The effects of charge build-up are strongly dependent on the device structure and on fabrication details. Since the damage is determined directly by the absorbed energy, the dose should be specified in these units (rad or Gray).

The increase in leakage current due to bulk damage is $\Delta i = \alpha \phi$ per unit volume, where ϕ is the particle fluence and α the damage coefficient ($\alpha \approx 2 \times 10^{-17}$ A/cm for minimum ionizing protons and pions after long-term annealing; roughly the same value applies for 1 MeV neutrons). The doping concentration in n-type silicon changes as $n = n_0 \exp(-\delta \phi) - \beta \phi$, where n_0 is the initial donor concentration,

 $\delta \approx 6 \times 10^{14}~{\rm cm}^2$ determines donor removal, and $\beta \approx 0.03~{\rm cm}^{-1}$ describes acceptor creation. This leads to an initial increase in resisitivity until type-inversion changes the net doping from n to p. At this point the resistivity decreases, with a corresponding increase in depletion voltage. The safe operating limit of depletion voltage ultimately limits the detector lifetime. Strip detectors have remained functional at fluences beyond $10^{14}~{\rm cm}^{-2}$ for minimum ionizing protons. At this damage level, charge loss due to recombination and trapping also seems to become significant.

25.6. Proportional and drift chambers

<u>Proportional chamber wire instability</u>: The limit on the voltage V for a wire tension T, due to mechanical effects when the electrostatic repulsion of adjacent wires exceeds the restoring force of wire tension, is given by (SI units) [46]

$$V \le \frac{s}{\ell C} \sqrt{4\pi\epsilon_0 T} , \qquad (25.11)$$

where s, ℓ , and C are the wire spacing, length, and capacitance per unit length. An approximation to C for chamber half-gap t and wire diameter d (good for $s \lesssim t$) gives [47]

$$V \lesssim 59T^{1/2} \left[\frac{t}{\ell} + \frac{s}{\pi \ell} \ln \left(\frac{s}{\pi d} \right) \right] ,$$
 (25.12)

where V is in kV, and T is in grams-weight equivalent.

<u>Proportional and drift chamber potentials</u>: The potential distributions and fields in a proportional or drift chamber can usually be calculated with good accuracy from the exact formula for the potential around an array of parallel line charges q (coul/m) along z and located at $y = 0, \ z = 0, \ \pm s, \ \pm 2s, \ldots$,

$$V(x,y) = -\frac{q}{4\pi \epsilon_0} \ln \left\{ 4 \left[\sin^2 \left(\frac{\pi x}{s} \right) + \sinh^2 \left(\frac{\pi y}{s} \right) \right] \right\} . \tag{25.13}$$

Errors from the presence of cathodes, mechanical defects, TPC-type edge effects, etc., are usually small and are beyond the scope of this review.

25.7. Time-projection chambers

Written November 1997 by M.T. Ronan (LBNL).

Detectors with long drift distances perpendicular to a multi-anode proportional plane provide three-dimensional information, with one being the time projection. A (typically strong) magnetic field parallel to the drift direction suppresses transverse diffusion ($\sigma=\sqrt{2Dt}$) by a factor

$$D(B)/D(0) = \frac{1}{1 + \omega^2 \tau^2}$$
, (25.14)

where D is the diffusion coefficient, $\omega=eB/mc$ is the cyclotron frequency, and τ is the mean time between collisions. Multiple measurements of dE/dx along the particle trajectory combined with the measurement of momentum in the magnetic field allows excellent particle identification [48], as can be seen in Fig. 25.3.

A typical gas-filled TPC consists of a long uniform drift region (1–2 m) generated by a central high-voltage membrane and precision concentric cylindrical field cages within a uniform, parallel magnetic field [49]. Details of construction and electron trajectories near the anode end are shown in Fig. 25.4. Signal shaping and processing using analog storage devices or FADC's allows excellent pattern recognition, track reconstruction, and particle identification within the same detector.

Typical values:

 $\begin{array}{ll} {\rm Gas \cdot Ar \, + \, (10\text{--}20\%) \, \, CH_4} & {\rm Pressure}(P) = 1\text{--}8.5 \, \, {\rm atm.} \\ E/P = 100\text{--}200 \, V/{\rm cm/atm} & B = 1\text{--}1.5 \, \, {\rm Tesla} \\ v_{\rm drift} = 5\text{--}7 \, \, {\rm cm/}\mu {\rm s} & \omega \tau = 1\text{--}8 \\ \sigma_{x \, \, {\rm or} \, \, y} = 100\text{--}200 \, \, \mu {\rm m} & \sigma_{z} = 0.2\text{--}1 \, \, {\rm mm} \\ \sigma_{dE/dx} = 2.5\text{--}5.5 \, \% \end{array}$

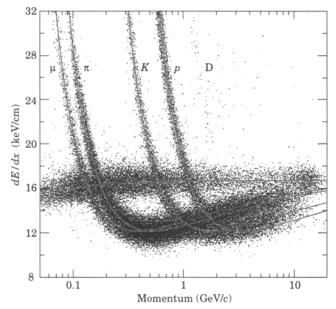

Figure 25.3: PEP4/9-TPC dE/dx measurements (185 samples @8.5 atm Ar-CH₄ 80–20%) in multihadron events. The electrons reach a Fermi plateau value of 1.4 times minimum. Muons from pion decays are separated from pions at low momentum; π/K are separated over all momenta except in the cross-over region. (Low-momentum protons and deuterons originate from hadron-nucleus collisions in inner materials such as the beam pipe.)

Truncated mean dE/dx resolution depends on the number and size of samples, and gas pressure:

$$\sigma_{dE/dx} \propto N^{-0.43} \times (P\ell)^{-0.32}$$
 (25.15)

Here N is the number of samples, ℓ is the sample size, and P is the pressure. Typical dE/dx distributions are shown in Fig. 25.3. Good three-dimensional two-track resolutions of about 1–1.5 cm are routinely achieved.

 $E \times B$ distortions arise from nonparallel E and B fields (see Eq. 2.6 in Ref. 49), and from the curved drift of electrons to the anode wires in the amplification region. Position measurement errors include contributions from the anode-cathode geometry, the track crossing angle (α) , $E \times B$ distortions, and from the drift diffusion of electrons

$$\sigma_{x \text{ or } y}^2 = \sigma_0^2 + \sigma_D^2 (1 + \tan^2 \alpha) L / L_{\text{max}} + \sigma_0^2 (\tan \alpha - \tan \psi)^2$$
 (25.16) .

where σ is the coordinate resolution, σ_0 includes the anode-cathode geometry contribution, ψ is the Lorentz angle, and L is the drift distance.

Space-charge distortions arise in high-rate environments, especially for low values of $\omega \tau$. However, they are mitigated by an effective gating grid (Fig. 25.4). Field uniformities of

$$\int (E_{\perp}/E) \, dz \lesssim 0.5-1 \text{ mm} , \qquad (25.17)$$

over 10-40 m³ volumes have been obtained. Laser tracks and calibration events allow mapping of any remnant drift non-uniformities.

25.8. Calorimeters

Electromagnetic calorimeters: The development of electromagnetic showers is discussed in the "Passage of Particles Through Matter" section (Sec. 23 of this Review). Formulae are given for the approximate description of average showers, but since the physics of electromagnetic showers is well understood, detailed and reliable Monte Carlo simulation is possible. EGS4 has emerged as the standard [50].

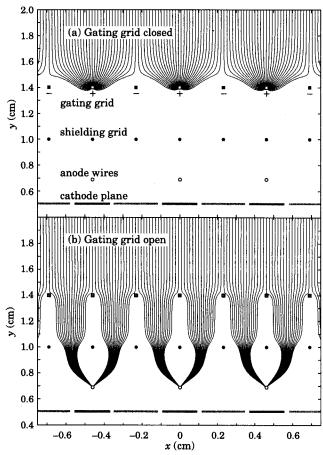

Figure 25.4: (a) Drifting electrons are collected on the gating grid until gated open by a triggering event. A shielding grid at ground potential is used to terminate the drift region. Electrons drifting through an open gating grid (b) pass through to the amplification region around the anode wires. Positive ions generated in the avalanche are detected on segmented cathode pads to provide precise measurements along the wire. The slow positive ions are blocked from entering the drift region by closing the gating grid after the electrons have drifted through.

The resolution of sampling calorimeters (hadronic and electromagnetic) is usually dominated by sampling fluctuations, leading to fractional resolution σ/E scaling inversely as the square root of the incident energy. Homogenous calorimeters, such as solid NaI(Tl), will in general not have resolution varying as $1/\sqrt{E}$. At high energies deviations from $1/\sqrt{E}$ occur because of noise, pedestal fluctuations, nonuniformities, calibration errors, and incomplete shower containment. Such effects are usually included by adding a constant term to σ/E , either in quadrature or (incorrectly) directly. In the case of the hadronic cascades discussed below, noncompensation also contributes to the constant term.

In Table 25.4 we give resolution as measured in detectors using typical EM calorimeter technologies. In almost all cases the installed calorimeters yield worse resolution than test beam prototypes for a variety of practical reasons. Where possible actual detector performance is given. For a fixed number of radiation lengths, the FWHM in sandwich detectors would be expected to be proportional to \sqrt{t} for t (= plate thickness) \geq 0.2 radiation lengths [51].

Given sufficient transverse granularity early in the calorimeter, position resolution of the order of a millimeter can be obtained.

<u>Hadronic calorimeters</u> [59,60]: The length scale appropriate for hadronic cascades is the nuclear interaction length, given very roughly by

$$\lambda_I \approx 35 \text{ g cm}^{-2} A^{1/3}$$
 (25.18)

Table 25.4: Resolution of typical electromagnetic calorimeters. E is in GeV.

Detector	Resolution
NaI(Tl) (Crystal Ball [52]; 20 X ₀)	$2.7\%/E^{1/4}$
Lead glass (OPAL [53])	$5\%/\sqrt{E}$
Lead-liquid argon (NA31 [54]; 80 cells: 27 X_0 , 1.5 mm Pb + 0.6 mm Al + 0.8 mm G10 + 4 mm LA)	$7.5\%/\sqrt{E}$
Lead-scintillator sandwich (ARGUS [55], LAPP-LAL [56])	$9\%/\sqrt{E}$
Lead-scintillator spaghetti (CERN test module) [57]	$13\%/\sqrt{E}$
Proportional wire chamber (MAC; 32 cells: 13 X_0 , 2.5 mm typemetal + 1.6 mm Al) [58]	$23\%/\sqrt{E}$

Longitudinal energy deposition profiles are characterized by a sharp peak near the first interaction point (from the fairly local deposition of EM energy resulting from π^0 's produced in the first interaction), followed by a more gradual development with a maximum at

$$x/\lambda_I \equiv t_{\text{max}} \approx 0.2 \ln(E/1 \text{ GeV}) + 0.7 \tag{25.19}$$

as measured from the front of the detector.

The depth required for containment of a fixed fraction of the energy also increases logarithmically with incident particle energy. The thickness of iron required for 95% (99%) containment of cascades induced by single hadrons is shown in Fig. 25.5 [61]. Two of the sets of data are from large neutrino experiments, while the third is from a commonly used parametrization. Depths as measured in nuclear interaction lengths presumably scale to other materials. From the same data it can be concluded that the requirement that 95% of the energy in 95% of the showers be contained requires 40 to 50 cm (2.4 to $3.0~\lambda_I$) more material material than for an average 95% containment.

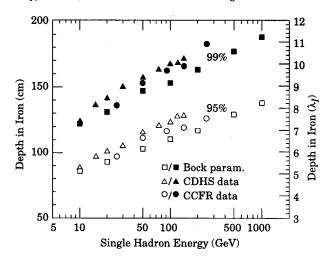

Figure 25.5: Required calorimeter thickness for 95% and 99% hadronic cascade containment in iron, on the basis of data from two large neutrino detectors and the parametrization of Bock et al. [61].

The transverse dimensions of hadronic showers also scale as λ_I , although most of the energy is contained in a narrow core.

The energy deposit in a hadronic cascade consists of a prompt EM component due to π^0 production and a slower component mainly due to low-energy hadronic activity. In general, these energy depositions are converted to electrical signals with different efficiencies [62]. The ratio of the conversion efficiencies is usually called the intrinsic e/h ratio. If e/h=1.0 the calorimeter is said to be compensating. If it differs from unity by more than 5% or 10%, detector performance is compromised because of fluctuations in the π^0 content of the cascades. Problems include:

- a) A skewed signal distribution;
- b) A response ratio for electrons and hadrons (the " e/π ratio") which is different from unity and depends upon energy;
- c) A nonlinear response to hadrons (the response per GeV is proportional to the reciprocal of e/π);
- d) A constant contribution to detector resolution, almost proportional to the degree of noncompensation. The coefficient relating the constant term to |1 e/h| is 14% according to FLUKA simulations, and 21% according to Wigman's calculations [59].

In most cases e/h is greater than unity, particularly if little hydrogen is present or if the gate time is short. This is because much of the low-energy hadronic energy is "hidden" in nuclear binding energy release, low-energy spallation products, etc. Partial correction for these losses occurs in a sampling calorimeter with thick plates, because a disproportionate fraction of electromagnetic energy is deposited in the inactive region. For this reason, a fully sensitive detector such as BGO or glass cannot be made compensating.

Compensation has been demonstrated in calorimeters with 2.5 mm scintillator sheets sandwiched between 3 mm depleted uranium plates [64] or 10 mm lead plates [65]; resolutions σ/E of $0.34/\sqrt{E}$ and $0.44/\sqrt{E}$ were obtained for these cases (E in GeV). The former was shown to be linear to within 2% over three orders of magnitude in energy, with approximately Gaussian signal distributions.

25.9. Measurement of particle momenta in a uniform magnetic field [71,72]

The trajectory of a particle with momentum p (in GeV/c) and charge ze in a constant magnetic field \overrightarrow{B} is a helix, with radius of curvature R and pitch angle λ . The radius of curvature and momentum component perpendicular to \overrightarrow{B} are related by

$$p\cos\lambda = 0.3zBR, \qquad (25.20)$$

where B is in tesla and R is in meters.

The distribution of measurements of the curvature $k \equiv 1/R$ is approximately Gaussian. The curvature error for a large number of uniformly spaced measurements on the trajectory of a charged particle in a uniform magnetic field can be approximated by

$$(\delta k)^2 = (\delta k_{\rm res})^2 + (\delta k_{\rm ms})^2$$
, (25.21)

where $\delta k = \text{curvature error}$

 $\delta k_{\rm res} =$ curvature error due to finite measurement resolution

 $\delta k_{\rm ms} =$ curvature error due to multiple scattering.

If many (≥ 10) uniformly spaced position measurements are made along a trajectory in a uniform medium,

$$\delta k_{\rm res} = \frac{\epsilon}{L'^2} \sqrt{\frac{720}{N+4}} , \qquad (25.22)$$

where N = number of points measured along track

L' = the projected length of the track onto the bending plane

 $\epsilon=$ measurement error for each point, perpendicular to the trajectory.

If a vertex constraint is applied at the origin of the track, the coefficient under the radical becomes 320.

For arbitrary spacing of coordinates s_i measured along the projected trajectory and with variable measurement errors ϵ_i the curvature error $\delta k_{\rm res}$ is calculated from:

$$(\delta k_{\rm res})^2 = \frac{4}{w} \frac{V_{ss}}{V_{ss}V_{s^2s^2} - (V_{ss^2})^2}, \qquad (25.23)$$

where V are covariances defined as $V_{s^ms^n}=\langle s^ms^n\rangle-\langle s^m\rangle\langle s^n\rangle$ with $\langle s^m\rangle=w^{-1}\sum(s_i^m/\epsilon_i^{\ 2})$ and $w=\sum\epsilon_i^{-2}$.

The contribution due to multiple Coulomb scattering is approximately

$$\delta k_{\rm ms} \approx \frac{(0.016)({\rm GeV}/c)z}{Lp\beta\cos^2\lambda}\sqrt{\frac{L}{X_0}} \ , \eqno(25.24)$$

where p = momentum (GeV/c)

z = charge of incident particle in units of e

L = the total track length

 X_0 = radiation length of the scattering medium (in units of length; the X_0 defined elsewhere must be multiplied by density)

 β = the kinematic variable v/c.

More accurate approximations for multiple scattering may be found in the section on Passage of Particles Through Matter (Sec. 23 of this *Review*). The contribution to the curvature error is given approximately by $\delta k_{\rm ms} \approx 8 s_{\rm plane}^{\rm rms}/L^2$, where $s_{\rm plane}^{\rm rms}$ is defined there.

25.10. Superconducting solenoids for collider detectors

Revised October 1997 by R.D. Kephart (FNAL).

25.10.1. Basic (approximate) equations: In all cases SI units are assumed, so that B is in tesla, E is in joules, dimensions are in meters, and $\mu_0 = 4\pi \times 10^{-7}$.

Magnetic field: The magnetic field at the center of a solenoid of length L and radius R, having N total turns and a current I is

$$B(0,0) = \frac{\mu_0 NI}{\sqrt{L^2 + 4R^2}} \,. \tag{25.25}$$

Stored energy: The energy stored in the magnetic field of any magnet is calculated by integrating B^2 over all space:

$$E = \frac{1}{2\mu_0} \int B^2 dV \ . \tag{25.26}$$

For a solenoid with an iron flux return in which the magnetic field is < 2T, the field in the aperture is approximately uniform and equal to $\mu_0 NI/L$. If the thickness of the coil is small, (which is the case if it is superconducting), then

$$E \approx (\pi/2\mu_0)B^2R^2L$$
 (25.27)

Cost of a superconducting solenoid [73]:

Cost (in M\$) =
$$0.523[(E/(1 \text{ MJ})]^{0.662}$$
 (25.28)

Magnetostatic computer programs: It is too difficult to solve the Biot-Savart equation for a magnetic circuit which includes iron components and so iterative computer programs are used. These include POISSON, TOSCA [74], and ANSYS [75].

25.10.2. Scaling laws for thin solenoids: For a detector in which the calorimetry is outside the aperture of the solenoid, the coil must be thin in terms of radiation and absorption lengths. This usually means that the coil is superconducting and that the vacuum vessel encasing it is of minimum real thickness and fabricated of a material with long radiation length. There are two major contributers to the thickness of a thin solenoid:

- 1. The conductor, consisting of the current-carrying superconducting material (usually Cu/Nb-Ti) and the quench protecting stabilizer (usually aluminum), is wound on the inside of a structural support cylinder (usually aluminum also). This package typically represents about 60% of the total thickness in radiation lengths. The thickness scales approximately as B^2R .
- 2. Approximately another 25% of the thickness of the magnet comes from the outer cylindrical shell of the vacuum vessel. Since this shell is susceptible to buckling collapse, its thickness is determined by the diameter, length, and the modulus of the material of which it is fabricated. When designing this shell to a typical standard, the real thickness is

$$t = P_c D^{2.5} [(L/D) - 0.45(t/D)^{0.5}] / 2.6Y^{0.4}, \qquad (25.29)$$

where t = shell thickness (in), D = shell diameter (in), L = shell length (in), Y = modulus of elasticity (psi), and $P_c =$ design collapse pressure (= 30 psi). For most large-diameter detector solenoids, the thickness to within a few percent is given by [76]

$$t = P_c D^{2.5} (L/D) / 2.6 Y^{0.4} . (25.30)$$

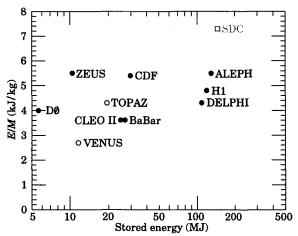

Figure 25.6: Ratio of stored energy to cold mass for existing thin detector solenoids. Solenoids in decommissioned detectors are indicated by open circles.

25.10.3. Properties of collider detector solenoids: The physical dimensions, central field, stored energy and thickness in radiation lengths normal to the beam line of the superconducting solenoids associated with the major colliders are given in Table 25.5.

Table 25.5: Properties of superconducting collider detector solenoids.

Experiment-Lab	Field (T)	Bore Dia (m)	Length (m)	Energy (MJ)	Thickness (X_0)
CDF-Fermilab	1.5	2.86	5.07	30	0.86
DØ -Fermilab	2.0	1.06	2.73	5.6	0.87
BaBar-SLAC	1.5	2.80	3.46	27.0	< 1.4
Topaz-KEK	1.2	2.72	5.4	19.5	0.70
Venus-KEK	0.75	3.4	5.64	12	0.52
Cleo II-Cornell	1.5	2.9	3.8	25	2.5
Aleph-CERN	1.5	5.0	7.0	130	1.7
Delphi-CERN	1.2	5.2	7.4	109	4.0
H1-DESY	1.2	5.2	5.75	120	1.2
Zeus-DESY	1.8	1.72	2.85	10.5	0.9

The ratio of stored energy to cold mass (E/M) is a useful performance measure. One would like the cold mass to be as small as possible to minimize the thickness, but temperature rise during a quench must also be minimized. Ratios as large as 8 kJ/kg may be possible (final temperature of 80 K after a fast quench with homogenous energy dump), but some contingency is desirable. This quantity is shown as a function of total stored energy for some major collider detectors in Fig. 25.6.

25.11. Other observations

dE/dx resolution in argon: Particle identification by dE/dx is dependent on the width of the distribution. For relativistic incident particles with charge e in a multiple-sample Ar gas counter with no lead [66],

$$\frac{dE}{dx}\Big|_{\text{FWHM}} / \frac{dE}{dx}\Big|_{\text{most probable}} = 0.96 N^{-0.46} (xp)^{-0.32} , \quad (25.31)$$

where N = number of samples, x = thickness per sample (cm), p = pressure (atm.). Most commonly used chamber gases (except Xe) give approximately the same resolution.

<u>Free electron drift velocities in liquid ionization chambers</u> [67–70]: Velocity as a function of electric field strength is given in

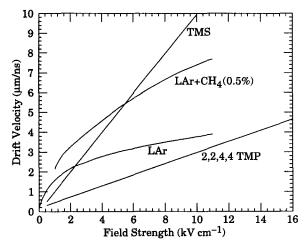

Figure 25.7: Electron drift velocity as a function of field strength for commonly used liquids.

26. RADIOACTIVITY AND RADIATION PROTECTION

Revised March 1998 by R.J. Donahue (LBNL) and A. Fassò (SLAC).

26.1. Definitions

The International Commission on Radiation Units and Measurements (ICRU) recommends the use of SI units. Therefore we list SI units first, followed by cgs (or other common) units in parentheses, where they differ.

- Unit of activity = becquerel (curie):
 - $1~\mathrm{Bq}=1~\mathrm{disintegration~s^{-1}}~[=1/(3.7\times10^{10})~\mathrm{Ci}]$
- Unit of absorbed dose = gray (rad):

$$1 \text{ Gy} = 1 \text{ joule kg}^{-1} \ (= 10^4 \text{ erg g}^{-1} = 100 \text{ rad})$$

$$= 6.24 \times 10^{12} \text{ MeV kg}^{-1} \text{ deposited energy}$$

- Unit of exposure, the quantity of x- or γ radiation at a point in space integrated over time, in terms of charge of either sign produced by showering electrons in a small volume of air about the point:
 - = 1 coul kg $^{-1}$ of air (roentgen; 1 $R = 2.58 \times 10^{-4}$ coul kg $^{-1}$)
 - $= 1 \text{ esu cm}^{-3} (= 87.8 \text{ erg released energy per g of air})$

Implicit in the definition is the assumption that the small test volume is embedded in a sufficiently large uniformly irradiated volume that the number of secondary electrons entering the volume equals the number leaving. This unit is somewhat historical, but appears on many measuring instruments.

• Unit of equivalent dose (for biological damage) = sievert [= 100 rem (roentgen equivalent for man)]: Equivalent dose in Sv = absorbed dose in grays $\times w_R$, where w_R (radiation weighting factor, formerly the quality factor Q) expresses long-term risk (primarily cancer and leukemia) from low-level chronic exposure. It depends upon the type of radiation and other factors, as follows [2]:

Table 26.1: Radiation weighting factors.

Radiation	w_R
X- and γ -rays, all energies	1
Electrons and muons, all energies	1
Neutrons < 10 keV	5
10–100 keV	10
> 100 keV to 2 MeV	20
2-20 MeV	10
> 20 MeV	5
Protons (other than recoils) > 2 MeV	5
Alphas, fission fragments, & heavy nuclei	20

26.2. Radiation levels [3]

- Natural annual background, all sources: Most world areas, whole-body equivalent dose rate ≈ (0.4-4) mSv (40-400 millirems). Can range up to 50 mSv (5 rems) in certain areas. U.S. average ≈ 3.6 mSv, including ≈ 2 mSv (≈ 200 mrem) from inhaled natural radioactivity, mostly radon and radon daughters (0.1-0.2 mSv in open areas. Average is for a typical house and varies by more than an order of magnitude. It can be more than two orders of magnitude higher in poorly ventilated mines).
- Cosmic ray background in counters (Earth's surface): $\sim 1 \text{ min}^{-1} \text{ cm}^{-2} \text{ sr.}$ For more accurate estimates and details, see the Cosmic Rays section (Sec. 20 of this *Review*).
- Fluxes (per cm²) to deposit one Gy, assuming uniform irradiation: $\approx (\text{charged particles}) 6.24 \times 10^9/(dE/dx)$, where dE/dx (MeV g⁻¹ cm²), the energy loss per unit length, may be obtained from the Mean Range and Energy Loss figures.
- $\approx 3.5 \times 10^9~\text{cm}^{-2}$ minimum-ionizing singly-charged particles in carbon.

 \approx (photons) $6.24\times10^9/[Ef/\lambda]$, for photons of energy E (MeV), attenuation length λ (g cm⁻²) (see Photon Attenuation Length figure), and fraction $f\lesssim 1$ expressing the fraction of the photon's energy deposited in a small volume of thickness $\ll \lambda$ but large enough to contain the secondary electrons.

 $\approx 2 \times 10^{11} \text{ photons cm}^{-2} \text{ for 1 MeV photons on carbon } (f \approx 1/2).$ (Quoted fluxes are good to about a factor of 2 for all materials.)

 Recommended limits to exposure of radiation workers (whole-body dose):*

CERN: 15 mSv yr^{-1}

U.K.: 15 mSv yr⁻¹

U.S.: 50 mSv yr⁻¹ (5 rem yr⁻¹) †

• Lethal dose: Whole-body dose from penetrating ionizing radiation resulting in 50% mortality in 30 days (assuming no medical treatment) 2.5-3.0 Gy (250-300 rads), as measured internally on body longitudinal center line. Surface dose varies due to variable body attenuation and may be a strong function of energy.

26.3. Prompt neutrons at accelerators

26.3.1. Electron beams: At electron accelerators neutrons are generated via photonuclear reactions from bremsstrahlung photons. Neutron yields from semi-infinite targets per unit electron beam power are plotted in Fig. 26.1 as a function of electron beam energy [4]. In the photon energy range 10–30 MeV neutron production results from the giant photonuclear resonance mechanism. Neutrons are produced roughly isotropically (within a factor of 2) and with a Maxwellian energy distribution described as:

$$\frac{dN}{dE_n} = \frac{E_n}{T^2} e^{-E_n/T} , \qquad (26.1)$$

where T is the nuclear temperature characteristic of the target nucleus, generally in the range of T=0.5-1.0 MeV. For higher energy photons the quasi-deuteron and photopion production mechanisms become important.

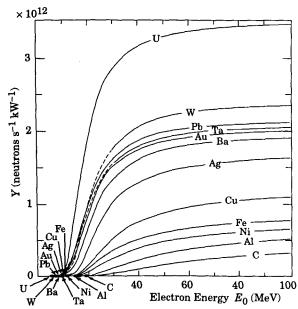

Figure 26.1: Neutron yields from semi-infinite targets, per kW of electron beam power, as a function of electron beam energy, disregarding target self-shielding.

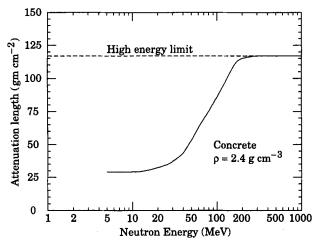

Figure 26.3: The variation of the attenuation length for monoenergetic neutrons in concrete as a function of neutron energy [5].

26.3.2. Proton beams: At proton accelerators neutron yields emitted per incident proton by different target materials are roughly independent [5] of proton energy between 20 MeV and 1 GeV and are given by the ratio C:Al:Cu-Fe:Sn:Ta-Pb = 0.3:0.6:1.0:1.5:1.7. Above 1 GeV neutron yield [6] is proportional to E^m , where $0.80 \le m \le 0.85$.

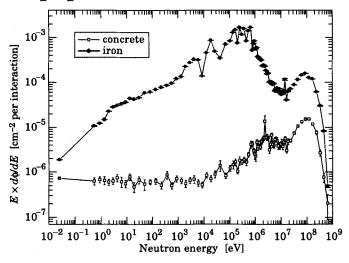

Figure 26.2: Calculated neutron spectrum from 205 GeV/c hadrons (2/3 protons and 1/3 π^+) on a thick copper target. Spectra are evaluated at 90° to beam and through 80 cm of normal density concrete or 40 cm of iron.

A typical neutron spectrum [7] outside a proton accelerator concrete shield is shown in Fig. 26.2. The shape of these spectra are generally characterized as having a thermal-energy peak which is very dependent on geometry and the presence of hydrogenic material, a low-energy evaporation peak around 2 MeV, and a high-energy spallation shoulder.

Letaw's [8] formula for the energy dependence of the inelastic proton cross-section (asymptotic values given in Table 6.1) for E < 2 GeV is:

$$\sigma(E) = \sigma_{\text{asympt}} \left[1 - 0.62e^{-E/200} \sin(10.9E^{-0.28}) \right] , \qquad (26.2)$$

and for E > 2 GeV:

$$\sigma_{\text{asympt}} = 45A^{0.7} [1 + 0.016 \sin(5.3 - 2.63 \ln A)],$$
 (26.3)

where σ is in mb, E is the proton energy in MeV and A is the mass number.

The neutron-attenuation length, λ , is shown in Fig. 26.3 for monoenergetic broad-beam conditions. These values give a satisfactory representation at depths greater than 1 m in concrete.

26.4. Dose conversion factors

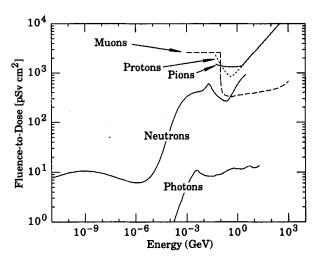

Figure 26.4: Fluence to dose equivalent conversion factors for various particles.

Fluence to dose equivalent factors are given in Fig. 26.4 for photons [9], neutrons [10], muons [11], protons and pions [12]. These factors can be used for converting particle fluence to dose for personnel protection purposes.

26.5. Accelerator-induced activity

The dose rate at 1 m due to spallation-induced activity by high energy hadrons in a 1 g medium atomic weight target can be estimated [13] from the following expression:

$$D = D_0 \Phi \ln[(T+t)/t] , \qquad (26.4)$$

where T is the irradiation time, t is the decay time since irradiation, Φ is the flux of irradiating hadrons (hadrons cm⁻² s⁻¹) and D_0 has a value of 5.2×10^{-17} [(Sv hr⁻¹)/(hadron cm⁻² s⁻¹)]. This relation is essentially independent of hadron energy above 200 MeV.

Dose due to accelerator-produced induced activity can also be estimated with the use of " ω factors" [5]. These factors give the dose rate per unit star density (inelastic reaction for E>50 MeV) after a 30-day irradiation and 1-day decay. The ω factor for steel or iron is $\simeq 3\times 10^{-12}$ (Sv cm³/star). This does not include possible contributions from thermal-neutron activation. Induced activity in concrete can vary widely depending on concrete composition, particularly with the concentration of trace quantities such as sodium. Additional information can be found in Barbier [14].

26.6. Photon sources

The dose rate from a gamma point source of C Curies emitting one photon of energy 0.07 < E < 4 MeV per disintegration at a distance of 30 cm is 6CE (rem/hr), or 60CE (mSv/hr), $\pm 20\%$.

The dose rate from a semi-infinite uniform photon source of specific activity C (μ Ci/g) and gamma energy E (MeV) is 1.07CE (rem/hr), or 10.7CE (mSv/hr).

26.7. Radiation levels in detectors at hadron colliders

An SSC Central Design Group task force studied the radiation levels to be expected in SSC detectors [15]. The study focused on scaling with energy, distance, and angle. As such, it is applicable to future detectors such as those at the LHC. Although superior detector-specific calculations have since been made, the scaling is in most cases not evident, and so the SSC results have some relevance. The SSC/CDG model assumed

- The machine luminosity at $\sqrt{s} = 40$ TeV is $\mathcal{L} = 10^{33}$ cm⁻²s⁻¹, and the pp inelastic cross section is $\sigma_{\rm inel} = 100$ mb. This luminosity is effectively achieved for 10^7 s yr⁻¹. The interaction rate is thus 10^8 s⁻¹, or 10^{15} yr⁻¹;
- All radiation comes from pp collisions at the interaction point:
- The charged particle distribution is (a) flat in pseudorapidity for $|\eta| < 6$ and (b) has a momentum distribution whose perpendicular component is independent of rapidity, which is taken as independent of pseudorapidity:

$$\frac{d^2N_{\rm ch}}{d\eta dp_{\perp}} = H f(p_{\perp}) \tag{26.5}$$

(where $p_{\perp} = p \sin \theta$). Integrals involving $f(p_{\perp})$ are simplified by replacing $f(p_{\perp})$ by $\delta(p_{\perp} - \langle p_{\perp} \rangle)$; in the worst case this approximation introduces an error of less than 10%;

- Gamma rays from π^0 decay are as abundant as charged particles. They have approximately the same η distribution, but half the mean momentum;
- At the SSC ($\sqrt{s}=40$ TeV), $H\approx 7.5$ and $\langle p_{\perp}\rangle\approx 0.6$ GeV/c; assumed values at other energies are given in Table 26.3. Together with the model discussed above, these values are thought to describe particle production to within a factor of two or better.

It then follows that the flux of charged particles from the interaction point passing through a normal area da located a distance r_{\perp} from the beam line is given by

$$\frac{dN_{\rm ch}}{da} = \frac{1.2 \times 10^8 \,\mathrm{s}^{-1}}{r_{\perp}^2} \ . \tag{26.6}$$

In a typical organic material, a relativistic charged particle flux of 3×10^9 cm⁻² produces an ionizing radiation dose of 1 Gy, where 1 Gy \equiv 1 joule kg⁻¹ (= 100 rads). The above result may thus be rewritten as dose rate,

$$\dot{D} = \frac{0.4 \text{ MGy yr}^{-1}}{(r_{\perp}/1 \text{ cm})^2} . \tag{26.7}$$

If a magnetic field is present, "loopers" may increase this dose rate by a factor of two ore more.

In a medium in which cascades can develop, the ionizing dose or neutron fluence is proportional to $dN_{\rm ch}/da$ multiplied by $\langle E \rangle^{\alpha}$, where $\langle E \rangle$ is the mean energy of the particles going through da and the power α is slightly less than unity. Since $E \approx p = p_{\perp}/\sin\theta$ and $r_{\perp} = r\sin\theta$, the above expression for $dN_{\rm ch}/da$ becomes

Dose or fluence[†] =
$$\frac{A}{r^2} \cosh^{2+\alpha} \eta = \frac{A}{r^2 \sin^{2+\alpha} \theta}$$
. (26.8)

The constant A contains the total number of interactions $\sigma_{\text{inel}} \int \mathcal{L} dt$, so the ionizing dose or neutron fluence at another accelerator scales as $\sigma_{\text{inel}} \int \mathcal{L} dt \, H \, \langle p_{\perp} \rangle^{\alpha}$.

The dose or fluence in a calorimeter scales as $1/r^2$, as does the neutron fluence inside a central cavity with characteristic dimension r.

Under all conditions so far studied, the neutron spectrum shows a broad log-normal distribution peaking at just under 1 MeV. In a 2 m radius central cavity of a detector with coverage down to $|\eta|=3$, the average neutron flux is $2\times 10^{12}~{\rm cm}^{-2}{\rm yr}^{-1}$, including secondary scattering contributions.

Values of A and α are given in Table 26.2 for several relevant situations. Examples of scaling to other accelerators are given in Table 26.3. It should be noted that the assumption that all radiation comes from the interaction point does not apply to the present generation of accelerators.

The constant A includes factors evaluated with cascade simulation programs as well as constants describing particle production at the interaction point. It is felt that each could introduce an error as large as a factor of two in the results.

Table 26.2: Coefficients $A/(100 \text{ cm})^2$ and α for the evaluation of calorimeter radiation levels at cascade maxima under SSC nominal operating conditions. At a distance r and angle θ from the interaction point the annual fluence or dose is $A/(r^2 \sin^{2+\alpha} \theta)$.

Quantity	$A/(100 \mathrm{~cm})^2$	Units	$\langle p_{\perp} angle$	α
Neutron flux	1.5×10^{12}	$\mathrm{cm^{-2}yr^{-1}}$	0.6 GeV/c	0.67
Dose rate from photons	124	$\rm Gy~\rm yr^{-1}$	$0.3~{ m GeV}/c$	0.93
Dose rate from hadrons	29	$\rm Gy~\rm yr^{-1}$	$0.6~{ m GeV}/c$	0.89

Table 26.3: A rough comparison of beam-collision induced radiation levels at the Tevatron, high-luminosity LHC, SSC, and a possible 100 TeV machine [16].

	Tevatron	LHC	SSC	100 TeV
\sqrt{s} (TeV)	1.8	15.4	40	100
$\mathscr{L}_{\text{nom}} \ (\text{cm}^{-2}\text{s}^{-1})$	2×10^{30}	$1.7\times10^{34^a}$	1×10^{33}	1×10^{34}
$\sigma_{ m inel}$	56 mb	84 mb	$100 \; \mathrm{mb}$	134 mb
H	3.9	6.2	7.5	10.6
$\langle p_{\perp} angle \; ({ m GeV}/c)$	0.46	0.55	0.60	0.70
Relative dose rate b	5×10^{-4}	11	1	20

- ^a High-luminosity option.
- ^b Proportional to $\mathcal{L}_{\text{nom }\sigma_{\text{inel}}} H \langle p_{\perp} \rangle^{0.7}$

Footnotes:

- * The ICRP recomendation [2] is 20 mSv yr⁻¹ averaged over 5 years, with the dose in any one year ≤ 50 mSv.
- † Many laboratories in the U.S. and elsewhere set lower limits.
- [‡] Dose is the time integral of dose rate, and fluence is the time integral of flux.

"Emission probability" is the probability per decay of a given emission; because of cascades these may total more than 100%. Only principal emissions are listed. EC means electron capture, and e^- means monoenergetic internal conversion (Auger) electron. The intensity of 0.511 MeV e^+e^- annihilation photons depends upon the number of stopped positrons. Endpoint β^\pm energies are listed. In some cases when energies are closely spaced, the γ -ray values are approximate weighted averages. Radiation from short-lived daughter isotopes is included where relevant.

Half-lives, energies, and intensities are from E. Browne and R.B. Firestone, Table of Radioactive Isotopes (John Wiley & Sons, New York, 1986), recent Nuclear Data Sheets, and X-ray and Gamma-ray Standards for Detector Calibration, IAEA-TECDOC-619 (1991)

Neutron data are from Neutron Sources for Basic Physics and Applications (Pergamon Press, 1983).

28. PROBABILITY

Revised May 1996 by D.E. Groom (LBNL) and F. James (CERN).

28.1. General [1-5]

Let x be a possible outcome of an observation. The probability of x is the relative frequency with which that outcome occurs out of a (possibly hypothetical) large set of similar observations. If x can take any value from a continuous range, we write $f(x;\theta) dx$ as the probability of observing x between x and x + dx. The function $f(x; \theta)$ is the probability density function (p.d.f.) for the random variable x, which may depend upon one or more parameters θ . If x can take on only discrete values (e.g., the non-negative integers), then $f(x;\theta)$ is itself a probability, but we shall still call it a p.d.f. The p.d.f. is always normalized to unit area (unit sum, if discrete). Both x and θ may have multiple components and are then often written as column vectors. If θ is unknown and we wish to estimate its value from a given set of data measuring x, we may use statistics (see Sec. 29).

The cumulative distribution function F(a) is the probability that $x \leq a$:

$$F(a) = \int_{-\infty}^{a} f(x) dx . \qquad (28.1)$$

Here and below, if x is discrete-valued, the integral is replaced by a sum. The endpoint a is expressly included in the integral or sum. Then $0 \le F(x) \le 1$, F(x) is nondecreasing, and $Prob(a < x \le b) =$ F(b) - F(a). If x is discrete, F(x) is flat except at allowed values of x, where it has discontinuous jumps equal to f(x).

Any function of random variables is itself a random variable, with (in general) a different p.d.f. The expectation value of any function

$$E[u(x)] = \int_{-\infty}^{\infty} u(x) f(x) dx, \qquad (28.2)$$

assuming the integral is finite. For u(x) and v(x) any two functions of x, E(u+v) = E(u) + E(v). For c and k constants, E(cu+k) =

The nth moment of a distribution is

$$\alpha_n \equiv E(x^n) = \int_{-\infty}^{\infty} x^n f(x) dx$$
, (28.3a)

and the nth moment about the mean of x, α_1 , is

$$m_n \equiv E[(x-\alpha_1)^n] = \int_{-\infty}^{\infty} (x-\alpha_1)^n f(x) dx. \qquad (28.3b)$$

The most commonly used moments are the mean μ and variance σ^2 :

$$\mu \equiv \alpha_1 \tag{28.4a}$$

$$\mu \equiv \alpha_1 \qquad (28.4a)$$

$$\sigma^2 \equiv \operatorname{Var}(x) \equiv m_2 = \alpha_2 - \mu^2 . \qquad (28.4b)$$

The mean is the location of the "center of mass" of the probability density function, and the variance is a measure of the square of its width. Note that $Var(cx + k) = c^2 Var(x)$.

Any odd moment about the mean is a measure of the skewness of the p.d.f. The simplest of these is the dimensionless coefficient of skewness $\gamma_1 \equiv m_3/\sigma^3$.

Besides the mean, another useful indicator of the "middle" of the probability distribution is the median x_{med} , defined by $F(x_{\rm med}) = 1/2$; i.e., half the probability lies above and half lies below x_{med} . For a given sample of events, x_{med} is the value such that half the events have larger x and half have smaller x (not counting any that have the same x as the median). If the sample median lies between two observed x values, it is set by convention halfway between them. If the p.d.f. for x has the form $f(x - \mu)$ and μ is both mean and median, then for a large number of events N, the variance of the median approaches $1/[4Nf^2(0)]$, provided f(0) > 0.

Let x and y be two random variables with a joint p.d.f. f(x, y). The marginal p.d.f. of x (the distribution of x with y unobserved) is

$$f_1(x) = \int_{-\infty}^{\infty} f(x, y) dy$$
, (28.5)

and similarly for the marginal p.d.f. $f_2(y)$. We define the conditional p.d.f. of x, given fixed y, by

$$f_3(y|x) f_1(x) = f(x,y)$$
. (28.6a)

Similarly, the conditional p.d.f. of y, given fixed x, is

$$f_4(x|y) f_2(y) = f(x,y)$$
. (28.6b)

From these definitions we immediately obtain Bayes' theorem [2]:

$$f_4(x|y) = \frac{f_3(y|x) f_1(x)}{f_2(y)} = \frac{f_3(y|x) f_1(x)}{\int f_3(y|x) f_1(x) dx}.$$
 (28.7)

The mean of x is

$$\mu_x = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \ f(x, y) \ dx \ dy = \int_{-\infty}^{\infty} x \ f_1(x) \ dx \ , \tag{28.8}$$

and similarly for y. The correlation between x and y is a measure of the dependence of one on the other:

$$\rho_{xy} = E\left[(x - \mu_x)(y - \mu_y) \right] / \sigma_x \, \sigma_y = \operatorname{Cov}(x, y) / \sigma_x \, \sigma_y , \qquad (28.9)$$

where σ_x and σ_y are defined in analogy with Eq. (28.4b). It can be shown that $-1 \le \rho_{xy} \le 1$. Here "Cov" is the covariance of x and y, a 2-dimensional analogue of the variance.

Two random variables are independent if and only if

$$f(x,y) = f_1(x) f_2(y)$$
. (28.10)

If x and y are independent then $\rho_{xy} = 0$; the converse is not necessarily true except for Gaussian-distributed x and y. If x and y are independent, $E[u(x)\ v(y)] = E[u(x)]\ E[v(y)],$ and $\mathrm{Var}(x+y)$ = Var(x)+Var(y); otherwise, Var(x+y) = Var(x)+Var(y)+2Cov(x, y), and E(u v) does not factor.

In a change of continuous random variables from $x \equiv (x_1, \ldots, x_n)$, with p.d.f. $f(x) = f(x_1, ..., x_n)$, to $y \equiv (y_1, ..., y_n)$, a one-to-one function of the x_i 's, the p.d.f. $g(y) = g(y_1, \ldots, y_n)$ is found by substitution for (x_1, \ldots, x_n) in f followed by multiplication by the absolute value of the Jacobian of the transformation; that is,

$$g(y) = f[w_1(y), \dots, w_n(y)] |J|$$
 (28.11)

The functions w_i express the inverse transformation, $x_i = w_i(y)$ for $i=1,\ldots,n,$ and |J| is the absolute value of the determinant of the square matrix $J_{ij} = \partial x_i/\partial y_j$. If the transformation from x to y is not one-to-one, the situation is more complex and a unique solution . may not exist. For example, if the change is to m < n variables, then a given y may correspond to more than one x, leading to multiple integrals over the contributions [1].

To change variables for discrete random variables simply substitute; no Jacobian is necessary because now f is a probability rather than a

If f depends upon a parameter set α , a change to a different parameter set $\phi_i = \phi_i(\alpha)$ is made by simple substitution; no Jacobian is used.

28.2. Characteristic functions

The characteristic function $\phi(u)$ associated with the p.d.f. f(x) is essentially its (inverse) Fourier transform, or the expectation value of

$$\phi(u) = E(e^{iux}) = \int_{-\infty}^{\infty} e^{iux} f(x) dx . \qquad (28.12)$$

It is often useful, and several of its properties follow [1].

It follows from Eqs. (28.3a) and (28.12) that the *n*th moment of the distribution f(x) is given by

$$i^{-n}\frac{d^n\phi}{du^n}\bigg|_{u=0} = \int_{-\infty}^{\infty} x^n f(x) dx = \alpha_n . \tag{28.13}$$

Thus it is often easy to calculate all the moments of a distribution defined by $\phi(u)$, even when f(x) is difficult to obtain.

If $f_1(x)$ and $f_2(y)$ have characteristic functions $\phi_1(u)$ and $\phi_2(u)$, then the characteristic function of the weighted sum ax + by is $\phi_1(au)\phi_2(bu)$. The addition rules for common distributions (e.g., that the sum of two numbers from Gaussian distributions also has a Gaussian distribution) easily follow from this observation.

Let the (partial) characteristic function corresponding to the conditional p.d.f. $f_2(x|z)$ be $\phi_2(u|z)$, and the p.d.f. of z be $f_1(z)$. The characteristic function after integration over the conditional value is

$$\phi(u) = \int \phi_2(u|z) f_1(z) dz . \qquad (28.14)$$

Suppose we can write ϕ_2 in the form

$$\phi_2(u|z) = A(u)e^{ig(u)z}$$
 (28.15)

Then

$$\phi(u) = A(u)\phi_1(g(u)) . (28.16)$$

The semi-invariants κ_n are defined by

$$\phi(u) = \exp\left(\sum_{1}^{\infty} \frac{\kappa_n}{n!} (iu)^n\right) = \exp\left(i\kappa_1 u - \frac{1}{2}\kappa_2 u^2 + \ldots\right) . \quad (28.17)$$

The κ_n 's are related to the moments α_n and m_n . The first few relations are

$$\kappa_1 = \alpha_1 \ (= \mu, \text{ the mean})$$

$$\kappa_2 = m_2 = \alpha_2 - \alpha_1^2 \ (= \sigma^2, \text{ the variance})$$

$$\kappa_3 = m_3 = \alpha_3 - 3\alpha_1\alpha_2 + 2\alpha_1^2 \ . \tag{28.18}$$

28.3. Some probability distributions

Table 28.1 gives a number of common probability density functions and corresponding characteristic functions, means, and variances. Further information may be found in Refs. 1-6; Ref. 6 has particularly detailed tables. Monte Carlo techniques for generating each of them may be found in our Sec. 30.4. We comment below on all except the trivial uniform distribution.

28.3.1. Binomial distribution: A random process with exactly two possible outcomes is called a Bernoulli process. If the probability of obtaining a certain outcome (a "success") in each trial is p, then the probability of obtaining exactly r successes $(r=0,1,2,\ldots,n)$ in n trials, without regard to the order of the successes and failures, is given by the binomial distribution f(r;n,p) in Table 28.1. If r successes are observed in n_r trials with probability p of a success, and if s successes are observed in n_s similar trials, then t=r+s is also binomial with $n_t=n_r+n_s$.

28.3.2. Poisson distribution: The Poisson distribution $f(r;\mu)$ gives the probability of finding exactly r events in a given interval of x (e.g., space and time) when the events occur independently of one another and of x at an average rate of μ per the given interval. The variance σ^2 equals μ . It is the limiting case $p \to 0$, $n \to \infty$, $np = \mu$ of the binomial distribution. The Poisson distribution approaches the Gaussian distribution for large μ .

Two or more Poisson processes (e.g., signal + background, with parameters μ_s and μ_b) that independently contribute amounts n_s and n_b to a given measurement will produce an observed number $n=n_s+n_b$, which is distributed according to a new Poisson distribution with parameter $\mu=\mu_s+\mu_b$.

28.3.3. Normal or Gaussian distribution: The normal (or Gaussian) probability density function $f(x; \mu, \sigma^2)$ given in Table 28.1 has mean $\overline{x} = \mu$ and variance σ^2 . Comparison of the characteristic function $\phi(u)$ given in Table 28.1 with Eq. (28.17) shows that all semi-invariants κ_n beyond κ_2 vanish; this is a unique property of the Gaussian distribution. Some properties of the distribution are:

rms deviation = σ probability x in the range $\mu \pm \sigma = 0.6827$ probability x in the range $\mu \pm 0.6745\sigma = 0.5$ expection value of $|x - \mu|$, $E(|x - \mu|) = (2/\pi)^{1/2}\sigma = 0.7979\sigma$ half-width at half maximum = $(2 \ln 2)^{1/2}\sigma = 1.177\sigma$

The cumulative distribution, Eq. (28.1), for a Gaussian with $\mu=0$ and $\sigma^2=1$ is related to the error function $\mathrm{erf}(y)$ by

$$F(x;0,1) = \frac{1}{2} \left[1 + \operatorname{erf}(x/\sqrt{2}) \right] . \tag{28.19}$$

The error function is tabulated in Ref. 6 and is available in computer math libraries and personel computer spreadsheets. For a mean μ and variance σ^2 , replace x by $(x - \mu)/\sigma$. The probability of x in a given range can be calculated with Eq. (29.36).

For x and y independent and normally distributed, z = ax + by obeys $f(z; a\mu_x + b\mu_y, a^2\sigma_x^2 + b^2\sigma_y^2)$; that is, the weighted means and variances add.

The Gaussian gets its importance in large part from the central limit theorem: If a continuous random variable x is distributed according to any p.d.f. with finite mean and variance, then the sample mean, \overline{x}_n , of n observations of x will have a p.d.f. that approaches a Gaussian as n increases. Therefore the end result $\sum^n x_i \equiv n\overline{x}_n$ of a large number of small fluctuations x_i will be distributed as a Gaussian, even if the x_i themselves are not.

For a set of n Gaussian random variables x with means μ and corresponding Fourier variables u, the characteristic function for a one-dimensional Gaussian is generalized to

$$\phi(\mathbf{x}; \boldsymbol{\mu}, S) = \exp\left[i\boldsymbol{\mu} \cdot \mathbf{u} - \frac{1}{2}\mathbf{u}^T S \mathbf{u}\right] . \tag{28.20}$$

From Eq. (28.13), the covariance about the mean is

$$E[(x_j - \mu_j)(x_k - \mu_k)] = S_{jk}. (28.21)$$

If the x are independent, then $S_{jk} = \delta_{jk}\sigma_j^2$, and Eq. (28.20) is the product of the c.f.'s of n Gaussians.

The covariance matrix S can be related to the correlation matrix defined by Eq. (28.9) (a sort of normalized covariance matrix). With the definition $\sigma_k^2 \equiv S_{kk}$, we have $\rho_{jk} = S_{jk}/\sigma_j \sigma_k$.

The characteristic function may be inverted to find the corresponding p.d.f.

$$f(x; \mu, S) = \frac{1}{(2\pi)^{n/2} \sqrt{|S|}} \exp\left[-\frac{1}{2}(x - \mu)^T S^{-1}(x - \mu)\right] (28.22)$$

where the determinant |S| must be greater than 0. For diagonal S (independent variables), $f(x; \mu, S)$ is the product of the p.d.f.'s of n Gaussian distributions.

Table 28.1. Some common probability density functions, with corresponding characteristic functions and	
means and variances. In the Table, $\Gamma(k)$ is the gamma function, equal to $(k-1)!$ when k is an integer.

Poisson	$f(r;\mu) = \frac{\mu^r e^{-\mu}}{r!} \; ; r = 0, 1, 2, \dots \; ; \mu > 0$	$\exp[\mu(e^{iu}-1)]$	$\overline{r}=\mu$	μ
Normal (Gaussian)	$f(x; \mu, \sigma^2) = \frac{1}{\sigma \sqrt{2\pi}} \exp(-(x - \mu)^2 / 2\sigma^2)$ $-\infty < x < \infty \; ; -\infty < \mu < \infty \; ; \sigma > 0$	$\exp(i\mu u - \frac{1}{2}\sigma^2 u^2)$	$\overline{x} = \mu$	σ^2
Multivariate Gaussian	$f(oldsymbol{x};oldsymbol{\mu},S) = rac{1}{(2\pi)^{n/2}\sqrt{ S }} \ imes \exp\left[-rac{1}{2}(oldsymbol{x}-oldsymbol{\mu})^TS^{-1}(oldsymbol{x}-oldsymbol{\mu}) ight] \ -\infty < oldsymbol{x}_j < \infty; -\infty < oldsymbol{\mu}_j < \infty; \det S > 0$	$\exp\left[i\boldsymbol{\mu}\cdot\boldsymbol{u}-rac{1}{2}\boldsymbol{u}^TS\boldsymbol{u} ight]$	μ	S_{jk}
χ^2	$f(z;n) = \frac{z^{n/2-1}e^{-z/2}}{2^{n/2}\Gamma(n/2)}$; $z \ge 0$	$(1-2iu)^{-n/2}$	$\overline{z} = n$	2n
Student's t	$f(t;n) = rac{1}{\sqrt{n\pi}} \; rac{\Gamma[(n+1)/2]}{\Gamma(n/2)} \left(1 + rac{t^2}{n} ight)^{-(n+1)/2} onumber \ -\infty < t < \infty \; ; \qquad n ext{ not required to be integer}$. - .	$ar{t}=0 \ ext{for } n\geq 2$	$n/(n-2)$ for $n \ge 3$
Gamma	$f(x;\lambda,k) = rac{x^{k-1}\lambda^k e^{-\lambda x}}{\Gamma(k)}\;; 0 < x < \infty\;;$ k not required to be integer	$(1-iu/\lambda)^{-k}$	$\overline{x} = k/\lambda$	k/λ^2

For n=2, $f(x; \mu, S)$ is

$$f(x_1, x_2; \ \mu_1, \mu_2, \sigma_1, \sigma_2, \rho) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}$$

$$\times \exp\left\{\frac{-1}{2(1-\rho^2)} \left[\frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2} \right] \right\}. \tag{28.23}$$

The marginal distribution of any x_i is a Gaussian with mean μ_i and variance S_{ii} . S is $n \times n$, symmetric, and positive definite. Therefore for any vector \mathbf{X} , the quadratic form $\mathbf{X}^T S^{-1} \mathbf{X} = C$, where C is any positive number, traces an n-dimensional ellipsoid as \mathbf{X} varies. If $X_i = (x_i - \mu_i)/\sigma_i$, then C is a random variable obeying the $\chi^2(n)$ distribution, discussed in the following section. The probability that \mathbf{X} corresponding to a set of Gaussian random variables x_i lies outside the ellipsoid characterized by a given value of $C = \chi^2$ is given by Eq. (28.24) and may be read from Fig. 28.1. For example, the "s-standard-deviation ellipsoid" occurs at $C = s^2$. For the two-variable case (n = 2), the point \mathbf{X} lies outside the one-standard-deviation ellipsoid with 61% probability. (This assumes that μ_i and σ_i are correct.) For $X_i = x_i/\sigma_i$, the ellipsoids of constant χ^2 have the same size and orientation but are centered at μ . The use of these ellipsoids as indicators of probable error is described in Sec. 29.6.4.

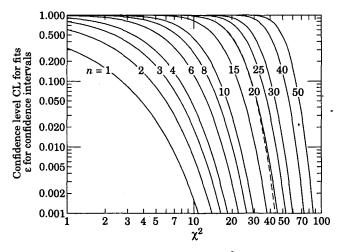

Figure 28.1: The confidence level versus χ^2 for n degrees of freedom, as defined in Eq. (28.24). The curve for a given n gives the probability that a value at least as large as χ^2 will be obtained in an experiment; e.g., for n=10, a value $\chi^2\gtrsim 18$ will occur in 5% of a large number of experiments. For a fit, the CL is a measure of goodness-of-fit, in that a good fit to a correct model is expected to yield a low χ^2 (see Sec. 29.5.0). For a confidence interval, α measures the probability that the interval does not cover the true value of the quantity being estimated (see Sec. 29.6). The dashed curve for n=20 is calculated using the approximation of Eq. (28.25).

28.3.4. χ^2 distribution: If x_1, \ldots, x_n are independent Gaussian distributed random variables, the sum $z = \sum^n (x_i - \mu_i)^2 / \sigma_i^2$ is distributed as a χ^2 with n degrees of freedom, $\chi^2(n)$. Under a linear transformation to n dependent Gaussian variables x_i' , the χ^2 at each transformed point retains its value; then $z = X'^T V^{-1}X'$ as in the previous section. For a set of z_i , each of which is $\chi^2(n_i)$, $\sum z_i$ is a new random variable which is $\chi^2(\sum n_i)$.

Fig. 28.1 shows the confidence level (CL) obtained by integrating the tail of f(z;n):

$$CL(\chi^2) = \int_{\chi^2}^{\infty} f(z; n) dz$$
. (28.24)

This is shown for a special case in Fig. 28.2, and is equal to 1.0 minus the cumulative distribution function $F(z=\chi^2;n)$. It is useful in evaluating the consistency of data with a model (see Sec. 29): The CL is the probability that a random repeat of the given experiment would observe a greater χ^2 , assuming the model is correct. It is also useful for confidence intervals for statistical estimators (see Sec. 29.6), in which case one is interested in the unshaded area of Fig. 28.2.

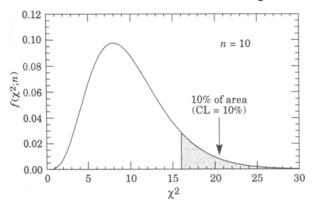

Figure 28.2: Illustration of the confidence level integral given in Eq. (28.24). This particlar example is for n = 10, where the area above 15.99 is 0.1.

Since the mean of the χ^2 distribution is equal to n, one expects in a "reasonable" experiment to obtain $\chi^2 \approx n$. While caution is necessary because of the width and skewness of the distribution, the "reduced χ^2 " $\equiv \chi^2/n$ is a sometimes useful quantity. Figure 28.3 shows χ^2/n for useful CL's as a function of n.

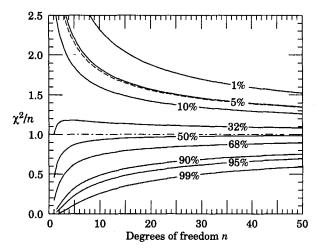

Figure 28.3: Confidence levels as a function of the "reduced χ^2 " $\equiv \chi^2/n$ and the number of degrees of freedom n. Curves are labeled by the probability that a measurement will give a value of χ^2/n greater than that given on the y axis; e.g., for n=10, a value $\chi^2/n \gtrsim 1.8$ can be expected 5% of the time.

For large n, the CL is approximately given by [1,7]

$$CL(\chi^2) \approx \frac{1}{\sqrt{2\pi}} \int_y^\infty e^{-x^2/2} dx$$
, (28.25)

where $y = \sqrt{2\chi^2} - \sqrt{2n-1}$. This approximation was used to draw the dashed curves in Fig. 28.1 (for n=20) and Fig. 28.3 (for CL = 5%). Since all the functions and their inverses are now readily available in standard mathematical libraries (such as IMSL, used to generate these figures, and personal computer spreadsheets, such as Microsoft \mathbb{R} Excel [8]), the approximation (and even figures and tables) are seldom needed.

28.3.5. Student's t distribution: Suppose that x and x_1, \ldots, x_n are independent and Gaussian distributed with mean 0 and variance 1. We then define

$$z = \sum_{i=1}^{n} x_i^2$$
, and $t = \frac{x}{\sqrt{z/n}}$. (28.26)

The variable z thus belongs to a $\chi^2(n)$ distribution. Then t is distributed according to a Student's t distribution with n degrees of freedom, f(t;n), given in Table 28.1.

The Student's t distribution resembles a Gaussian distribution with wide tails. As $n \to \infty$, the distribution approaches a Gaussian. If n=1, the distribution is a *Cauchy* or *Breit-Wigner* distribution. The mean is finite only for n>1 and the variance is finite only for n>2, so for n=1 or n=2, t does not obey the central limit theorem.

As an example, consider the sample mean $\overline{x} = \sum x_i/n$ and the sample variance $s^2 = \sum (x_i - \overline{x})^2/(n-1)$ for normally distributed random variables x_i with unknown mean μ and variance σ^2 . The sample mean has a Gaussian distribution with a variance σ^2/n , so the variable $(\overline{x} - \mu)/\sqrt{\sigma^2/n}$ is normal with mean 0 and variance 1. Similarly, $(n-1) s^2/\sigma^2$ is independent of this and is χ^2 distributed with n-1 degrees of freedom. The ratio

$$t = \frac{(\overline{x} - \mu)/\sqrt{\sigma^2/n}}{\sqrt{(n-1) s^2/\sigma^2 (n-1)}} = \frac{\overline{x} - \mu}{\sqrt{s^2/n}}$$
 (28.27)

is distributed as f(t; n-1). The unknown true variance σ^2 cancels, and t can be used to test the probability that the true mean is some particular value μ .

In Table 28.1, n in f(t;n) is not required to be an integer. A Student's t distribution with nonintegral n > 0 is useful in certain applications.

28.3.6. Gamma distribution: For a process that generates events as a function of x (e.g., space or time) according to a Poisson distribution, the distance in x from an arbitrary starting point (which may be some particular event) to the k^{th} event belongs to a gamma distribution, $f(x; \lambda, k)$. The Poisson parameter μ is λ per unit x. The special case k = 1 (i.e., $f(x; \lambda, 1) = \lambda e^{-\lambda x}$) is called the exponential distribution. A sum of k' exponential random variables x_i is distributed as $f(\sum x_i; \lambda, k')$.

The parameter k is not required to be an integer. For $\lambda = 1/2$ and k = n/2, the gamma distribution reduces to the $\chi^2(n)$ distribution.

29. STATISTICS

Revised April 1998 by F. James (CERN).

29.1. Parameter estimation [1-4]

A probability density function $f(x;\alpha)$ with known parameters α enables us to predict the frequency with which random data x will take on a particular value (if discrete) or lie in a given range (if continuous). In *parametric* statistics we have the opposite problem of estimating the parameters α from a set of actual observations.

A statistic is any function of the data, plus known constants, which does not depend upon any of the unknown parameters. A statistic is a random variable if the data have random errors. An estimator is any statistic whose value (the estimate $\widehat{\alpha}$) is intended as a meaningful guess for the value of the parameter α , or the vector α if there is more than one parameter.

Since we are free to choose any function of the data as an estimator of the parameter α , we will try to choose that estimator which has the best properties. The most important properties are (a) consistency, (b) bias, (c) efficiency, and (d) robustness.

- (a) An estimator is said to be *consistent* if the estimate $\hat{\alpha}$ converges to the true value α as the amount of data increases. This property is so important that it is possessed by all commonly used estimators.
- (b) The bias, $b = E(\widehat{\alpha}) \widehat{\alpha}$, is the difference between the true value and the expectation of the estimates, where the expectation value is taken over a hypothetical set of similar experiments in which $\widehat{\alpha}$ is constructed the same way. When b=0 the estimator is said to be unbiased. The bias may be due to statistical properties of the estimator or to systematic errors in the experiment. If we can estimate the b we can subtract it from $\widehat{\alpha}$ to obtain a new $\widehat{\alpha}' \equiv \widehat{\alpha} b$. However, b may depend upon α or other unknowns, in which case we usually try to choose an estimator which minimizes its average size.
- (c) Efficiency is the inverse of the ratio between the variance of the estimates $Var(\widehat{\alpha})$ and the minimum possible value of the variance. Under rather general conditions, the minimum variance is given by the Rao-Cramér-Frechet bound:

$$Var_{min} = [1 + \partial b/\partial \alpha]^2/I(\alpha);$$
 (29.1)

$$I(\alpha) = E \left\{ \left[\frac{\partial}{\partial \alpha} \sum_{i=1}^{n} \ln f(x_i; \alpha) \right]^2 \right\} .$$

(Compare with Eq. (29.6) below.) The sum is over all data and b is the bias, if any; the x_i are assumed independent and distributed as $f(x_i; \alpha)$, and the allowed range of x must not depend upon α . Mean-squared error, $\operatorname{mse} = E[(\widehat{\alpha} - \alpha)^2] = V(\widehat{\alpha}) + b^2$ is a convenient quantity which combines in the appropriate way the errors due to bias and efficiency.

(d) Robustness; is the property of being insensitive to departures from assumptions in the p.d.f. due to such factors as noise.

For some common estimators the above properties are known exactly. More generally, it is always possible to evaluate them by Monte Carlo simulation. Note that they will often depend on the unknown α .

29.2. Data with a common mean

Suppose we have a set of N independent measurements y_i assumed to be unbiased measurements of the same unknown quantity μ with a common, but unknown, variance σ^2 resulting from measurement error. Then

$$\widehat{\mu} = \frac{1}{N} \sum_{i=1}^{N} y_i = E(y)$$
 (29.2)

$$\widehat{\sigma}^2 = \frac{1}{N-1} \sum_{i=1}^{N} (y_i - \widehat{\mu})^2 = \frac{N}{N-1} \left(E(y^2) - \widehat{\mu}^2 \right)$$
 (29.3)

are unbiased estimators of μ and σ^2 . The variance of $\hat{\mu}$ is σ^2/N . If the common p.d.f. of the y_i is Gaussian, these estimates are uncorrelated. Then, for large N, the standard deviation of $\hat{\sigma}$ (the "error of the

error") is $\sigma/\sqrt{2N}$. Again if the y_i are Gaussian, $\widehat{\mu}$ is an efficient estimator for μ . Otherwise the mean is in general not the most efficient estimator. For example, if the y follow a double-exponential distribution, the most efficient estimator of the mean is the sample median (the value for which half the y_i lie above and half below). This is discussed in more detail in Ref. 2, section 8.7.

If σ^2 is known, it does not improve the estimate $\widehat{\mu}$, as can be seen from Eq. (29.2); however, if μ is known, substitute it for $\widehat{\mu}$ in Eq. (29.3) and replace N-1 by N, to obtain a somewhat better estimator of σ^2 .

If the y_i have different, known, variances σ_i^2 , then the weighted average

$$\widehat{\mu} = \frac{1}{m} \sum_{i}^{N} w_i \ y_i \ , \tag{29.4}$$

is an unbiased estimator for μ with smaller variance than Eq. (29.2), where $w_i = 1/\sigma_i^2$ and $w = \sum w_i$. The standard deviation of $\widehat{\mu}$ is $1/\sqrt{w}$.

29.3. The method of maximum likelihood

29.3.1. Parameter estimation by maximum likelihood:

"From a theoretical point of view, the most important general method of estimation so far known is the *method of maximum likelihood*" [3]. We suppose that a set of independently measured quantities x_i came from a p.d.f. $f(x;\alpha)$, where α is an unknown set of parameters. The method of maximum likelihood consists of finding the set of values, $\hat{\alpha}$, which maximizes the joint probability density for all the data, given by

$$\mathscr{L}(\alpha) = \prod_{i} f(x_i; \alpha) , \qquad (29.5)$$

where \mathcal{L} is called the likelihood. It is usually easier to work with $\ln \mathcal{L}$, and since both are maximized for the same set of α , it is sufficient to solve the *likelihood equation*

$$\frac{\partial \ln \mathcal{L}}{\partial \alpha_n} = 0 \ . \tag{29.6}$$

When the solution to Eq. (29.6) is a maximum, it is called the maximum likelihood estimate of α . The importance of the approach is shown by the following proposition, proved in Ref. 1:

If an efficient estimate $\hat{\alpha}$ of α exists, the likelihood equation will have a unique solution equal to $\hat{\alpha}$.

In evaluating \mathcal{L} , it is important that any normalization factors in the f's which involve α be included. However, we will only be interested in the maximum of \mathcal{L} and in ratios of \mathcal{L} at different α 's; hence any multiplicative factors which do not involve the parameters we want to estimate may be dropped; this includes factors which depend on the data but not on α . The results of two or more independent experiments may be combined by forming the product of the \mathcal{L} 's, or the sum of the $\ln \mathcal{L}$'s.

Most commonly the solution to Eq. (29.6) will be found using a general numerical minimization program such as the CERN program MINUIT [8] which contains considerable code to take account of the many special cases and problems which can arise.

Under a one-to-one change of parameters from α to $\beta = \beta(\alpha)$, the maximum likelihood estimate $\widehat{\alpha}$ transforms to $\beta(\widehat{\alpha})$. That is, the maximum likelihood solution is invariant under change of parameter. However, many properties of $\widehat{\alpha}$, in particular the bias, are not invariant under change of parameter.

29.3.2. Confidence intervals from the likelihood function:

The covariance matrix V may be estimated from

$$V_{nm} = \left(E \left[-\frac{\partial^2 \ln \mathcal{L}}{\partial \alpha_n \partial \alpha_m} \Big|_{\widehat{\alpha}} \right] \right)^{-1} . \tag{29.7}$$

In the asymptotic case (or a linear model with Gaussian errors), $\mathscr L$ is Gaussian, $\ln \mathscr L$ is a (multidimensional) parabola, and the second derivative in Eq. (29.7) is constant, so the "expectation" operation has no effect. This leads to the usual approximation of calculating the error matrix of the parameters by inverting the second derivative matrix of $\ln \mathscr L$. In this asymptotic case, it can be seen that a numerically equivalent way of determining s-standard-deviation errors is from the contour given by the α' such that

$$\ln \mathcal{L}(\alpha') = \ln \mathcal{L}_{\text{max}} - s^2/2 , \qquad (29.8)$$

where $\ln \mathcal{L}_{\text{max}}$ is the value of $\ln \mathcal{L}$ at the solution point (compare with Eq. (29.32), below). The extreme limits of this contour parallel to the α_n axis give an approximate s-standard-deviation confidence interval in α_n . These intervals may not be symmetric and in pathological cases they may even consist of two or more disjoint intervals.

Although asymptotically Eq. (29.7) is equivalent to Eq. (29.8) with s=1, the latter is a better approximation when the model deviates from linearity. This is because Eq. (29.8) is invariant with respect to even a non-linear transformation of parameters α , whereas Eq. (29.7) is not. Still, when the model is non-linear or errors are not Gaussian, confidence intervals obtained with both these formulas are only approximate. The true coverage of these confidence intervals can always be determined by a Monte Carlo simulation, or exact confidence intervals can be determined as in Sec. 29.6.3.

29.3.3. Application to Poisson-distributed data:

In the case of Poisson-distributed data in a counting experiment, the unbinned maximum likelihood method (where the index i in Eq. (29.5) labels events) is preferred if the total number of events is very small. If there are enough events to justify binning them in a histogram, then one may alternatively maximize the likelihood function for the contents of the bins (so i labels bins). This is equivalent to minimizing [5]

$$\chi^2 = \sum_{i} \left[2(N_i^{\rm th} - N_i^{\rm obs}) + 2N_i^{\rm obs} \ln(N_i^{\rm obs}/N_i^{\rm th}) \right]. \tag{29.9}$$

where N_i^{obs} and N_i^{th} are the observed and theoretical (from f) contents of the ith bin. In bins where $N_i^{\text{obs}} = 0$, the second term is zero. This function asymptotically behaves like a classical χ^2 for purposes of point estimation, interval estimation, and goodness-of-fit. It also guarantees that the area under the fitted function f is equal to the sum of the histogram contents (as long as the overall normalization of f is effectively left unconstrained during the fit), which is not the case for χ^2 statistics based on a least-squares procedure with traditional weights.

29.4. Propagation of errors

Suppose that $F(x;\alpha)$ is some function of variable(s) x and the fitted parameters α , with a value \widehat{F} at $\widehat{\alpha}$. The variance matrix of the parameters is V_{mn} . To first order in $\alpha_m - \widehat{\alpha}_m$, F is given by

$$F = \widehat{F} + \sum_{m} \frac{\partial F}{\partial \alpha_{m}} (\alpha_{m} - \widehat{\alpha}_{m}) , \qquad (29.10)$$

and the variance of F about its estimator is given by

$$(\Delta F)^2 = E[(F - \widehat{F})^2] = \sum_{mn} \frac{\partial F}{\partial \alpha_m} \frac{\partial F}{\partial \alpha_n} V_{mn} , \qquad (29.11)$$

evaluated at the x of interest. For different functions F_j and F_k , the covariance is

$$E[(F_j - \widehat{F}_j)(F_k - \widehat{F}_k)] = \sum_{mn} \frac{\partial F_j}{\partial \alpha_m} \frac{\partial F_k}{\partial \alpha_n} V_{mn} . \tag{29.12}$$

If the first-order approximation is in serious error, the above results may be very approximate. \widehat{F} may be a biased estimator of F even if the $\widehat{\alpha}$ are unbiased estimators of α . Inclusion of higher-order terms or direct evaluation of F in the vicinity of $\widehat{\alpha}$ will help to reduce the bias.

29.5. Method of least squares

The method of least squares can be derived from the maximum likelihood theorem. We suppose a set of N measurements at points x_i . The *i*th measurement y_i is assumed to be chosen from a Gaussian distribution with mean $F(x_i; \alpha)$ and variance σ_i^2 . Then

$$\chi^2 = -2\ln \mathcal{L} + \text{constant} = \sum_{i=1}^{N} \frac{[y_i - F(x_i; \alpha)]^2}{\sigma_i^2} . \qquad (29.13)$$

Finding the set of parameters α which maximizes \mathcal{L} is the same as finding the set which minimizes χ^2 .

In many practical cases one further restricts the problem to the situation in which $F(x_i; \alpha)$ is a linear function of the α_m 's,

$$F(x_i;\alpha) = \sum_n \alpha_n f_n(x) , \qquad (29.14)$$

where the f_n are k linearly independent functions (e.g., 1, x, x^2 , ..., or Legendre polynomials) which are single-valued over the allowed range of x. We require $k \leq N$, and at least k of the x_i must be distinct. We wish to estimate the linear coefficients α_n . Later we will discuss the nonlinear case.

If the point errors $\epsilon_i=y_i-F(x_i;\alpha)$ are Gaussian, then the minimum χ^2 will be distributed as a χ^2 random variable with n = N - k degrees of freedom. We can then evaluate the goodnessof-fit (confidence level) from Figs. 28.1 or 28.3, as per the earlier discussion. The confidence level expresses the probability that a worse fit would be obtained in a large number of similar experiments under the assumptions that: (a) the model $y = \sum \alpha_n f_n$ is correct and (b) the errors ϵ_i are Gaussian and unbiased with variance σ_i^2 . If this probability is larger than an agreed-upon value (0.001, 0.01, or 0.05 are common choices), the data are consistent with the assumptions; otherwise we may want to find improved assumptions. As for the converse, most people do not regard a model as being truly inconsistent unless the probability is as low as that corresponding to four or five standard deviations for a Gaussian $(6\times10^{-3}~{\rm or}~6\times10^{-5};{\rm see~Sec.}~29.6.4)$. If the ϵ_i are not Gaussian, the method of least squares still gives an answer, but the goodness-of-fit test would have to be done using the correct distribution of the random variable which is still called " χ^2 ."

Finding the minimum of χ^2 in the linear case is straightforward:

$$-\frac{1}{2}\frac{\partial \chi^2}{\partial \alpha_m} = \sum_{i} f_m(x_i) \left(\frac{y_i - \sum_{n} \alpha_n f_n(x_i)}{\sigma_i^2} \right)$$
$$= \sum_{i} \frac{y_i f_m(x_i)}{\sigma_i^2} - \sum_{n} \alpha_n \sum_{i} \frac{f_n(x_i) f_m(x_i)}{\sigma_i^2} . \tag{29.15}$$

With the definitions

$$g_m = \sum_{i} y_i f_m(x_i) / \sigma_i^2$$
 (29.16)

and

$$V_{mn}^{-1} = \sum_{i} f_n(x_i) f_m(x_i) / \sigma_i^2 , \qquad (29.17)$$

the k-element column vector of solutions $\hat{\alpha}$, for which $\partial \chi^2/\partial \alpha_m=0$ for all m, is given by

$$\widehat{\boldsymbol{\alpha}} = \boldsymbol{V} \, \boldsymbol{g} \, . \tag{29.18}$$

With this notation, χ^2 for the special case of a linear fitting function (Eq. (29.14)) can be rewritten in the compact form

$$\chi^2 = \chi_{\min}^2 + (\alpha - \widehat{\alpha})^T V^{-1} (\alpha - \widehat{\alpha}) . \qquad (29.19)$$

Nonindependent y_i 's

Eq. (29.13) is based on the assumption that the likelihood function is the product of independent Gaussian distributions. More generally, the measured y_i's are not independent, and we must consider them as

coming from a multivariate distribution with nondiagonal covariance matrix S, as described in Sec. 28.3.3. The generalization of Eq. (29.13) is

$$\chi^2 = \sum_{jk} [y_j - F(x_j; \alpha)] S_{jk}^{-1} [y_k - F(x_k; \alpha)] . \qquad (29.20)$$

In the case of a fitting function that is linear in the parameters, one may differentiate χ^2 to find the generalization of Eq. (29.15), and with the extended definitions

$$g_m = \sum_{jk} y_j \ f_m(x_k) S_{jk}^{-1}$$

$$V_{mn}^{-1} = \sum_{jk} f_n(x_j) \ f_m(x_k) S_{jk}^{-1}$$
(29.21)

solve Eq. (29.18) for the estimators $\hat{\alpha}$.

The problem of constructing the covariance matrix S is simplified by the fact that contributions to S (not to its inverse) are additive. For example, suppose that we have three variables, all of which have independent statistical errors. The first two also have a common error resulting in a positive correlation, perhaps because a common baseline with its own statistical error (variance s^2) was subtracted from each. In addition, the second two have a common error (variance a^2), but this time the values are anticorrelated. This might happen, for example, if the sum of the two variables is a constant. Then

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} s^2 & s^2 & 0 \\ s^2 & s^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & a^2 & -a^2 \\ 0 & -a^2 & a^2 \end{pmatrix} . \tag{29.22}$$

If unequal amounts of the common baseline were subtracted from variables 1, 2, and 3—e.g., fractions f_1 , f_2 , and f_3 , then we would have

$$S = \begin{pmatrix} \sigma_1^2 & 0 & 0 \\ 0 & \sigma_2^2 & 0 \\ 0 & 0 & \sigma_3^2 \end{pmatrix} + \begin{pmatrix} f_1^2 s^2 & f_1 f_2 s^2 & f_1 f_3 s^2 \\ f_1 f_2 s^2 & f_2^2 s^2 & f_2 f_3 s^2 \\ f_1 f_3 s^2 & f_2 f_3 s^2 & f_3^2 s^2 \end{pmatrix} .$$
 (29.23)

While in general this "two-vector" representation is not possible, it underscores the procedure: Add zero-determinant correlation matrices to the matrix expressing the independent variation.

Care must be taken when fitting to correlated data, since off-diagonal contributions to χ^2 are not necessarily positive. It is even possible for all of the residuals to have the same sign.

Example: straight-line fit

For the case of a straight-line fit, $y(x) = \alpha_1 + \alpha_2 x$, one obtains, for independent measurements y_i , the following estimates of α_1 and α_2 ,

$$\widehat{\alpha}_1 = (g_1 \ \Lambda_{22} - g_2 \ \Lambda_{12})/D \ ,$$
 (29.24)

$$\widehat{\alpha}_2 = (g_2 \ \Lambda_{11} - g_1 \ \Lambda_{12})/D \ , \tag{29.25}$$

where

$$(\Lambda_{11}, \Lambda_{12}, \Lambda_{22}) = \sum_{i=1}^{n} (1, x_i, x_i^2) / \sigma_i^2 , \qquad (29.26a)$$

$$(g_1, g_2) = \sum_{i} (1, x_i) y_i / \sigma_i^2 . \qquad (29.26b)$$

respectively, and

$$D = \Lambda_{11} \Lambda_{22} - (\Lambda_{12})^{2} . \tag{29.27}$$

The covariance matrix of the fitted parameters is:

$$\begin{pmatrix} V_{11} & V_{12} \\ V_{12} & V_{22} \end{pmatrix} = \frac{1}{D} \begin{pmatrix} \Lambda_{22} & -\Lambda_{12} \\ -\Lambda_{12} & \Lambda_{11} \end{pmatrix} . \tag{29.28}$$

The estimated variance of an interpolated or extrapolated value of y at point x is:

$$(\widehat{y} - y_{\text{true}})^2 \Big|_{\text{est}} = \frac{1}{\Lambda_{11}} + \frac{\Lambda_{11}}{D} \left(x - \frac{\Lambda_{12}}{\Lambda_{11}} \right)^2$$
 (29.29)

29.5.1. Confidence intervals from the chisquare function:

If y is not linear in the fitting parameters α , the solution vector may have to be found by iteration. If we have a first guess α_0 , then we may expand to obtain

$$\left. \frac{\partial \chi^2}{\partial \alpha} \right|_{\alpha} = \left. \frac{\partial \chi^2}{\partial \alpha} \right|_{\alpha_0} + V_{\alpha_0}^{-1} \cdot (\alpha - \alpha_0) + \dots , \qquad (29.30)$$

where $\partial \chi^2/\partial \alpha$ is a vector whose mth component is $\partial \chi^2/\partial \alpha_m$, and $(V_{mn}^{-1})=\frac{1}{2}\partial^2\chi^2/\partial \alpha_m\partial \alpha_n$. (See Eqns. 29.7 and 29.17. When evaluated at $\widehat{\alpha}$, V^{-1} is the inverse of the covariance matrix.) The next iteration toward $\widehat{\alpha}$ can be obtained by setting $\partial \chi^2/\partial \alpha_m|_{\alpha}=0$ and neglecting higher-order terms:

$$\alpha = \alpha_0 - V_{\alpha_0} \cdot \partial \chi^2 / \partial \alpha|_{\alpha_0} . \tag{29.31}$$

If V is constant in the vicinity of the minimum, as it is when the model function is linear in the parameters, then χ^2 is parabolic as a function of α and Eq. (29.31) gives the solution immediately. Otherwise, further iteration is necessary. If the problem is highly nonlinear, considerable difficulty may be encountered. There may be secondary minima, and χ^2 may be decreasing at physical boundaries. Numerical methods have been devised to find such solutions without divergence [7,8]. In particular, the CERN program MINUIT [8] offers several iteration schemes for solving such problems.

Note that minimizing any function proportional to χ^2 (or maximizing any function proportional $\ln \mathcal{L}$) will result in the same parameter set $\widehat{\alpha}$. Hence, for example, if the variances σ_j^2 are known only up to a common constant, one can still solve for $\widehat{\alpha}$. One cannot, however, evaluate goodness-of-fit, and the covariance matrix is known only to within the constant multiplier. The scale can be estimated at least roughly from the value of χ^2 compared to its expected value.

Additional information can be extracted from the behavior of the (normalized) residuals, $r_j = (y_j - F(x_j; \alpha)/\sigma_j)$, which should themselves distribute normally with a mean of 0.

If the data covariance matrix S has been correctly evaluated (or, equivalently, the σ_j 's, if the data are independent), then the s-standard deviation limits on the parameters are given by a set α'

$$\chi^2(\alpha') = \chi^2_{\min} + s^2 . {(29.32)}$$

This equation gives confidence intervals in the same sense as 29.8, and all the discussion of Sec. 29.3.2 applies as well here, substituting $-\chi^2/2$ for $\ln \mathcal{L}$.

29.6. Exact confidence intervals

29.6.1. Two methodologies:

There are two different approaches to statistical inference, which we may call Frequentist and Bayesian. For the cases considered up to now, both approaches give the same numerical answers, even though they are based on fundamentally different assumptions. However, for exact results for small samples and for measurements near a physical boundary, the different approaches may yield very different confidence limits, so we are forced to make a choice. There is an enormous amount of literature devoted to the question of Bayesian vs non-Bayesian methods, most of it written by people who are fervent advocates of one or the other methodology, which often leads to exaggerated conclusions. For a reasonably balanced discussion, we recommend the following articles: by a statistician [9], and by a physicist [6].

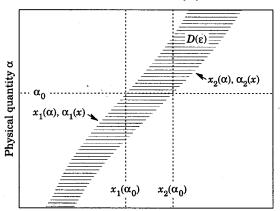

29.6.2. Bayesian: The Bayesian concept of probability is not based on limiting frequencies, but is more general and includes degrees of belief. It can therefore be used for experiments which cannot be repeated, where a frequency definition of probability would not be applicable (for example, one can consider the probability that it will rain tomorrow). Bayesian methods also allow for a natural way to input additional information such as physical boundaries and subjective information; in fact they require as input the prior distribution for any parameter to be estimated.

The Bayesian methodology, while well adapted to decision-making situations, is not in general appropriate for the objective presentation of experimental data. This can be seen from the following example.

An experiment sets out to measure the value of a parameter whose true value cannot be negative (such as the neutrino mass squared), but let us assume that the true value is in fact zero. We should then expect that about half of the time, an unbiased experimental measurement should yield a negative (unphysical) result. Now if our experiment produces a negative result, the question arises what value to report. If we wish to make a decision concerning the most likely value of this parameter, we would use a Bayesian approach which would assure that the reported value is positive, since it would be nonsense to assert that the most likely value is one which cannot be true. On the other hand, if we wish to report an unbiased result which can be combined with other measurements, it is better to report the unphysical result. Everyone understands what it means to quote a result of, for example, $m^2 = -1.2 \pm 2.0$ eV². This result could then be averaged with other results, half of which would be positive, and the average would eventually converge toward zero, the true value. If Bayesian estimates are averaged, they do not converge to the true value, since they have all been forced to be positive.

29.6.3. Frequentist, or classical confidence intervals: As the name implies, the Frequentist concept of probability is based entirely on the limiting frequency, so it only makes sense in situations where experiments are repeatable, at least in principle. This is clearly the case for the kind of data we are concerned with, and the methods we present here are based on the Frequentist point of view.

The classical construction of exact confidence intervals which we describe here was first proposed by Neyman [10].

Possible experimental values x

Figure 29.1: Confidence intervals for a single unknown parameter α . One might think of the p.d.f. $f(x;\alpha)$ as being plotted out of the paper as a function of x along each horizontal line of constant α . The domain $D(\varepsilon)$ contains a fraction $1-\varepsilon$ of the area under each of these functions.

We wish to set limits on the parameter α whose true value is fixed but unknown. The properties of our experimental apparatus are expressed in the function $f(x;\alpha)$ which gives the probability of observing data x if the true value of the parameter is α . This function must be known, otherwise it is impossible to interpret the results of an experiment. For a large complex experiment, this function is usually determined numerically using Monte Carlo simulation.

Given the function $f(x; \alpha)$, we can find for every value of α , two values $x_1(\alpha, \varepsilon)$ and $x_2(\alpha, \varepsilon)$ such that repeated experiments would produce results x in the interval $x_1 < x < x_2$ a fraction $1 - \varepsilon$ of the time, where

$$P(x_1 < x < x_2) = 1 - \varepsilon = \int_{x_1}^{x_2} f(x; \alpha) dx . \qquad (29.33)$$

This situation is shown in Fig. 29.1, where the region between the curves $x_1(\alpha, \varepsilon)$ and $x_2(\alpha, \varepsilon)$ is indicated by the domain $D(\varepsilon)$. We require that the curves $x_1(\alpha, \varepsilon)$ and $x_2(\alpha, \varepsilon)$ be monotonic functions of α , so they can be labeled either as functions of x or of α . Dropping the argument ε for simplicity, we may then label the curve $x_1(\alpha)$ as $\alpha_1(x)$ and $x_2(\alpha)$ as $\alpha_2(x)$. Now consider some arbitrary particular value of α , say α_0 , as indicated in the figure. We notice from the figure that for all values of x between $x_1(\alpha_0)$ and $x_2(\alpha_0)$, it happens that α_0 lies between $\alpha_1(x)$ and $\alpha_2(x)$. Thus we can write:

$$P[x_1(\alpha_0) < x < x_2(\alpha_0)] = 1 - \varepsilon = P[\alpha_2(x) < \alpha_0 < \alpha_1(x)].$$
 (29.34)

And since, by construction, this is true for any value α_0 , we can drop the subscript 0 and obtain the relationship we wanted to establish for the probability that the confidence limits will contain the true value of α :

$$P[\alpha_2(x) < \alpha < \alpha_1(x)] = 1 - \varepsilon. \tag{29.35}$$

In this probability statement, α_1 and α_2 are the random variables (not α), and we can verify that the statement is true, as a limiting ratio of frequencies in random experiments, for any assumed value of α . In a particular real experiment, the numerical values α_1 and α_2 are determined by applying the algorithm to the real data, and the probability statement appears to be a statement about the true value α since this is the only unknown remaining in the equation. It should however be understood that it gives only the probability of obtaining values α_1 and α_2 which include the true value of α , in an ensemble of identical experiments. Any method which gives confidence intervals that contain the true value with probability $1-\varepsilon$ (no matter what the true value of α is) is said to have coverage. The frequentist intervals as constructed above have coverage by construction. Coverage is considered the most important property of confidence intervals [6].

The condition of coverage Eq. (29.33) does not determine x_1 and x_2 completely, since any range which gives the desired value of the integral would give the same coverage. Additional criteria are needed to determine the intervals uniquely. The most common criterion is to choose central intervals such that the area of the excluded tail on either side is $\varepsilon/2$. This criterion is sufficient in most cases, but there is a more general ordering principle which reduces to centrality in the usual cases and produces confidence intervals with better properties when in the neighborhood of a physical limit. This ordering principle, which consists of taking the interval which includes the largest values of a likelihood ratio, is described by Feldman and Cousins [11].

29.6.4. Gaussian errors:

If the data are such that the distribution of the estimator(s) satisfies the central limit theorem discussed in Sec. 28.3.3, the function $f(x;\alpha)$ is the Gaussian distribution. If there is more than one parameter being estimated, the multivariate Gaussian is used. For the univariate case with known σ ,

$$1 - \varepsilon = \int_{\mu - \delta}^{\mu + \delta} e^{\frac{-(x - \mu)^2}{2\sigma^2}} dx = \operatorname{erf}\left(\frac{\delta}{\sqrt{2}\sigma}\right)$$
 (29.36)

is the probability that the measured value x will fall within $\pm \delta$ of the true value μ . From the symmetry of the Gaussian with respect to x and μ , this is also the probability that the true value will be within $\pm \delta$ of the measured value. Fig. 29.2 shows a $\delta = 1.64\sigma$ confidence interval unshaded. The choice $\delta = \sqrt{\text{Var}(\mu)} \equiv \sigma$ gives an interval called the *standard error* which has $1 - \varepsilon = 68.27\%$ if σ is known. Confidence coefficients ε for other frequently used choices of δ are given in Table 29.1. For other δ , find ε as the ordinate of Fig. 28.1 on the n=1 curve at $\chi^2=(\delta/\sigma)^2$. We can set a one-sided (upper or lower) limit by excluding above $\mu+\delta$ (or below $\mu-\delta$); ε 's for such limits are 1/2 the values in Table 29.1.

For multivariate α the scalar $\text{Var}(\mu)$ becomes a full variance-covariance matrix. Assuming a multivariate Gaussian, Eq. (28.22), and subsequent discussion the standard error ellipse for the pair $(\widehat{\alpha}_m, \widehat{\alpha}_n)$ may be drawn as in Fig. 29.3.

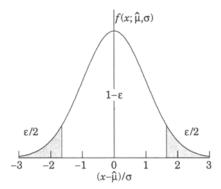

Figure 29.2: Illustration of a symmetric 90% confidence interval (unshaded) for a measurement of a single quantity with Gaussian errors. Integrated probabilities, defined by ε , are as shown.

Table 29.1: Area of the tails ε outside $\pm \delta$ from the mean of a Gaussian distribution.

$\varepsilon~(\%)$	δ	ϵ (%)	δ
31.73	1σ	20	1.28σ
4.55	2σ	10	1.64σ
0.27	3σ	5	1.96σ
6.3×10^{-3}	4σ	1	2.58σ
5.7×10^{-5}	5σ	0.1	3.29σ
2.0×10^{-7}	6σ	0.01	3.89σ

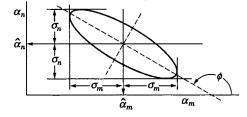

Figure 29.3: Standard error ellipse for the estimators $\widehat{\alpha}_m$ and $\widehat{\alpha}_n$. In this case the correlation is negative.

The minimum χ^2 or maximum likelihood solution is at $(\widehat{\alpha}_m, \widehat{\alpha}_n)$. The standard errors σ_m and σ_n are defined as shown, where the ellipse is at a constant value of $\chi^2 = \chi^2_{\min} + 1$ or $\ln \mathscr{L} = \ln \mathscr{L}_{\max} - 1/2$. The angle of the major axis of the ellipse is given by

$$\tan 2\phi = \frac{2\rho_{mn} \ \sigma_m \ \sigma_n}{\sigma_m^2 - \sigma_n^2} \ . \tag{29.37}$$

For non-Gaussian or nonlinear cases, one may construct an analogous contour from the same χ^2 or $\ln \mathcal{L}$ relations. Any other parameters $\hat{\alpha}_\ell, \ell \neq m, n$ must be allowed freely to find their optimum values for every trial point.

For any unbiased procedure (e.g., least squares or maximum likelihood) being used to estimate k parameters α_i , $i=1,\ldots,k$, the probability $1-\varepsilon$ that the true values of all k lie within the s-standard deviation ellipsoid may be found from Fig. 28.1. Read the ordinate as ε ; the correct value of ε occurs on the n=k curve at $\chi^2=s^2$. For example, for k=2, the probability that the true values of α_1 and α_2 simultaneously lie within the one-standard-deviation error ellipse (s=1), centered on $\widehat{\alpha}_1$ and $\widehat{\alpha}_2$, is 39%. This probability only assumes Gaussian errors, unbiased estimators, and that the model describing the data in terms of the α_i is correct.

29.6.5. Upper limits and two-sided intervals:

When a measured value is close to a physical boundary, it is natural to report a one-sided confidence interval (usually an upper limit). It is straightforward to force the procedure of Sec. 29.6.3 to produce only an upper limit, by setting $x_2 = \infty$ in Eq. (29.33). Then x_1 is uniquely determined. Clearly this procedure will have the desired coverage, but only if we always choose to set an upper limit. In practice one might decide after seeing the data whether to set an upper limit or a two-sided limit. In this case the upper limits calculated by Eq. (29.33) will not give exact coverage, as has been noted in Ref. 11.

In order to correct this problem and assure coverage in all circumstances, it is necessary to adopt a *unified procedure*, that is, a single ordering principle which will provide coverage globally. Then it is the *ordering principle* which decides whether a one-sided or two-sided interval will be reported for any given set of data. The appropriate unified procedure and ordering principle are given in Ref. 11. We reproduce below the main results.

29.6.6. Gaussian data close to a boundary:

One of the most controversial statistical questions in physics is how to report a measurement which is close to the edge or even outside of the allowed physical region. This is because there are several admissible possibilities depending on how the result is to be used or interpreted. Normally one or more of the following should be reported:

- (a) In any case, the actual measurement should be reported, even if it is outside the physical region. As with any other measurement, it is best to report the value of a quantity which is nearly Gaussian distributed if possible. Thus one may choose to report mass squared rather than mass, or $\cos\theta$ rather than θ . For a complex quantity z close to zero, report Re(z) and Im(z) rather than amplitude and phase of z. Data carefully reported in this way can be unbiased, objective, easily interpreted and combined (averaged) with other data in a straightforward way, even if it lies partly or wholly outside the physical region. The reported error is a direct measure of the intrinsic accuracy of the result, which cannot always be inferred from the upper limits proposed below.
- (b) If the data are to be used to make a decision, for example to determine the dimensions of a new experimental apparatus for an improved measurement, it may be appropriate to report a Bayesian upper limit, which must necessarily contain subjective feelings about the possible values of the parameter, as well as containing information about the physical boundary. Its interpretation requires knowledge of the prior distribution which was necessarily used to obtain it.
- (c) If it is desired to report an upper limit in an objective way such that it has a well-defined statistical meaning in terms of a limiting frequency, then report the Frequentist confidence bound(s) as given by the unified Feldman-Cousins approach. This algorithm always gives a non-null interval (that is, the confidence limits are always inside the physical region, even for a measurement well outside the physical region), and still has correct global coverage. These confidence limits for a Gaussian measurement close to a non-physical boundary are summarized in Fig. 29.4. Additional tables are given in Ref. 11.

29.6.7. Poisson data for small samples:

When the observable is restricted to integer values (as in the case of Poisson and binomial distributions), it is not generally possible to construct confidence intervals with exact coverage for all values of α . In these cases the integral in Eq. (29.33) becomes a sum of finite contributions and it is no longer possible (in general) to find consecutive terms which add up exactly to the required confidence level $1-\varepsilon$ for all values of α . Thus one constructs intervals which happen to have exact coverage for a few values of α , and unavoidable over-coverage for all other values. This is the best that can be done and still guarantee coverage for any true value.

In addition to the problem posed by the discreteness of the data, we usually have to contend with possible background whose expectation must be evaluated separately and may not be known precisely. For these reasons, the reporting of this kind of data is even more controversial than the Gaussian data near a boundary as discussed above. This is especially true when the number of observed counts is

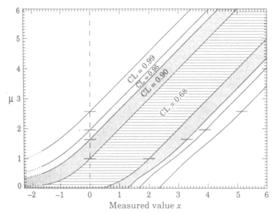

Figure 29.4: Plot of 99%, 95%, 90%, and 68.27% ("one σ ") confidence intervals for a physical quantity μ based on a Gaussian measurement x (in units of standard deviations), for the case where the true value of μ cannot be negative. The curves become straight lines above the horizontal tick marks. The probability of obtaining an experimental value at least as negative as the left edge of the graph (x=-2.33) is less than 1%. Values of x more negative than -1.64 (dotted segments) are less than 5% probable, no matter what the true value of μ .

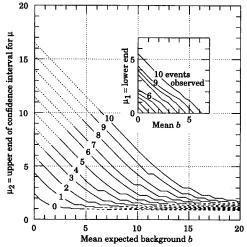

Figure 29.5: 90% confidence intervals $[\mu_1, \mu_2]$ on the number of signal events as a function of the expected number of background events b. For example, if the expected background is 8 events and 5 events are observed, then the signal is 2.60 or less with 90% confidence. Dotted portions of the μ_2 curves on the upper left indicate regions where μ_1 is non-zero (as shown by the inset). Dashed portions in the lower right indicate regions where the probability of obtaining the number of events observed or fewer is less than 1%, even if $\mu = 0$. Horizontal curve sections occur because of discrete number statistics. Tables showing these data as well as the CL = 68.27%, 95%, and 99% results are given in Ref. 11.

greater than the expected background. As for the Gaussian case, there are at least three possibilities for reporting such results depending on how the result is to be used:

- (a) In any case, the actual measurements should be reported, which means (1) the number of recorded counts, (2) the expected background, possibly with its error, and (3) normalization factor which turns the number of counts into a cross section, decay rate, etc. As with Gaussian data, this data can be combined with that of other experiments, to make improved upper limits for example.
- (b) A Bayesian upper limit may be reported. This has the advantages and disadvantages of any Bayesian result as discussed above. It is especially difficult to find an acceptable prior probability distribution for this case.

Table 29.2: Poisson limits $[\mu_1, \mu_2]$ for n_0 observed events in the absence of background.

CI = 90%			CI = 95%		
n_0	μ_1	μ_2	μ_1	μ_2	
0	0.00	2.44	0.00	3.09	
1	0.11	4.36	0.05	5.14	
2	0.53	5.91	0.36	6.72	
3	1.10	7.42	0.82	8.25	
4	1.47	8.60	1.37	9.76	
5	1.84	9.99	1.84	11.26	
6	2.21	11.47	2.21	12.75	
7	3.56	12.53	2.58	13.81	
8	3.96	13.99	2.94	15.29	
9	4.36	15.30	4.36	16.77	
10	5.50	16.50	4.75	17.82	

(c) An upper limit (or confidence region) with optimal coverage can be reported using the unified approach of Ref. 11. At the moment these confidence limits have been calculated only for the case of exactly known background expectation. The main results can be read from Fig. 29.5 or from Table 29.2; more extensive tables can be found in Ref. 11.

None of the above gives a single number which quantifies the quality or sensitivity of the experiment. This is a serious shortcoming of most upper limits including those of method (c), since it is impossible to distinguish, from the upper limit alone, between a clean experiment with no background and a lucky experiment with fewer observed counts than expected background. For this reason, we suggest that in addition to (a) and (c) above, a measure of the sensitivity should be reported whenever expected background is larger or comparable to the number of observed counts. The best such measure we know of is that proposed and tabulated in Ref. 11, defined as the average upper limit that would be attained by an ensemble of experiments with the expected background and no true signal.

30. MONTE CARLO TECHNIQUES

Revised July 1995 by S. Youssef (SCRI, Florida State University).

Monte Carlo techniques are often the only practical way to evaluate difficult integrals or to sample random variables governed by complicated probability density functions. Here we describe an assortment of methods for sampling some commonly occurring probability density functions.

30.1. Sampling the uniform distribution

Most Monte Carlo sampling or integration techniques assume a "random number generator" which generates uniform statistically independent values on the half open interval [0, 1). Although such a generator is, strictly speaking, impossible on a finite digital computer, generators are nevertheless available which pass extensive batteries of tests for statistical independence and which have periods which are so long that, for practical purposes, values from these generators can be considered to be uniform and statistically independent. In particular, the lagged-Fibonacci based generator introduced by Marsaglia, Zaman, and Tsang [1] is efficient, has a period of approximately 10^{43} , produces identical sequences on a wide variety of computers and, passes the extensive "DIEHARD" battery of tests [2]. Many commonly available congruential generators fail these tests and often have sequences (typically with periods less than 2^{32}) which can be easily exhausted on modern computers and should therefore be avoided [3].

30.2. Inverse transform method

If the desired probability density function is f(x) on the range $-\infty < x < \infty$, its cumulative distribution function (expressing the probability that $x \le a$) is given by Eq. (28.1). If a is chosen with probability density f(a), then the integrated probability up to point a, F(a), is itself a random variable which will occur with uniform probability density on [0,1]. If x can take on any value, and ignoring the endpoints, we can then find a unique x chosen from the p.d.f. f(s) for a given x if we set

$$u = F(x) , (30.1)$$

provided we can find an inverse of F, defined by

$$x = F^{-1}(u) . (30.2)$$

This method is shown in Fig. 30.1a.

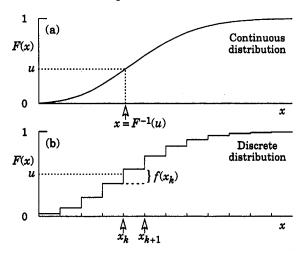

Figure 30.1: Use of a random number u chosen from a uniform distribution (0,1) to find a random number x from a distribution with cumulative distribution function F(x).

For a discrete distribution, F(x) will have a discontinuous jump of size $f(x_k)$ at each allowed $x_k, k = 1, 2, \cdots$. Choose u from a uniform distribution on (0,1) as before. Find x_k such that

$$F(x_{k-1}) < u \le F(x_k) \equiv \text{Prob}(x \le x_k) = \sum_{i=1}^k f(x_i);$$
 (30.3)

then x_k is the value we seek (note: $F(x_0) \equiv 0$). This algorithm is illustrated in Fig. 30.1b.

30.3. Acceptance-rejection method (Von Neumann)

Very commonly an analytic form for F(x) is unknown or too complex to work with, so that obtaining an inverse as in Eq. (30.2) is impractical. We suppose that for any given value of x the probability density function f(x) can be computed and further that enough is known about f(x) that we can enclose it entirely inside a shape which is C times an easily generated distribution h(x) as illustrated in Fig. 30.2.

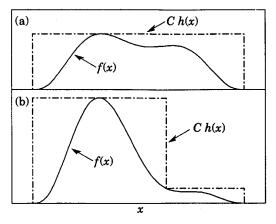

Figure 30.2: Illustration of the acceptance-rejection method. Random points are chosen inside the upper bounding figure, and rejected if the ordinate exceeds f(x). Lower figure illustrates importance sampling.

Frequently h(x) is uniform or is a normalized sum of uniform distributions. Note that both f(x) and h(x) must be normalized to unit area and therefore the proportionality constant C>1. To generate f(x), first generate a candidate x according to h(x). Calculate f(x) and the height of the envelope Ch(x); generate u and test if $uCh(x) \leq f(x)$. If so, accept x; if not reject x and try again. If we regard x and uCh(x) as the abscissa and ordinate of a point in a two-dimensional plot, these points will populate the entire area Ch(x) in a smooth manner; then we accept those which fall under f(x). The efficiency is the ratio of areas, which must equal 1/C; therefore we must keep C as close as possible to 1.0. Therefore we try to choose Ch(x) to be as close to f(x) as convenience dictates, as in the lower part of Fig. 30.2. This practice is called importance sampling, because we generate more trial values of x in the region where f(x) is most important.

30.4. Algorithms

Algorithms for generating random numbers belonging to many different distributions are given by Press [4], Ahrens and Dieter [5], Rubinstein [6], Everett and Cashwell [7], Devroye [8], and Walck [9]. For many distributions alternative algorithms exist, varying in complexity, speed, and accuracy. For time-critical applications, these algorithms may be coded in-line to remove the significant overhead often encountered in making function calls. Variables named "u" are assumed to be independent and uniform on (0,1).

In the examples given below, we use the notation for the variables and parameters given in Table 28.1.

30.4.1. Sine and cosine of random angle:

Generate u_1 and u_2 . Then $v_1 = 2u_1 - 1$ is uniform on (-1,1), and $v_2 = u_2$ is uniform on (0,1). Calculate $r^2 = v_1^2 + v_2^2$. If $r^2 > 1$, start over. Otherwise, the sine (S) and cosine (C) of a random angle are given by

$$S = 2v_1v_2/r^2$$
 and $C = (v_1^2 - v_2^2)/r^2$. (30.4)

30.4.2. Gaussian distribution:

If u_1 and u_2 are uniform on (0,1), then

$$z_1 = \sin 2\pi u_1 \sqrt{-2 \ln u_2}$$
 and $z_2 = \cos 2\pi u_1 \sqrt{-2 \ln u_2}$ (30.5)

are independent and Gaussian distributed with mean 0 and $\sigma = 1$.

There are many faster variants of this basic algorithm. For example, construct $v_1=2u_1-1$ and $v_2=2u_2-1$, which are uniform on (-1,1). Calculate $r^2=v_1^2+v_2^2$, and if $r^2>1$ start over. If $r^2<1$, it is uniform on (0,1). Then

$$z_1 = v_1 \sqrt{\frac{-2 \ln r^2}{r^2}}$$
 and $z_2 = v_2 \sqrt{\frac{-2 \ln r^2}{r^2}}$ (30.6)

are independent numbers chosen from a normal distribution with mean 0 and variance 1. $z_i' = \mu + \sigma z_i$ distributes with mean μ and variance σ^2 .

For a multivariate Gaussian, see the algorithm in Ref. 10.

30.4.3. $\chi^2(n)$ distribution:

For n even, generate n/2 uniform numbers u_i ; then

$$y = -2\ln\left(\prod_{i=1}^{n/2} u_i\right) \quad \text{is} \quad \chi^2(n) \ . \tag{30.7}$$

For n odd, generate (n-1)/2 uniform numbers u_i and one Gaussian z as in Sec. 30.4.2; then

$$y = -2 \ln \left(\prod_{i=1}^{(n-1)/2} u_i \right) + z^2 \quad \text{is} \quad \chi^2(n) . \tag{30.8}$$

For $n \gtrsim 30$ the much faster Gaussian approximation for the χ^2 may be preferable: generate z as in Sec. 30.4.2 and use $y = \left[z + \sqrt{2n-1}\right]^2/2$; if $z < -\sqrt{2n-1}$ reject and start over.

30.4.4. Gamma distribution:

All of the following algorithms are given for $\lambda=1$. For $\lambda\neq 1$, divide the resulting random number x by λ .

- If k = 1 (the exponential distribution), accept $x = -(\ln u)$.
- If 0 < k < 1, initialize with $v_1 = (e + k)/e$ (with e = 2.71828... being the natural log base). Generate u_1 , u_2 . Define $v_2 = v_1u_1$.

Case 1: $v_2 \le 1$. Define $x = v_2^{1/k}$. If $u_2 \le e^{-x}$, accept x and stop, else restart by generating new u_1, u_2 .

Case 2: $v_2 > 1$. Define $x = -\ln([v_1 - v_2]/k)$. If $u_2 \le x^{k-1}$, accept x and stop, else restart by generating new u_1, u_2 . Note that, for k < 1, the probability density has a pole at x = 0, so that return values of zero due to underflow must be accepted or otherwise dealt with.

• Otherwise, if k > 1, initialize with c = 3k - 0.75. Generate u_1 and compute $v_1 = u_1(1 - u_1)$ and $v_2 = (u_1 - 0.5)\sqrt{c/v_1}$. If $x = k + v_2 - 1 \le 0$, go back and generate new u_1 ; otherwise generate u_2 and compute $v_3 = 64v_1^3u_2^2$. If $v_3 \le 1 - 2v_2^2/x$ or if $\ln v_3 \le 2\{[k-1]\ln[x/(k-1)] - v_2\}$, accept x and stop; otherwise go back and generate new u_1 .

30.4.5. Binomial distribution:

If $p \le 1/2$, iterate until a successful choice is made: begin with k=1; compute $P_k=q^n$ [for $k \ne 1$ use $P_k \equiv f(r_k;n,p)$, and store P_k into B; generate u. If $u \le B$ accept $r_k=k-1$ and stop; otherwise increment k by 1 and compute next P_k and add to B; generate a new u and repeat. If we arrive at k=n+1, stop and accept $r_{n+1}=n$. If p>1/2 it will be more efficient to generate r from f(r;n,q), i.e., with p and q interchanged, and then set $r_k=n-r$.

30.4.6. Poisson distribution:

Iterate until a successful choice is made: Begin with k=1 and set A=1 to start. Generate u. Replace A with uA; if now $A<\exp(-\mu)$, where μ is the Poisson parameter, accept $n_k=k-1$ and stop. Otherwise increment k by 1, generate a new u and repeat, always starting with the value of A left from the previous try. For large $\mu(\gtrsim 10)$ it may be satisfactory (and much faster) to approximate the Poisson distribution by a Gaussian distribution (see our Probability chapter, Sec. 28.3.3) and generate z from f(z;0,1); then accept $x=\max(0,[\mu+z\sqrt{\mu}+0.5])$ where $[\]$ signifies the greatest integer \le the expression.

30.4.7. Student's t distribution:

For n>0 degrees of freedom (n not necessarily integer), generate x from a Gaussian with mean 0 and $\sigma^2=1$ according to the method of 30.4.2. Next generate y, an independent gamma random variate with k=n/2 degrees of freedom. Then $z=x\sqrt{2n}/\sqrt{y}$ is distributed as a t with n degrees of freedom.

For the special case n=1, the Breit-Wigner distribution, generate u_1 and u_2 ; set $v_1=2u_1-1$ and $v_2=2u_2-1$. If $v_1^2+v_2^2\leq 1$ accept $z=v_1/v_2$ as a Breit-Wigner distribution with unit area, center at 0.0, and FWHM 2.0. Otherwise start over. For center M_0 and FWHM Γ , use $W=z\Gamma/2+M_0$.

31. MONTE CARLO PARTICLE NUMBERING SCHEME

Revised April 1998 by L. Garren (Fermilab), I.G. Knowles (Edinburgh U.), T. Sjöstrand (Lund U.), and T. Trippe (LBNL).

The PDG particle numbering scheme [1] is designed to facilitate interfacing between the event generator and analysis packages used in particle physics. It is used in several generators, e.g. HERWIG and PYTHIA/JETSET, and in the /HEPEVT/ [2] standard interface. After consultation [3], the scheme has been revised to better match the practice of program authors. The revised scheme includes numbering of states by orbital and radial quantum numbers to allow systematic inclusion of quark model states which are as yet undiscovered, and also includes numbering for hypothetical particles such as SUSY particles. The general form is a 7-digit number:

$$\pm n \, n_r \, n_L \, n_{q_1} \, n_{q_2} \, n_{q_3} \, n_J$$
.

This encodes information about the particle's spin, flavor content, and internal quantum numbers. The details are as follows:

- 1. Particles are given positive numbers, antiparticles negative numbers. The PDG convention for mesons is used, so that K^+ and B^+ are particles.
- 2. Quarks and leptons are numbered consecutively starting from 1 and 11 respectively; to do this they are first ordered by family and within families by weak isospin.
- 3. In composite quark systems (diquarks, mesons, and baryons) $n_{q_{1-3}}$ are quark numbers used to specify the quark content, while the rightmost digit $n_J = 2J + 1$ gives the system's spin (except for the K_S^0 and K_L^0). The scheme does not cover particles of spin
- 4. Diquarks have 4-digit numbers with $n_{q_1} \ge n_{q_2}$ and $n_{q_3} = 0$.
- 5. The numbering of mesons is guided by the nonrelativistic (L-Sdecoupled) quark model, as listed in Table 13.2. This leads to several differences with the earlier numbering [4] for excited mesons.
 - a. The numbers specifying the meson's quark content conform to the convention $n_{q_1}=0$ and $n_{q_2}\geq n_{q_3}.$ The special case K_I^0 is the sole exception to this rule.
 - b. The quark numbers of flavorless, light (u, d, s) mesons are: 11 for the member of the isotriplet (π^0, ρ^0, \ldots) , 22 for the lighter isosinglet (η, ω, \ldots) , and 33 for the heavier isosinglet (η', ϕ, \ldots) . Since isosinglet mesons are often large mixtures of $u\overline{u} + d\overline{d}$ and $s\overline{s}$ states, 22 and 33 are assigned by mass and do not necessarily specify the dominant quark composition.
 - c. The special numbers 310 and 130 are given to the K_S^0 and K_L^0 respectively.
 - d. The fifth digit n_L is reserved to distinguish mesons of the same total (J) but different spin (S) and orbital (L) angular momentum quantum numbers. For J > 0 the numbers are: $(L,S) = (J-1,1) n_L = 0, (J,0) n_L = 1, (J,1) n_L = 2$ and (J+1,1) $n_L=3$. For the exceptional case J=0 the numbers are (0,0) $n_L = 0$ and (1,1) $n_L = 1$ (i.e. $n_L = L$). See Table 31.1.

Table 31.1: Meson numbering logic. Here qq stands for $n_{q2} n_{q3}$

	L = J	- 1, <i>S</i>	= 1	L = J	, S =	0	L = J	, <i>S</i> =	1	L = J	7 + 1,	S=1
J	code	J^{PC}	L	code	$J^{\overline{PC}}$	L	code	J^{PC}	L	code	J^{PC}	\overline{L}
0	_	_	_	00qq1	0-+	0			_	10qq1	0++	1
1	00qq3	1	0	10qq3	1+-	1	20qq3	1++	1	30qq3	1	2
2	00qq5	2++	1 .	10 <i>qq</i> 5	2-+	2	20qq5	2	2	30qq5	2++	3
3	00qq7	3	2	10qq7	3+-	3	20qq7	3++	3	30qq7	3	4
4	00qq9	4++					20qq9					5

e. If a set of physical mesons correspond to a (non-negligible) mixture of basis states, differing in their internal quantum numbers, then the lightest physical state gets the smallest

- basis state number. For example the $K_1(1270)$ is numbered 10313 $(1^1P_1 K_{1B})$ and the $K_1(1400)$ is numbered 20313 $(1^3P_1\ K_{1A}).$
- f. The sixth digit n_r is used to label mesons radially excited above the ground state.
- g. Numbers have been assigned for complete $n_r = 0$ S- and P-wave multiplets, even where states remain to be identified.
- h. In some instances assignments within the $q\bar{q}$ meson model are only tentative; here best guess assignments are made.
- i. Many states appearing in the Meson Listings are not yet assigned within the $q\bar{q}$ model. Here $n_{q_{2-3}}$ and n_J are assigned according to the state's likely flavors and spin; all such unassigned light isoscalar states are given the flavor code 22. Within these groups $n_L = 0, 1, 2, \ldots$ is used to distinguish states of increasing mass. These states are flagged using n = 9. It is to be expected that these numbers will evolve as the nature of the states are elucidated.
- 6. The numbering of baryons is again guided by the nonrelativistic quark model, see Table 13.4.
 - a. The numbers specifying a baryon's quark content are such
 - that in general $n_{q_1} \ge n_{q_2} \ge n_{q_3}$. b. Two states exist for J=1/2 baryons containing 3 different types of quarks. In the lighter baryon $(\Lambda, \Xi, \Omega, \ldots)$ the light quarks are in an antisymmetric (J = 0) state while for the heavier baryon $(\mathfrak{L}^0, \mathfrak{T}', \Omega', \ldots)$ they are in a symmetric (J=1) state. In this situation n_{q_2} and n_{q_3} are reversed for the lighter state, so that the smaller number corresponds to the lighter baryon.
 - c. At present most Monte Carlos do not include excited baryons and no systematic scheme has been developed to denote them, though one is foreseen. In the meantime, use of the PDG 96 [4] numbers for excited baryons is recommended.
- 7. The gluon, when considered as a gauge boson, has official number 21. In codes for glueballs, however, 9 is used to allow a notation in close analogy with that of hadrons.
- 8. The pomeron and odderon trajectories and a generic reggeon trajectory of states in QCD are assigned codes 990, 9990, and 110 respectively, where the final 0 indicates the indeterminate nature of the spin, and the other digits reflect the expected "valence" flavor content. We do not attempt a complete classification of all reggeon trajectories, since there is currently no need to distinguish a specific such trajectory from its lowest-lying member.
- Two-digit numbers in the range 21-30 are provided for the Standard Model gauge bosons and Higgs.
- 10. Codes 81-100 are reserved for generator-specific pseudoparticles and concepts.
- 11. The search for physics beyond the Standard Model is an active area, so these codes are also standardized as far as possible.
 - a. A standard fourth generation of fermions is included by analogy with the first three.
 - b. The graviton and the boson content of a two-Higgs-doublet scenario and of additional SU(2)×U(1) groups are found in the range 31-40.
 - c. "One-of-a-kind" exotic particles are assigned numbers in the range 41-80.
 - d. Fundamental supersymmetric particles are identified by adding a nonzero n to the particle number. The superpartner of a boson or a left-handed fermion has n = 1 while the superpartner of a right-handed fermion has n = 2. When mixing occurs, such as between the winos and charged Higgsinos to give charginos, or between left and right sfermions, the lighter physical state is given the smaller basis state number.
 - e. Technicolor states have n = 3. In the absence of a unique theory we only number generic states whose digits reflect the techniquark content.
 - f. Excited (composite) quarks and leptons are identified by setting n=4.

- 12. Occasionally program authors add their own states. To avoid confusion, these should be flagged by setting $nn_r = 99$.
- 13. Concerning the non-99 numbers, it may be noted that only quarks, excited quarks, squarks, and diquarks have $n_{q_3}=0$; only diquarks, baryons, and the odderon have $n_{q_1}\neq 0$; and only mesons, the reggeon, and the pomeron have $n_{q_1}=0$ and $n_{q_2}\neq 0$. Concerning mesons (not antimesons), if n_{q_1} is odd then it labels a quark and an antiquark if even.

This text and lists of particle numbers can be found on the WWW [5]. The StdHep Monte Carlo standardization project [6] maintains the list of PDG particle numbers, as well as numbering schemes from most event generators and software to convert between the different schemes.

Footnotes to the Tables:

- *) Numbers which have changed since the 1996 Review [4] are in bold face. Numbers which were not assigned in the 1996 Review [4] are in regular type.
- a) Particulary in the third generation, the left and right sfermion states may mix, as shown. The lighter mixed state is given the smaller number.
- b) The physical $\widetilde{\chi}$ states are admixtures of the pure $\widetilde{\gamma}$, \widetilde{Z}^0 , \widetilde{W}^+ , \widetilde{H}^0_1 , \widetilde{H}^0_2 , and \widetilde{H}^+ states. c) In this draft we have only provided one generic leptoquark code. More general classifications according to spin, weak isospin and flavor content would lead to a host of states, that could be added as the need arises.
- d) Σ^* and Ξ^* are alternate names for $\Sigma(1385)$ and $\Xi(1530)$.

32. CLEBSCH-GORDAN COEFFICIENTS, SPHERICAL HARMONICS,

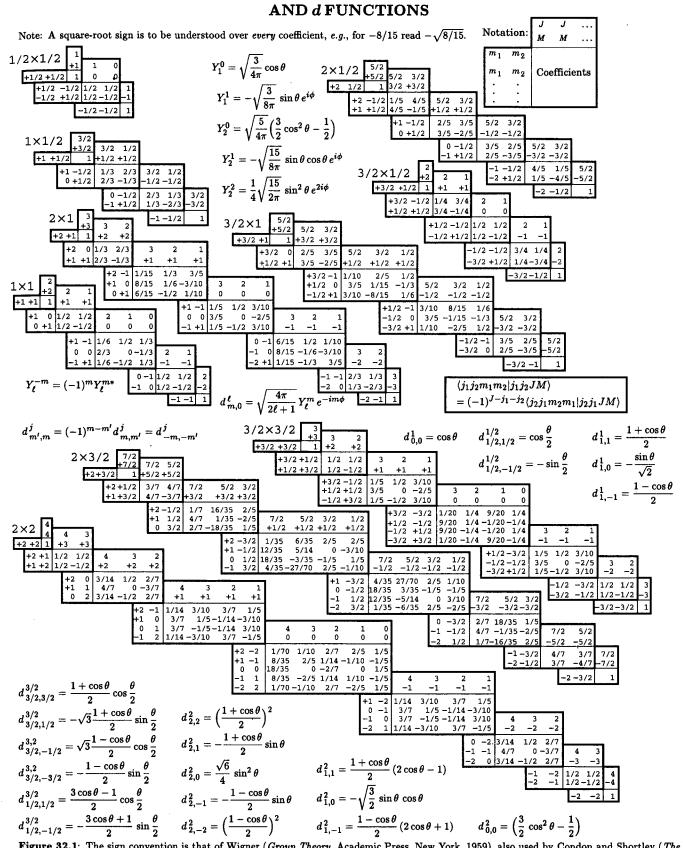

Figure 32.1: The sign convention is that of Wigner (*Group Theory*, Academic Press, New York, 1959), also used by Condon and Shortley (*The Theory of Atomic Spectra*, Cambridge Univ. Press, New York, 1953), Rose (*Elementary Theory of Angular Momentum*, Wiley, New York, 1957), and Cohen (*Tables of the Clebsch-Gordan Coefficients*, North American Rockwell Science Center, Thousand Oaks, Calif., 1974). The coefficients here have been calculated using computer programs written independently by Cohen and at LBNL.

33. SU(3) ISOSCALAR FACTORS AND REPRESENTATION MATRICES

Written by R.L. Kelly (LBNL).

The most commonly used SU(3) isoscalar factors, corresponding to the singlet, octet, and decuplet content of $8\otimes 8$ and $10\otimes 8$, are shown at the right. The notation uses particle names to identify the coefficients, so that the pattern of relative couplings may be seen at a glance. We illustrate the use of the coefficients below. See J.J de Swart, Rev. Mod. Phys. 35, 916 (1963) for detailed explanations and phase conventions.

 $A \sqrt{\ }$ is to be understood over every integer in the matrices; the exponent 1/2 on each matrix is a reminder of this. For example, the $\Xi \to \Omega K$ element of the $10 \to 10 \otimes 8$ matrix is $-\sqrt{6}/\sqrt{24} = -1/2$.

Intramultiplet relative decay strengths may be read directly from the matrices. For example, in decuplet \to octet + octet decays, the ratio of $\Omega^* \to \varXi \overline{K}$ and $\Delta \to N\pi$ partial widths is, from the $10 \to 8 \times 8$ matrix.

$$\frac{\Gamma(\Omega^* \to \Xi \overline{K})}{\Gamma(\Delta \to N\pi)} = \frac{12}{6} \times \text{ (phase space factors)}. \tag{33.1}$$

Including isospin Clebsch-Gordan coefficients, we obtain, e.g.,

$$\frac{\Gamma(\Omega^{*-} \to \Xi^0 K^-)}{\Gamma(\Delta^+ \to p \pi^0)} = \frac{1/2}{2/3} \times \frac{12}{6} \times p.s.f. = \frac{3}{2} \times p.s.f.$$
 (33.2)

Partial widths for $8 \to 8 \otimes 8$ involve a linear superposition of 8_1 (symmetric) and 8_2 (antisymmetric) couplings. For example,

$$\Gamma(\Xi^* \to \Xi \pi) \sim \left(-\sqrt{\frac{9}{20}} g_1 + \sqrt{\frac{3}{12}} g_2\right)^2$$
 (33.3)

The relations between g_1 and g_2 (with de Swart's normalization) and the standard D and F couplings that appear in the interaction Lagrangian,

$$\mathcal{L} = -\sqrt{2} D \operatorname{Tr} (\{\overline{B}, B\}M) + \sqrt{2} F \operatorname{Tr} ([\overline{B}, B] M) , \qquad (33.4)$$

where $[\overline{B}, B] \equiv \overline{B}B - B\overline{B}$ and $\{\overline{B}, B\} \equiv \overline{B}B + B\overline{B}$, are

$$D = \frac{\sqrt{30}}{40} g_1 , \qquad F = \frac{\sqrt{6}}{24} g_2 . \qquad (33.5)$$

Thus, for example,

$$\Gamma(\Xi^* \to \Xi \pi) \sim (F - D)^2 \sim (1 - 2\alpha)^2$$
, (33.6)

where $\alpha \equiv F/(D+F)$. (This definition of α is de Swart's. The alternative D/(D+F), due to Gell-Mann, is also used.)

The generators of SU(3) transformations, λ_a (a=1,8), are 3×3 matrices that obey the following commutation and anticommutation relationships:

$$[\lambda_a, \lambda_b] \equiv \lambda_a \lambda_b - \lambda_b \lambda_a = 2i f_{abc} \lambda_c \tag{33.7}$$

$$\{\lambda_a,\ \lambda_b\} \equiv \lambda_a \lambda_b + \lambda_b \lambda_a = \frac{4}{3} \delta_{ab} I + 2 d_{abc} \lambda_c \ , \eqno(33.8)$$

where I is the 3×3 identity matrix, and δ_{ab} is the Kronecker delta symbol. The f_{abc} are odd under the permutation of any pair of indices, while the d_{abc} are even. The nonzero values are

1 -- 8 -- 8

$$(\Lambda) \rightarrow (N\overline{K} \ \Sigma \pi \ \Lambda \eta \ \Xi K) = \frac{1}{\sqrt{8}} (2 \ 3 \ -1 \ -2)^{1/2}$$

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \ \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \ \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

$$\lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

Equation (33.7) defines the Lie algebra of SU(3). A general d-dimensional representation is given by a set of $d \times d$ matrices satisfying Eq. (33.7) with the f_{abc} given above. Equation (33.8) is specific to the defining 3-dimensional representation.

34. SU(n) MULTIPLETS AND YOUNG DIAGRAMS

Written by C.G. Wohl (LBNL).

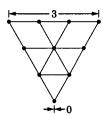

This note tells (1) how SU(n) particle multiplets are identified or labeled, (2) how to find the number of particles in a multiplet from its label, (3) how to draw the Young diagram for a multiplet, and (4) how to use Young diagrams to determine the overall multiplet structure of a composite system, such as a 3-quark or a meson-baryon system.

In much of the literature, the word "representation" is used where we use "multiplet," and "tableau" is used where we use "diagram."

34.1. Multiplet labels

An SU(n) multiplet is uniquely identified by a string of (n-1) nonnegative integers: $(\alpha, \beta, \gamma, \ldots)$. Any such set of integers specifies a multiplet. For an SU(2) multiplet such as an isospin multiplet, the single integer α is the number of *steps* from one end of the multiplet to the other (i.e., it is one fewer than the number of particles in the multiplet). In SU(3), the two integers α and β are the numbers of steps across the top and bottom levels of the multiplet diagram. Thus the labels for the SU(3) octet and decuplet

are (1,1) and (3,0). For larger n, the interpretation of the integers in terms of the geometry of the multiplets, which exist in an (n-1)-dimensional space, is not so readily apparent.

The label for the SU(n) singlet is $(0,0,\ldots,0)$. In a flavor SU(n), the n quarks together form a $(1,0,\ldots,0)$ multiplet, and the n antiquarks belong to a $(0,\ldots,0,1)$ multiplet. These two multiplets are *conjugate* to one another, which means their labels are related by $(\alpha,\beta,\ldots) \leftrightarrow (\ldots,\beta,\alpha)$.

34.2. Number of particles

The number of particles in a multiplet, $N=N(\alpha,\beta,\ldots)$, is given as follows (note the pattern of the equations).

In SU(2), $N = N(\alpha)$ is

$$N = \frac{(\alpha + 1)}{1} . \tag{34.1}$$

In SU(3), $N = N(\alpha, \beta)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} . \tag{34.2}$$

In SU(4), $N = N(\alpha, \beta, \gamma)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\gamma+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \cdot \frac{(\beta+\gamma+2)}{2} \cdot \frac{(\alpha+\beta+\gamma+3)}{3}.$$
(34.3)

Note that in Eq. (34.3) there is no factor with $(\alpha + \gamma + 2)$: only a consecutive sequence of the label integers appears in any factor. One more example should make the pattern clear for any SU(n). In SU(5), $N = N(\alpha, \beta, \gamma, \delta)$ is

$$N = \frac{(\alpha+1)}{1} \cdot \frac{(\beta+1)}{1} \cdot \frac{(\gamma+1)}{1} \cdot \frac{(\delta+1)}{1} \cdot \frac{(\alpha+\beta+2)}{2} \cdot \frac{(\beta+\gamma+2)}{2} \times \frac{(\gamma+\delta+2)}{2} \cdot \frac{(\alpha+\beta+\gamma+3)}{3} \cdot \frac{(\beta+\gamma+\delta+3)}{3} \cdot \frac{(\alpha+\beta+\gamma+\delta+4)}{4} (34.4)$$

From the symmetry of these equations, it is clear that multiplets that are conjugate to one another have the same number of particles, but so can other multiplets. For example, the SU(4) multiplets (3,0,0) and (1,1,0) each have 20 particles. Try the equations and see.

34.3. Young diagrams

A Young diagram consists of an array of boxes (or some other symbol) arranged in one or more left-justified rows, with each row being at least as long as the row beneath. The correspondence between a diagram and a multiplet label is: The top row juts out α boxes to the right past the end of the second row, the second row juts out β boxes to the right past the end of the third row, etc. A diagram in SU(n) has at most n rows. There can be any number of "completed" columns of n boxes buttressing the left of a diagram; these don't affect the label. Thus in SU(3) the diagrams

represent the multiplets (1,0), (0,1), (0,0), (1,1), and (3,0). In any SU(n), the quark multiplet is represented by a single box, the antiquark multiplet by a column of (n-1) boxes, and a singlet by a completed column of n boxes.

34.4. Coupling multiplets together

The following recipe tells how to find the multiplets that occur in coupling two multiplets together. To couple together more than two multiplets, first couple two, then couple a third with each of the multiplets obtained from the first two, etc.

First a definition: A sequence of the letters a, b, c, \ldots is admissible if at any point in the sequence at least as many a's have occurred as b's, at least as many b's have occurred as c's, etc. Thus abcd and aabcb are admissible sequences and abb and acb are not. Now the recipe:

- (a) Draw the Young diagrams for the two multiplets, but in one of the diagrams replace the boxes in the first row with a's, the boxes in the second row with b's, etc. Thus, to couple two SU(3) octets (such as the π -meson octet and the baryon octet), we start with \square and
- ^{a a} . The unlettered diagram forms the upper left-hand corner of all the enlarged diagrams constructed below.
- (b) Add the a's from the lettered diagram to the right-hand ends of the rows of the unlettered diagram to form all possible legitimate Young diagrams that have no more than one a per column. In general, there will be several distinct diagrams, and all the a's appear in each diagram. At this stage, for the coupling of the two SU(3) octets, we have:

- (c) Use the b's to further enlarge the diagrams already obtained, subject to the same rules. Then throw away any diagram in which the full sequence of letters formed by reading right to left in the first row, then the second row, etc., is not admissible.
 - (d) Proceed as in (c) with the c's (if any), etc.

The final result of the coupling of the two SU(3) octets is:

Here only the diagrams with admissible sequences of a's and b's and with fewer than four rows (since n=3) have been kept. In terms of multiplet labels, the above may be written

$$(1,1)\otimes(1,1)=(2,2)\oplus(3,0)\oplus(0,3)\oplus(1,1)\oplus(1,1)\oplus(0,0)$$
.

In terms of numbers of particles, it may be written

$$\mathbf{8} \otimes \mathbf{8} = \mathbf{27} \oplus \mathbf{10} \oplus \mathbf{\overline{10}} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1} .$$

The product of the numbers on the left here is equal to the sum on the right, a useful check. (See also Sec. 13 on the Quark Model.)

35. KINEMATICS

Revised May 1996 by J.D. Jackson (LBNL),

Throughout this section units are used in which $\hbar = c = 1$. The following conversions are useful: $\hbar c = 197.3 \text{ MeV fm}, (\hbar c)^2 = 0.3894$ $(GeV)^2$ mb.

35.1. Lorentz transformations

The energy E and 3-momentum p of a particle of mass m form a 4-vector p=(E,p) whose square $p^2\equiv E^2-|p|^2=m^2$. The velocity of the particle is $\beta = p/E$. The energy and momentum (E^*, p^*) viewed from a frame moving with velocity β_f are given by

$$\begin{pmatrix} E^* \\ p_{\parallel}^* \end{pmatrix} = \begin{pmatrix} \gamma_f & -\gamma_f \beta_f \\ -\gamma_f \beta_f & \gamma_f \end{pmatrix} \begin{pmatrix} E \\ p_{\parallel} \end{pmatrix} , \quad p_T^* = p_T , \quad (35.1)$$

where $\gamma_f=(1-\beta_f^2)^{-1/2}$ and p_T (p_\parallel) are the components of p perpendicular (parallel) to β_f . Other 4-vectors, such as the spacetime coordinates of events, of course transform in the same way. The scalar product of two 4-momenta $p_1 \cdot p_2 = E_1 E_2 - p_1 \cdot p_2$ is invariant (frame independent).

35.2. Center-of-mass energy and momentum

In the collision of two particles of masses m_1 and m_2 the total center-of-mass energy can be expressed in the Lorentz-invariant form

$$E_{\rm cm} = \left[(E_1 + E_2)^2 - (\mathbf{p}_1 + \mathbf{p}_2)^2 \right]^{1/2} ,$$

= $\left[m_1^2 + m_2^2 + 2E_1E_2(1 - \beta_1\beta_2\cos\theta) \right]^{1/2} ,$ (35.2)

where θ is the angle between the particles. In the frame where one particle (of mass m_2) is at rest (lab frame),

$$E_{\rm cm} = (m_1^2 + m_2^2 + 2E_{1\,{\rm lab}}\,m_2)^{1/2}$$
 (35.3)

The velocity of the center-of-mass in the lab frame is

$$\beta_{\rm cm} = p_{\rm lab}/(E_{\rm 1\,lab} + m_2)$$
, (35.4)

where $p_{lab} \equiv p_{l \, lab}$ and

$$\gamma_{\rm cm} = (E_{1\,\rm lab} + m_2)/E_{\rm cm}$$
 (35.5)

The c.m. momenta of particles 1 and 2 are of magnitude

$$p_{\rm cm} = p_{\rm lab} \frac{m_2}{E_{\rm cm}} . \tag{35.6}$$

For example, if a $0.80~{\rm GeV}/c$ kaon beam is incident on a proton target, the center of mass energy is 1.699 GeV and the center of mass momentum of either particle is 0.442 GeV/c. It is also useful to note that

$$E_{\rm cm} dE_{\rm cm} = m_2 dE_{1\,\rm lab} = m_2 \beta_{1\,\rm lab} dp_{\rm lab}$$
 (35.7)

35.3. Lorentz-invariant amplitudes

The matrix elements for a scattering or decay process are written in terms of an invariant amplitude $-i\mathcal{M}$. As an example, the S-matrix for $2 \rightarrow 2$ scattering is related to \mathcal{M} by

$$\langle p'_{1}p'_{2} | S | p_{1}p_{2} \rangle = I - i(2\pi)^{4} \delta^{4}(p_{1} + p_{2} - p'_{1} - p'_{2}) \times \frac{\mathscr{M}(p_{1}, p_{2}; p'_{1}, p'_{2})}{(2E_{1})^{1/2} (2E_{2})^{1/2} (2E'_{1})^{1/2} (2E'_{2})^{1/2}} . (35.8)$$

The state normalization is such that

$$\langle p'|p\rangle = (2\pi)^3 \delta^3(p-p') . \qquad (35.9)$$

35.4. Particle decays

The partial decay rate of a particle of mass M into n bodies in its rest frame is given in terms of the Lorentz-invariant matrix element ₩ bv

$$d\Gamma = \frac{(2\pi)^4}{2M} |\mathcal{M}|^2 d\Phi_n (P; p_1, \dots, p_n), \qquad (35.10)$$

where $d\Phi_n$ is an element of n-body phase space given by

$$d\Phi_n(P; p_1, \ldots, p_n) = \delta^4 \left(P - \sum_{i=1}^n p_i \right) \prod_{i=1}^n \frac{d^3 p_i}{(2\pi)^3 2E_i} . \tag{35.11}$$

This phase space can be generated recursively, viz.

$$d\Phi_n(P; p_1, \ldots, p_n) = d\Phi_i(q; p_1, \ldots, p_i)$$

$$\times d\Phi_{n-j+1}(P; q, p_{i+1}, \ldots, p_n)(2\pi)^3 dq^2,$$
 (35.12)

where $q^2 = (\sum_{i=1}^j E_i)^2 - \left|\sum_{i=1}^j p_i\right|^2$. This form is particularly useful in the case where a particle decays into another particle that subsequently decays.

35.4.1. Survival probability: If a particle of mass M has mean proper lifetime τ (= 1/ Γ) and has momentum (E, p), then the probability that it lives for a time to or greater before decaying is given by

$$P(t_0) = e^{-t_0 \Gamma/\gamma} = e^{-Mt_0 \Gamma/E} , \qquad (35.13)$$

and the probability that it travels a distance x_0 or greater is

$$P(x_0) = e^{-Mx_0 \Gamma/|p|}. (35.14)$$

35.4.2. Two-body decays:

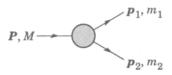

Figure 35.1: Definitions of variables for two-body decays.

In the rest frame of a particle of mass M, decaying into 2 particles labeled 1 and 2,

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M} , \qquad (35.15)$$

$$|p_1| = |p_2|$$

$$=\frac{\left[\left(M^2-(m_1+m_2)^2\right)\left(M^2-(m_1-m_2)^2\right)\right]^{1/2}}{2M},\qquad(35.16)$$

and

$$d\Gamma = \frac{1}{32\pi^2} |\mathcal{M}|^2 \frac{|p_1|}{M^2} d\Omega , \qquad (35.17)$$

where $d\Omega = d\phi_1 d(\cos \theta_1)$ is the solid angle of particle 1.

35.4.3. Three-body decays:

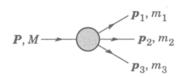

Figure 35.2: Definitions of variables for three-body decays.

Defining $p_{ij}=p_i+p_j$ and $m_{ij}^2=p_{ij}^2$, then $m_{12}^2+m_{23}^2+m_{13}^2=M^2+m_1^2+m_2^2+m_3^2$ and $m_{12}^2=(P-p_3)^2=M^2+m_3^2-2ME_3$, where E_3 is the energy of particle 3 in the rest frame of M. In that frame, the momenta of the three decay particles lie in a plane. The relative orientation of these three momenta is fixed if their energies are known. The momenta can therefore be specified in space by giving three Euler angles (α,β,γ) that specify the orientation of the final system relative to the initial particle. Then

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M} |\mathcal{M}|^2 dE_1 dE_2 d\alpha d(\cos \beta) d\gamma. \qquad (35.18)$$

Alternatively

$$d\Gamma = \frac{1}{(2\pi)^5} \frac{1}{16M^2} |\mathcal{M}|^2 |p_1^*| |p_3| dm_{12} d\Omega_1^* d\Omega_3 , \qquad (35.19)$$

where $(|p_1^*|, \Omega_1^*)$ is the momentum of particle 1 in the rest frame of 1 and 2, and Ω_3 is the angle of particle 3 in the rest frame of the decaying particle. $|p_1^*|$ and $|p_3|$ are given by

$$|\mathbf{p}_1^*| = \frac{\left[\left(m_{12}^2 - (m_1 + m_2)^2\right)\left(m_{12}^2 - (m_1 - m_2)^2\right)\right]^{1/2}}{2m_{12}},$$
 (35.20a)

and

$$|\mathbf{p}_3| = \frac{\left[\left(M^2 - (m_{12} + m_3)^2\right)\left(M^2 - (m_{12} - m_3)^2\right)\right]^{1/2}}{2M}$$
 (35.20b)

[Compare with Eq. (35.16).]

If the decaying particle is a scalar or we average over its spin states, then integration over the angles in Eq. (35.18) gives

$$d\Gamma = \frac{1}{(2\pi)^3} \frac{1}{8M} |\mathcal{M}|^2 dE_1 dE_2$$

$$= \frac{1}{(2\pi)^3} \frac{1}{32M^3} |\mathcal{M}|^2 dm_{12}^2 dm_{23}^2 . \tag{35.21}$$

This is the standard form for the Dalitz plot.

35.4.3.1. Dalitz plot: For a given value of m_{12}^2 , the range of m_{23}^2 is determined by its values when p_2 is parallel or antiparallel to p_3 :

$$(m_{23}^2)_{\text{max}} =$$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} - \sqrt{E_3^{*2} - m_3^2}\right)^2 , \qquad (35.22a)$$

$$(m_{23}^2)_{\text{min}} =$$

$$(E_2^* + E_3^*)^2 - \left(\sqrt{E_2^{*2} - m_2^2} + \sqrt{E_3^{*2} - m_3^2}\right)^2$$
 (35.22b)

Here $E_2^*=(m_{12}^2-m_1^2+m_2^2)/2m_{12}$ and $E_3^*=(M^2-m_{12}^2-m_3^2)/2m_{12}$ are the energies of particles 2 and 3 in the m_{12} rest frame. The scatter plot in m_{12}^2 and m_{23}^2 is called a Dalitz plot. If $|\mathcal{M}|^2$ is constant, the allowed region of the plot will be uniformly populated with events [see Eq. (35.21)]. A nonuniformity in the plot gives immediate information on $|\mathcal{M}|^2$. For example, in the case of $D\to K\pi\pi$, bands appear when $m_{(K\pi)}=m_{K^*(892)}$, reflecting the appearance of the decay chain $D\to K^*(892)\pi\to K\pi\pi$.

35.4.4. Kinematic limits: In a three-body decay the maximum of $|p_3|$, [given by Eq. (35.20)], is achieved when $m_{12} = m_1 + m_2$, i.e., particles 1 and 2 have the same vector velocity in the rest frame of the decaying particle. If, in addition, $m_3 > m_1, m_2$, then $|p_3|_{\max} > |p_1|_{\max}$, $|p_2|_{\max}$.

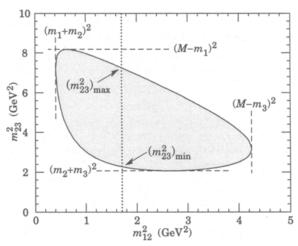

Figure 35.3: Dalitz plot for a three-body final state. In this example, the state is $\pi^+\overline{K}^0p$ at 3 GeV. Four-momentum conservation restricts events to the shaded region.

35.4.5. Multibody decays: The above results may be generalized to final states containing any number of particles by combining some of the particles into "effective particles" and treating the final states as 2 or 3 "effective particle" states. Thus, if $p_{ijk...} = p_i + p_j + p_k + \ldots$, then

$$m_{ijk...} = \sqrt{p^2_{ijk...}}, \qquad (35.23)$$

and $m_{ijk...}$ may be used in place of e.g., m_{12} in the relations in Sec. 35.4.3 or 35.4.3.1 above.

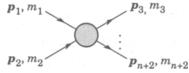

Figure 35.4: Definitions of variables for production of an *n*-body final state.

35.5. Cross sections

The differential cross section is given by

$$d\sigma = \frac{(2\pi)^4 |\mathcal{M}|^2}{4\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2}}$$

$$\times d\Phi_n(p_1 + p_2; p_3, \dots, p_{n+2}). \tag{35.24}$$

[See Eq. (35.11).] In the rest frame of $m_2(lab)$,

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = m_2 p_{1 \, \text{lab}} ; \qquad (35.25a)$$

while in the center-of-mass frame

$$\sqrt{(p_1 \cdot p_2)^2 - m_1^2 m_2^2} = p_{1\text{cm}} \sqrt{s} . \tag{35.25b}$$

35.5.1. Two-body reactions:

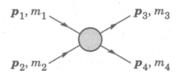

Figure 35.5: Definitions of variables for a two-body final state.

Two particles of momenta p_1 and p_2 and masses m_1 and m_2 scatter to particles of momenta p_3 and p_4 and masses m_3 and m_4 ; the Lorentz-invariant Mandelstam variables are defined by

$$s = (p_1 + p_2)^2 = (p_3 + p_4)^2$$

= $m_1^2 + 2E_{\underline{1}}E_2 - 2p_1 \cdot p_2 + m_2^2$, (35.26)

$$t = (p_1 - p_3)^2 = (p_2 - p_4)^2$$

= $m_1^2 - 2E_1E_3 + 2p_1 \cdot p_3 + m_3^2$, (35.27)

$$u = (p_1 - p_4)^2 = (p_2 - p_3)^2$$

= $m_1^2 - 2E_1E_4 + 2p_1 \cdot p_4 + m_4^2$, (35.28)

and they satisfy

$$s + t + u = m_1^2 + m_2^2 + m_3^2 + m_4^2 . (35.29)$$

The two-body cross section may be written as

$$\frac{d\sigma}{dt} = \frac{1}{64\pi s} \frac{1}{|\mathbf{p}_{1cm}|^2} |\mathcal{M}|^2 . \tag{35.30}$$

In the center-of-mass frame

$$t = (E_{1\text{cm}} - E_{3\text{cm}})^2 - (p_{1\text{cm}} - p_{3\text{cm}})^2 - 4p_{1\text{cm}} p_{3\text{cm}} \sin^2(\theta_{\text{cm}}/2)$$

$$= t_0 - 4p_{1cm} p_{3cm} \sin^2(\theta_{cm}/2) , \qquad (35.31)$$

where $\theta_{\rm cm}$ is the angle between particle 1 and 3. The limiting values t_0 ($\theta_{\rm cm}=0$) and t_1 ($\theta_{\rm cm}=\pi$) for $2\to 2$ scattering are

$$t_0(t_1) = \left[\frac{m_1^2 - m_3^2 - m_2^2 + m_4^2}{2\sqrt{s}} \right]^2 - (p_{1\,\text{cm}} \mp p_{3\,\text{cm}})^2 . \tag{35.32}$$

In the literature the notation t_{\min} (t_{\max}) for t_0 (t_1) is sometimes used, which should be discouraged since $t_0 > t_1$. The center-of-mass energies and momenta of the incoming particles are

$$E_{1\text{cm}} = \frac{s + m_1^2 - m_2^2}{2\sqrt{s}}$$
, $E_{2\text{cm}} = \frac{s + m_2^2 - m_1^2}{2\sqrt{s}}$, (35.33)

For $E_{3\rm cm}$ and $E_{4\rm cm}$, change m_1 to m_3 and m_2 to m_4 . Then

$$p_{i \text{ cm}} = \sqrt{E_{i \text{ cm}}^2 - m_i^2} \text{ and } p_{1 \text{ cm}} = \frac{p_{1 \text{ lab}} m_2}{\sqrt{s}}$$
 (35.34)

Here the subscript lab refers to the frame where particle 2 is at rest. [For other relations see Eqs. (35.2)–(35.4).]

35.5.2. Inclusive reactions: Choose some direction (usually the beam direction) for the z-axis; then the energy and momentum of a particle can be written as

$$E = m_T \cosh y \,, \, p_x \,, \, p_y \,, \, p_z = m_T \sinh y \,,$$
 (35.35)

where m_T is the transverse mass

$$m_T^2 = m^2 + p_x^2 + p_y^2 , (35.36)$$

and the rapidity y is defined by

$$y = \frac{1}{2} \ln \left(\frac{E + p_z}{E - p_z} \right)$$

$$= \ln \left(\frac{E + p_z}{m_x} \right) = \tanh^{-1} \left(\frac{p_z}{E} \right) . \tag{35.37}$$

Under a boost in the z-direction to a frame with velocity β , $y \to y - \tanh^{-1} \beta$. Hence the shape of the rapidity distribution dN/dy is invariant. The invariant cross section may also be rewritten

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi \, dy \, p_T dp_T} \Longrightarrow \frac{d^2\sigma}{\pi \, dy \, d(p_T^2)} \,. \tag{35.38}$$

The second form is obtained using the identity $dy/dp_z = 1/E$, and the third form represents the average over ϕ .

Feynman's x variable is given by

$$x = \frac{p_z}{p_{z \max}} \approx \frac{E + p_z}{(E + p_z)_{\max}} \quad (p_T \ll |p_z|) .$$
 (35.39)

In the c.m. frame,

$$x \approx \frac{2p_{z\,\mathrm{cm}}}{\sqrt{s}} = \frac{2m_T \sinh y_{\mathrm{cm}}}{\sqrt{s}} \tag{35.40}$$

րով

$$=(y_{\rm cm})_{\rm max} = \ln(\sqrt{s}/m)$$
. (35.41)

For $p \gg m$, the rapidity [Eq. (35.37)] may be expanded to obtain

$$y = \frac{1}{2} \ln \frac{\cos^2(\theta/2) + m^2/4p^2 + \dots}{\sin^2(\theta/2) + m^2/4p^2 + \dots}$$
$$\approx -\ln \tan(\theta/2) \equiv \eta$$
 (35.42)

where $\cos \theta = p_x/p$. The pseudorapidity η defined by the second line is approximately equal to the rapidity y for $p \gg m$ and $\theta \gg 1/\gamma$, and in any case can be measured when the mass and momentum of the particle is unknown. From the definition one can obtain the identities

$$\sinh \eta = \cot \theta$$
, $\cosh \eta = 1/\sin \theta$, $\tanh \eta = \cos \theta$. (35.43)

35.5.3. Partial waves: The amplitude in the center of mass for elastic scattering of spinless particles may be expanded in Legendre polynomials

$$f(k,\theta) = \frac{1}{k} \sum_{\ell} (2\ell + 1) a_{\ell} P_{\ell}(\cos \theta) , \qquad (35.44)$$

where k is the c.m. momentum, θ is the c.m. scattering angle, $a_{\ell} = (\eta_{\ell}e^{2i\delta_{\ell}} - 1)/2i$, $0 \le \eta_{\ell} \le 1$, and δ_{ℓ} is the phase shift of the ℓ^{th} partial wave. For purely elastic scattering, $\eta_{\ell} = 1$. The differential cross section is

$$\frac{d\sigma}{d\Omega} = |f(k,\theta)|^2 . {(35.45)}$$

The optical theorem states that

$$\sigma_{\text{tot}} = \frac{4\pi}{k} \text{Im} f(k,0) , \qquad (35.46)$$

and the cross section in the ℓ^{th} partial wave is therefore bounded:

$$\sigma_{\ell} = \frac{4\pi}{k^2} (2\ell + 1) |a_{\ell}|^2 \le \frac{4\pi (2\ell + 1)}{k^2} . \tag{35.47}$$

The evolution with energy of a partial-wave amplitude a_{ℓ} can be displayed as a trajectory in an Argand plot, as shown in Fig. 35.6.

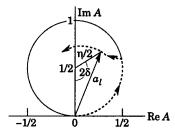

Figure 35.6: Argand plot showing a partial-wave amplitude a_{ℓ} as a function of energy. The amplitude leaves the unitary circle where inelasticity sets in $(\eta_{\ell} < 1)$.

The usual Lorentz-invariant matrix element \mathcal{M} (see Sec. 35.3 above) for the elastic process is related to $f(k,\theta)$ by

$$\mathscr{M} = -8\pi\sqrt{s} f(k,\theta) , \qquad (35.48)$$

so

$$\sigma_{\rm tot} = -\frac{1}{2p_{\rm lab} m_2} \, {\rm Im} \, \mathcal{M}(t=0) \; ,$$
 (35.49)

where s and t are the center-of-mass energy squared and momentum transfer squared, respectively (see Sec. 35.4.1).

35.5.3.1. Resonances: The Breit-Wigner (nonrelativistic) form for an elastic amplitude a_ℓ with a resonance at c.m. energy E_R , elastic width $\Gamma_{\rm el}$, and total width $\Gamma_{\rm tot}$ is

$$a_{\ell} = \frac{\Gamma_{\rm el}/2}{E_R - E - i\Gamma_{\rm tot}/2} , \qquad (35.50)$$

where E is the c.m. energy. As shown in Fig. 35.7, in the absence of background the elastic amplitude traces a counterclockwise circle with center $ix_{\rm el}/2$ and radius $x_{\rm el}/2$, where the elasticity $x_{\rm el}=\Gamma_{\rm el}/\Gamma_{\rm tot}$. The amplitude has a pole at $E=E_R-i\Gamma_{\rm tot}/2$.

The spin-averaged Breit-Wigner cross section for a spin-J resonance produced in the collision of particles of spin S_1 and S_2 is

$$\sigma_{BW}(E) = \frac{(2J+1)}{(2S_1+1)(2S_2+1)} \frac{\pi}{k^2} \frac{B_{\rm in} B_{\rm out} \Gamma_{\rm tot}^2}{(E-E_R)^2 + \Gamma_{\rm tot}^2/4} , \quad (35.51)$$

where k is the c.m. momentum, E is the c.m. energy, and $B_{\rm in}$ and $B_{\rm out}$ are the branching fractions of the resonance into the entrance and exit channels. The 2S+1 factors are the multiplicities of the incident spin states, and are replaced by 2 for photons. This expression is valid only for an isolated state. If the width is not small, $\Gamma_{\rm tot}$ cannot be treated as a constant independent of E. There are many other forms for σ_{BW} , all of which are equivalent to the one given here in the narrow-width case. Some of these forms may be more appropriate if the resonance is broad.

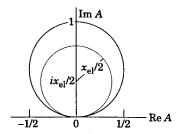

Figure 35.7: Argand plot for a resonance.

The relativistic Breit-Wigner form corresponding to Eq. (35.50) is:

$$a_{\ell} = \frac{-m\Gamma_{\rm el}}{s - m^2 + im\Gamma_{\rm tot}} \ . \tag{35.52}$$

A better form incorporates the known kinematic dependences, replacing $m\Gamma_{\rm tot}$ by $\sqrt{s}\,\Gamma_{\rm tot}(s)$, where $\Gamma_{\rm tot}(s)$ is the width the resonance particle would have if its mass were \sqrt{s} , and correspondingly $m\Gamma_{\rm el}$ by $\sqrt{s}\,\Gamma_{\rm el}(s)$ where $\Gamma_{\rm el}(s)$ is the partial width in the incident channel for a mass \sqrt{s} :

$$a_{\ell} = \frac{-\sqrt{s}\,\Gamma_{\rm el}(s)}{s - m^2 + i\sqrt{s}\,\Gamma_{\rm tot}(s)} \,. \tag{35.53}$$

For the Z boson, all the decays are to particles whose masses are small enough to be ignored, so on dimensional grounds $\Gamma_{\rm tot}(s) = \sqrt{s}\,\Gamma_0/m_Z$, where Γ_0 defines the width of the Z, and $\Gamma_{\rm el}(s)/\Gamma_{\rm tot}(s)$ is constant. A full treatment of the line shape requires consideration of dynamics, not just kinematics. For the Z this is done by calculating the radiative corrections in the Standard Model.

36. CROSS-SECTION FORMULAE FOR SPECIFIC PROCESSES

Revised April 1998 by R.N. Cahn (LBNL).

36.1. Leptoproduction

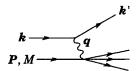

Figure 36.1: Kinematic quantities for description of lepton-nucleon scattering. k and k' are the four-momenta of incoming and outgoing leptons, P is the four-momentum of a nucleon with mass M. The exchanged particle is a γ , W^{\pm} , or Z^0 ; it transfers four-momentum q = k - k' to the target.

Invariant quantities:

 $\nu = \frac{q \cdot P}{M} = E - E' \text{ is the lepton's energy loss in the lab (in earlier literature sometimes } \nu = q \cdot P). \text{ Here, } E \text{ and } E' \text{ are the initial and final lepton energies in the lab.}$

 $Q^2 = -q^2 = 2(EE' - \overrightarrow{k} \cdot \overrightarrow{k}') - m_\ell^2 - m_{\ell'}^2 \text{ where } m_\ell(m_{\ell'}) \text{ is the initial}$ (final) lepton mass. If $EE' \sin^2(\theta/2) \gg m_\ell^2$, $m_{\ell'}^2$, then

 $pprox 4EE'\sin^2(\theta/2)$, where θ is the lepton's scattering angle in the lab.

 $x=rac{Q^2}{2M
u}$ In the parton model, x is the fraction of the target nucleon's momentum carried by the struck quark. [See section on Quantum Chromodynamics (Sec. 9 of this *Review*.)]

 $y = rac{q \cdot P}{k \cdot P} = rac{
u}{E}$ is the fraction of the lepton's energy lost in the lab.

 $W^2 = (P+q)^2 = M^2 + 2M\nu - Q^2$ is the mass squared of the system recoiling against the lepton.

$$s = (k+P)^2 = \frac{Q^2}{xy} + M^2$$

36.1.1. Leptoproduction cross sections:

$$\frac{d^{2}\sigma}{dx\,dy} = \nu (s - M^{2}) \, \frac{d^{2}\sigma}{d\nu\,dQ^{2}} = \frac{2\pi\,M\nu}{E^{I}} \frac{d^{2}\sigma}{d\Omega_{\text{lab}}\,dE^{I}}$$

$$= x(s - M^{2}) \, \frac{d^{2}\sigma}{dx\,d\Omega^{2}} \, . \tag{36.1}$$

36.1.2. Leptoproduction structure functions: The neutral-current process, $eN \to eX$, at low Q^2 is just electromagnetic and parity conserving. It can be written in terms of two structure functions $F_1^{\rm em}(x,Q^2)$ and $F_2^{\rm em}(x,Q^2)$:

$$\frac{d^2\sigma}{dx\,dy} = \frac{4\pi\,\alpha^2(s-M^2)}{Q^4} \times \left[(1-y)\,F_2^{\rm em} + y^2\,xF_1^{\rm em} - \frac{M^2}{(s-M^2)}\,xy\,F_2^{\rm em} \right] . (36.2)$$

The charged-current processes, $e^-N \to \nu X$, $\nu N \to e^-X$, and $\overline{\nu}N \to e^+X$, are parity violating and can be written in terms of three structure functions $F_1^{\rm CC}(x,Q^2)$, $F_2^{\rm CC}(x,Q^2)$, and $F_3^{\rm CC}(x,Q^2)$:

$$\frac{d^2\dot{\sigma}}{dx\;dy} = \frac{G_F^2\;(s-M^2)}{2\pi} \frac{M_W^4}{(Q^2+M_W^2)^2} \eqno(36.3)$$

$$\times \; \left\{ \left[1 - y - \frac{M^2 x y}{(s - M^2)} \right] F_2^{\rm CC} + \frac{y^2}{2} \; 2x \, F_1^{\rm CC} \pm (y - \frac{y^2}{2}) \; x \, F_3^{\rm CC} \right\} \, ,$$

where the last term is positive for the e^- and ν reactions and negative for $\overline{\nu}N \to e^+ X$. As explained below there are different structure functions for charge-raising and charge-lowering currents.

36.1.3. Structure functions in the QCD parton model: In the QCD parton model, the structure functions defined above can be expressed in terms of parton distribution functions. The quantity $f_i(x,Q^2)dx$ is the probability that a parton of type i (quark, antiquark, or gluon), carries a momentum fraction between x and x+dx of the nucleon's momentum in a frame where the nucleon's momentum is large. For the cross section corresponding to the neutral-current process $ep \to eX$, we have for $s \gg M^2$ (in the case where the incoming electron is either left- (L) or right- (R) handed):

$$\frac{d^{2}\sigma}{dx\ dy} = \frac{\pi\alpha^{2}}{sx^{2}\ y^{2}} \left[\sum_{q} \left(x f_{q} \left(x, Q^{2} \right) + x f_{\overline{q}} \left(x, Q^{2} \right) \right) \right] \times \left[A_{q} + (1 - y)^{2} B_{q} \right]. \tag{36.4}$$

Here the index q refers to a quark flavor (i.e., u, d, s, c, b, or t), and

$$\begin{split} A_q &= \left(-q_q + g_{Lq} \; g_{Le} \; \frac{Q^2}{Q^2 + M_Z^2} \right)^2 + \left(-q_q + g_{Rq} \; g_{Re} \; \frac{Q^2}{Q^2 + M_Z^2} \right)^2, \\ B_q &= \left(-q_q + g_{Rq} \; g_{Le} \; \frac{Q^2}{Q^2 + M_Z^2} \right)^2 + \left(-q_q + g_{Lq} \; g_{Re} \; \frac{Q^2}{Q^2 + M_Z^2} \right)^2. \end{split}$$

Here q_q is the charge of flavor q. For a left-handed electron, $g_{Re}=0$ and $g_{Le}=(-1/2+\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, while for a right-handed electron, $g_{Le}=0$ and $g_{Re}=(\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$. For the quarks, $g_{Lq}=(T_3-q_q\sin^2\theta_W)/(\sin\theta_W\cos\theta_W)$, and $g_{Rq}=(-q_q\sin^2\theta_W)$ / $(\sin\theta_W\cos\theta_W)$.

For neutral-current neutrino (antineutrino) scattering, the same formula applies with g_{Le} replaced by $g_{L\nu}=1/(2\sin\theta_W\cos\theta_W)$ ($g_{L\overline{\nu}}=0$) and g_{Re} replaced by $g_{R\nu}=0$ [$g_{R\overline{\nu}}=-1/(2\sin\theta_W\cos\theta_W)$].

In the case of the charged-current processes $e_L^-p\to \nu X$ and $\overline{\nu}p\to e^+X$, Eq. (36.3) applies with

$$F_{2} = 2xF_{1} = 2x \Big[f_{u}(x, Q^{2}) + f_{c}(x, Q^{2}) + f_{t}(x, Q^{2}) + f_{\overline{d}}(x, Q^{2}) + f_{\overline{b}}(x, Q^{2}) + f_{\overline{b}}(x, Q^{2}) \Big] , \qquad (36.7)$$

$$F_{3} = 2 \Big[f_{u}(x, Q^{2}) + f_{c}(x, Q^{2}) + f_{t}(x, Q^{2}) - f_{\overline{d}}(x, Q^{2}) - f_{\overline{b}}(x, Q^{2}) \Big] . \qquad (36.8)$$

For the process $\nu p \to e^- X$:

$$F_{2} = 2xF_{1} = 2x \left[f_{d}(x,Q^{2}) + f_{s}(x,Q^{2}) + f_{b}(x,Q^{2}) + f_{\overline{u}}(x,Q^{2}) + f_{\overline{c}}(x,Q^{2}) + f_{\overline{c}}(x,Q^{2}) + f_{\overline{t}}(x,Q^{2}) \right],$$
(36.9)

$$F_{3} = 2 \left[f_{d}(x,Q^{2}) + f_{s}(x,Q^{2}) + f_{b}(x,Q^{2}) - f_{\overline{u}}(x,Q^{2}) - f_{\overline{c}}(x,Q^{2}) - f_{\overline{c}}(x,Q^{2}) \right].$$
(36.10)

36.2. e^+e^- annihilation

For pointlike, spin-1/2 fermions, the differential cross section in the c.m. for $e^+e^- \to f\bar{f}$ via single photon annihilation is (θ is the angle between the incident electron and the produced fermion; $N_c=1$ if f is a lepton and $N_c=3$ if f is a quark).

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \beta \left[1 + \cos^2 \theta + (1 - \beta^2) \sin^2 \theta \right] Q_f^2 , \qquad (36.11)$$

where β is the velocity of the final state fermion in the c.m. and Q_f is the charge of the fermion in units of the proton charge. For $\beta \to 1$,

$$\sigma = N_c \frac{4\pi\alpha^2}{3s} Q_f^2 = N_c \frac{86.8 Q_f^2 \ nb}{s(GeV/c^2)} \ . \tag{36.12}$$

At higher energies, the Z^0 (mass M_Z and width Γ_Z) must be included. If the mass of a fermion f is much less than the mass of the Z^0 , then the differential cross section for $e^+e^- \to f\bar{f}$ is

$$\frac{d\sigma}{d\Omega} = N_c \frac{\alpha^2}{4s} \left\{ (1 + \cos^2 \theta) \left[Q_f^2 - 2\chi_1 v_e v_f Q_f + \chi_2 (a_e^2 + v_e^2) (a_f^2 + v_f^2) \right] + 2\cos \theta \left[-2\chi_1 a_e a_f Q_f + 4\chi_2 a_e a_f v_e v_f \right] \right\}$$
(36.13)

where

$$\chi_{1} = \frac{1}{16 \sin^{2} \theta_{W} \cos^{2} \theta_{W}} \frac{s(s - M_{Z}^{2})}{(s - M_{Z}^{2})^{2} + M_{Z}^{2} \Gamma_{Z}^{2}},$$

$$\chi_{2} = \frac{1}{256 \sin^{4} \theta_{W} \cos^{4} \theta_{W}} \frac{s^{2}}{(s - M_{Z}^{2})^{2} + M_{Z}^{2} \Gamma_{Z}^{2}},$$

$$a_{e} = -1,$$

$$v_{e} = -1 + 4 \sin^{2} \theta_{W},$$

$$a_{f} = 2T_{3f},$$

$$v_{f} = 2T_{3f} - 4Q_{f} \sin^{2} \theta_{W},$$
(36.14)

where $T_{3f}=1/2$ for $u,\ c$ and neutrinos, while $T_{3f}=-1/2$ for $d,\ s,\ b,$ and negatively charged leptons.

At LEP II it may be possible to produce the orthodox Higgs boson, H, (see the mini-review on Higgs bosons) in the reaction $e^+e^- \to HZ^0$, which proceeds dominantly through a virtual Z^0 . The Standard Model prediction for the cross section [3] is

$$\sigma(e^{+}e^{-} \to HZ^{0}) = \frac{\pi\alpha^{2}}{24} \cdot \frac{2K}{\sqrt{s}} \cdot \frac{K^{2} + 3M_{Z}^{2}}{(s - M_{Z}^{2})^{2}} \cdot \frac{1 - 4\sin^{2}\theta_{W} + 8\sin^{4}\theta_{W}}{\sin^{4}\theta_{W}\cos^{4}\theta_{W}}.$$
(36.15)

where K is the c.m. momentum of the produced H or Z^0 . Near the production threshold, this formula needs to be corrected for the finite width of the Z^0 .

36.3. Two-photon process at e^+e^- colliders

When an e^+ and an e^- collide with energies E_1 and E_2 , they emit dn_1 and dn_2 virtual photons with energies ω_1 and ω_2 and 4-momenta q_1 and q_2 . In the equivalent photon approximation, the cross section for $e^+e^- \to e^+e^-X$ is related to the cross section for $\gamma\gamma \to X$ by (Ref. 1)

$$d\sigma_{e^{+}e^{-}\rightarrow e^{+}e^{-}X}\left(s\right) = dn_{1} dn_{2} d\sigma_{\gamma\gamma\rightarrow X}\left(W^{2}\right) \tag{36.16}$$

where $s = 4E_1E_2$, $W^2 = 4\omega_1\omega_2$ and

$$dn_{i} = \frac{\alpha}{\pi} \left[1 - \frac{\omega_{i}}{E_{i}} + \frac{\omega_{i}^{2}}{2E_{i}^{2}} - \frac{m_{e}^{2}\omega_{i}^{2}}{(-q_{i}^{2})E_{i}^{2}} \right] \frac{d\omega_{i}}{\omega_{i}} \frac{d(-q_{i}^{2})}{(-q_{i}^{2})} \ . \eqno(36.17)$$

After integration (including that over q_i^2 in the region $m_e^2 \omega_i^2 / E_i(E_i - \omega_i) \le -q_i^2 \le (-q^2)_{\text{max}}$), the cross section is

$$\sigma_{e^{+}e^{-} \to e^{+}e^{-}X}(s) = \frac{\alpha^{2}}{\pi^{2}} \int_{z_{th}}^{1} \frac{dz}{z} \left[f(z) \left(\ln \frac{(-q^{2})_{\text{max}}}{m_{e}^{2}z} - 1 \right)^{2} - \frac{1}{3} \left(\ln \frac{1}{z} \right)^{3} \right] \sigma_{\gamma\gamma \to X}(zs) ;$$

$$f(z) = \left(1 + \frac{1}{2}z \right)^{2} \ln \frac{1}{z} - \frac{1}{2} (1 - z)(3 + z) ;$$

$$z = \frac{W^{2}}{s} . \tag{36.18}$$

The quantity $(-q^2)_{\max}$ depends on properties of the produced system X, in particular, $(-q^2)_{\max} \sim m_{\rho}^2$ for hadron production (X=h) and $(-q^2)_{\max} \sim W^2$ for lepton pair production $(X=\ell^+\ell^-,\ell^-,\ell^-,\ell^-)$

For production of a resonance of mass m_R and spin $J \neq 1$

$$\begin{split} \sigma_{e^{+}e^{-}\to e^{+}e^{-}R}(s) &= (2J+1)\frac{8\alpha^{2}\Gamma_{R\to\gamma\gamma}}{m_{R}^{3}} \\ &\times \left[f(m_{R}^{2}/s) \left(\ln \frac{sm_{V}^{2}}{m_{2}^{2}m_{P}^{2}} - 1 \right)^{2} - \frac{1}{3} \left(\ln \frac{s}{m_{P}^{2}} \right)^{3} \right] \end{split} \tag{36.19}$$

where m_V is the mass that enters into the form factor of the $\gamma\gamma \to R$ transition: $m_V \sim m_\rho$ for $R=\pi^0,~\rho^0,~\omega,~\phi,~\dots,~m_V \sim m_R$ for $R=c\bar{c}$ or $b\bar{b}$ resonances.

36.4. Inclusive hadronic reactions

One-particle inclusive cross sections $Ed^3\sigma/d^3p$ for the production of a particle of momentum p are conveniently expressed in terms of rapidity (see above) and the momentum p_T transverse to the beam direction (defined in the center-of-mass frame)

$$E\frac{d^3\sigma}{d^3p} = \frac{d^3\sigma}{d\phi\,dy\,p_T dp_T} \ . \tag{36.20}$$

In the case of processes where p_T is large or the mass of the produced particle is large (here large means greater than 10 GeV), the parton model can be used to calculate the rate. Symbolically

$$\sigma_{\text{hadronic}} = \sum_{ij} \int f_i(x_1, Q^2) f_j(x_2, Q^2) dx_1 dx_2 \, \hat{\sigma}_{\text{partonic}} , \quad (36.21)$$

where $f_i(x, Q^2)$ is the parton distribution introduced above and Q is a typical momentum transfer in the partonic process and $\hat{\sigma}$ is the partonic cross section. Some examples will help to clarify. The production of a W^+ in pp reactions at rapidity y in the center-of-mass frame is given by

$$\begin{split} \frac{d\sigma}{dy} &= \frac{G_F \, \pi \sqrt{2}}{3} \\ &\times \tau \bigg[\cos^2 \theta_c \bigg(u(x_1 \; , \; M_W^2) \; \overline{d} \; (x_2, M_W^2) \\ &\quad + \; u(x_2 \; , \; M_W^2) \; \overline{d} \; (x_1, M_W^2) \bigg) \\ &\quad + \; \sin^2 \theta_c \bigg(u(x_1 \; , \; M_W^2) \; \overline{s} \; (x_2 \; , \; M_W^2) \\ &\quad + \; s(x_2, M_W^2) \; \overline{u} \; (x_1, M_W^2) \bigg) \bigg] \; , \; (36.22) \end{split}$$

where $x_1 = \sqrt{\tau} \ e^y$, $x_2 = \sqrt{\tau} \ e^{-y}$, and $\tau = M_W^2/s$. Similarly the production of a jet in pp (or $p\bar{p}$) collisions is given by

$$\frac{d^3\sigma}{d^2p_T dy} = \sum_{ij} \int f_i(x_1, p_T^2) f_j(x_2, p_T^2) \times \left[\widehat{s} \frac{d\widehat{\sigma}}{d\widehat{t}} \right]_{ij} dx_1 dx_2 \delta(\widehat{s} + \widehat{t} + \widehat{u}), \quad (36.23)$$

where the summation is over quarks, gluons, and antiquarks. Here

$$s = (p_1 + p_2)^2 , (36.24)$$

$$t = (p_1 - p_{\text{iet}})^2 , \qquad (36.25)$$

$$u = (p_2 - p_{\text{jet}})^2 , (36.26)$$

 p_1 and p_2 are the momenta of the incoming p and p (or \overline{p}) and \widehat{s} , \widehat{t} , and \widehat{u} are s, t, and u with $p_1 \to x_1 p_1$ and $p_2 \to x_2 p_2$. The partonic cross section $\widehat{s}[(d\widehat{\sigma})/(d\widehat{t})]$ can be found in Ref. 2. Example: for the process $gg \to q\overline{q}$,

$$\widehat{s} \frac{d\sigma}{dt} = 3\alpha_s^2 \frac{(\widehat{t}^2 + \widehat{u}^2)}{8\widehat{s}} \left[\frac{4}{9\,\widehat{t}\,\widehat{u}} - \frac{1}{\widehat{s}^2} \right] . \tag{36.27}$$

The prediction of Eq. (36.23) is compared to data from the UA1 and UA2 collaborations in Fig. 38.8 in the Plots of Cross Sections and Related Quantities section of this *Review*.

The associated production of a Higgs boson and a gauge boson is analogous to the process $e^+e^- \to HZ^0$ in Sec. 36.2. The required parton-level cross sections [4], averaged over initial quark colors, are

$$\begin{split} \sigma(q_i \overline{q}_j \to W^\pm H) &= \frac{\pi \alpha^2 |V_{ij}|^2}{36 \sin^4 \theta_W} \cdot \frac{2K}{\sqrt{s}} \cdot \frac{K^2 + 3M_W^2}{(s - M_W^2)^2} \\ \sigma(q \overline{q} \to Z^0 H) &= \frac{\pi \alpha^2 (a_q^2 + v_q^2)}{144 \sin^4 \theta_W \cos^4 \theta_W} \cdot \frac{2K}{\sqrt{s}} \cdot \frac{K^2 + 3M_Z^2}{(s - M_Z^2)^2} \end{split}$$

Here V_{ij} is the appropriate element of the Kobayashi-Maskawa matrix and K is the c.m. momentum of the produced H. The axial and vector couplings are defined as in Sec. 36.2.

36.5. One-particle inclusive distributions

In order to describe one-particle inclusive production in e^+e^- annihilation or deep inelastic scattering, it is convenient to introduce a fragmentation function $D_i^h\left(z,Q^2\right)$ where $D_i^h\left(z,Q^2\right)$ is the number of hadrons of type h and momentum between zp and (z+dz)p produced in the fragmentation of a parton of type i. The Q^2 evolution is predicted by QCD and is similar to that of the parton distribution functions [see section on Quantum Chromodynamics (Sec. 9 of this Review)]. The $D_i^h(z,Q^2)$ are normalized so that

$$\sum_{h} \int z D_i^h (z, Q^2) dz = 1.$$
 (36.28)

If the contributions of the Z boson and three-jet events are neglected, the cross section for producing a hadron h in e^+e^- annihilation is given by

$$\frac{1}{\sigma_{\rm had}} \frac{d\sigma}{dz} = \frac{\sum_{i} e_{i}^{2} D_{i}^{h} (z, Q^{2})}{\sum_{i} e_{i}^{2}} , \qquad (36.29)$$

where e_i is the charge of quark-type i, $\sigma_{\rm had}$ is the total hadronic cross section, and the momentum of the hadron is $zE_{\rm cm}/2$.

In the case of deep inelastic muon scattering, the cross section for producing a hadron of energy E_h is given by

$$\frac{1}{\sigma_{\rm tot}} \frac{d\sigma}{dz} = \frac{\sum_{i} e_{i}^{2} q_{i}(x, Q^{2}) D_{i}^{h}(z, Q^{2})}{\sum_{i} e_{i}^{2} q_{i}(x, Q^{2})} , \qquad (36.30)$$

where $E_h = \nu z$. (For the kinematics of deep inelastic scattering, see Sec. 35.4.2 of the Kinematics section of this *Review*.) The fragmentation functions for light and heavy quarks have a different z dependence; the former peak near z=0. They are illustrated in Figs. 37.1 and 37.2 in the section on "Heavy Quark Fragmentation in e^+e^- Annihilation" (Sec. 37 of this *Review*).

37. HEAVY-QUARK FRAGMENTATION IN e^+e^- ANNIHILATION

Written January 1998 by D. Besson (University of Kansas).

Measurement of the fragmentation functions of heavy quarks provides information about non-perturbative particle production in a variety of experimental environments. The CDF observation of high p_T $J/\psi(1S)$ production rates far in excess of the extant theoretical predictions prompted the development of the color octet model $(e.g.,\ p\overline{p}\to gg\to \chi_c\to \psi+{\rm X})$ and highlighted the role of gluon fragmentation in charmonium production. Recent results from both LEP and HERA have also helped elucidate the gluonic contribution to charmed meson production. Current estimates from LEP are that gluon fragmentation accounts for approximately half of the D^* production in the lowest momentum region (the lowest quarter of the allowed kinematic region).

Many functional forms have been suggested to describe these momentum spectra for heavy quarks produced in e^+e^- annihilations. The functional form given by Peterson et al. [1] in terms of just one free parameter ϵ_P has found widespread use; other parameterizations are also given in the literature [2]. The earliest Peterson form was a function of one variable z, defined for a heavy-quark Q, light-quark \overline{q} system as the ratio of the energy plus the longitudinal momentum of the hadron $Q\overline{q}$ to the sum of the energy and momentum of the heavy quark after accounting for initial state radiation, gluon bremsstrahlung, and final state radiation: $z = (E + p_{\parallel})_{Q\overline{q}}/(E + p_{Q})$. The main advantage of this variable is that it is relativistically invariant with respect to boosts in the direction of the primary quark. Unfortunately, as this quantity is not directly accessible, experiments typically use other scaling variables which are close approximations to z—either $x^+ = (p_{||} + E)_{hadron}/(p_{||} + E)_{max}$, $x_p = p/p_{max}$, or $x_E = E_{\rm hadron}/E_{\rm beam}$

The Peterson functional form is:

$$\frac{dN}{dz} = \frac{1}{z[1 - (1/z) - \epsilon_P/(1-z)]^2}$$
(37.1)

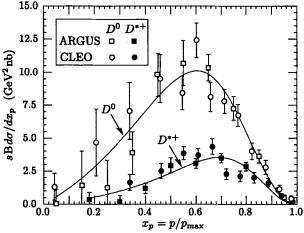

Figure 37.1: Efficiency-corrected inclusive cross section measurements for the production of D^0 and D^{*+} in e^+e^- measurements at $\sqrt{s}\approx 10$ GeV. The variable x_p is related to the Peterson variable z, but is not identical to it.

The bulk of the available fragmentation function data on charmed mesons (excluding $J/\psi(1S)$) is from measurements at $\sqrt{s}=10$ GeV. Shown in Fig. 37.1 are the efficiency-corrected (but not branching ratio corrected) CLEO [3] and ARGUS [4] inclusive cross sections $(s\cdot Bd\sigma/dx_p)$ in units of GeV²-nb, with $x_p=p/p_{\rm max}$) for the production of pseudoscalar D^0 and vector D^{*+} in e^+e^- annihilations at $\sqrt{s}\approx 10$ GeV. For the D^0 , B represents the branching fraction for $D^0\to K^-\pi^+$; for the D^{*+} , B represents the product branching fraction: $D^{*+}\to D^0\pi^+$; $D^0\to K^-\pi^+$. These inclusive spectra have not been corrected for cascades from higher states, nor for radiative effects. Note that since the momentum spectra are sensitive to

radiative corrections, comparison of charm spectra at $\sqrt{s}=10$ GeV cannot be compared directly with spectra at higher center-of-mass energies, and must be appropriately evolved.

Fits to the combined CLEO and ARGUS D^0 and D^{*+} data give $\epsilon_P(D^0)=0.135\pm0.01$ and $\epsilon_P(D^*)=0.078\pm0.008$; these are indicated in the solid curves. Measurement of the fragmentation functions for a variety of particles has allowed comparisons between mesons and baryons, and particles of different spin structure, as shown in Table 37.1

Table 37.1: The Peterson momentum hardness parameter ϵ_P as obtained from $e^+e^- \rightarrow (\text{particle}) + X$ measurements.

Particle	L	\sqrt{s}	ϵ_P	Reference
D^0	0	10 GeV	0.135 ± 0.01	[3]
D^{*+}	0	10 GeV	0.078 ± 0.008	[3]
D_s^*	0	10 GeV	$0.04^{+0.03}_{-0.01}$	[5]
$D_1^0(2420)$	1	10 GeV	$0.034^{+0.018}_{-0.012}$	[6]
$D_2^0(2460)$	1	10 GeV	0.015 ± 0.004	[6]
$D_1^+(2420)$	1	10 GeV	$0.020^{+0.011}_{-0.006}$	[7]
$D_2^+(2460)$	1	10 GeV	0.013 ± 0.007	[7]
$D_{s1}(2536)$	1	10 GeV	$0.06^{+0.035}_{-0.03}$	[8]
$D_{s2}(2573)$	1	10 GeV	$0.027^{+0.043}_{-0.016}$	[9]
Λ_c	0	10 GeV	0.25 ± 0.03	[10,11]
$arvarepsilon_c$	0	10 GeV	0.23 ± 0.05	[12,13]
Σ_c	0	10 GeV	0.29 ± 0.06	[14,15]
\varSigma_c^*	0	10 GeV	$0.30^{+0.10}_{-0.07}$	[16]
\mathcal{Z}_{c}^{*+}	0	10 GeV	$0.24^{+0.22}_{-0.10}$	[17]
\varXi_c^{*0}	0	10 GeV	$0.22^{+0.15}_{-0.08}$	[18]
$\overline{\Lambda_{c,1}}$	1	10 GeV	0.059 ± 0.028	[19,20]
$A_{c,2}$	1	10 GeV	0.053 ± 0.012	[19,21]
$arphi_{c,2}$	1	10 GeV	$0.058^{+0.037}_{-0.021}$	[22]
b hadrons	_	90 GeV	$0.0047^{+0.0010}_{-0.0008}$	[23]

We note from Table 37.1 that the mass dependence of ϵ_P is less marked than the dependence on the orbital angular momentum structure of the charmed hadron being measured. Orbitally excited L=1 charmed hadrons $(D_J, D_{s,J}, \text{and } \Lambda_{c,J})$ show consistently harder spectra (i.e., smaller values of ϵ_P) than the L=0 ground states, whereas the data for the ground state charmed baryons Λ_c and Ξ_c show agreement with the lighter (by ≈ 400 –600 MeV) ground-state D and D_s charmed mesons. To some extent, the harder spectra of L=1 hadrons can be attributed to the fact that all the L=1 charmed hadrons will eventually decay into L=0 hadrons.

Bottom-flavored hadrons at LEP have been measured to have an even harder momentum spectrum than charmed hadrons at lower energies [23-25]. Qualitatively, whereas charm spectra peak at $x_p \approx 0.6$, the spectra of bottom hadrons peak at $x_p \approx 0.8$. This is as expected in the Peterson model, where the value ϵ_P is expected to vary as the ratio of the effective light quark mass to the heavy quark mass in a heavy quark + light (di)quark hadron. In the case of charm, the Peterson functional form provides an acceptable description of the shape of the x_p distribution, provided the appropriate ϵ_P value is independently determined for each separate species of charmed particle. However, unlike charm, the numbers of fully reconstructed b-flavored hadrons is too small to allow a statistically compelling measure of ϵ_P for each separate bottom hadron. Consequently, a b-enriched sample is isolated kinematically, using, e.g., a high p_T lepton and/or a displaced vertex to tag a primary b quark. The x_p distribution therefore includes all b-flavored hadrons in the sample, and does not yet allow a straightforward species-by-species ϵ_P extraction. Additional uncertainties in the case of bottom arise from the sensitivity of ϵ_P to the fragmentation model used to non-perturbatively evolve the initial $q\overline{q}$ system into final state hadrons.

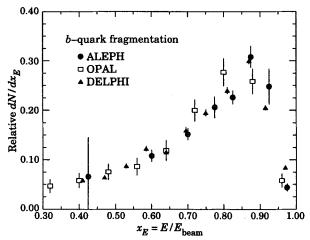

Figure 37.2: Fractional energy distribution for b-quark fragmentation for inclusive b production at LEP.

In general, the b-quark fragmentation function distribution is found to be somewhat narrower than the shape of the Peterson function; this may be due to a systematic underestimate of soft gluon emission in event generators, and/or uncertainties in the appropriate mix of b-flavored hadrons. The match of a single Peterson function to data is therefore much more difficult for bottom than charm at this time, although there is relatively good agreement from experiment to experiment, as seen in Fig. 37.2, which displays the fragmentation function data from OPAL [23], ALEPH [24], and DELPHI [25].

38. PLOTS OF CROSS SECTIONS AND RELATED QUANTITIES

NOTE: THE FIGURES IN THIS SECTION ARE INTENDED TO SHOW THE REPRESENTATIVE DATA.
THEY ARE NOT MEANT TO BE COMPLETE COMPILATIONS OF ALL THE WORLD'S RELIABLE DATA.

Structure Functions

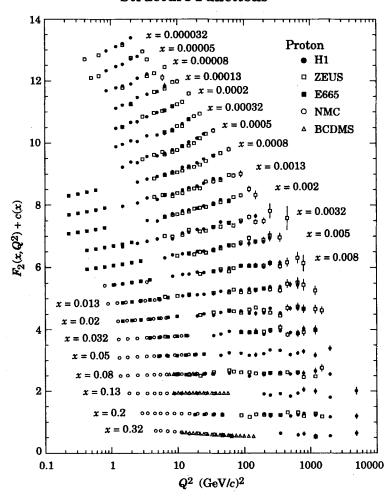

Figure 38.1: The proton structure function F_2^p measured in electromagnetic scattering of electrons (H1, ZEUS) and muons (BCDMS, E665, NMC), in the kinematic domain of the HERA data, for x > 0.00003; cf. Fig. 38.2 for data at smaller x. Only statistical errors are shown. The data are plotted as a function of Q^2 in bins of fixed x. The H1 binning in x is used in this plot; the ZEUS, BCDMS, E665 and NMC data are rebinned to the x values of the H1 data using a phenomenological parametrization. For the purpose of plotting, a constant $c(x) = 0.6(i_x - 0.4)$ is added to F_2^p , where i_x is the number of the x bin ranging from $i_x = 1$ (x = 0.32) to $i_x = 21$ (x = 0.000032). References: H1—S. Aid et al., Nucl. Phys. B470, 3 (1996); C. Adloff et al., Nucl. Phys. B497, 3 (1997); ZEUS—M. Derrick et al., Z. Phys. C72, 399 (1996); J. Breitweg et al., Phys. Lett. B407, 432 (1997); BCDMS—A.C. Benvenuti et al., Phys. Lett. B223, 485 (1989); E665—M.R. Adams et al., Phys. Rev. D54, 3006 (1996); NMC—M. Arneodo et al., Phys. Lett. B364, 107 (1995). (Courtesy of R. Voss, 1997.)

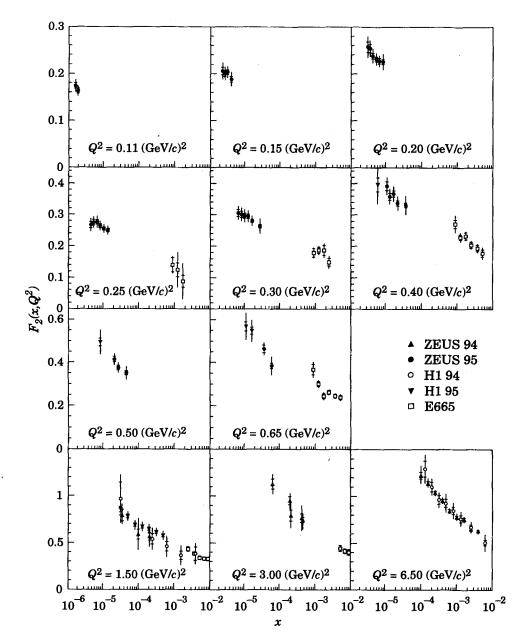

Figure 38.2: The proton structure function F_2^p at small x and Q^2 , measured in electromagnetic scattering of electrons (H1, ZEUS) and muons (E665). The data are plotted as a function of x in bins of fixed Q^2 . References: **ZEUS 94**—M. Derrick *et al.*, Z. Phys. **C72**, 399 (1996); **ZEUS 95**—J. Breitweg *et al.*, Phys. Lett. **B407**, 432 (1997); **H1 94**—S. Aid *et al.*, Nucl. Phys. **B470**, 3 (1996); **H1 95**—C. Adloff *et al.*, Nucl. Phys. **B497**, 3 (1997); **E665**—M.R. Adams *et al.*, Phys. Rev. **D54**, 3006 (1996). (Courtesy of R. Voss, 1997.)

Structure Functions

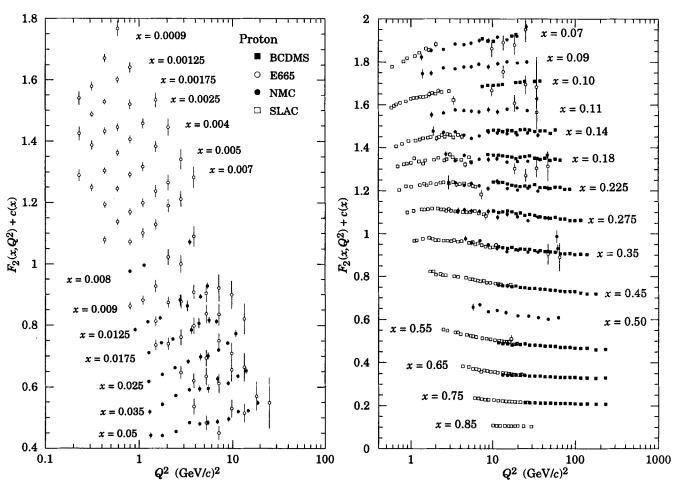

Figure 38.3: The proton structure function F_2^p measured in electromagnetic scattering of electrons (SLAC) and muons (BCDMS, E665, NMC), shown as a function of Q^2 for bins of fixed x. Only statistical errors are shown. For the purpose of plotting, a constant $c(x) = 0.1i_x$ is added to F_2^p where i_x is the number of the x bin, ranging from 1 (x = 0.05) to 14 (x = 0.0009) on the left-hand figure, and from 1 (x = 0.85) to 15 (x = 0.07) on the right-hand figure. For HERA data in the kinematic range of this figure, see Fig. 38.1. References: BCDMS—A.C. Benvenuti et al., Phys. Lett. B223, 485 (1989); E665—M.R. Adams et al., Phys. Rev. D54, 3006 (1996); NMC—M. Arneodo et al., Phys. Lett. B364, 107 (1995). SLAC—L.W. Whitlow et al., Phys. Lett. B282, 475 (1992). (Courtesy of R. Voss, 1996.)

Structure Functions

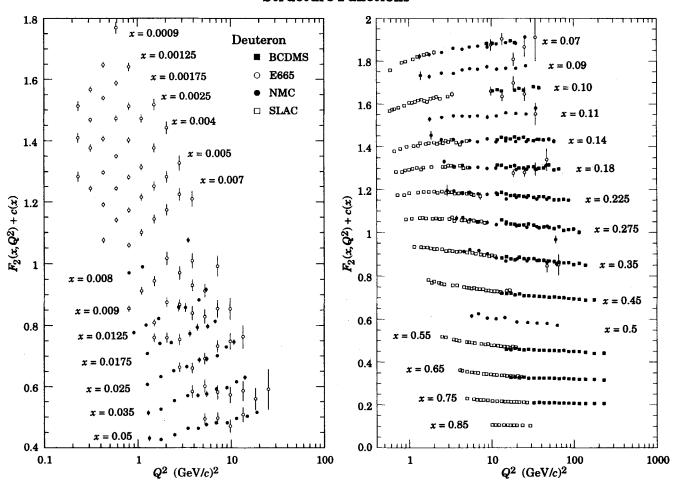

Figure 38.4: As Fig. 38.3, for the deuteron structure function F_2^d . References: BCDMS—A.C. Benvenuti *et al.*, Phys. Lett. B237, 592 (1990). E665, NMC, SLAC—same references as Fig. 38.3. (Courtesy of R. Voss, 1996.)

Structure Functions

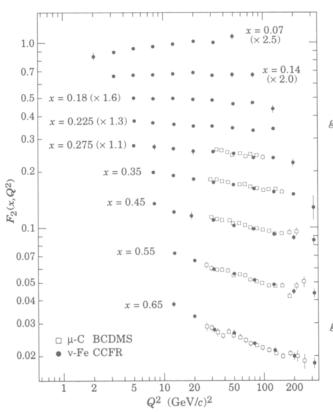

Figure 38.5: The nucleon structure function F_2 measured in deep inelastic scattering of muons on carbon (BCDMS) and neutrinos on iron (CCFR). The data are shown versus Q^2 , for bins of fixed x, and have been scaled by the factors shown in parentheses. References: BCDMS—A.C. Benvenuti et al., Phys. Lett. B195, 91 (1987); CCFR—S.R. Mishra et al., NEVIS-1465 (1992). (Courtesy of R. Voss, 1996.)

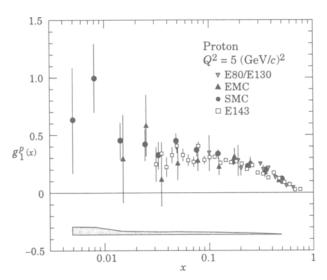

Figure 38.6: The spin-dependent structure function $g_1(x)$ of the proton measured in deep inelastic scattering of polarized electrons (E80, E130, E143) and muons (EMC, SMC), shown at $Q^2 = 5 \, GeV^2$. Only statistical errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded

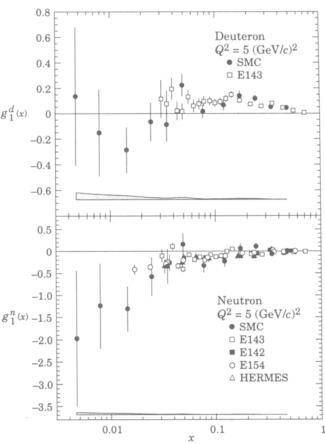

Figure 38.7: The spin-dependent structure function $g_1(x)$ of the deuteron (top) and the neutron (bottom) measured in deep inelastic scattering of polarized electrons (E142, E143, E154, HERMES) and muons (SMC). The SMC and E143 results for the neutron are evaluated from the difference of deuteron and proton data; the E142, E154, and HERMES results were obtained with polarized ³He targets. Only statistical errors are shown with the data points. As an example, the SMC systematic error is indicated by the shaded area. All results except the HERMES data are shown at $Q^2 = 5$ GeV²; the HERMES results are shown at the average Q^2 of the respective data point which varies from $Q^2 = 1.22$ GeV² at x = 0.033 to $Q^2 = 5.25$ GeV² at x = 0.464. References: E142—P.L. Anthony et al., Phys. Rev. Lett. 71, 959 (1993); E143-K. Abe et al., Phys. Rev. Lett. 75, 25 (1995); E154-K. Abe et al., Phys. Lett. B405, 180 (1997) and hep-ph/9705344 v2 (1997); HERMES-K. Ackerstaff et al., Phys. Lett. B404, 383 (1997); SMC-D. Adams et al., Phys. Lett. **B396**, 338 (1997). (Courtesy of R. Voss, 1997.)

area. References: **E80**—M.J. Alguard *et al.*, Phys. Rev. Lett. **37**, 1261 (1976); ibid. **41**, 70 (1978); **E130**—G. Baum *et al.*, Phys. Rev. Lett. **51**, 1135 (1983); **E143**—K. Abe *et al.*, Phys. Rev. Lett. **74**, 346 (1995); **EMC**—J. Ashman *et al.*, Nucl. Phys. **B328**, 1 (1989); **SMC**—B. Adeva *et al.*, Phys. Lett. **B412**, 414 (1997). In this plot, the E80, E130 and EMC data have been reevaluated using up-to-date parametrizations of F_2^p and $R = \sigma_L/\sigma_T$. (Courtesy of R. Voss, 1997.)

Jet Production in pp and $\bar{p}p$ Interactions

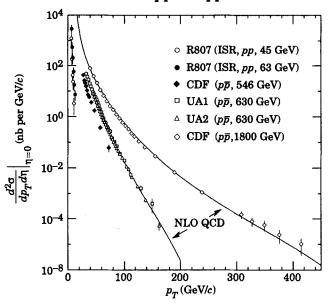

Figure 38.8: Differential cross sections for observation of a single jet of pseudorapidity $\eta=0$ as a function of the jet transverse momentum. CDF—F. Abe et al., Phys. Rev. Lett. 70, 1376 (1993); UA1—G. Arnison et al., Phys. Lett. B172, 461 (1986); UA2—J. Alitti et al., Phys. Lett. B257, 232 (1991); R807—T. Akesson et al., Phys. Lett. B123, 133 (1983). Next-to-leading order QCD curves are shown for 630 GeV and 1800 GeV. (Courtesy of S. Geer, FNAL, 1995.)

Direct γ Production in $\overline{p}p$ Interactions

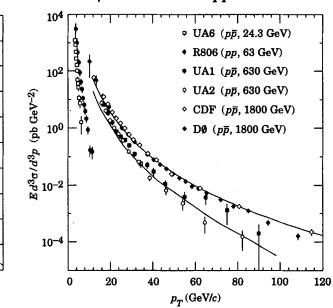

Figure 38.9: Differential cross sections for observation of a single photon of pseudorapidity $\eta=0$ as a function of the photon transverse momentum R806—E. Anassontzis et al., Z. Phys. C13, 277 (1982); UA6—A. Bernasconi et al., Phys. Lett. B206, 163 (1988); UA1—C. Albajar et al., Phys. Lett. B209, 385 (1988); UA2—J. Alitti et al., Phys. Lett. B288, 386 (1992); CDF—F. Abe et al., Phys. Rev. Lett. 73, 2662 (1994); \mathcal{DO} —S. Abachi et al., Phys. Rev. Lett. 77, 5011 (1996). Next-to-leading order QCD curves are shown for 630 GeV and 1800 GeV. (Courtesy of S. Geer, FNAL, 1995.)

Pseudorapidity Distributions in $\bar{p}p$ Interactions

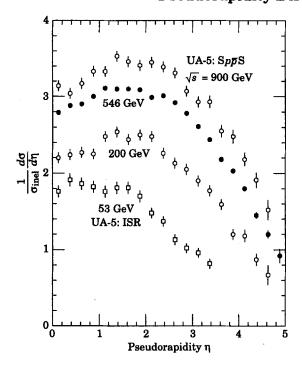

Figure 38.10: Charge particle pseudorapidity distributions in $p\bar{p}$ collisions for 53 GeV $\leq \sqrt{s} \leq$ 900 GeV. The number per pseudorapidity interval is about 10% higher if the rate is normalized excluding singly diffractive events rather than to the total inelastic rate. $Sp\bar{p}S$ data are from G.J. Alner et al., Z. Phys. C33, 1 (1986), and ISR data are from K. Alpgård et al., Phys. Lett. 112B, 193 (1982). CDF nonsingle-diffractive results at $\sqrt{s}=630$ and 1800 GeV are given in F. Abe et al., Phys. Rev. D41, 2330 (1990). (Courtesy of D.R. Ward, Cambridge Univ., 1991.)

Average Hadron Multiplicities in Hadronic e^+e^- Annihilation Events

Table 38.1: Average hadronic multiplicities per hadronic e^+e^- annihilation event at $\sqrt{s}\approx 10$, 29–35, and 91 GeV. The rates given include decay products from resonances with $c\tau<10$ cm, and include charge conjugated states. (Updated September 1997 by O. Biebel.)

- (a) $B(D_s \to \eta \pi, \eta' \pi)$ has been used (RPP 1994).
- (b) The Standard Model $B(Z \to b\bar{b}) = 0.217$ was used.
- (c) $x_p = p/p_{\text{beam}} > 0.1$ only.
- (d) Extrapolation to the unobserved region using the shape predicted by JETSET.
- (e) Any charge state (i.e., B_d^* , B_u^* , or B_s^*).
- (f) $B(Z \rightarrow hadrons) = 0.699$ has been used (RPP 1994).
- (g) $x_E = E[K_2^*(1430)^0]/E_{\text{beam}} < 0.3 \text{ only.}$
- (h) Any charge state (i.e., B_d^{**} , B_u^{**} , or B_s^{**}).
- (i) The value was taken from the cross section of the $\Lambda_c^+ \to p\pi K$, assuming the branching fraction to be $(3.2 \pm 0.7)\%$ (RPP 1992).

Fragmentation in e^+e^- Annihilation

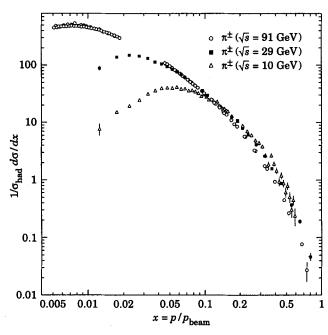

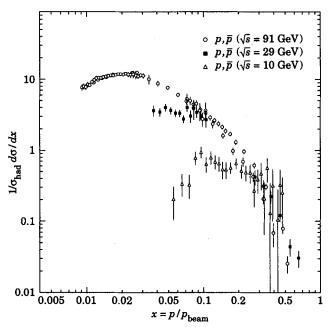

Figure 38.11: Fragmentation into π^{\pm} in e^+e^- annihilations: Inclusive cross sections $(1/\sigma_{\rm had})(d\sigma/dx)$, with $x=p/p_{\rm beam}$. The indicated errors are statistical and systematic errors added in quadrature.

 \triangle : rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8%: **ARGUS**—H. Albrecht et al., Z. Phys. C44, 547 (1989).

\blacksquare: rate at $\sqrt{s} = 29$ GeV **TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988).

 \bigcirc : rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV **ALEPH**—D. Buskulic *et al.*, Z. Phys. C66, 355 (1995); **OPAL**—R. Akers *et al.*, Z. Phys. C63, 181 (1994). (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1995.)

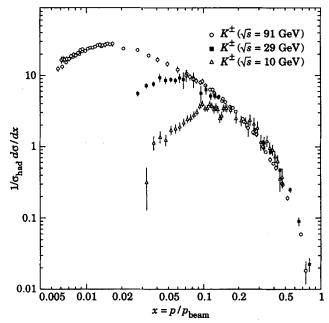

Figure 38.12: Fragmentation into K^{\pm} in e^+e^- annihilations: Inclusive cross sections $(1/\sigma_{\rm had})(d\sigma/dx)$, with $x=p/p_{\rm beam}$. The indicated errors are statistical and systematic errors added in quadrature.

 \triangle : rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8%: **ARGUS**—H. Albrecht *et al.*, Z. Phys. C44, 547 (1989).

E: rate at $\sqrt{s} = 29$ GeV **TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988).

 \bigcirc : rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV ALEPH—D. Buskulic et al., Z. Phys. C66, 355 (1995); DELPHI—P. Abreu et al., Nucl. Phys. B444, 3 (1995); OPAL—R. Akers et al., Z. Phys. C63, 181 (1994). (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1995.)

Figure 38.13: Fragmentation into $p\overline{p}$ in e^+e^- annihilations: Inclusive cross sections $(1/\sigma_{\rm had})(d\sigma/dx)$, with $x=p/p_{\rm beam}$. The indicated errors are statistical and systematic errors added in quadrature

 \triangle : rate at $\sqrt{s} = 9.98$ GeV; an overall uncertainty of 1.8%. This rate is obtained from the measured \bar{p} rate by scaling with a factor of two: **ARGUS**—H. Albrecht *et al.*, Z. Phys. C44, 547 (1989).

■: rate at $\sqrt{s} = 29$ GeV: **TPC**—H. Aihara *et al.*, Phys. Rev. Lett. **61**, 1263 (1988).

O: rate for hadronic decays of the Z at $\sqrt{s} = 91.2$ GeV: **ALEPH**—D. Buskulic et al., Z. Phys. C66, 355 (1995). **DELPHI**—P. Abreu et al., Nucl. Phys. **B444**, 3 (1995). **OPAL**—R. Akers et al., Z. Phys. C63, 181 (1994). (Courtesy of O. Biebel, S. Bethke, and D. Lanske, RWTH, Aachen, 1995.)

Annihilation Cross Section Near M_Z

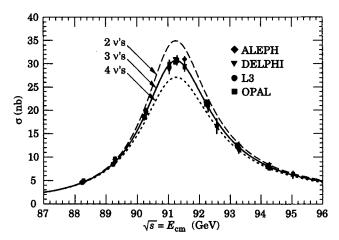

Figure 38.14: Data from the ALEPH, DELPHI, L3, and OPAL Collaborations for the cross section in e^+e^- annihilation into hadronic final states as a function of c.m. energy near the Z. LEP detectors obtained data at the same energies; some of the points are obscured by overlap. The curves show the predictions of the Standard Model with three species (solid curve) and four species (dashed curve) of light neutrinos. The asymmetry of the curves is produced by initial-state radiation. References:

ALEPH: D. Decamp et al., Z. Phys. C53, 1 (1992). **DEPHI**: P. Abreu et al., Nucl. Phys. **B367**, 511 (1992). **L3**: B. Adeva et al., Z. Phys. C51, 179 (1991). **OPAL**: G. Alexander et al., Z. Phys. C52, 175 (1991).

Average e^+e^- , pp, and $\overline{p}p$ Multiplicity

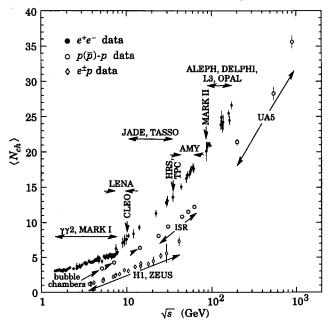

Figure 38.15: Average multiplicity as a function of \sqrt{s} for e^+e^- and $p\bar{p}$ annihilations, and pp and ep collisions. The indicated errors are statistical and systematic errors added in quadrature, except when no systematic errors are given. Files of the data shown in this figure are given in http://wwwinfo.cern.ch/b/biebel/www/RPP98/.

 e^+e^- : All e^+e^- measurements include contributions from K_s^0 and Λ decays with the exception of the L3 measurements. The $\gamma\gamma2$ and MARK I measurements contain a systematic 5% error. The five points at the Z resonance have been spread horizontally for clarity: **OPAL**: P.D. Acton et al., Z. Phys. **C53**, 539 (1992) and references therein, **OPAL**: R. Akers et al., Z. Phys. **C68**, 203 (1995), **ALEPH**: D. Buskulic et al., Z. Phys. **C69**, 15 (1995), **ALEPH**: D. Buskulic et al., Z. Phys. **C73**, 409 (1997), **DELPHI**: P. Abreu et al., Z. Phys. C, CERN-PPE/97-108, **DELPHI**: P. Abreu et al., Phys. Lett. **B372**, 172 (1996), **L3**: M. Acciarri et al., Phys. Lett. **B371**, 137 (1996), **L3**: M. Acciarri et al., Phys. Lett. **B404**, 390 (1997), **OPAL**: K. Ackerstaff et al., Z. Phys. **C75**, 193 (1997).

 $e^{\pm}p$: Multiplicities have been measured in the current fragmentation region of the Breit frame: **H1**: C. Adloff *et al.*, Nucl. Phys. **B**, DESY 97-108, **ZEUS**: M. Derrick *et al.*, Z. Phys. **C67**, 93 (1995).

 $p(\bar{p})$: The errors of the $p(\bar{p})$ measurements are the quadratically added statistical and systematic errors, except for the bubble chamber measurements for which only statistical errors are given in the references. The values measured by UA5 exclude single diffractive dissociation: bubble chamber: J. Benecke *et al.*, Nucl. Phys. B76, 29 (1976), bubble chamber: W.M. Morse *et al.*, Phys. Rev. D15, 66 (1977), ISR: A. Breakstone *et al.*, Phys. Rev. D30, 528 (1984), UA5: G.J. Alner *et al.*, Phys. Lett. B, 476 (1986), UA5: R.E. Ansorge *et al.*, Z. Phys. C43, 357 (1989).

(Courtesy of O. Biebel, RWTH, Aachen, 1997.)

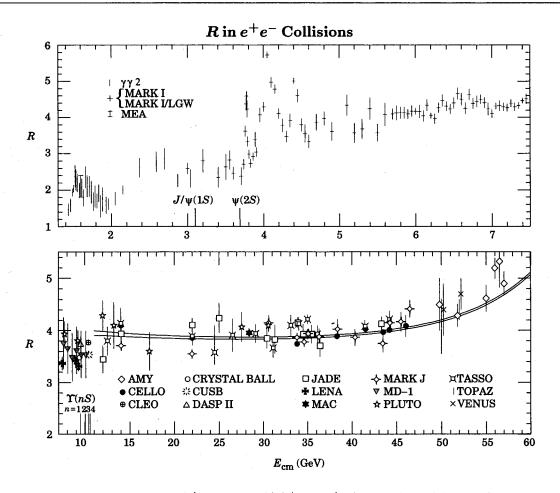

Figure 38.16: Selected measurements of $R \equiv \sigma(e^+e^- \to \text{hadrons})/\sigma(e^+e^- \to \mu^+\mu^-)$, where the annihilation in the numerator proceeds via one photon or via the Z. Measurements in the vicinity of the Z mass are shown in the following figure. The denominator is the calculated QED single-photon process; see the section on Cross-Section Formulae for Specific Processes. Radiative corrections and, where important, corrections for two-photon processes and τ production have been made. Note that the ADONE data $(\gamma\gamma^2)$ and MEA is for ≥ 3 hadrons. The points in the $\psi(3770)$ region are from the MARK I—Lead Glass Wall experiment. To preserve clarity only a representative subset of the available measurements is shown—references to additional data are included below. Also for clarity, some points have been combined or shifted slightly (<4%) in $E_{\rm cm}$, and some points with low statistical significance have been omitted. Systematic normalization errors are not included; they range from $\sim 5-20\%$, depending on experiment. We caution that especially the older experiments tend to have large normalization uncertainties. Note the suppressed zero. The horizontal extent of the plot symbols has no significance. The positions of the $J/\psi(1S)$, $\psi(2S)$, and the four lowest T vector-meson resonances are indicated. Two curves are overlaid for $E_{\rm cm} > 11$ GeV, showing the theoretical prediction for R, including higher order QCD [M. Dine and J. Sapirstein, Phys. Rev. Lett. 43, 668 (1979)] and electroweak corrections. The Λ values are for 5 flavors in the $\overline{\rm MS}$ scheme and are $\Lambda_{\rm MS}^{(5)} = 60$ MeV (lower curve) and $\Lambda_{\rm MS}^{(5)} = 250$ MeV (upper curve). (Courtesy of F. Porter, 1992.) References (including-several references to data not appearing in the figure and some references to preliminary data):

Table 38.2: Total hadronic cross section. Regge theory suggests a parameterization of total cross sections as

$$\begin{split} \sigma_{AB} &= X_{AB} s^{\epsilon} + Y_{1AB} s^{-\eta_1} + Y_{2AB} s^{-\eta_2} \\ \sigma_{\overline{A}B} &= X_{AB} s^{\epsilon} + Y_{1AB} s^{-\eta_1} - Y_{2AB} s^{-\eta_2} \end{split}$$

where X_{AB}, Y_{iAB} are in mb and s is in GeV². The exponents ϵ, η_1 , and η_2 are independent of the particles A, \overline{A} , and B and represent the pomeron, and lower-lying C-even and C-odd exchanges, respectively. Requiring $\eta_1 = \eta_2$ results in much poorer fits. In addition to total cross section, the measured ratio of the real to the imaginary part of the forward scattering amplitude can be included in the fits by assuming that the C-even and C-odd amplitudes have the simple behavior $(-s)^{\alpha} \pm s^{\alpha}$, where $\alpha = 1 + \epsilon, 1 + \eta_1, 1 + \eta_2$. Fits were made to the data for $p^{\pm}p, \pi^{\pm}p, K^{\pm}p, \gamma p$, and $\gamma \gamma$. The exponents $\epsilon = 0.095(2), \eta_1 = 0.34(2)$, and $\eta_2 = 0.55(2)$ thus obtained were then fixed and used as inputs to a fit to a larger data sample that included cross sections on deuterons and neutrons. In the initial fit only data above $\sqrt{s_{\min}} = 12$ GeV were used. In the subsequent fit, data above $p_{\text{lab}} = 10$ GeV (hadronic collisions) and $\sqrt{s_{\min}} = 4$ GeV (γp and $\gamma \gamma$) collisions were used.

The fitted functions are shown in the following figures, along with one-standard-deviation error bands. When the reduced χ^2 is greater than one, a scale factor has been included. Where appropriate, statistical and systematic errors were combined quadratically. Vertical arrows indicate lower limits on the p_{lab} or E_{cm} range used in the fits. The user may decide on the range of applicability of the extrapolated curves. The data were extracted from the PPDS accessible at http://wwwppds.ihep.su:8001/ppds.html or http://pdg.lbl.gov Computer-readable data files are also available at http://pdg.lbl.gov. ¹LAKES 98 report limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2 A$ via the Maxwell-Proca equations, where μ is the proton mass and A is the ambient vector potential in the Lorentz gauge. This is the most conservative limit reported, in which $\mathbf{A} \approx (1 \, \mu \, \mathbf{G}) \times (600 \, \mathrm{pc})$ is based on the Galactic field. 2 FISCHBACH 94 report $< 8 \times 10^{-16}$ with unknown CL. We report Baysian CL used elsewhere in these Listings and described in the Statistics section.

CHERNIKOV 92 measures the photon mass at 1.24 K, following a theoretical suggestion that electromagnetic gauge invariance might break down at some low critical temperature. See the erratum for a correction, included here, to the published result.

⁴ RYAN 85 measures the photon mass at 1.36 K (see the footnote to CHERNIKOV 92). ⁵ CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theo-

rem. Some of the arguments given only in unpublished references.

6 See criticism questioning the validity of these results in KROLL 71 and GOLDHABER 71.

$< 2 \times 10^{-32}$	COCCONI	88 TOF	resolution Pulsar f ₁ — f ₂ TOF

7 RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.

8 See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAF-

OMITTED FROM SUMMARY TABLE

gravitor MASS

All of the following limits are obtained assuming Yukawa potential in weak field limit. VANDAM 70 argue that a massive field cannot approach general relativity in the zero-mass limit; however, see GOLD-HABER 74 and references therein. h_0 is the Hubble constant in units of 100 km s $^{-1}$ Mpc $^{-1}$.

<8 × 10 ⁴	HARE	73	2γ decay		

¹ DAMOUR 91 is an analysis of the orbital period change in binary pulsar PSR 1913+16, and confirms the general relativity prediction to 0.8%. "The theoretical importance of and confirms the general relativity prediction to 0.8%. "The theoretical importance of the [rate of orbital period decay] measurement has long been recognized as a direct confirmation that the gravitational interaction propagates with velocity \boldsymbol{c} (which is the immediate cause of the appearance of a damping force in the binary pulsar system) and thereby as a test of the existence of gravitational radiation and of its quadrupolar nature." TAYLOR 93 adds that orbital parameter studies now agree with general relativity to 0.5%, and set limits on the level of scalar contribution in the context of a family of tensor (spin 2)-biscalar theories

NOTE ON THE MASS OF THE W BOSON

Written March 1998 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

Till 1995 the production and study of the W boson was the exclusive domain of the $\bar{p}p$ colliders at CERN and FNAL. W production in these hadron colliders is tagged by a high p_T lepton from W decay. Owing to unknown parton-parton effective energy and missing energy in the longitudinal direction, the experiments reconstruct only the transverse mass of the Wand derive the W mass from comparing the transverse mass distribution with Monte Carlo predictions as a function of M_W .

In 1996 the energy of LEP was increased in two steps to 161 GeV and 172 GeV, allowing the production of pairs of W bosons. A precise knowledge of the e^+e^- centre of mass energy enables one to reconstruct the W mass even if one of them decays leptonically. At LEP two methods have been used to obtain the W mass. In the first method the measured W-pair production cross sections, $\sigma(e^+e^- \to W^+W^-)$, have been used to determine the W mass using the Standard Model based dependence of this cross section on M_W (see Fig. 1). At 161 GeV, which is just above the W-pair production threshold, this dependence is a much more sensitive function of the W mass than at higher energies.

W⁺W⁻ cross section at LEP

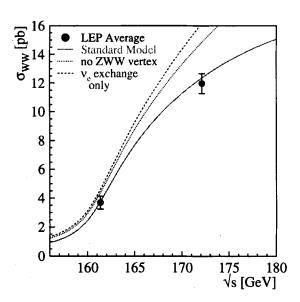

Figure 1: The W-pair cross section as a function of the center-of-mass energy. The data points are the LEP averages. The solid line is the Standard Model prediction. For comparison the figure contains also the cross section if the ZWW coupling did not exist (dotted line), or if only the t-channel ν_e exchange diagram existed (dashed line).

In the second method, which is used at the higher energies, the W mass has been determined by directly reconstructing the W from its decay products.

Each LEP experiment has combined their own mass values properly taking into account the common systematic errors. We have then combined their values into a LEP average leading to: $m_W = 80.49 \pm 0.14$ GeV. The error includes in the systematics a LEP energy uncertainty of ± 30 MeV and, in the case of the reconstruction method for the $q\bar{q}q\bar{q}$ channel, a possible effect of "color reconnection" and "Bose-Einstein correlations" between quarks from different W's. In our combination, the last two effects have been treated as 100% correlated between the experiments.

OUR AVERAGE is obtained by combining this LEP value with other measurements assuming no common systematics.

Combining published and unpublished preliminary Collider and LEP results (as of end of March 1998) yields an average W-boson mass of 80.375 ± 0.064 GeV (80.40 ± 0.09 GeV for p-pColliders and 80.35 ± 0.09 GeV for LEP).

The Standard Model prediction from the electroweak fit, excluding the direct W mass measurements from LEP and Tevatron, gives a W-boson mass of 80.364 ± 0.035 GeV.

W MASS

OUR FIT uses the W and Z mass, mass difference, and mass ratio measurements

 $^{
m 1}$ ABREU 988 obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining with ABREU 97 authors find: $M(W)=80.33\pm0.30\pm0.06\pm0.03$ (LEP)

² ACKERSTAFF 980 obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. When both W mass and width are varied they obtain $M(W)=80.30\pm0.27\pm0.095$ GeV. The systematic error includes ±0.03 GeV due to the beam energy uncertainty and ±0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic fl-BD with ACKERSTAFF 96B authors find: $M(W) = 80.35 \pm 0.24 \pm 0.07 \pm 0.03$ (LEP) GeV.

3 ACKERSTAFF 98D derive this value from their measured W W production cross section σ_{WW} =12.3 \pm 1.3 \pm 0.4 pb using the Standard Model depen at the given c.m. energy.

⁴ BARATE 98B obtain this value from a fit to the reconstructed W mass distribution. The W width was taken as its Standard Model value at the fitted W mass. The systematic or willin was taken as its standard model value at the fitted W mass. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.032 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining with the M_W values from cross section measurements at 161 and 172 GeV (BARATE 97 and BARATE 97s) authors find: $M(W) = 80.51 \pm 0.23 \pm 0.08$ GeV.

 5 ABREU 97 derive this value from their measured W-W production cross section σ_{WW} = 3.67 $^{+0.97}_{-0.85}$ \pm 0.19 pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. The systematics include an error of ± 0.03 GeV arising from the beam energy uncertainty.

⁶ACCIARRI 97 derive this value from their measured W-W production cross section $\sigma_{WW} = 2.89^{+0.81}_{-0.70} \pm 0.14$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. Statistical and systematic errors are added in quadrature and the last error of ± 0.03 GeV arises from the beam energy uncertainty. The same result is given by a fit of the production cross sections to the data.

⁷ACCIARRI 97M derive this value from their measured WW production cross section $\sigma_{WW}=12.27^{+1.41}_{-1.32}\pm0.23$ pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. Combining with ACCIARRI 97 authors find M(W)=10.00 $80.78^{+0.45}_{-0.41}\pm0.03$ GeV where the last error is due to beam energy uncertainty.

⁸ ACCIARRI 975 obtain this value from a fit to the reconstructed W mass distribution. The Which was taken as its Standard Model value at the fitted W mass. When both W mass and width are varied they obtain $M(W) = 80.72 + 0.31 \pm 0.09$ GeV. The systematic error includes ± 0.03 GeV due to the beam energy uncertainty and ± 0.05 GeV due to the possible color reconnection and Bose-Einstein effects in the purely hadronic final state. Combining with ACCIARRI 97 and ACCIARRI 97M authors find: $M(W) = \pm 0.05$ GeV $80.75^{+0.26}_{-0.27}\pm0.03$ (LEP) GeV.

 9 BARATE 97 derive this value from their measured W-W production cross section σ_{WW} = 4.23 \pm 0.73 \pm 0.19 pb using the Standard Model dependence of σ_{WW} on M_W at the given c.m. energy. The systematics include an error of \pm 0.03 GeV arising from the beam energy uncertainty.

10 BARATE 975 derive this value from their measured W W production cross section σ_{WW}
= 11.71 \pm 1.23 \pm 0.28 pb using the Standard Model dependence of σ_{WW} on M_W at
the given c.m. energy. The errors quoted on the mass are statistical only. Combining
with BARATE 97 authors find: $M(W)=80.20\pm0.33\pm0.09\pm0.03$ (LEP) GeV.

¹¹ ABACHI 96E fit the transverse mass distribution of 5982 $W \rightarrow e \nu_e$ decays. An error of \pm 160 MeV due to the uncertainty in the absolute energy scale of the EM calorimeter is included in the total systematics.

12 ACKERSTAFF 968 derive this value from an analysis of the predicted M_W dependence of their accepted four-fermion cross section, explicitly taking into account interference effects. The systematics include an error of ±0.03 GeV arising from the beam energy uncertainty.

13 ABE 95P use 3268 $W\to \mu\nu_\mu$ events to find $M=80.310\pm0.205\pm0.130$ GeV and 5718 $W\to e\nu_e$ events to find $M=80.490\pm0.145\pm0.175$ GeV. The result given here combines these while accounting for correlated uncertainties.

¹⁴ ABE 90c result from $W\to e\nu$ is 79.91 \pm 0.35 \pm 0.24 \pm 0.19(scale) GeV and from $W\to \mu\nu$ is 79.90 \pm 0.53 \pm 0.32 \pm 0.08(scale) GeV.

¹⁵ AID 96D derive this value as a propagator mass using the Q^2 shape and magnitude of the e^{\pm} charged-current cross sections. $Q^2 > 5000 \, \text{GeV}^2$ events with p_T of the outgoing lepton $> 25 \, \text{GeV}/c$ are used.

 16 ALITTI 92B result has two contributions to the systematic error (± 0.83); one (± 0.81) cancels in m_W/m_Z and one (± 0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

17 There are two contributions to the systematic error (± 0.84) : one (± 0.81) which cancels in m_W/m_Z and one (± 0.21) which is non-cancelling. These were added in quadrature.

18 ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

 19 ALBAJAR 89 result is from a total sample of 299 $W \to e \nu$ events.

²⁰ ALBAJAR 89 result is from a total sample of 67 $W \to \mu \nu$ events.

²¹ ALBAJAR 89 result is from $W \to \tau \nu$ events.

W/Z MASS RATIO

W WIDTH

90G CDF

ARE

 $E_{\mathsf{CM}}^{ar{p}ar{p}} = 1.8 \; \mathsf{TeV}$

The CDF and DØ widths labelled "extracted value" are obtained by measuring $R=[\sigma(W)/\sigma(Z)]$ [$\Gamma(W\to e\nu_e)]/(B(Z\to ee)\Gamma(W))$ where the bracketed quantities can be calculated with plausible reliability. $\Gamma(W)$ is then extracted by using a value of $B(Z\to ee)$ measured at LEP. The UA1 and UA2 widths used $R=[\sigma(W)/\sigma(Z)]$ [$\Gamma(W\to e\nu_e)/\Gamma(Z\to ee)$] $\Gamma(Z)/\Gamma(W)$ and the measured value of $\Gamma(Z)$. The Standard Model prediction is 2.067 \pm 0.021 (ROSNER 94).

²⁵ ABACHI 975 obtain this value from a fit to the reconstructed V mass section V mas

²⁶ ABE 95C use the tail of the transverse mass distribution of $W \to e \nu_e$ decays.

 27 ABE 95W measured $R=10.90\pm0.32\pm0.29$. They use $m_{W}\!=\!80.23\pm0.18$ GeV, $\sigma(W)/\sigma(Z)=3.35\pm0.03$, $\Gamma(W\to e\nu)=225.9\pm0.9$ MeV, $\Gamma(Z\to e^+e^-)=83.98\pm0.18$ MeV, and $\Gamma(Z)=2.4969\pm0.0038$ GeV. 28 ALITTI 92 measured $R=10.4^{+0.7}_{-0.6}\pm0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from

²⁸ ALITTI 92 measured $R=10.4^{+0.7}_{-0.6}\pm0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_S^2)$ calculations using $m_W=80.14\pm0.27$ GeV, and $m_Z=91.175\pm0.021$ GeV along with the corresponding value of $\sin^2\!\theta_W=0.2274$. They use $\sigma(W)/\sigma(Z)=3.26\pm0.07\pm0.05$ and $\Gamma(Z)=2.487\pm0.010$ GeV.

²⁹ ALBAJAR 91 measured $R=9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using $m_W=80.18\pm0.28$ GeV and $m_Z=91.172\pm0.031$ GeV along with $\sin^2\theta_W=0.2322\pm0.0014$. They use $\sigma(W)/\sigma(Z)=3.23\pm0.05$ and $\Gamma(Z)=2.498\pm0.020$ GeV.

30 ABE 92: report $1216\pm38^{+27}_{-31}W\to\mu\nu$ and $106\pm10^{+0.2}_{-1}Z\to\mu^+\mu^-$ events which are combined with 2426 $W\to e\nu$ events of ABE 91c to derive the ratio σ_W B($W\to \ell\nu$)/ σ_Z B($Z\to\ell^+\ell^-$)= $10.0\pm0.6\pm0.4$. Finally the value of $\Gamma(Z)$ measured by LEP 92 is used to extract $\Gamma(W)$.

31 ABE 90 extract $\Gamma(W)=2.19\pm0.20$ by using the value $\Gamma(Z)=2.57\pm0.07$ GeV. However, in ABE 91c they update their analysis with a new LEP value $\Gamma(Z)=2.496\pm0.016$; the value $\Gamma(W)=2.12\pm0.20$ above reflects this update. They measured $R=10.2\pm0.8\pm0.4$, assumed $\sin^2\theta_W=0.229\pm0.007$, and took predicted values $\sigma(W)/\sigma(Z)=3.23\pm0.03$ and $\Gamma(W\to e\nu)/\Gamma(Z\to ee)=2.70\pm0.02$. This yields $\Gamma(W)/\Gamma(Z)=0.85\pm0.08$. The quoted error for $\Gamma(W)$ includes systematic uncertainties. $E_{CM}^{\rm em}=1.8$ TeV.

³² ALITTI 90c used the same technique as described for ABE 90. They measured $R = 9.38^{+0.82}_{-0.72} \pm 0.25$, obtained $\Gamma(W)/\Gamma(Z) = 0.902 \pm 0.074 \pm 0.024$. Using $\Gamma(Z) = 2.546 \pm 0.032$ GeV, they obtained the $\Gamma(W)$ value quoted above and the limits $\Gamma(W) < 2.56$ (2.64) GeV at the 90% (95%) CL. $E_{\rm CM}^{p\bar{p}} = 546,630$ GeV.

³³ ALBAJAR 89 result is from a total sample of 299 $W \rightarrow e \nu$ events.

 34 If systematic error is neglected, result is $^{2.7}_{-1.5}^{+1.4}$ GeV. This is enhanced subsample of 172 total events.

W ANOMALOUS MAGNETIC MOMENT (△κ)

The full magnetic moment is given by $\mu_W=e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa=1$ and $\lambda=0$. Some papers have defined $\Delta\kappa=1-\kappa$ and assume that $\lambda=0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the W boson becomes manifest.

 35 ABE 95G report $-1.3<\kappa<3.2$ for $\lambda=0$ and $-0.7<\lambda<0.7$ for $\kappa=1$ in $p\overline{p}\to e\nu_e\gamma X$ and $\mu\nu_\mu\gamma X$ at $\sqrt{s}=1.8$ TeV.

 36 ALITTI 92c measure $\kappa=1^{+2.6}_{-2.2}$ and $\lambda=0^{+1.7}_{-1.8}$ in $p\overline{p}\to e\nu\gamma+$ X at $\sqrt{s}=630$ GeV. At 95%CL they report $-3.5<\kappa<5.9$ and $-3.6<\lambda<3.5$. 37 SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4<\kappa<3.7$ at 96%CL

 3 SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative W decay.

³⁸ SAMUEL 91 use preliminary CDF data for $p\overline{p}\to W\gamma X$ to obtain $-11.3 \le \Delta\kappa \le 10.9$. Note that their $\kappa=1-\Delta\kappa$.

 39 GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa\lesssim 65~(M_W^2/\Lambda^2)$.

 40 GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu \overline{\nu} \gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their $\Delta\kappa$ has the opposite sign as our definition.

41 VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa|<33$ (m_W/Λ). In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta\kappa$.

Gauge & Higgs Boson Particle Listings

W

 42 GRAU 85 uses the muon anomaly to derive a coupled ilmit on the anomalous magnetic dipole and electric quadrupole (λ) moments 1.05 $> \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda=0$.

the Standard Model $\lambda=0$.

43 SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa|\lesssim 190$ $(m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa|\lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa|\lesssim 150~(m_W/\Lambda)^4$ if $|\Delta\kappa|\ll 100$

44 HERZOG 84 consider the contribution of W-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

W+ DECAY MODES

W⁻ modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_I/Γ)	Confidence level

[a] ℓ indicates each type of lepton (e, μ , and τ), not sum over them.

CONSTRAINED FIT INFORMATION

Overall fits are performed to determine the branching ratios of the W. For each LEP experiment the correlation matrix of the leptonic branching ratios is used. A first fit determines three individual leptonic branching ratios, $\mathsf{B}(W\to e\nu_e),\,\mathsf{B}(W\to \mu\nu_\mu),\,\mathsf{and}\,\mathsf{B}(W\to \tau\nu_\tau).$ This fit has a $\chi^2=9.0$ for 17 degrees of freedom. The second fit assumes lepton universality and determines the leptonic branching ratio $\mathsf{B}(W\to \ell\nu_\ell),\,\mathsf{from}$ which one also derives the hadronic branching ratio, assuming $\mathsf{B}(W\to hadrons)=1-3\cdot\mathsf{B}(W\to \ell\nu_\ell).$ This fit has a $\chi^2=10.9$ for 19 degrees of freedom.

W BRANCHING RATIOS

The LEP collaborations obtain the W branching ratios by a fit to their measured cross sections of the final states $e^+e^-\to W^+W^-\to q \overline{q} e \nu_e$, $q \overline{q} \mu \nu_\mu$, $q \overline{q} \tau \nu_\tau$, $q \overline{q} q \overline{q}$, $\ell \nu_\ell \ell \nu_\ell$. The leptonic branching ratios and $\sigma(e^+e^-\to W^+W^-)$ at the respective center-of-mass energies are the fitted parameters. Two fits are performed, one without and one assuming lepton universality. The hadronic branching ratio is derived from the second fit assuming $B(W\to hadrons)=1-3\cdot B(W\to \ell \nu_\ell)$.

$$\Gamma(\ell^+\nu)/\Gamma_{\rm total}$$
 ℓ indicates average over $e,\ \mu,\ {\rm and}\ \tau$ modes, not sum over modes.

⁴⁶ ABE 95w result is from a measurement of σ B($W \rightarrow e\nu$)/ σ B($Z \rightarrow e^+e^-$) = 10.90±0.32±0.29, the theoretical prediction for the cross section ratio, the experimental knowledge of $\Gamma(Z \rightarrow e^+e^-)$ = 83.98 ± 0.18 MeV, and $\Gamma(Z)$ = 2.4969 ± 0.0038.

47 The first error was obtained by adding the statistical and systematic experimental uncertainties in quadrature. The second error reflects the dependence on theoretical prediction of total W cross section: $\sigma(546 \text{ GeV}) = 4.7 + \frac{1}{0.7}$ nb and $\sigma(630 \text{ GeV}) = 5.8 + \frac{1}{1.0}$ nb.

See ALTARELLI 85. 48 ABE 91C result is from a measurement of $\sigma B(W \to e \nu)/\sigma B(Z \to e^+e^-)$, the theoretical prediction for the cross section ratio, and the experimental knowledge of $\Gamma(Z \to e^+e^-)/\Gamma(Z \to all)$.

⁴⁹ ALBAJAR 89 experiment determines values of branching ratio times production cross

THE Z BOSON

Revised February 1998 by C. Caso (Univ. of Genova) and A. Gurtu (Tata Inst.)

Precision measurements at the Z-boson resonance using electron-positron colliding beams began in 1989 at the SLC and at LEP. During 1989-95, the four CERN experiments have made high-statistics studies of the Z. The availability of longitudinally polarized electron beams at the SLC since 1993 has enabled a precision determination of the effective electroweak mixing angle $\sin^2 \overline{\theta}_W$ that is competitive with the CERN results on this parameter.

The Z-boson properties reported in this section may broadly be categorized as:

- The standard 'lineshape' parameters of the Z consisting of its mass, M_Z , its total width, Γ_Z , and its partial decay widths, $\Gamma(\text{hadrons})$, and $\Gamma(\ell \bar{\ell})$ where $\ell = e, \mu, \tau, \nu$;
- Z asymmetries in leptonic decays and extraction of Z couplings to charged and neutral leptons;
- The b- and c-quark-related partial widths and charge asymmetries which require special techniques;
- Determination of Z decay modes and the search for modes that violate known conservation laws;
- Average particle multiplicities in hadronic Z decay.

For the lineshape-related Z properties there are no new published LEP results after those included in the 1994 edition of this compilation. The reason for this is the identification in mid 1995 of a new systematic effect which shifts the LEP energy by a few MeV. This is due to a drift of the dipole field in the LEP magnets caused by parasitic currents generated by electrically powered trains in the Geneva area. The LEP Energy Working Group has been studying the implications of this for the Z-lineshape properties which would be obtained after analysis of the high statistics 1993-95 data. The main consequence of this effect is expected to be in the determination of the Z mass.

Details on Z-parameter determination and the study of $Z \to b\bar{b}$, $c\bar{c}$ at LEP and SLC are given in this note.

The standard 'lineshape' parameters of the Z are determined with increasing precision from an analysis of the production cross sections of these final states in e^+e^- collisions. The $Z \to \nu \overline{\nu}(\gamma)$ state is identified directly by detecting single photon production and indirectly by subtracting the visible partial widths from the total width. Inclusion in this analysis of the forward-backward asymmetry of charged leptons, $A_{FB}^{(0,\ell)}$, of the τ polarization, $P(\tau)$, and its forward-backward asymmetry, $P(\tau)^{fb}$, enables the separate determination of the effective vector (\overline{g}_V) and axial vector (\overline{g}_A) couplings of the Z to these leptons and the ratio $(\overline{g}_V/\overline{g}_A)$ which is related to the effective electroweak mixing angle $\sin^2 \overline{\theta}_W$ (see the "Electroweak Model and Constraints on New Physics" Review).

Determination of the b- and c-quark-related partial widths and charge asymmetries involves tagging the b and c quarks. Traditionally this was done by requiring the presence of a prompt lepton in the event with high momentum and high transverse momentum (with respect to the accompanying jet). Precision vertex measurement with silicon detectors has enabled one to do impact parameter and lifetime tagging. Neuralnetwork techniques have also been used to classify events as b or non-b on a statistical basis using event-shape variables. Finally, the presence of a charmed meson (D/D^*) has been used to tag heavy quarks.

Z-parameter determination

LEP is run at a few energy points on and around the Z mass constituting an energy 'scan.' The shape of the cross-section variation around the Z peak can be described by a Breit-Wigner ansatz with an energy-dependent total width [1-3]. The three main properties of this distribution, viz., the position of the peak, the width of the distribution, and the height of the peak, determine respectively the values of M_Z , Γ_Z , and $\Gamma(e^+e^-) \times$ $\Gamma(f\overline{f})$, where $\Gamma(e^+e^-)$ and $\Gamma(f\overline{f})$ are the electron and fermion partial widths of the Z. The quantitative determination of these parameters is done by writing analytic expressions for these cross sections in terms of the parameters and fitting the calculated cross sections to the measured ones by varying these parameters, taking properly into account all the errors. Singlephoton exchange (σ_{γ}^0) and γ -Z interference $(\sigma_{\gamma Z}^0)$ are included, and the large (~25 %) initial-state radiation (ISR) effects are taken into account by convoluting the analytic expressions over a 'Radiator Function' [1-4] H(s,s'). Thus for the process

$$\sigma_f(s) = \int H(s, s') \, \sigma_f^0(s') \, ds' \tag{1}$$

$$\sigma_f^0(s) = \sigma_Z^0 + \sigma_{\gamma}^0 + \sigma_{\gamma Z}^0 \tag{2}$$

$$\sigma_{Z}^{0} = \frac{12\pi}{M_{Z}^{2}} \frac{\Gamma(e^{+}e^{-})\Gamma(f\overline{f})}{\Gamma_{Z}^{2}} \frac{s \Gamma_{Z}^{2}}{(s - M_{Z}^{2})^{2} + s^{2}\Gamma_{Z}^{2}/M_{Z}^{2}} (3)$$

$$\sigma_{\gamma}^{0} = \frac{4\pi\alpha^{2}(s)}{3s} Q_{f}^{2} N_{c}^{f} \tag{4}$$

$$\sigma_{\gamma Z}^{0} = -\frac{2\sqrt{2}\alpha(s)}{3} \left(Q_{f}G_{F}N_{c}^{f}g_{Ve}g_{Vf}\right) \times \frac{(s - M_{Z}^{2})M_{Z}^{2}}{(s - M_{Z}^{2})^{2} + s^{2}\Gamma_{Z}^{2}/M_{Z}^{2}}$$
(5)

where Q_f is the charge of the fermion, $N_c^f = 3(1)$ for quark (lepton) and g_{Vf} is the neutral vector coupling of the Z to the fermion-antifermion pair $f\bar{f}$.

· Since $\sigma_{\gamma Z}^0$ is expected to be much less than σ_Z^0 , the LEP Collaborations have generally calculated the interference term in the framework of the Standard Model using the best known values of g_V . This fixing of $\sigma_{\gamma Z}^0$ leads to a tighter constraint on M_Z and consequently a smaller error on its fitted value.

Defining

$$A_f = 2 \frac{g_{Vf} \cdot g_{Af}}{(g_{Vf}^2 + g_{Af}^2)} \tag{6}$$

where g_{Af} is the neutral axial-vector coupling of the Z to $f\overline{f}$, the lowest-order expressions for the various lepton-related asymmetries on the Z pole are [5–7] $A_{FB}^{(0,\ell)}=(3/4)A_eA_f$, $P(\tau)=-A_{\tau}$, $P(\tau)^{fb}=-(3/4)A_e$, $A_{LR}=A_e$. The full analysis takes into account the energy dependence of the asymmetries. Experimentally A_{LR} is defined as $(\sigma_L-\sigma_R)/(\sigma_L+\sigma_R)$ where $\sigma_{L(R)}$ are the $e^+e^-\to Z$ production cross sections with left- (right)-handed electrons.

In terms of g_A and g_V , the partial decay width of the Z to $f\overline{f}$ can be written as

$$\Gamma(f\overline{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi} (g_{Vf}^2 + g_{Af}^2) N_c^f (1 + \delta_{\text{QED}}) (1 + \delta_{\text{QCD}})$$
 (7)

where $\delta_{\rm QED}=3\alpha Q_f^2/4\pi$ accounts for final-state photonic corrections and $\delta_{\rm QCD}=0$ for leptons and $\delta_{\rm QCD}=(\alpha_s/\pi)+1.409(\alpha_s/\pi)^2-12.77(\alpha_s/\pi)^3$ for quarks, α_s being the strong coupling constant at $\mu=M_Z$.

In the above framework, the QED radiative corrections have been explicitly taken into account by convoluting over the ISR and allowing the electromagnetic coupling constant to run [8]: $\alpha(s) = \alpha/(1-\Delta\alpha)$. On the other hand, weak radiative corrections that depend upon the assumptions of the electroweak theory and on the values of the unknown M_{top} and M_{Higgs} are accounted for by absorbing them into the couplings, which are then called the effective couplings \bar{g}_V and \bar{g}_A (or alternatively the effective parameters of the \star scheme of Kennedy and Lynn [9]).

S-matrix approach to the Z

While practically all experimental analyses of LEP/SLC data have followed the 'Breit-Wigner' approach described above, an alternative S-matrix-based analysis is also possible. The Z, like all unstable particles, is associated with a complex pole in the S matrix. The pole position is process independent and gauge invariant. The mass, \overline{M}_Z , and width, $\overline{\Gamma}_Z$, can be defined in terms of the pole in the energy plane via [10–13]

$$\overline{s} = \overline{M}_Z^2 - i\overline{M}_Z\overline{\Gamma}_Z \tag{8}$$

leading to the relations

$$\overline{M}_Z = M_Z / \sqrt{1 + \Gamma_Z^2 / M_Z^2}$$

$$\approx M_Z - 34.1 \text{ MeV}$$

$$\overline{\Gamma}_Z = \Gamma_Z / \sqrt{1 + \Gamma_Z^2 / M_Z^2}$$

$$\approx \Gamma_Z - 0.9 \text{ MeV} .$$
(10)

Some authors [14] choose to define the Z mass and width via

$$\overline{s} = (\overline{M}_Z - \frac{i}{2}\overline{\Gamma}_Z)^2 \tag{11}$$

which yields $\overline{M}_Z \approx M_Z - 26$ MeV, $\overline{\Gamma}_Z \approx \Gamma_Z - 1.2$ MeV.

The L3 and OPAL Collaborations at LEP (ACCIARRI 97K and ACKERSTAFF 97C) have analyzed their data using the S-matrix approach as defined in Eq. (8), in addition to

the conventional one. They observe a downward shift in the Z mass as expected.

Handling the large-angle e^+e^- final state

Unlike other $f\overline{f}$ decay final states of the Z, the e^+e^- final state has a contribution not only from the s-channel but also from the t-channel and s-t interference. The full amplitude is not amenable to fast calculation, which is essential if one has to carry out minimization fits within reasonable computer time. The usual procedure is to calculate the non-s channel part of the cross section separately using the Standard Model programs ALIBABA [15] or TOPAZO [16] with the measured value of $M_{\rm top}$, and the 'central' value of $M_{\rm Higgs}$ (300 GeV) and add it to the s-channel cross section calculated as for other channels. This leads to two additional sources of error in the analysis: firstly, the theoretical calculation in ALIBABA itself is known to be accurate to $\sim 0.5\%$, and secondly, there is uncertainty due to the error on M_{top} and the unknown value of M_{Higgs} (60-1000 GeV). These additional errors are propagated into the analysis by including them in the systematic error on the $e^+e^$ final state.

Errors due to uncertainty in LEP energy determination [17-21]

The systematic errors related to the LEP energy measurement can be classified as:

- The absolute energy scale error;
- Energy-point-to-energy-point errors due to the nonlinear response of the magnets to the exciting currents;
- Energy-point-to-energy-point errors due to possible higher-order effects in the relationship between the dipole field and beam energy;
- Energy reproducibility errors due to various unknown uncertainties in temperatures, tidal effects, corrector settings, RF status, etc. Since one groups together data taken at 'nominally same' energies in different fills, it can be assumed that these errors are uncorrelated and are reduced by $\sqrt{N_{\rm fill}}$ where $\overline{N}_{\rm fill}$ is the (luminosity weighted) effective number of fills at a particular energy point.

At each energy point the last two errors can be summed into one point-to-point error.

Choice of fit parameters

The LEP Collaborations have chosen the following primary set of parameters for fitting: M_Z , Γ_Z , $\sigma_{\rm hadron}^0$, $R({\rm lepton})$, $A_{FB}^{(0,\ell)}$, where $R({\rm lepton}) = \Gamma({\rm hadrons})/\Gamma({\rm lepton})$, $\sigma_{\rm hadron}^0 = 12\pi\Gamma(e^+e^-)\Gamma({\rm hadrons})/M_Z^2\Gamma_Z^2$. With a knowledge of these fitted parameters and their covariance matrix, any other parameter can be derived. The main advantage of these parameters

is that they form the **least correlated** set of parameters, so that it becomes easy to combine results from the different LEP experiments.

Thus, the most general fit carried out to cross section and asymmetry data determines the nine parameters: M_Z , Γ_Z , $\sigma_{\rm hadron}^0$, R(e), $R(\mu)$, $R(\tau)$, $A_{FB}^{(0,e)}$, $A_{FB}^{(0,\mu)}$, $A_{FB}^{(0,\tau)}$. Assumption of lepton universality leads to a five-parameter fit determining M_Z , Γ_Z , $\sigma_{\rm hadron}^0$, $R({\rm lepton})$, $A_{FB}^{(0,\ell)}$. The use of only cross-section data leads to six- or four-parameter fits if lepton universality is or is not assumed, *i.e.*, $A_{FB}^{(0,\ell)}$ values are not determined.

In order to determine the best values of the effective vector and axial vector couplings of the charged leptons to the Z, the above mentioned nine- and five-parameter fits are carried out with added constraints from the measured values of A_{τ} and A_{e} obtained from τ polarization studies at LEP and the determination of A_{LR} at SLC.

Combining results from the LEP and SLC experiments [22]

Each LEP experiment provides the values of the parameters mentioned above together with the full covariance matrix. The statistical and experimental systematic errors are assumed to be uncorrelated among the four experiments. The sources of common systematic errors are i) the LEP energy uncertainties, and ii) the effect of theoretical uncertainty in calculating the small-angle Bhabha cross section for luminosity determination and in estimating the non-s channel contribution to the large-angle Bhabha cross section. Using this information, a full covariance matrix, V, of all the input parameters is constructed and a combined parameter set is obtained by minimizing $\chi^2 = \Delta^T V^{-1} \Delta$, where Δ is the vector of residuals of the combined parameter set to the results of individual experiments.

Non-LEP measurement of a Z parameter, $(e.g., \Gamma(e^+e^-)$ from SLD) is included in the overall fit by calculating its value using the fit parameters and constraining it to the measurement.

Study of $Z \rightarrow b\overline{b}$ and $Z \rightarrow c\overline{c}$

In the sector of c- and b-physics the LEP experiments have measured the ratios of partial widths $R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons})$ and $R_c = \Gamma(Z \to c\bar{c})/\Gamma(Z \to \text{hadrons})$ and the forward-backward (charge) asymmetries $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$. Several of the analyses have also determined other quantities, in particular the semileptonic branching ratios, $B(b \to \ell)$ and $B(b \to c \to \ell^+)$, the average $B^0\bar{B}^0$ mixing parameter $\bar{\chi}$ and the probabilities for a c-quark to fragment into a D^+ , a D_s , a D^{*+} , or a charmed baryon. The latter measurements do not concern properties of the Z boson and hence they are not covered in this section. However, they are correlated with the electroweak parameters, and since the mixture of b hadrons is different from the one at the $\Upsilon(4S)$, their values might differ from those measured at the $\Upsilon(4S)$.

All the above quantities are correlated to each other since:

- Several analyses (for example the lepton fits) determine more than one parameter simultaneously;
- Some of the electroweak parameters depend explicitly on the values of other parameters (for example R_b depends on R_c);
- Common tagging and analysis techniques produce common systematic uncertainties.

The LEP Electroweak Heavy Flavour Working Group has developed [23] a procedure for combining the measurements taking into account known sources of correlation. The combining procedure determines eleven parameters: the four parameters of interest in the electroweak sector, R_b , R_c , $A_{FB}^{b\bar{b}}$, and $A_{FB}^{c\bar{c}}$ and, in addition, $B(b \to \ell)$, $B(b \to c \to \ell^+)$, $\bar{\chi}$, $f(D^+)$, $f(D_s)$, $f(c_{\rm baryon})$ and $P(c \to D^{*+}) \times B(D^{*+} \to \pi^+ D^0)$, to take into account their correlations with the electroweak parameters. Before the fit both the peak and off-peak asymmetries are translated to $\sqrt{s} = 91.26$ GeV using the predicted dependence from ZFITTER [4].

Summary of the measurements and of the various kinds of analysis

The measurements of R_b and R_c fall into two classes. In the first, named single-tag measurement, a method for selecting b and c events is applied and the number of tagged events is counted. The second technique, named double-tag measurement, is based on the following principle: if the number of events with a single hemisphere tagged is N_t and with both hemispheres tagged is N_{tt} , then given a total number of N_{had} hadronic Z decays one has:

$$\frac{N_t}{2N_{had}} = \varepsilon_b R_b + \varepsilon_c R_c + \varepsilon_{uds} (1 - R_b - R_c) \tag{12}$$

$$\frac{N_{tt}}{N_{\text{had}}} = \mathcal{C}_b \varepsilon_b^2 R_b + \mathcal{C}_c \varepsilon_c^2 R_c + \mathcal{C}_{uds} \varepsilon_{uds}^2 (1 - R_b - R_c)$$
 (13)

where ε_b , ε_c , and ε_{uds} are the tagging efficiencies per hemisphere for b, c, and light quark events, and $C_q \neq 1$ accounts for the fact that the tagging efficiencies between the hemispheres may be correlated. In tagging the b one has $\varepsilon_b \gg \varepsilon_c \gg \varepsilon_{uds}$, $C_b \approx 1$. Neglecting the c and uds background and the hemisphere correlations, these equations give:

$$\varepsilon_b = 2N_{tt}/N_t \tag{14}$$

$$R_b = N_t^2 / (4N_{tt}N_{had}) . ag{15}$$

The double-tagging method has thus the great advantage that the tagging efficiency is directly derived from the data, reducing the systematic error of the measurement. The backgrounds, dominated by $c\bar{c}$ events, obviously complicate this simple picture, and their level must still be inferred by other means. The rate of charm background in these analyses depends explicitly on the value of R_c . The correlations in the

tagging efficiencies between the hemispheres (due for instance to correlations in momentum between the b hadrons in the two hemispheres) are small but nevertheless lead to further systematic uncertainties.

The measurements in the b- and c-sector can be grouped in the following categories:

- Lepton fits which use hadronic events with one or more leptons in the final state. Each analysis usually gives several electroweak parameters chosen among: R_b , R_c , $A_{FB}^{b\bar{b}}$, $A_{FB}^{c\bar{c}}$, $B(b \to \ell)$, $B(b \to c \to \ell^+)$ and $\overline{\chi}$. The output parameters are then correlated. The dominant sources of systematics are due to lepton identification, to other semileptonic branching ratios and to the modelling of the semileptonic decay;
- Event shape tag for R_h ;
- Lifetime (and lepton) double-tagging measurements
 of R_b. These are the most precise measurements
 of R_b and obviously dominate the combined result.
 The main sources of systematics come from the
 charm contamination and from estimating the hemisphere b-tagging efficiency correlation. The charm
 rejection has been improved (and hence the systematic errors reduced) by using either the information
 of the secondary vertex invariant mass or the information from the energy of all particles at the
 secondary vertex and their rapidity;
- Measurements of A^{bb}_{FB} using lifetime tagged events with a hemisphere charge measurement. Their contribution to the combined result has roughly the same weight as the lepton fits;
- Analyses with D/D*± to measure R_c. These measurements make use of several different tagging techniques (inclusive/exclusive double tag, inclusive single/double tag, exclusive double tag, reconstruction of all weakly decaying D states) and no assumptions are made on the energy dependence of charm fragmentation;
- Analyses with $D/D^{*\pm}$ to measure $A_{FB}^{c\bar{c}}$ or simultaneously $A_{FB}^{b\bar{b}}$ and $A_{FB}^{c\bar{c}}$;
- Measurements of A_b and A_c from SLD, using several tagging methods (lepton, D/D^* , and impact parameter). These quantities are directly extracted from a measurement of the left-right forward-backward asymmetry in $c\bar{c}$ and $b\bar{b}$ production using a polarized electron beam.

Averaging procedure

All the measurements are provided by the LEP Collaborations in the form of tables with a detailed breakdown of the systematic errors of each measurement and its dependence on other electroweak parameters. The averaging proceeds via the following steps:

- Define and propagate a consistent set of external inputs such as branching ratios, hadron lifetimes, fragmentation models etc. All the measurements are also consistently checked to ensure that all use a common set of assumptions (for instance since the QCD corrections for the forward-backward asymmetries are strongly dependent on the experimental conditions, the data are corrected before combining);
- Form the full (statistical and systematic) covariance matrix of the measurements. The systematic correlations between different analyses are calculated from the detailed error breakdown in the measurement tables. The correlations relating several measurements made by the same analysis are also used:
- Take into account any explicit dependence of a measurement on the other electroweak parameters. As an example of this dependence we illustrate the case of the double-tag measurement of R_b, where c-quarks constitute the main background. The normalization of the charm contribution is not usually fixed by the data and the measurement of R_b depends on the assumed value of R_c, which can be written as:

$$R_b = R_b^{\text{meas}} + a(R_c) \frac{(R_c - R_c^{\text{used}})}{R_c} , \qquad (16)$$

where R_b^{meas} is the result of the analysis which assumed a value of $R_c = R_c^{\text{used}}$ and $a(R_c)$ is the constant which gives the dependence on R_c ;

 Perform a X² minimization with respect to the combined electroweak parameters.

After the fit the average peak asymmetries $A_{FB}^{c\bar{c}}$ and A_{FB}^{bb} are corrected for the energy shift and for QED, γ exchange, and γZ interference effects to obtain the corresponding pole asymmetries $A_{FB}^{0,c}$ and $A_{FB}^{0,b}$. A small correction is also applied to both R_b and R_c to account for the contribution of γ exchange.

Z MASS

The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. We believe that this set is the most free of correlations. Common systematic errors are taken into account. For more details, see the 'Note on the Z Boson.'

The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma-Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 97K and ACKERSTAFF 97C for a detailed investigation of both these issues.

A new source of LEP energy variation was discovered in mid 1995: an energy change of a few MeV is correlated with the passage of a train on nearby railway tracks. The LEP energy working group is studying the implications of this effect for the high statistics data recorded since 1993. The main consequence of this is expected to be a shift in the overall LEP energy values leading to a corresponding shift in the value of m_Z . The LEP collaborations have consequently deferred publication of their results on Z lineshape and lepton forward-backward asymmetries based on 1993 and later data.

Because of the high current interest, we mention here the following preliminary results, but do not average them or include them in the Listings or Tables.

Combining published and unpublished preliminary LEP results (as of end of February 1998) yields an average Z-boson mass of 91.1867 \pm 0.0020 GeV, with a total width of 2.4948 \pm 0.0025 GeV.

Γ ₄₃	$\mu^+ \tau^{r}$	LF	[b] < 1.2	× 10 ⁻⁵ 95%

- [a] ℓ indicates each type of lepton $(e, \mu, \text{ and } \tau)$, not sum over them.
- [b] The value is for the sum of the charge states of particle/antiparticle states
- [c] See the Particle Listings below for the γ energy range used in this measurement.
- [d] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

In our fit $\Gamma(\ell^+\ell^-)$ is defined as the partial Z width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the 'Note on the Z Boson.'

      by their value of (3C_{1/3} + 2C_{2/3}) = 6.720 \pm 0.076.
 as explained in the Note on the 2 boson. As a class check we now easy performed a weighted average of the R_C measurements taking into account the various common systematic errors. Assuming that the smallest common systematic error is fully
         correlated, we obtain R_{c}=0.171\pm0.009.
         Because of the high current interest, we mention the following preliminary results
         here, but do not average them or include them in the Listings or Tables. Combining
         published and unpublished preliminary LEP and SLD electroweak results (as of end of February 1998) yields R_{\rm C}=0.1734\pm0.0048. The Standard Model predicts R_{\rm C}=0.1734\pm0.0048.
         0.1723 for m_t=175~{\rm GeV} and M_H=300~{\rm GeV}.

 Γ_2/Γ_1

0.151 ±0.008 ±0.041

⁴⁶ ABREU 920 DLPH E = 88-94 GeV 40 ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstruced in several decay channels and in the opposite jet a slow plon

(opposite charge inclusive $D^{\bullet\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{\star\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ± 0.006 due to the external branching ratios.

41 ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0 , D^+ , D^+_s , and Λ^+_c , and assuming that strange-charmed baryons account for the 15% of the Λ_c^+ production. An uncertainty of ± 0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

42 ABREU 950 perform a maximum likelihood fit to the combined p and p_{T} distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0124 models and branching ratios.

43 BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

 44 ABREU 931 assume that the $D_{
m S}$ and charmed baryons are equally produced at LEP and CLEO (10 GeV) energies.

45 AKERS 950 use the presence of a $D^{*\pm}$ to tag $Z \to c\overline{c}$ with $D^* \to D^0\pi$ and $D^0 \to c\overline{c}$ $K\pi$. They measure $P_C * \Gamma(c\overline{c})/\Gamma(\text{hadrons})$ to be $(1.006 \pm 0.055 \pm 0.061) \times 10^{-3}$, where P_c is the product branching ratio B($c \to D^*$)B($D^* \to D^0 \pi$)B($D^0 \to K \pi$). Assuming that P_c remains unchanged with energy, they use its value $(7.1\pm0.5)\times10^{-3}$ determined at CESR/PETRA to obtain $\Gamma(c\overline{c})/\Gamma$ (hadrons). The second error of AKERS 950 includes an uncertainty of ±0.011 from the uncertainty on P_c .

46 ABREU 920 use the neural network techinque to tag heavy flavour events among a sample of 123k selected hadronic events. The systematic error consists of three due to Monte Carlo (MC) parametrization (0.023), choice of MC model (0.033) and detector effects (0.009) added in quadrature.

 $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$

EVTS

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the "Note on the Z boson." As a cross check we have also performed a weighted average of the R_b measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. For $R_C=0.177$ (as given by OUR FIT above), we obtain $R_b=0.2169\pm0.0012$. For an expected Standard Model value of $R_C=0.1723$, our weighted average gives $R_b = 0.2172 \pm 0.0012$.

Because of the high current interest, we mention the following preliminary results here, but do not average them or include them in the Listings or Tables. Combining published and unpublished preliminary LEP and SLD electroweak results (as of end of February 1998) yields $R_b=$ 0.2170 \pm 0.0009. The Standard Model predicts $R_b=$ 0.2158 for $m_t=$ 175 GeV and $M_H=$ 300 GeV.

47 ABE 98D use a double tag based on 3D impact parameter with reconstruction of secondary vertices. The charm background is reduced by requiring the invariant mass at the secondary vertex to be above 2 GeV. The systematic error includes an uncertainty of ± 0.0002 due to the uncertainty on R_C .

48 ACKERSTAFF 97K use lepton and/or separated decay vertex to tag independently each hemisphere. Comparing the numbers of single- and double-tagged events, they determine the b-tagging efficiency directly from the data.

49 BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \rightarrow b\bar{b}$ candidates. They further use cand uds-selection tags to identify the background. For R_c different from its Standard Model value of 0.172, R_b varies as $-0.019 \times (R_c - 0.172)$.

50 ABREU 96 obtain this result combining several analyses (double lifetime tag, mixed tag and multivariate analysis). This value is obtained assuming $R_c = \Gamma(c\overline{c})/\Gamma(\text{hadrons}) = 0.172$. For a value of R_C different from this by an amount ΔR_C the change in the value is given by -0.087 ΔR_C .

 51 ABREU 95D perform a maximum likelihood fit to the combined p and p_{T} distributions of single and dilepton samples. The second error includes an uncertainty of ± 0.0023 due to models and branching ratios.

 52 BUSKULIC 94G perform a simultaneous fit to the ho and ho_{T} spectra of both single and

53 ADRIANI 93E use a multidimensional analysis based on a neural network approach.

54 AKERS 93B use a simultaneous fit to single and dilepton events (electrons and muons) to tag $Z \rightarrow b\overline{b}$.

 55 JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of \geq 3 tracks with significant Impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (± 0.014).

56 BARATE 97E combine a lifetime tag with a mass cut based on the mass difference between c hadrons and b hadrons.

57 Detween C nations and D nations.

57 ABE 966 obtain this value by combining results from three different b-tagging methods (2D impact parameter, 3D impact parameter, and 3D displaced vertex).

58 ABREU 950 obtain this result combining several analyses (double-lifetime tag and mixed ABREU 950 obtain this result containing several analyses (account metrific tag and mixed tags). The second error contains an uncertainty of ± 0.0029 due to the total systematics and an uncertainty of ± 0.0016 due to an 8% variation of $\Gamma(c\overline{c})/\Gamma(\text{hadrons})$ around its Standard Model value (0.171 \pm 0.014). Combining with their own lepton analysis, ABREU 950 obtain 0.2210 \pm 0.0033 \pm 0.0003 (models) \pm 0.0014 [$\Gamma(c\overline{c})/\Gamma(\text{hadrons})$].

⁵⁹ABREU 95J obtain this value with a multivariate analysis based on event shape and particle trajectories near the interaction point. The second error contains an uncertainty of ± 0.0012 due to an 8% variation of $\Gamma(c\overline{c})/\Gamma(\text{hadrons})$ around its Standard Model value (0.171 + 0.014).

60 AKERS 95B select events based on the lepton and/or vertex tag independently in each hemisphere. Comparing the numbers of single- and double-tagged events, they determine the b-tagging efficiency directly from data.

61 BUSKULIC 93N use event shape and high p_T lepton discriminators applied to both

 62 ABREU 92 result is from an indirect technique. They measure the lifetime $au_{\mathcal{B}}$, but use a world average of τ_B independent of $\Gamma(b\overline{b})$ and compare to their $\Gamma(b\overline{b})$ dependent lifetime from a hadron sample.

63 ABREU 92K use boosted—sphericity technique to tag and enrich the b-b content with a sample of 50k hadronic events. Most of the systematic error is from hadronization uncertainty.

64 ABREU 920 use the neural network technique to tag heavy flavour events among a sample of 123k selected hadronic events. The systematic error consists of three parts: due to Monte Carlo (MC) parametrization (0.010), choice of MC model (0.008), and detector effects (0.011) added in quadrature.

⁶⁵ KRAL 90 used isolated leptons and found $\Gamma(b\overline{b})/\Gamma(\text{total}) = 0.17^{+0.07}_{-0.06} + 0.03^{+0.03}_{-0.03}$

Z VECTOR COUPLINGS TO CHARGED LEPTONS

These quantities are the effective vector couplings of the Z to charged leptons. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the ${\cal Z}$ asymmetry parameters, $A_{\rm e}$ and $A_{\rm T}$, or $\nu_{\rm e}$ scattering. The fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and $A_{\rm e}$ and $A_{\rm T}$ measurements. See "Note on the Z boson"

Within the current data set, the reason for the smallness of $g_{1\ell}^{tt}$ compared to $\mathbf{g}_{V}^{\mathbf{e}}$ and $\mathbf{g}_{V}^{ au}$ is due to the large value of $A_{\mathbf{e}}$ which is heavily weighted by the SLD result. This large value of $A_{\mathcal{C}}$ leads to a large value of $g_{\mathcal{V}}^{\mathcal{C}}$. Since $m{g}_{m{V}}^{\mu}$ is obtained using the relation $A_{FB}^{\mu}=0.75{ imes}A_{e}{ imes}A_{\mu}$, a large value of g_V^e leads to a SMALL value of g_V^e . Concerning the τ , its g_V gets mainly determined directly from A_τ which is obtained from a measurement of the τ polarization (see "Note on the Z boson").

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the 'Note on the Z

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the $e^+\,e^-$ production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

139 ABE 97 obtain this result from a measurement of the observed left-right charge asymmetry, $A_Q^{
m obs}=0.225\pm0.056\pm0.019$, in hadronic Z decays. If they combine this value of $A_{\rm C}^{\rm Obs}$ with their earlier measurement of $A_{LR}^{\rm Obs}$ they determine $A_{\rm e}$ to be 0.1574 \pm 0.0197 \pm 0.0067 independent of the beam polarization.

140 ABE 97E measure the left-right asymmetry in hadronic Z production. This value (statistical and systematic errors added in quadrature) leads to $\sin^2\!\theta_W^{\rm eff} = 0.23060 \pm$

141 ABE 97N obtain this direct measurement using the lef-right cross section asymmetry and the left-right forward-backward asymmetry in leptonic decays of the Z boson obtained with a polarized electron beam.

 142 ALEXANDER 960 measure the au-lepton polarization and the forward-backward polarization asymmetry.

143 ABE 95J obtain this result from polarized Bhabha scattering.

¹⁴⁴Derived from the measurement of forward-backward au polarization asymmetry.

 145 BUSKULIC 95Q obtain this result fitting the au polarization as a function of the polar auproduction angle.

146 ABE 94C measured the left-right asymmetry in Z production. This value leads to $\sin^2\!\theta_W = 0.2292 \pm 0.0009 \pm 0.0004$. 147 ABE 93 measured the left-right asymmetry in Z production.

Ap.

This quantity is directly extracted from a measurement of the left-right forwardbackward asymmetry in $\mu^+\mu^-$ production at SLC using a polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.102±0.034	3788	¹⁴⁸ ABE	97N SLD	Ecm = 91.27 GeV

 $^{^{148} \}mbox{ABE}$ 97N obtain this direct measurement using the lef-right cross section asymmetry and the left-right forward-backward asymmetry in $\mu^+\mu^-$ decays of the Z boson obtained with a polarized electron beam.

The LEP Collaborations derive this quantity from the measurement of the average τ polarization in $Z\to \tau^+\tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z\to \tau^+\tau^-$ produced using a polarized e beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A.

 154 ABE 95K obtain an enriched sample of $b\,\overline{b}$ events tagging with the impact parameter. A momentum-weighted charge sum is used to identify the charge of the underlying b quark. 155 ABE 95L tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract A_b and A_c . Combining with ABE 95K, they quote 0.89 \pm 0.09 \pm 0.06.

TRANSVERSE SPIN CORRELATIONS IN $Z \rightarrow \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in \boldsymbol{Z} decays may be expressed in terms of the vector and axial-vector couplings:

$$\begin{split} C_{TT} &= \frac{|\boldsymbol{g}_{A}^{T}|^{2} - |\boldsymbol{g}_{V}^{T}|^{2}}{|\boldsymbol{g}_{A}^{T}|^{2} + |\boldsymbol{g}_{V}^{T}|^{2}} \\ C_{TN} &= -2 \frac{|\boldsymbol{g}_{A}^{T}| |\boldsymbol{g}_{V}^{T}|}{|\boldsymbol{g}_{A}^{T}|^{2} + |\boldsymbol{g}_{V}^{T}|^{2}} \sin(\boldsymbol{\Phi}_{\boldsymbol{g}_{V}^{T}} - \boldsymbol{\Phi}_{\boldsymbol{g}_{A}^{T}}) \end{split}$$

 C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane)

The longitudinal au polarization $P_{ au}$ (= $-A_{ au}$) is given by:

$$P_{\tau} = -2\frac{|\mathbf{g}_{A}^{\tau}||\mathbf{g}_{V}^{\tau}|}{|\mathbf{g}_{A}^{\tau}|^{2} + |\mathbf{g}_{V}^{\tau}|^{2}}\cos(\Phi_{\mathbf{g}_{V}^{\tau}} - \Phi_{\mathbf{g}_{A}^{\tau}})$$

Here Φ is the phase and the phase difference $\Phi_{{\cal g}_{V}^{T}}-\Phi_{{\cal g}_{A}^{T}}$ can be obtained using both the measurements of C_{TN} and $P_{ au}$.

¹⁶⁴ ACKERSTAFF 97T measure the forward-backward asymmetry of various fast hadrons made of light quarks. Then using SU(2) isospin symmetry and flavor independence for down and strange quarks authors solve for the different quark types. The value reported here corresponds then to the forward-backward asymmetry for "down-type" quarks.

165 ABREU 95G require the presence of a high-momentum charged kaon or Λ⁰ to tag the s quark. An unresolved s- and d-quark asymmetry of (11.2 ± 3.1 ± 5.4)% is obtained by tagging the presence of a high-energy neutron or neutral kaon in the hadron calorimeter.

A(0,c) CHARGE ASYMMETRY IN e+e- → cc

OUR FIT, which is obtained by a simultaneous fit to several c- and bquark measurements as explained in the "Note on the Z boson," refers to the Z pole asymmetry. As a cross check we have also performed a weighted average of the "near peak" measurements taking into account the various common systematic errors. We have assumed that the smallest common systematic error is fully correlated. Applying to this combined "peak" measurement QCD, QED, and energy-dependence corrections, our weighted average gives a pole asymmetry of $(7.20 \pm 0.64)\%$.

- 176 ACKERSTAFF 97P tag b quarks using lifetime. The quark charge is measured using both jet charge and vertex charge, a weighted sum of the charges of tracks in a jet which contains a tagged secondary vertex.
- 177 ALEXANDER 97C identify the b and c events using a D/D^* tag.
- 178 ALEXANDER 96 tag heavy flavors using one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average $B^0-\overline{B}^0$ mixing.
- 179 BUSKULIC 960 tag b-quark flavor and charge using high transverse momentum leptons. The asymmetry value at the Z peak is obtained using a charm charge asymmetry of 6.17%.

 180 ABREU 95E require the presence of a $D^{*\pm}$ to identify c and b quarks.
- 181 ABREU 95K Identify c and b quarks using both electron and muon semileptonic decays. The systematic error includes an uncertainty of ± 0.3 due to the mixing correction ($X=0.115\pm0.011$).
- 182 ABREU 95K tag b quarks using lifetime; the quark charge is identified using jet charge. The systematic error includes an uncertainty of ± 0.3 due to the mixing correction (X = 0.115 ± 0.011).
- 183 ACCIARRI 94D use both electron and muon semileptonic decays.
- 184 BUSKULIC 941 use the lifetime tag method to obtain a high purity sample of $Z \to b \bar{b}$ events and the hemisphere charge technique to obtain the jet charge.
- events and the nemisphere charge technique to obtain the jet charge. 185 AKERS 95s tag b quarks using lifetime; the quark charge is measured using jet charge. These asymmetry values are obtained using $R_b = \lceil (bb) \rceil \lceil (\text{hadrons}) = 0.216$. For a value of R_b different from this by an amount ΔR_b , the change in the asymmetry values is given by $-K\Delta R_b$, where K = 0.082, 0.471, and 0.855 for \sqrt{s} values of 89.52, 91.25, and 92.94 GeV respectively. Replaced by ACKERSTAFF 97P.
- and 92.94 GeV respectively. Replaced by ACKERSTAFF 97P.

 186 BUSKULIC 94c perform a simultaneous fit to the p and p_T spectra of both single and dilepton events. Replaced by BUSKULIC 96q.

 187 ACTON 93K use the lepton tagging technique. The systematic error includes the uncertainty on the mixing parameter. Replaced by ALEXANDER 96.

 188 AKERS 93D Identify the b and c decays using D*. Replaced by ALEXANDER 97C.

 189 B tagging via its semimuonic decay. Experimental value corrected using average LEP

- B^0 - \overline{B}^0 mixing parameter $\chi = 0.143 \pm 0.023$.
- 190 ADRIANI 92D use both electron and muon semileptonic decays. For this measurement ADRIANI 92D average over all √s values to obtain a single result.
- 191 ADRIANI 92D use both electron and muon semileptonic decays. The quoted systematic error is common to all measurements. The peak value is superseded by ACCIARRI 94D.

CHARGE ASYMMETRY IN e+e- → qq

Summed over five lighter flavors

Experimental and Standard Model values are somewhat event-selection endent. Standard Model expectations contain some assumptions on B^0 - \overline{B}^0 mixing and on other electroweak parameters.

8.2 ±2.9	8.5	43.6	GREENSHAW	89 JADE

192 ABREU 921 has 0.14 systematic error due to uncertainty of quark fragmentation.

193 ACTON 921 use the weight function method on 259k selected Z → hadrons events. The systematic error includes a contribution of 0.2 due to B⁰-B⁰ mixing effect, 0.4 due to Monte Carlo (MC) fragmentation uncertainties and 0.3 due to MC statistics. ACTON 92L derive a value of $\sin^2\!\theta_W^{\rm eff}$ to be 0.2321 \pm 0.0017 \pm 0.0028.

Higgs Bosons — H^0 and H^{\pm} , Searches for

THE HIGGS BOSON

Revised October 1997 by I. Hinchliffe (LBNL).

The Standard Model [1] contains one neutral scalar Higgs boson, which is a remnant of the mechanism that breaks the $SU(2) \times U(1)$ symmetry and generates the W and Z boson masses. The Higgs couples to quarks and leptons of mass m_f with a strength $gm_f/2M_W$. Its coupling to W and Z bosons is of strength g, where g is the coupling constant of the SU(2) gauge theory. The branching ratio of the Higgs boson into various final states is shown in Fig. 1.

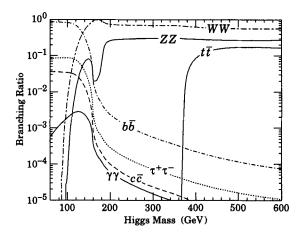

Figure 1: The branching ratio of the Higgs boson into $\gamma\gamma$, $\tau\bar{\tau}$, $b\bar{b}$, $t\bar{t}$, $c\bar{c}$, ZZ, and WW as a function of the Higgs mass. For ZZ and WW, if $M_H < 2M_Z$ (or $M_H < 2M_W$), the value indicated is the rate to ZZ^* (or WW^*) where Z^* (W^*) denotes a virtual Z (W). The $c\bar{c}$ rate depends sensitively on the poorly-determined charmed quark mass.

The Higgs coupling to stable matter is very small while its coupling to the top quark and to W and Z bosons is substantial. Hence its production is often characterized by a low rate and a poor signal to background ratio. A notable exception would be its production in the decay of the Z boson (for example $Z \to Hq\overline{q}$). Since large numbers of Z's can be produced and the coupling of the Z to the Higgs is unsuppressed, experiments at LEP are now able to rule out a significant range of Higgs masses.

If the Higgs mass is very large, the couplings of the Higgs to itself and to longitudinally polarized gauge bosons become large. Requiring that these couplings remain weak enough so that perturbation theory is applicable implies that $M_H \lesssim 1$ TeV [2]. While this is not an absolute bound, it is an indication of the mass scale at which one can no longer speak of an elementary Higgs boson. This fact is made more clear if one notes that the width of the Higgs boson is proportional to the cube of its mass (for $M_H > 2M_Z$) and that a boson of mass 1 TeV has a width of 500 GeV.

A scalar field theory of the type that is used to describe Higgs self-interactions can only be an effective theory (valid over a limited range of energies) if the Higgs self-coupling and hence the Higgs mass is finite. An upper bound on the Higgs mass can then be determined by requiring that the coupling has a finite value at all scales up to the Higgs mass [3]. Nonperturbative calculations using lattice [4] gauge theory that compute at arbitrary values of the Higgs coupling indicate that $M_H \lesssim 770$ GeV.

Gauge & Higgs Boson Particle Listings Higgs Bosons — H^0 and H^{\pm}

If the Higgs mass were small, then the vacuum (ground) state with the correct value of M_W would cease to be the true ground state of the theory [5]. A theoretical constraint can then be obtained from the requirement that our universe is in the true minimum of the Higgs potential [6]. The constraint depends upon the top quark mass and upon the scale (Λ) up to which the Standard Model remains valid. This scale must be at least 1 TeV, resulting in the constraint [7] $M_H > 52 \text{ GeV} +$ 0.64 ($M_{\rm top}$ -175 GeV). This constraint is weaker than that from the failure to directly observe the Higgs boson. The bound increases monotonically with the scale, for $\Lambda = 10^{19} \text{ GeV}$, $M_H > 135 \text{ GeV} + 1.9 (M_{\text{top}} - 175 \text{ GeV}) - 680 (\alpha_s(M_Z) - 0.117).$ This constraint may be too restrictive. Strictly speaking we can only require that the predicted lifetime of our universe, if it is not at the true minimum of the Higgs potential, be longer than its observed age [8,9]. For $\Lambda = 1$ TeV there is no meaningful constraint; and for $\Lambda = 10^{19} \text{ GeV } M_H > 130 \text{ GeV} +$ $2.3 (M_{\text{top}} - 175 \text{ GeV}) - 815(\alpha_s(M_Z) - 0.117)$ [10].

Experiments at LEP are able to exclude a large range of Higgs masses. They search for the decay $Z \to HZ^*$ or $e^+e^- \to ZH$. Here Z^* refers to a virtual Z boson that can appear in the detector as e^+e^- , $\mu^+\mu^-$, $\tau^+\tau^-$, $\nu\bar{\nu}$ (i.e., missing energy) or hadrons. The experimental searches have considered both $H \to$ hadrons and $H \to \tau^+\tau^-$. The best limits are shown in the Particle Listings below.

Precision measurement of electroweak parameters such as M_W , $M_{\rm top}$, and the various asymmetries at LEP and SLC are sensitive enough that they can constrain the Higgs mass through its effect in radiative corrections. The current unpublished limit is $M_H < 450$ GeV, at 95% CL with a central value of $M_H = 127^{+127}_{-72}$ GeV [11]. See also the article in this Review on the "Electroweak Model and Constraints on New Physics."

The process $e^+e^- \rightarrow ZH$ [12] should enable neutral Higgs bosons of masses up to 95 GeV to be discovered at LEP at a center-of-mass energy of 190 GeV [13]. The current unpublished limits corresponding to the failure to observe this process at LEP imply $M_H > 77.5$ GeV at 95% CL [14]. If the Higgs is too heavy to be observed at LEP, there is a possibility that it could be observed at the Tevatron via the processes $p\bar{p} \to HZX$ [15] and $p\bar{p} \to WHX$ [16]. Failing this, its discovery will have to wait until experiments at the LHC. If the neutral Higgs boson has mass greater than $2M_Z$, it will likely be discovered via its decay to ZZ and the subsequent decay of the Z's to charged leptons (electrons or muons) or of one Z to charged leptons and the other to neutrinos. A challenging region is that between the ultimate limit of LEP and $2M_Z$. At the upper end of this range the decay to a real and a virtual Z, followed by the decay to charged leptons is available. The decay rate of the Higgs boson into this channel falls rapidly as M_H is reduced and becomes too small for $M_H \lesssim 140$ GeV. For masses below this, the decays $H \to \gamma \gamma$ and possibly $H \to b\bar{b}$ [17] are expected to be used. The former has a small branching ratio and large background, the latter has a large branching ratio, larger background and a final state that is difficult to fully reconstruct [18].

Extensions of the Standard Model, such as those based on supersymmetry [19], can have more complicated spectra of Higgs bosons. The simplest extension has two Higgs doublets whose neutral components have vacuum expectation values v_1 and v_2 , both of which contribute to the W and Z masses. The physical particle spectrum contains one charged Higgs boson (H^{\pm}) , two neutral scalars (H_1^0, H_2^0) ,* and one pseudoscalar (A) [20]. See also the articles in this Review on Supersymmetry.

In the simplest version of the supersymmetric model (see the *Reviews* on Supersymmetry), the mass of the lightest of these scalars depends upon the top quark mass, the ratio v_2/v_1 ($\equiv \tan \beta$), and the masses of the other supersymmetric particles. For $M_{\rm top}=174$ GeV, there is a bound $M_{H_1^0}\lesssim 130$ GeV [21,22] at large $\tan \beta$. The bound reduces as $\tan \beta$ is lowered.

The H_1^0 , H_2^0 , and A couplings to fermions depend on v_2/v_1 and are either enhanced or suppressed relative to the couplings in the Standard Model. As the masses of H_2^0 and A increase, the mass of H_1^0 approaches the bound, and the properties of this lightest state become indistinguishable from those a Standard Model Higgs boson of the same mass. This observation is important since the discovery of a single Higgs boson at LEP with Standard Model couplings would not be evidence either for or against the minimal supersymmetric model. However the failure to find a Higgs boson of mass less than 130 GeV would be definite evidence against the minimal supersymmetric Standard Model. In more complicated supersymmetric models, there is always a Higgs boson of mass less than 160 GeV.

Experiments at LEP are able to exclude ranges of masses for neutral Higgs particles in these models. Production processes that are exploited are $e^+e^- \to ZH_1^0$ and $e^+e^- \to AH_1^0$. No signal is seen; the mass limits are (weakly) dependent upon the masses of other supersymmetric particles and upon $\tan \beta$. Currently $M_{H_1^0}$, $M_A > 62$ GeV. See the Particle Listings below on H_1^0 , Mass Limits in Supersymmetric Models.

Charged Higgs bosons can be pair-produced in e^+e^- annihilation. Searches for charged Higgs bosons depend on the assumed branching fractions to $\nu\tau$, $c\bar{s}$, and $c\bar{b}$. Data from LEP now exclude charged Higgs bosons of mass less than 54.5 GeV [23]. See the Particle Listings for details of the H^\pm Mass Limit.

A charged Higgs boson could also be produced in the decay of a top quark, $t \to H^+b$. A search at CDF excludes $M_{H^+} < 147$ GeV for $\tan \beta > 100$ where the branching ratio $H^+ \to \tau \nu$ is large and at $\tan \beta < 1$ where the BR $(t \to H^+b)$ is large [24]. The region at intermediate values of $\tan \beta$ will be probed as the number of produced top quarks increases. Searches for these non-standard Higgs bosons will be continued at LEP [13] and at LHC [25]

H⁰ (Higgs Boson) MASS LIMITS

These limits apply to the Higgs boson of the three-generation Standard Model with the minimal Higgs sector. Limits that depend on the $Ht\bar{t}$ coupling may also apply to a Higgs boson of an extended Higgs sector whose couplings to up-type quarks are comparable to or larger than those of the standard one-doublet model H^0 couplings.

For comprehensive reviews, see Gunion, Haber, Kane, and Dawson, "The Higgs Hunter's Guide," (Addison-Wesley, Menio Park, CA, 1990) and R.N. Cahn, Reports on Progress in Physics 52 389 (1989). For a review of theoretical bounds on the Higgs mass, see M. Sher, Physics Reports (Physics Letters C) 179 273 (1989).

Limits from Coupling to Z/W^{\pm}

'OUR LIMIT' is taken from the LEP Higgs Boson Searches Working group (BOCK 97), where the combination of the results of ACCIARRI 970, BARATE 970, ACKER-STAFF 98H, and ABREU 98E was performed.

¹ Search for $e^+e^- \to ZH^0$ at $E_{\rm cm}=161$, 170, and 172 GeV in the final states $H^0 \to q \overline{q}$ with $Z \to \ell^+\ell^-$, $\nu \overline{\nu}$, $q \overline{q}$, and $\tau^+\tau^-$, and $H^0 \to \tau^+\tau^-$ with $Z \to \ell^+\ell^-$ and $q \overline{q}$. The limits also includes the data from Z decay by each experiment.

24. The limits associated WH^0 production in $p\overline{p}$ collisions at $\sqrt{s}=1.8$ TeV with $W\to t\nu_1$, $H^0\to b\overline{b}$ and find the cross-section limit $\sigma\cdot B(H^0\to b\overline{b})<(14-19)$ pb (95% CL) for $m_H=70-120$ GeV. This limit is one to two orders of magnitude larger than the expected cross section in the Standard Model.

³ ACKERSTAFF 97E searched for $e^+e^- \to ZH^0$ at $E_{\rm cm}=$ 161 GeV for the final states $(q\overline{q})(b\overline{b}),\ (\nu p)(q\overline{q}),\ (\tau^+\tau^-)(q\overline{q}),\ (q\overline{q})(\tau^+\tau^-),\ (e^+e^-)(q\overline{q}),\ {\rm and}\ (\mu^+\mu^-)(q\overline{q})$ [the $Z(H^0)$ decay products are in the first (second) parentheses]. The limit includes the results of ALEXANDER 97. Two additional low-mass candidate events are seen, consistent with expected backgrounds.

⁴ ALEXANDER 97 complements the study in ALEXANDER 96. With the inclusion of the search for $Z \to H^0 + (e^+e^-, \mu^+\mu^-)$, with $H^0 \to q\bar{q}$. One additional candidate event is found in the $\mu\mu$ channel, consistent with expected backgrounds.

⁵ ACCIARRI 96i searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \nu p)$ with $H^0 \to q \overline{q}$. Two $e^+e^-H^0$ candidate events with large recoiling mass (above 30 GeV) were found consistent with the background expectations.

 6 ACCIARRI 961 give B(Z $\rightarrow H^0\gamma)\times$ B(H^0 $\rightarrow q\overline{q})<6.9–22.9 <math display="inline">\times$ 10 $^{-6}$ (95%CL) for 20 < m_{H^0} <80 GeV.

7 ALEXANDER 96H give B($Z \to H^0 \gamma$)×B($H^0 \to q \overline{q}$) < 1–4 × 10⁻⁵ (95%CL) and B($Z \to H^0 \gamma$)×B($H^0 \to b \overline{b}$) < 0.7–2 × 10⁻⁵ (95%CL) in the range 20 < m_{H^0} <80

- ⁸ALEXANDER 96L searched for final states with monojets or acoplanar dijets. Two observed candidate events are consistent with expected backgrounds.
- 9 BUSKULIC 96R searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \nu\bar{\nu})$ with $H^0 \to q\bar{q}$. Three candidate events in the $\mu\mu$ channel are consistent with expected backgrounds. ¹⁰ ABREU 94G searched for $Z \to H^0 + (e^+e^-, \mu^+\mu^-, \tau^+\tau^-, \nu\bar{\nu})$ with $H^0 \to q\bar{q}$.
- Four $\ell^+\ell^-$ candidates were found (all yielding low mass) consistent with expected back-
- 11 AKERS 94B searched for $Z \rightarrow H^0 + (e^+e^-, \mu^+\mu^-, \nu\overline{\nu})$ with $H^0 \rightarrow q\overline{q}$. One $\nu\overline{\nu}$ and one $\mu^+\mu^-$ candidate were found consistent with expected backgrounds. ¹² ADRIANI 93C searched for $Z\to H^0+(\nu\overline{\nu},e^+e^-,\mu^+\mu^-)$ with H^0 decaying hadroni-
- cally or to $\tau \bar{\tau}$. Two e^+e^- and one $\mu^+\mu^-$ candidates are found consistent with expected background.
- ¹³ BUSKULIC 93H searched for $Z \rightarrow H^0 \nu \overline{\nu}$ (acoplanar jets) and $Z \rightarrow H^0 + (e^+e^-, e^-)$ $\mu^{+}\mu^{-}$) (lepton pairs in hadronic events).
- 14 GROSS 93 combine data taken by four LEP experiments through 1991.
 15 ABREU 92D give $\sigma(e^+e^-\to Z\to H^0\gamma)$ -B($H^0\to$ hadrons) <8 pb (95% CL) for m_{H^0} <75 GeV and E_{γ} >8 GeV.
- ¹⁶ ABREU 92J searched for $Z \rightarrow H^0 + (ee, \mu\mu, \tau\tau, \nu\overline{\nu})$ with $H^0 \rightarrow q\overline{q}$. Only one candidate was found, in the channel ee + 2jets, with a dijet mass 35.4 ± 5 GeV/ c^2 , consistent with the expected background of 1.0 \pm 0.2 events in the 3 channels $e^+e^ \mu^+\mu^-$, $\tau^+\tau^-$, and of 2.8 \pm 1.3 events in all 4 channels. This paper excludes 12–38 GeV. The range 0–12 GeV is eliminated by combining with the analyses of ABREU 90C and ABREU 918.
- and ABREU 91B. 17 ADEVA 92B searched for $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu, \tau \tau)$ with $H^0 \to$ anything, $Z \to H^0 + \tau \tau$ with $H^0 \to q \overline{q}$, and $Z \to H^0 + q \overline{q}$ with $H^0 \to \tau \tau$. The analysis excludes the range $30 < m_{H^0} < 52$ GeV.
- ¹⁸ ADRIANI 92F give $\sigma(e^+e^- \rightarrow Z \rightarrow H^0\gamma) \cdot B(H^0 \rightarrow hadrons) < (2-10) pb (95% CL)$ hadrons) $<(0.7-3) \times 10^{-4}$ (95% CL).
- ¹⁹ DECAMP 92 searched for most possible final states for $Z \rightarrow H^0 Z^*$.
- ²⁰ ABREU 91B searched for $Z \rightarrow H^0 + \ell \bar{\ell}$ with missing H^0 and $Z \rightarrow H^0 + (\nu \bar{\nu}, \ell \bar{\ell}, \ell \bar{\ell})$ $q\overline{q}$) with $H^0 \rightarrow ee$.
- ²¹ ACTON 91 searched for $e^+e^- \rightarrow Z^*H^0$ where $Z^* \rightarrow e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$ and H^0 anything. Without assuming the minimal Standard Model mass-lifetime relationship, the limit is $m_{H^0} > 9.5 \,\mathrm{GeV}$.
- ²² ADEVA 91 searched for $Z \rightarrow H^0 + (\mu\mu, ee, \nu\overline{\nu})$. This paper only excludes 15 < $m_{H^0} <$ 41.8 GeV. The 0–15 GeV range is excluded by combining with the analyses of previous L3 papers.
- ²³ ADEVA 91D obtain a limit B($Z \rightarrow H^0 \gamma$)·B($H^0 \rightarrow \text{hadrons}$) < 4.7 × 10⁻⁴ (95%CL) for $m_{H^0} = 30-86$ GeV. The limit is not sensitive enough to exclude a standard H^0
- ²⁴ AKRAWY 91 searched for the channels $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu, \tau \tau)$ with $H^0 \to$
- $q\overline{q}$, $\tau\tau$, and $Z\to H^0q\overline{q}$ with $H^0\to \tau\tau$. qq, $\tau\tau$, and $z\to H^-qq$ with $H^0\to \tau\tau$. 25 AKRAWY 91c searched the decay channels $Z\to H^0+(\nu\overline{\nu},\,ee,\,\mu\mu)$ with $H^0\to q\overline{q}$. 26 ABE 90E looked for associated production of H^0 with W^\pm or Z in $p\overline{p}$ collisions at \sqrt{s}
- = 1.8 TeV. Searched for H^0 decays into $\mu^+\mu^-$, $\pi^+\pi^-$, and K^+K^- . Most of the excluded region is also excluded at 95% CL.
- ²⁷ ABREU 90C searched for the channels $Z \to H^0 + (\nu \overline{\nu}, ee, \mu \mu)$ and $H^0 + q \overline{q}$ for m_H < 1 GeV.
- $m_H < 1$ GeV. 28 ADEVA 90H searched for $Z \to H^0 + (\mu \mu, \ ee, \ \nu \overline{\nu})$. 29 ADEVA 90N looked for $Z \to H^0 + (ee, \ \mu \mu)$ with missing H^0 and with $H^0 \to ee$. uu. π⁺π⁻. K⁺K⁻.
- 30 AKRAWY 90C based on 825 nb $^{-1}$. The decay $Z \rightarrow H^0 \nu \bar{\nu}$ with $H^0 \rightarrow \tau \bar{\tau}$ or $q \bar{q}$ provides the most powerful search means, but the quoted results sum all channels.
- ³¹ AKRAWY 90P looked for $Z \to H^0 + (ee, \mu\mu)$ (H^0 missing) and $Z \to H^0 \nu \overline{\nu}$, $H^0 \to H^0 \nu \overline{\nu}$
- 32 DECAMP 90 limits based on 11,550 Z events. They searched for Z \rightarrow $H^0+(\nu\overline{\nu},\,e\,e,$ $\mu\mu$, $\tau\tau$, (\overline{q}) . The decay $Z\to H^0\nu\overline{\nu}$ provides the most powerful search means, but the quoted results sum all channels. Different analysis methods are used for $m_{H^0} < 2m_{\mu}$ where Higgs would be long-lived. The 99% confidence limits exclude $m_{H^0}=0.040-12$
- GeV. 33 DECAMP 90H limits based on 25,000 $Z \rightarrow$ hadron events.
- ³⁴ DECAMP 90M looked for $Z \to H^0\ell\ell$, where H^0 decays outside the detector. ³⁵ DECAMP 90N searched for the channels $Z \to H^0 + (\nu \bar{\nu}, \ e e, \ \mu \mu, \ \tau \tau)$ with $H^0 \to H^0$

H⁰ Indirect Mass Limits from Electroweak Analysis

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review D54 1 (1996)) Edition of this Review. For indirect limits obtained from other considerations of theoretical nature, see the review on "The Higgs boson."

36 CHANOWITZ 98 fits LEP and SLD Z-decay-asymmetry data (as reported in ABBA-NEO 97), and explores the sensitivity of the fit to the weight ascribed to measurements that are individually in significant contradiction with the direct-search limits. Various prescriptions are discussed, and significant variations of the 95%CL Higgs-mass upper limits are found. The Higgs-mass central value varies from 100 to 250 GeV and the 95%CL upper limit from 340 GeV to the TeV scale.

37 DEBOER 978 fit to LEP and SLD data (as reported in ALCARAZ 96), as well as m_W and m_t from CDF/DØ and CLEO $b \to s \gamma$ data (ALAM 95). $1/\alpha(m_Z) = 128.90 \pm 0.09$ is used.

- ³⁸ DEGRASSI 97 is a two-loop calculation of M_W and $\sin^2\theta_{
 m eff}^{
 m lept}$ as a function of m_H , using $\sin^2\! heta_{
 m aff}^{
 m lept}$ 0.23165(24) as reported in ALCARAZ 96, $m_t=$ 175 \pm 6 GeV, and $\Deltalpha_{
 m had}=$ 0.0280(9).
- 39 DITTMAIER 97 flt to m_W and LEP/SLC data as reported in ALCARAZ 96, with m_t = 175 \pm 6 GeV, $1/\alpha(m_Z^2)$ = 128.89 \pm 0.09. Exclusion of the SLD data gives m_H = 261^{+224}_{-128} GeV. Taking only the data on m_t , m_W , $\sin^2\theta$ eff., and Γ^{lept}_Z , the authors get $m_H=190^{+174}_{-102}$ GeV and $m_H=296^{+243}_{-143}$ GeV, with and without SLD data, respectively. The 95% CL upper limit is given by 550 GeV (800 GeV removing the SLD
- ⁴⁰ RENTON 97 fit to LEP and SLD data (as reported in ALCARAZ 96), as well as m_W and m_t from $p\overline{p}$, and low-energy νN data available in early 1997. $1/\alpha(m_Z)=128.90\pm0.09$
- 41 DITTMAIER 96 fit to m_W , LEP, and SLD data available in the Summer of 1995 (with and without m_t =180 \pm 12 GeV from CDF/DØ), leaving out R_b and R_C . They argue that the low Higgs mass obtained in some electroweak analyses is an artifact of including the observed value of R_b , which is incompatible with the rest of the data. Exclusion of the SLD data pushes the 90%CL limit on m_{H^0} above 1 TeV.
- 42 ELLIS 96c fit to LEP, SLD, m_{W_i} neutral-current data available in the summer of 1996, plus $m_t=175\pm 6$ GeV from CDF/DØ . The fit yields $m_t=172\pm 6$ GeV.
- 43 GURTU 96 studies the effect of the mutually incompatible SLD and LEP asymmetry data on the determination of m_{H} . Use is made of data available in the Summer of 1996. The quoted value is obtained by increasing the errors à la PDG. A fit ignoring the SLD data yields 267^{+242}_{-135} GeV.
- ⁴⁴ CHANKOWSKI 95 fit to LEP, SLD, and W mass data available in the spring of 1995 plus $m_t=176\pm13$ GeV. Exclusion of the SLD data increases the mass to $m_H=121-58$ GeV (m_H <800 GeV at 95% CL).
- 45 ERLER 95 fit to LEP, SLC, W mass, and various low-energy data available in the summer of 1994 plus m_t =174 \pm 16 GeV from CDF. The limit without m_t is 880 GeV. However, the preference for lighter m_H is due to R_b and A_{LR} , both of which do not agree well with the Standard Model prediction.
- 46 MATSUMOTO 95 fit to LEP, SLD, W mass, and various neutral current data available In the summer of 1994 plus m_t =180 \pm 13 GeV from CDF/DØ , and the LEP direct limit m_H >63 GeV. $\alpha_s(m_Z)$ = 0.124 is used. Fixing $\alpha_s(m_Z)$ = 0.116 lowers the upper limit to 440 GeV. Dependence on $\alpha(m_Z)$ is given in the paper.
- 47 ELLIS 94B fit to LEP, SLD, W mass, neutral current data available in the spring of 1994 plus $m_t=167\pm12$ GeV determined from CDF/DØ $t\bar{t}$ direct searches. $\alpha_g(m_Z)=0.118\pm0.007$ is used. The fit yields $m_{\bar{t}}=162\pm9$ GeV. A fit without the SLD data gives $m_H = 130^{+320}_{-90}$ GeV.
- 48 GURTU 94 fit to LEP, SLD, W mass, neutral current data available in the spring of 1994 as well as $m_t = 174 \pm 16$ GeV. A fit without $\Gamma(Z \rightarrow b \, \overline{b})/\Gamma(Z \rightarrow hadrons)$ gives $m_H = 120^{+364}_{-60}$ GeV.
- ⁴⁹ MONTAGNA 94 flt to LEP and SLD, W-mass data together with $m_t=174\pm17$ GeV. Although the data favor smaller Higgs masses, the authors do not regard it significant.

${\it H}^{0}$ (Higgs Boson) MASS LIMITS in Extended Higgs Models

The parameter x denotes the Higgs coupling to charge -1/3 quarks and charged leptons relative to the value in the standard one-Higgs-doublet model.

In order to prevent flavor-changing neutral currents in models with more than one Higgs doublet, only one of the Higgs doublets can couple to quarks of charge 2/3. The same requirement applies independently to charge -1/3 quarks and to leptons. Higgs couplings can be enhanced or suppressed.

50 ACCIARRI SER	searches for e				hadrons and HO decayl

 $ightarrow ZH^0$ events, with Zlearches for e Invisibly. The limit assumes SM production cross section, and $B(Z \rightarrow \text{Invisible})=100\%$. For limits under other assumptions, see their Fig. 5b.

 51 ACKERSTAFF 988 search for associate production of a $\gamma\gamma$ resonance and a $q\,\overline{q}$, $\nu\overline{
u}$, or $\ell^+\ell^-$ pair in e^+e^- annihilation at $\sqrt{s}\simeq 91$, 130–140, and 161–172 GeV. The cross-section limit $\sigma(e^+e^-\to H^0Z^{(*)})$ B($H^0\to\gamma\gamma$) < 0.29–0.83 pb (95%CL) is obtained for $m_H=40$ –160 GeV at $\sqrt{s}=161$ –172 GeV, σ -B<0.09 pb for $m_H=40$ –80 GeV at $\sqrt{s} \simeq 91$ GeV. See also their Fig. 9 for the limit on $\sigma(H^0)$ B($H^0 \to \gamma \gamma$)/ $\sigma(H^0_{SM})$.

52 KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no H_1^0 Z Z coupling and obtain $m_{H_1^0}$ \gtrsim

5 GeV or $m_{A^0} \gtrsim$ 5 GeV for $an\!eta >$ 50. Other Higgs bosons are assumed to be much

heavler. Sae Figs. 5 and 6 of ACCIARRI 961 for the excluded region in the $(m_{H^0}, \Gamma(Z \to Z^*H^0))$ plane (normalized to the Standard Model Higgs) for a general Higgs having a similar decay signature to Standard Model Higgs boson or decaying invisibly.

54 These limits are for H^0 with the standard coupling to Z but decaying to weakly interacting

⁵⁵ ACCIARRI 96J give B($Z \rightarrow H^0 + \text{hadrons}) \times B(H^0 \rightarrow \gamma \gamma) < 2.3-6.9 \times 10^{-6}$ for 20 <m_H⁰ <70 GeV.

⁵⁶ ALEXANDER 96H give B($Z \rightarrow H^0 + q\bar{q}$)×B($H^0 \rightarrow \gamma\gamma$) < 2 × 10⁻⁶ in the range $40 < m_{H^0} < 80 \text{ GeV}.$

 57 See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0}-m_{A^0}$ plane for general two-doublet models. For $an\!eta>\!1$, the region $m_{H^0}\!+\!m_{A^0}\!\lesssim\!87$ GeV, $m_{H^0}<\!47$ GeV is

58 BRAHMACHARI 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. If H^0 coupling to Z is at least $1/\sqrt{2}$ of the Standard Model H^0 , the DECAMP 92 limit of 48 GeV changes within ± 6 GeV for arbitrary $B(H^0 \rightarrow SM-like)+B(H^0 \rightarrow SM-like)$ invisible)=1.

59 See Fig. 1 of BUSKULIC 931 for the limit on ZZH^O coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson or decaying invisibly. If the decay rate for $Z \rightarrow H^0 Z^*$ is >10% of the minimal Standard Model rate, then m_{H^0} >40

GeV. For the standard rate the limit is 58 GeV.

60 LOPEZ-FERNANDEZ 93 consider Higgs limit from Z decay when the Higgs decays to invisible modes. See Fig. 2 for excluded region in m_{H0}-ZZH coupling plane with arbitrary B($H^0 \rightarrow \text{SM-like}$)+B($H^0 \rightarrow \text{invisible}$)=1. m_H >50 GeV is obtained if the

H^O coupling strength to the Z is greater than 0.2 times the Standard Model rate.

61 See Fig. 1 of ADRIANI 92G for the limit on ZZH^O coupling for a general Higgs having a similar decay signature to Standard Model Higgs boson. For most masses below 30 GeV, the rate for $Z \rightarrow H_1^0 Z^*$ is less than 10% of the Standard Model rate.

 62 PICH 92 analyse H^0 with m_{H^0} <2 m_μ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and π^\pm , η rare decays are

 64 DECAMP 91F search for $Z \to H^0 \ell^+ \ell^-$ where H^0 escapes before decaying. Combining this with DECAMP 90M and DECAMP 90N, they obtain B(Z \rightarrow H⁰ $\ell^+\ell^-$)/B(Z \rightarrow $\ell^+\ell^-) < 2.5 \times 10^{-3} (95\% \text{CL}) \text{ for } m_{H^0} < 60 \text{ GeV}.$

65 See Figs. 1, 3, 4, 5 of DECAMP 911 for excluded regions for the masses and mixing angles in general two-doublet models.

⁶⁶ AKRAWY 90P limit is valid for any H^0 having $\Gamma(Z \rightarrow H^0 Z^*)$ more than 0.57 times that for the Standard Higgs boson

 67 DAVIER 89 give excluded region in m_{H^0} -x plane for m_{H^0} ranging from 1.2 MeV to 50

 68 SNYDER 89 give limits on B(B $\rightarrow~H^0$ X)-B(H^0 $\rightarrow~e^+e^-)$ for 100 $<~m_{H^0}~<$ 200 MeV, cτ < 24 mm.

⁶⁹ First order QCD correction included with $\alpha_s \approx 0.2$. Their figure 4 shows the limits vs.

 70 ALBRECHT 85.1 found no mono-energetic photons in both arphi(1S) and arphi(2S) radiative decays in the range 0.5 GeV $< E(\gamma) <$ 4.0 GeV with typically BR< 0.01 for $\Upsilon(1S)$ and BR< 0.02 for $\Upsilon(2S)$ at 90% CL. These upper limits are 5–10 times the prediction of the standard Higgs-doublet model. The quoted 90% limit B($\Upsilon(1S) \to H^0 \gamma$) $< 1.5 \times 10^{-3}$ at $E(\gamma)=1.07$ GeV contradicts previous Crystal Ball observation of $(4.7\pm1.1)\times10^{-3}$; see their reference 3. Their figure 8a shows the upper limits of x^2 as a function of $E(\gamma)$ by assuming no QCD corrections. We used $m_{H^0} = m_{\Upsilon} (1 - 2E(\gamma)/m_{\Upsilon})^{1/2}$.

H₁ (Higgs Boson) MASS LIMITS In Supersymmetric Models

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars $[H_1^0$ and H_2^0 , where we define $m_{H_1^0} < m_{H_2^0}^{0}$.

a pseudoscalar (A^0) , and a charged Higgs pair (H^\pm) . H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the theory which can be chosen to be m_{A0} and $\tan \beta = \nu_2/\nu_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \le$

 m_Z , $m_{H_2^0} \ge m_Z$, $m_{A^0} \ge m_{H_1^0}$, and $m_{H^{\pm}} \ge m_W$. However, as described in the "Note on Supersymmetry," recent calculations of one-loop radiative corrections show that these relations may be violated. Many experimental analyses have not taken into account these corrections; footnotes indicate when these corrections are included. The results assume no invisible H^0 or A^0 decays.

 71 ABREU 98E search for $e^+e^- oup H_0^1$ A^0 in the final state $b\bar{b}b\bar{b}$ and $q\bar{q}\tau^+\tau^-$ at $\sqrt{s}=161$ –172 GeV. The results from the SM Higgs search described in the same paper are also used to set these limits. Two-loop radiative corrections are included with $m_{\mathrm{top}}=1$ 175 GeV, $M_{SUSY} = 1$ TeV, and maximal scalar top mixings.

⁷²BARATE 97P search for $e^+e^- o H_1^0 A^0$ in the final state $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$ at \sqrt{s} = 130-172 GeV and combine with BARATE 970 limit on $e^+e^- \rightarrow H_1^0 Z$. Two-loop radiative corrections are included with $m_{\mathrm{top}} = 175$ GeV and $M_{\mathrm{SUSY}} = 1$ TeV, and maximal scalar top mixings. The invisible decays $H_1^0 \to \tilde{\chi}^0 \tilde{\chi}^0$ are not allowed in the analysis, as ruled out in the relevant kinematic region by BUSKULIC 96K.

73 ACCIARRI 97N search for $e^+e^- \rightarrow H_1^0 A^0$ in four-jet final states at $\sqrt{s}=130$ –172 GeV. Cross-section limits are obtained for $|m_{H_1^0}-m_{A^0}|\approx$ 0, 10, and 20 GeV.

 74 ALEXANDER 97 search for $Z \rightarrow H_1^0\,Z^*$ and $Z \rightarrow H_1^0\,A^0$ and use Γ_Z (nonstandard) < 13.9 MeV. Radiative corrections using two-loop renormalization group equations are included with $m_{\tilde{t}} <$ 195 GeV and the MSSM parameter space is widely scanned. Possible Invisible decay mode $H_1^0 \to \widetilde{\chi}^0 \widetilde{\chi}^0$ is included in the analysis.

75 ABREU 95H search for $\hat{Z} \rightarrow H_1^0 Z^*$ and $Z \rightarrow H_1^0 A^0$. Two-loop corrections are included with m_t =170 GeV, $m_{\widetilde{t}}$ =1 TeV. Including only one-loop corrections does not change the

 76 ROSIEK 95 study the dependence of $m_{H_1^0}$ limit on various supersymmetry parameters.

They argue that H_1^0 as light as 25 GeV is not excluded by ADRIANI 92G data in the region $m_{A^0}\sim 60$ GeV if $m_{\widetilde{t}}\lesssim 200$ GeV and $\widetilde{t}_L\cdot\widetilde{t}_R$ mixing is large. 77 ABREU 940 study $H_1^0A^0\to$ four Jets and combine with ABREU 94G analysis. The

limit applies if the H_1^0 A^0 mass difference is <4 GeV.

⁷⁸ AKERS 94I search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections are included with $m_t <$ 200 GeV, $m_{\widetilde{t}} <$ 1 TeV. See Fig. 10 for limits for $\tan \beta <$ 1.

⁷⁹BUSKULIC 93I search for $Z \rightarrow H_1^0 Z^*$ and $Z \rightarrow H_1^0 A^0$. One-loop corrections are Included with any m_t , $m_{\tilde{t}} > m_t$;

⁸⁰ ABREU 92J searched for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$ with H_1^0 , $A^0 \to \tau \tau$ or jet-jet.

Small mass values are excluded by ABREU 91B. 81 ADRIANI 92G search for $Z \rightarrow H_1^0 Z^*$, $Z \rightarrow H_1^0 A^0 \rightarrow 4b$, $bb\tau\tau$, 4τ , 6b (via $H^0 \rightarrow H_1^0 A^0 \rightarrow H_1^0 A$ A^0A^0), and include constraints from $\Gamma(Z)$. One-loop corrections to the Higgs potential are included with 90< m_{t} <250 GeV, m_{t} < $m_{\widetilde{t}}$ <1 TeV.

⁸² ABREU 91B result is based on negative search for $Z \rightarrow H_1^0 f \overline{f}$ and the limit on invisible Z width $\Gamma(Z \rightarrow H_1^0 A^0) < 39$ MeV (95%CL), assuming $m_{A^0} < m_{H_1^0}$.

83 ABREU 91B result obtained by combining with analysis of ABREU 901.

- ⁸⁴ AKRAWY 91C result from $Z \rightarrow H_1^0 A^0 \rightarrow 4$ jet or $\tau^+ \tau^- JJ$ or 4τ and $Z \rightarrow H_1^0 Z^*$ $(H_0^0 \to q\bar{q}, Z^* \to \nu\bar{\nu}\, \sigma\, r\, e^+e^-\, \sigma\, \mu^+\mu^-)$. See paper for the excluded region for the case $\tan \beta < 1$. Although these limits do not take into account the one-loop radiative corrections, the authors have reported unpublished results including these corrections and showed that the excluded region becomes larger.
- 85 BLUEMLEIN 91 excluded certain range of $an\!eta$ for $m_{H_1^0} <$ 120 MeV, $m_{\mathcal{A}^0} <$ 80 MeV.
- ⁸⁶ DECAMP 911 searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to 4$ jets or $\tau \tau j j$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied top and squark masses.
- 87 ABREU 90E searched for $Z \rightarrow H_1^0 A^0$ and $Z \rightarrow H_1^0 Z^*$. $m_{H_1^0} < 210$ MeV is not excluded by this analysis.
- ⁸⁸ ADEVA 90R result is from $Z \to H_1^0 A^0 \to 4$ jet or $\tau \tau j j$ or 4τ and $Z \to H_1^0 Z^*$. Some region of $m_{H_1^0} < 4$ GeV is not excluded by this analysis.
- ⁸⁹ DECAMP 90E look for $Z \to H_1^0 A^0$ as well as $Z \to H_1^0 \ell^+ \ell^-$, $Z \to H_1^0 \nu \overline{\nu}$ with 18610 Z decays. Their search includes signatures in which H_1^0 and A^0 decay to $\gamma\gamma$, e^+e^- , $\mu^+\mu^-$, $\tau^+\tau^-$, or $q\overline{q}$. See their figures of $m_{H_1^0}$ vs. $\tan\!eta$.
- 90 DECAMP 90H is similar to DECAMP 90E but with 25,000 Z decays. 91 DECAMP 90M looked for $Z \rightarrow H^0\ell\ell$, where H_1^0 decays outside the detector. This excludes a region in the $(m_{H^0}, \tan\beta)$ plane centered at $m_{H^0}=50$ MeV, $\tan\beta=0.5$. This limit together with DECAMP 90E result excludes $m_{H^0_1}<3$ GeV for any $\tan\beta$.

A⁰ (Pseudoscalar Higgs Boson) MASS LIMITS in Supersymmetric Models

Limits on the A^0 mass from e^+e^- collisions arise from direct searches in the $e^+e^-\to A^0\,H_1^0$ channel and indirectly from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the "Note on Supersymmetry," at the one-loop level and in the simplest cases, these relations depend on the masses of the t quark and \tilde{t} squarks. The limits are weaker for larger t and \tilde{t} masses, while they increase with the inclusion of two-loop radiative corrections. Some specific examples of these dependences are provided in the footnotes to the listed papers.

- 92 ABREU 98E search for $e^+\,e^-\to\,H_1^0\,A^0$ in the final state $b\,\overline{b}\,b\,\overline{b}$ and $q\,\overline{q}\,\tau^+\tau^-$ at $\sqrt{s}=161-172$ GeV. The results from the SM Higgs search described in the same paper are also used to set these limits. Two-loop radiative corrections are included with $m_{\rm top}=$ 175 GeV, $M_{\mbox{SUSY}}=1\,\mbox{TeV}$, and maximal scalar top mixings.
- 93 BARATE 97P search for $e^+e^- \rightarrow H_1^0 A^0$ in the final state $b \overline{b} b \overline{b}$ and $b \overline{b} \tau^+ \tau^-$ at \sqrt{s} = 130–172 GeV and combine with BARATE 970 limit on e⁺ e⁻ \rightarrow $H_{0}^{0}Z$. Two-loop radiative corrections are included with $m_{\mathrm{top}}=$ 175 GeV and $M_{\mathrm{SUSY}}=$ 1 TeV, and maximal scalar top mixings. The invisible decays $H_1^0 \to \widetilde{\chi}^0 \widetilde{\chi}^0$ are not allowed in the analysis, as ruled out in the relevant kinematic region by BUSKULIC 96K.
- 94 ACCIARRI 97N search for $e^+e^- \rightarrow H_1^0 A^0$ in four-jet final states at $\sqrt{s}=130$ –172 GeV. Cross-section limits are obtained for $|m_{H_1^0} - m_{A^0}| = 0$, 10, and 20 GeV.
- 95 ALEXANDER 97 search for $Z\to H_1^0Z^*$ and $Z\to H_1^0A^0$ and use Γ_Z (nonstandard) < 13.9 MeV. Radiative corrections using two-loop renormalization group equations are included with $m_{\tilde{t}}<$ 195 GeV and the MSSM parameter space is widely scanned. Possible invisible decay mode $H_1^0 \to \widetilde{\chi}^0 \widetilde{\chi}^0$ is included in the analysis. The limit improves to 44 GeV for $\tan\!\beta \gtrsim$ 1.5, but goes to 0 for $\tan\!\beta <$ 0.9 and $m_t >$ 195 GeV.
- 44 GeV for tanh \lesssim 1.5, but goes to 0 for tanh < 0.9 and m_t > 195 GeV.

 96 KEITH 97 uses Tevatron data on $t\bar{t}$ production to estimate $B(t \rightarrow H^+b) < 0.3$ at 95%CL. The resulting constraints on m_{H^+} and the one-loop MSSM relation between m_{H^+} and m_{A^0} give rise to the limit shown on m_{A^0} .

 97 ABREU 95H search for $Z \rightarrow H_1^0 Z^*$ and $Z \rightarrow H_1^0 A^0$. One-loop corrections are included with $m_t = 170$ GeV, $m_{\tilde{t}} = 1$ TeV. The limit becomes weak for larger m_t : at $m_t = 190$ GeV, the limit is 14 GeV. The limit at $m_t = 170$ GeV would increase to 39 GeV

- If two-loop radiative corrections were included. $m_{\widetilde{t}}$ and $m_{\widetilde{\widetilde{t}}}$ dependences are shown in
- 98 ABREU 940 study $H_1^0A^0 \rightarrow$ four jets and combine with ABREU 94G analysis. The limit applies if the H_1^{0} - A^{0} mass difference is <4 GeV.
- ⁹⁹ AKERS 94I search for $Z \rightarrow H_1^0 Z^*$ and $Z \rightarrow H_1^0 A^0$. One-loop corrections are included with $m_t < 200$ GeV, $m_{\tilde{t}} < 1$ TeV. See Fig. 10 for limits for $\tan \beta < 1$.
- 100 BUSKULIC 931 search for $Z \to H_1^0 Z^*$ and $Z \to H_1^0 A^0$. One-loop corrections to the Higgs potential are included with any $m_{\tilde{t}}, m_{\tilde{t}} > m_{\tilde{t}}$. For $m_{\tilde{t}} = 140$ GeV and $m_{\tilde{t}} = 1$ TeV, the limit is $m_{A0} > 45$ GeV. Assumes no invisible H^0 or A^0 decays.

- 101 ELLIS 93 analyze possible constraints on the MSSM Higgs sector by electroweak precision measurements and find that m_{A0} is not constrained by the electroweak data.

 102 ABREU 921 searched for $Z \rightarrow H_0^1 Z^*$ and $Z \rightarrow H_1^0 A^0$ with $H_1^0 A^0 \rightarrow \tau \tau$ or jet-jet. Small mass values are excluded by ABREU 91B.

 103 ADRIANI 926 search for $Z \rightarrow H_1^0 Z^*$, $Z \rightarrow H_1^0 A^0 \rightarrow 4b$, $bb\tau \tau$, 4τ , 6b (via $H^0 \to A^0 A^0$), and include constraints from $\Gamma(Z)$. One-loop corrections are included with $90 < m_t < 250$ GeV, $m_t < m_{\widetilde t} < 1$ TeV. The region $m_{A^0} < 11$ GeV is allowed if $42 < m_{\widetilde H^0} < 62$ GeV, but is excluded by other experiments.
- 104 BUSKULIC 92 limit is from $\Gamma(Z)$, $Z\to H_1^0Z^*$, and $Z\to H_1^0A^0$. The limit is valid for any $m_{H_1^0}$ below the the theoretical limit $m_{H_1^0}<64$ GeV which holds for $m_{A^0}\sim 0$ in
- the minimal supersymmetric model. One-loop radiative corrections are included. 105 AKRAWY 91C result from $Z \to H_1^0 A^0 \to 4$ jet or $\tau^+ \tau^- jj$ or 4τ . See paper for the excluded region for the case $\tan \beta < 1$. 106 DECAMP 91I searched for $Z \to H_1^0 Z^*$, and $Z \to H_1^0 A^0 \to 4$ jets or $\tau \tau jj$ or $3A^0$. Their limits take into account the one-loop radiative corrections to the Higgs potential with varied top and squark masses. For $m_t = 140$ GeV and $m_{\widetilde{q}} = 1$ TeV, the limit is $m_t = 21$ GeV. $m_{A^0} > 31 \text{ GeV}.$
- 107 ABREU 90E searched $Z \rightarrow H_1^0 A^0$ and $Z \rightarrow H_1^0 Z^*$. $m_{A^0} <$ 210 MeV is not excluded
- 108 ADEVA 90R result is from $Z \to H_1^0 A^0 \to 4$ jet or $\tau \tau j j$ or 4τ and $Z \to H_1^0 Z^*$. Some region of $m_{A^0} < 5$ GeV is not excluded by this analysis.

MASS LIMITS for Associated Higgs Production in e^+e^- Interactions

In multi-Higgs models, associated production of Higgs via virtual or real Z in e^+e^- annihilation, $e^+e^-\to H_1^0H_2^0$, is possible if H_1^0 and H_2^0 have opposite CP eigenvalues. Limits are for the mass of the heavier Higgs H_2^0 in two-doublet models.

Higgs Bosons — H^0 and H^{\pm}

- ^{114}LOW 89 assume that H_1^0 escapes the detector. The limit is for maximal mixing. A reduced limit of 24 GeV is obtained for the case $H_2^0 \rightarrow H_1^0 f \overline{f}$. Limits for a Higgs-triplet model are also discussed. $E_{\text{CM}}^{\text{ee}} = 50\text{--}60.8 \text{ GeV}.$
- $^{115}\,\mathrm{The}$ limit assumes maximal mixing and that H_{1}^{0} escapes the detector.
- 116 ASH 85 assumes that H_1^0 escapes undetected. The bound applies up to a mixing sup-

H[±] (Charged Higgs) MASS LIMITS

Most of the following limits assume $B(H^+ \rightarrow \tau^+ \nu) + B(H^+ \rightarrow c\overline{s}) = 1$. DE-CAMP 901, BEHREND 87, and BARTEL 86 assume $B(H^+ \rightarrow \tau^+ \nu) + B(H^+ \rightarrow \tau^+ \nu)$ $c\overline{s}$) + B($H^+ \rightarrow c\overline{b}$) = 1. All limits from Z decays as well as ADACHI 90B assume that H^+ has weak isospin $T_3 = +1/2$.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review D54 1 (1996)) Edition of this Review.

The limits are also applicable to pointlike techni-pions. For a discussion of techniparticles, see EICHTEN 86.

In the following tan eta is the ratio of the two vacuum expectation values in the twodoublet model

85

140 BEHREND

142 BARTEL

- 119 ACCIARRI 97F give a limit $m_{H^+}>2.6$ taneta GeV (90%CL) from their limit on the exclusive $B \rightarrow \tau \nu_{\tau}$ branching ratio.
- 120 AMMAR 978 measure the Michel parameter ρ from $\tau \to e \nu \nu$ decays and assmes e/μ universality to extract the Michel η parameter from $\tau \to \mu \nu \nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model $m_{H^+} > 0.97$ tan β GeV (90% CL).
- 121 COARASA 97 reanalyzed the constraint on the $(m_{H^\pm}, \tan\beta)$ plane derived from the inclusive $B \to \tau \nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- 122 GUCHAIT 97 studies the constraints on $m_{H^{\pm}}$ set by Tevatron data on $\ell \tau$ final states in $t\bar{t} \rightarrow (Wb)(Hb), W \rightarrow \ell\nu, H \rightarrow \tau\nu_{\tau}$. See Fig. 2 for the excluded region.
- 123 MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_{\rm C} \to \tau \nu_{\tau}$ background to $B_{\rm U} \to \tau \nu_{\tau}$ decays. Stronger limits are obtained.
- 124 STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^+} > 1.5 \tan\beta$ GeV (90% CL) for a two-doublet model. See also STAHL 94. 125 ABE 96G search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at $E_{\rm c}$
- 1.8 TeV. For the currently observed value of the top mass, the search is not sensitive enough to exclude a charged Higgs boson of any mass. 126 ALEXANDER 961 search for the final states $H^+H^- \to \tau \nu_{\tau} \tau \nu_{\tau}$, $\tau \nu_{\tau} c\bar{s}$, $c\bar{s}\bar{c}s$. Limit for $B(\tau \nu_{\tau}) = 1 \text{ is 45.5 GeV}.$
- 127 ALAM 95 measure the inclusive $b \to s \gamma$ branching ratio at $\Upsilon(4S)$ and give B(b s_{γ})< 4.2 × 10⁻⁴ (95% CL), which translates to the limit m_{H^+} >[244 + 63/(tan β)^{1.3}] GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this
- 128 BUSKULIC 95 give a limit $m_{H^+} > 1.9 \tan \beta$ GeV (90%CL) for Type-II models from $b \rightarrow$ $\tau \nu_{\tau} X$ branching ratio, as proposed in GROSSMAN 94.

- 129 ABREU 940 study $H^+H^-\to c\bar s\bar s\bar s\bar s$ (four-jet final states) and $H^+H^-\to \tau\nu_\tau\tau\nu_\tau$. Limit for B $(\tau\nu_\tau)$ = 1 is 45.4 GeV.
- 130 HEWETT 93 and BARGER 93 analyze charged Higgs contribution to $b
 ightarrow s \gamma$ in twodoublet models with the CLEO limit $B(b\to s\gamma)<8.4\times10^{-4}$ (90% CL) and find lower limits on m_{H^\pm} in the type of model (model II) in which different Higgs are responsible for up-type and down-type quark masses. HEWETT 93 give $m_{H^\pm}>110$ (70) GeV for m_t >150 (120) GeV using m_b = 5 GeV. BARGER 93 give m_{H^+} >155 GeV for m_t = 150 GeV using m_b = 4.25 GeV. The authors employ leading logarithmic QCD corrections and emphasize that the limits are quite sensitive to m_b .
- 131 BELANGER 93 make an analysis similar to BARGER 93 and HEWETT 93 with an improved CLEO limit $B(b\to s\gamma)<5.4\times10^{-4}$ (95%CL). For the Type II model, the limit $m_{H^+}>540$ (300) GeV for $m_t>150$ (120) GeV is obtained. The authors employ leading logarithmic QCD corrections.
- 132 ADRIANI 92G limit improves to 44 GeV if B($au
 u_{ au}$) > 0.4.
- 133 Studled $H^+H^- \rightarrow (\tau \nu) + (\tau \nu)$, $H^+H^- \rightarrow (\tau \nu) + \text{hadrons}$, $H^+H^- \rightarrow \text{hadrons}$.
- ¹³⁴DECAMP 92 limit improves to 45.3 GeV for B($\tau\nu$)=1.
- 135 YUZUKI 91 assume photon exchange. The limit is valid for any decay mode $H^+
 ightarrow e
 u_{
 m s}$ $\mu\nu$, $\tau\nu$, $q\overline{q}$ with five flavors. For B($\ell\nu$) = 1, the limit improves to 25.0 GeV.
- $^{136}\,\mathrm{ABREU}$ 908 limit improves to 36 GeV for $\mathrm{B}(\tau\nu)=1.$
- $137\,\mathrm{ADACHI}$ 908 limit improves to 22 GeV for B(au
 u) = 0.6.
- $^{138} \, \mathrm{ADEVA}$ 90M limit improves to 42.5 GeV for $\mathrm{B}(\tau \nu) = 1.$
- $^{139}\,\mathrm{AKRAWY}$ 90K limit improves to 43 GeV for $\mathrm{B}(\tau\,\nu)=$ 1.
- 140 If B(H+ $\rightarrow \tau^+ \nu$) = 100%, the DECAMP 901 limit improves to 43 GeV.
- 141 SMITH 90B limit applies for $v_2/v_1 > 2$ in a model in which H_2 couples to u-type quarks
- 142 Studied $H^+H^- \rightarrow (\tau \nu) + (\tau \nu), H^+H^- \rightarrow (\tau \nu) + \text{hadrons.}$ Search for muon opposite hadronic shower.

MASS LIMITS for H±± (doubly-charged Higgs boson)

VALUE (GeV)	CL%	DOCUMENT ID		TECN	<u>COMMENT</u>
>45.6	95	143 ACTON	92M	OPAL	
• • • We do not use	the follow	ving data for averag	es, fits	, limits,	etc. • • •
		144 GORDEEV	97	SPEC	muonium conversion
		¹⁴⁵ ASAKA	95	THEO

>25.5	95	146 ACTON			$T_3(H^{++})=0$
none 6.5-36.6	95	¹⁴⁷ SWARTZ	90	MRK2	$T_3(H^{++}) = +1$
none 7.3-34.3	95	147 SWARTZ			$T_3(H^{++}) = 0$

- ¹⁴³ACTON 92M limit assumes $H^{\pm\pm} \rightarrow \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.
- 144 GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}}>210$ GeV if the Yukawa copulings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- 145 ASAKA 95 point out that H++ decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does
- 146 ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

09E ED1 C2 1

ARREII

147 SWARTZ 90 assume $H^{\pm\pm} \rightarrow \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

Heavy Bosons Other Than Higgs Bosons, Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons.

WR (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 898, and COLANGELO 91. $g_R=g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 898. Limits on the W_L - W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 1 The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from KI-Kg mass difference.
- 2 STAHL 97 limit is from fit to au-decay parameters.
- 3 ALLET 96 measured polarization-asymmetry correlaton in $^{12}{\rm N}\beta^+$ decay. The listed limit assumes zero $\it L-R$ mixing.
- KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_{\nu} \cdot \sigma_{\rho} \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.
- of polarized neutrons. Zero mixing assumed. See any nozine 1307 775. KUZNETSOV 948 limit is from measurements of the asymmetry $\langle \vec{p}\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. 6 BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t =200 GeV and slightly improves for smaller m_t .
- 7 SEVERIJNS 93 measured polarization-asymmetry correlation in $^{107} \ln \beta^+$ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum. §IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+ \nu_\mu$ decay and obtain ξP_{μ} > 0.990 (90%CL). If W_R couples to $u\bar{s}$ with full weak strength ($V_{u\bar{s}}^R$ =1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general
- $|V_{us}^R|^2=1-|V_{ud}^R|^2$. 9 POLAK 928 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming C=0. Supersedes POLAK 91.
- 10 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
- 11 COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
- 12 POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming 5=0. Superseded by POLAK 92B.
- 13 BARBIERI 898 limit holds for $m_{
 u_R} \le 10$ MeV
- 14 LANGACKER 898 limit is for any $_{PR}^{}$ mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
- class or right-handed quark mixing matrices. 15 BALKE 88 limit is for $m_{\nu_e R} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy. 16 JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+
- 17 STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e⁺ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
- ¹⁸ BERGSMA 83 set limit m_{W_2}/m_{W_1} >1.9 at CL = 90%.

 19 CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from V-A at the high momentum end of the decay ${
m e^+}$ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R}~>$ 240 GeV. Assumes a light right-handed neutrino.

²⁰BEALL 82 limit is obtained assuming that W_R contribution to $K_I^0 - K_S^0$ mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L - W_R Mixing Angle ζ Lighter mass eigenstate $W_1 = W_L \cos \zeta - W_R \sin \zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

VALUE CL% **DOCUMENT ID** TECN COMMENT • • • We do not use the following data for averages, fits, limits, etc. • • • ²¹ BARENBOIM 97 < 0.0333 RVUE μ decay ²² MISHRA < 0.04 CCFR VN scattering 92 -0.0006 to 0.0028 ²³ AQUINO RVUE 90 24 BARBIERI [none 0.00001-0.02] 89B ASTR SN 1987A 25 JODIDIO < 0.040 ELEC ²⁵ JODIDIO -0.056 to 0.040 86 ELEC

 21 The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from

²²MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_{\mu}$ N ightarrow $\overline{\nu}_{\mu}$ X events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m_{W_1}^2/m_{W_2}^2)$ < 0.0015. The limit is independent of ν_R mass.

23 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed 24 BARBIERI 898 limit holds for $m_{\nu_R} \leq$ 10 MeV.

²⁵ First JODIDIO 86 result assumes $m_{W_R} = \infty$, second is for unconstrained m_{W_R} .

THE W' SEARCHES

Written October 1997 by K.S. Babu, C. Kolda, and J. March-Russell (IAS/Princeton).

Any electrically charged gauge boson outside of the Standard Model is generically denoted W'. A W' always couples to two different flavors of fermions, similar to the W boson. In particular, if a W' couples quarks to leptons it is a leptoquark

The most attractive candidate for W' is the W_R gauge boson associated with the left-right symmetric models [1]. These models seek to provide a spontaneous origin for parity violation in weak interactions. Here the gauge group is extended to $SU(3)_C \times SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ with the Standard Model hypercharge identified as $Y = T_{3R} + (B-L)/2$, T_{3R} being the third component of $SU(2)_R$. The fermions transform under the gauge group in a left-right symmetric fashion: $q_L(3, 2, 1, 1/3) +$ $q_R(3,1,2,1/3)$ for quarks and $\ell_L(1,2,1,-1) + \ell_R(1,1,2,-1)$ for leptons. Note that the model requires the introduction of right-handed neutrinos, which can facilitate the see-saw mechanism for explaining the smallness of the ordinary neutrino masses. A Higgs bidoublet $\Phi(1,2,2,0)$ is usually employed to generate quark and lepton masses and to participate in the electroweak symmetry breaking. Under left-right (or parity) symmetry, $q_L \leftrightarrow q_R$, $\ell_L \leftrightarrow \ell_R$, $W_L \leftrightarrow W_R$ and $\Phi \leftrightarrow \Phi^{\dagger}$.

After spontaneous symmetry breaking, the two W bosons of the model, W_L and W_R , will mix. The physical mass eigenstates are denoted as

$$W_1 = \cos \zeta W_L + \sin \zeta W_R, \qquad W_2 = -\sin \zeta W_L + \cos \zeta W_R$$
 (1)

with W_1 identified as the observed W boson. The most general Lagrangian that describes the interactions of the $W_{1,2}$ with the quarks can be written as [2]

$$\mathcal{L} = -\frac{1}{\sqrt{2}} \overline{u} \gamma_{\mu} \left[\left(g_L \cos \zeta \, V^L P_L - g_R e^{i\omega} \sin \zeta \, V^R P_R \right) W_1^{\mu} \right.$$
$$+ \left. \left(g_L \sin \zeta \, V^L P_L + g_R e^{i\omega} \cos \zeta \, V^R P_R \right) W_2^{\mu} \right] d + h.c.(2)$$

where $g_{L,R}$ are the SU(2)_{L,R} gauge couplings, $P_{L,R} = (1 \mp \gamma_5)/2$ and $V^{L,R}$ are the left- and right-handed CKM matrices in the quark sector. The phase ω reflects a possible complex mixing parameter in the W_L - W_R mass-squared matrix. Note that there is CP violation in the model arising from the right-handed currents even with only two generations. The Lagrangian for leptons is identical to that for quarks, with the replacements $u \to \nu$, $d \to e$ and the identification of $V^{L,R}$ with the CKM matrices in the leptonic sector.

If parity invariance is imposed on the Lagrangian, then $g_L = g_R$. Furthermore, the Yukawa coupling matrices that arise from coupling to the Higgs bidoublet Φ will be Hermitian. If in addition the vacuum expectation values of Φ are assumed to be real, the quark and lepton mass matrices will also be Hermitian, leading to the relation $V^L = V^R$. Such models are called manifest left-right symmetric models and are approximately realized with a minimal Higgs sector [3]. If instead parity and CP are both imposed on the Lagrangian, then the Yukawa coupling matrices will be real symmetric and, after spontaneous CP violation, the mass matrices will be complex symmetric. In this case, which is known in the literature as pseudo-manifest left-right symmetry, $V^L = (V^R)^*$.

Indirect constraints: In minimal version of manifest or pseudo-manifest left-right symmetric models with $\omega = 0$ or π , there are only two free parameters, ζ and M_{W_2} , and they can be constrained from low energy processes. In the large M_{W_2} limit, stringent bounds on the angle ζ arise from three processes. (i) Nonleptonic K decays: The decays $K \to 3\pi$ and $K \rightarrow 2\pi$ are sensitive to small admixtures of right-handed currents. Assuming the validity of PCAC relations in the Standard Model it has been argued in Ref. 4 that the success in the $K \to 3\pi$ prediction will be spoiled unless $|\zeta| < 4 \times 10^{-3}$. (ii) $b \rightarrow s\gamma$: The amplitude for this process has an enhancement factor m_t/m_h relative to the Standard Model and thus can be used to constrain ζ yielding the limit $-0.01 \le \zeta \le 0.003$ [5]. (iii) Universality in weak decays: If the right-handed neutrinos are heavy, the right-handed admixture in the charged current will contribute to β decay and K decay, but not to the μ decay. This will modify the extracted values of V_{ud}^L and V_{us}^L . Demanding that the difference not upset the three generation unitarity of the CKM matrix, a bound $|\zeta| \leq 10^{-3}$ has been

If the ν_R are heavy, leptonic and semileptonic processes do not constrain ζ since the emission of ν_R will not be kinematically allowed. However, if the ν_R is light enough to be emitted in μ decay and β decay, stringent limits on ζ do arise. For example, $|\zeta| \leq 0.039$ can be obtained from polarized μ decay [7] in the large M_{W_2} limit of the manifest left-right model. Alternatively, in the $\zeta = 0$ limit, there is a constraint $M_{W_2} \geq 484$ GeV from direct W_2 exchange. For the constraint on the case in which M_{W_2} is not taken to be heavy, see Ref. 2. There are also cosmological and astrophysical constraints on M_{W_2} and ζ in scenarios with a light ν_R . During nucleosynthesis the

process $e^+e^- \to \nu_R \overline{\nu}_R$, proceeding via W_2 exchange, will keep the ν_R in equilibrium leading to an overproduction of ⁴He unless M_{W_2} is greater than about 1 TeV [8]. Likewise the ν_{eR} produced via $e_R^- p \rightarrow n \nu_R$ inside a supernova must not drain too much of its energy, leading to limits $M_{W_2} > 16$ TeV and $|\zeta| \leq 3 \times 10^{-5}$ [9]. Note that models with light ν_R do not have a see-saw mechanism for explaining the smallness of the neutrino masses, though other mechanisms may arise in variant models [10].

The mass of W_2 is severely constrained (independent of the value of ζ) from K_L - K_S mass-splitting. The box diagram with exchange of one W_L and one W_R has an anomalous enhancement and yields the bound $M_{W_2} \geq 1.6$ TeV [11] for the case of manifest or pseudo-manifest left-right symmetry. If the ν_R have Majorana masses, another constraint arises from neutrinoless double β decay. Combining the experimental limit from $^{76}\mathrm{Ge}$ decay with arguments of vacuum stability, a limit of $M_{W_2} \ge 1.1 \text{ TeV has been obtained [12]}.$

Direct search limits: Limits on M_{W_2} from direct searches depend on the available decay channels of W_2 . If ν_R is heavier than W_2 , the decay $W_2^+ \to \ell_R^+ \nu_R$ will be forbidden kinematically. Assuming that ζ is small, the dominant decay of W_2 will be into dijets. UA2 [13] has excluded a W_2 in the mass range of 100 to 251 GeV in this channel. $D \varnothing$ excludes the mass range of 340 to 680 GeV [14], while CDF excludes the mass range of 300 to 420 GeV for such a W_2 [15]. If ν_R is lighter than W_2 , the decay $W_2^+ \to e_R^+ \nu_R$ is allowed. The ν_R can then decay into $e_RW_R^*$, leading to an eejj signature. DØ has a limit of $M_{W_2} > 720$ GeV if $m_{\nu_R} \ll M_{W_2}$; the bound weakens, for example, to 650 GeV for $m_{\nu_R} = M_{W_2}/2$ [16]. CDF finds $M_{W_2} > 652$ GeV if ν_R is stable and much lighter than W_2 [17]. All of these limits assume manifest or pseudo-manifest left-right symmetry. See [16] for some variations in the limits if the assumption of left-right symmetry is relaxed.

•Alternative models: W' gauge bosons can also arise in other models. We shall briefly mention some such popular models, but for details we refer the reader to the original literature. The alternate left-right model [18] is based on the same gauge group as the left-right model, but arises in the following way: In E_6 unification, there is an option to identify the righthanded down quarks as $SU(2)_R$ singlets or doublets. If they are $SU(2)_R$ doublets, one recovers the conventional left-right model; if they are singlets it leads to the alternate left-right model. A similar ambiguity exists in the assignment of lefthanded leptons; the alternate left-right model assigns them to a (1,2,2,0) multiplet. As a consequence, the ordinary neutrino remains exactly massless in the model. One important difference from the usual left-right model is that the limit from the K_L - K_S mass difference is no longer applicable, since the d_R do not couple to the W_R . There is also no limit from polarized μ decay, since the $SU(2)_R$ partner of e_R can receive a large Majorana mass. Other W' models include the un-unified Standard Model of Ref. 19 where there are two different SU(2) gauge groups,

one each for the quarks and leptons; models with separate SU(2) gauge factors for each generation [20]; and the SU(3)_C \times $SU(3)_L \times U(1)$ model of Ref. 21.

Leptoquark gauge bosons: The $SU(3)_C \times U(1)_{B-L}$ part of the gauge symmetry discussed above can be embedded into a simple $SU(4)_C$ gauge group [22]. The model then will contain leptoquark gauge boson as well, with couplings of the type $\{(\overline{e}_L\gamma_\mu d_L + \overline{\nu}_L\gamma_\mu u_L)W'^\mu + (L \to R)\}$. The best limit on such leptoquark W' comes from nonobservation of $K_L \to \mu e$, which requires $M_{W'} \geq 1400$ TeV; for the corresponding limits on less conventional leptoquark flavor structures, see Ref. 23. Thus such a W' is inaccessible to direct searches with present machines which are sensitive to vector leptoquark masses of order 300 GeV only.

MASS LIMITS for W' (A Heavy-Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\bar{p} \to W'X$ with W' decaying to the mode indicated in the comments. New decay channels $(e.g., W' \to WZ)$ are assumed to be suppressed. UA1 and UA2 experiments assume that the $t\,\overline{b}$ channel is not open.

- 26 For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.
- 27 ABE 97G search for new particle decaying to dijets.
- ²⁸ ABACHI 95E assume that the decay $W' \rightarrow WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.
- 29 ABE 95M assume that the decay $W'\to WZ$ is suppressed and the (right-handed) neutrino is light, noninteracting, and stable. If $m_{\nu}{=}60$ GeV, for example, the effect on the mass limit is neglibible.
- 30 ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $\Gamma(W')/m_{W'} = \Gamma(W)/m_W$ and $B(W' \rightarrow JJ) = 2/3$. This corresponds to W_R with $m_{\nu_R} > m_{W_R}$ (no leptonic decay) and $W_R \to t \, \overline{b}$ allowed. See their Fig. 4 for limits in the $m_{W'} - \hat{B}(q\overline{q})$ plane.
- 31 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to
- the inclusion of the assumed K factor.

 32 ABE 91F assume leptonic branching ratio of 1/12 for each lepton flavor. The limit from the $e\nu$ ($\mu\nu$) mode alone is 490 (435) GeV. These limits apply to W_R if $m_{\nu_R}\lesssim 15$ GeV and ν_R does not decay in the detector. Cross section limit $\sigma\cdot {\rm B}<(1$ –10) pb is given for $m_{W'}=100$ –550 GeV; see Fig. 2.
- 33 ALITTI 91 search is based on two-jet invariant mass spectrum, assuming B($W' \to q \overline{q}$) = 67.6%. Limit on σ · B as a function of two-jet mass is given in Fig. 7.
- 34 ALBAJAR 89 cross section limit at 630 GeV is $\sigma(W')$ B(e ν) < 4.1 pb (90% CL). 35 See Fig. 5 of ANSARI 87D for the excluded region in the $m_{W'}^{-}[(g_{W'q})^2 \; {\rm B}(W' \to W')]$ $e\overline{\nu}$)] plane. Note that the quantity $(g_{W'g})^2$ B($W' \rightarrow e\overline{\nu}$) is normalized to unity for
- the standard W couplings.
- the standard w couplings.

 36 ARNISON 868 find no excess at large p_T in 148 $W \rightarrow e \nu$ events. Set limit $\sigma \times B(e \nu)$ <10 pb at CL = 90% at $E_{\rm CM}$ = 546 and 630 GeV.

 37 ARNISON 830 find among 47 $W \rightarrow e \nu$ candidates no event with excess p_T . Also set $\sigma \times B(e \nu)$ <30 pb with CL = 90% at $E_{\rm CM}$ = 540 GeV.

THE Z' SEARCHES

Written October 1997 by K.S. Babu, C. Kolda, and J. March-Russell (IAS/Princeton).

If the Standard Model is enhanced by additional gauge symmetries or embedded into a larger gauge group, there will arise new heavy gauge bosons, some of which generically are electrically neutral. Such a gauge boson is called a Z'. Consider the most general renormalizable Lagrangian describing the complete set of interactions of the neutral gauge bosons among themselves and with fermions, which is that of the Standard Model plus the following new pieces [1,2,3]:

$$\begin{split} \mathcal{L}_{Z'} &= -\frac{1}{4} \widehat{F}'_{\mu\nu} \widehat{F}'^{\mu\nu} - \frac{\sin \chi}{2} \widehat{F}'_{\mu\nu} \widehat{F}^{\mu\nu} + \frac{1}{2} \widehat{M}_{Z'}^2 \widehat{Z}'_{\mu} \widehat{Z}'^{\mu} \\ &+ \delta \widehat{M}^2 \, \widehat{Z}'_{\mu} \widehat{Z}^{\mu} - \frac{\widehat{g}'}{2} \sum_{i} \overline{\psi}_{i} \gamma^{\mu} (f_{V}^{i} - f_{A}^{i} \gamma^{5}) \psi_{i} \widehat{Z}'_{\mu} \end{split} \tag{1}$$

where $\widehat{F}_{\mu\nu}, \widehat{F}'_{\mu\nu}$ are the field strength tensors for the hypercharge \hat{B}_{μ} gauge boson and the Z' respectively before any diagonalizations are performed, ψ_i are the matter fields with Z'vector and axial charges f_V^i and f_A^i , and \widehat{Z}_μ is the electroweak Z boson in this basis. (See the Review on "Electroweak Model and Constraints on New Physics" for the Standard Model pieces of the Lagrangian.) The mass terms are assumed to come from spontaneous symmetry breaking via scalar expectation values. The above Lagrangian is general to all abelian and non-abelian extensions, except that $\chi = 0$ for the non-abelian case since then $\widehat{F}'_{\mu\nu}$ is not gauge invariant. Most analyses take $\chi=0$ even for the abelian case.

Going to the physical eigenbasis requires diagonalizing both the gauge kinetic and mass terms, with mass eigenstates denoted Z_1 and Z_2 , where we choose Z_1 to be the observed Z boson. The interaction Lagrangian for Z_1 has the form, to leading order in the mixing angle ξ ($s_W \equiv \sin \theta_W$, etc.):

$$\mathcal{L}_{Z_{1}} = -\frac{e}{2s_{W}c_{W}} \left(1 + \frac{\alpha T}{2} \right) \overline{\psi}_{i} \gamma^{\mu} \left\{ \left(g_{V}^{i} + \xi \tilde{f}_{V}^{i} \right) - \left(g_{A}^{i} + \xi \tilde{f}_{A}^{i} \right) \gamma^{5} \right\} \psi_{i} Z_{1\mu}$$

$$(2)$$

where

$$\xi \simeq \frac{-\cos \chi (\delta \widehat{M}^2 + \widehat{M}_Z^2 s_W \sin \chi)}{\widehat{M}_{Z'}^2 - \widehat{M}_Z^2 \cos^2 \chi + \widehat{M}_Z^2 s_W^2 \sin^2 \chi + 2 \delta \widehat{M}^2 s_W \sin \chi} . \quad (3)$$

We have made the identifications $g_A^i = T_3^i$, $g_V^i = T_3^i - 2Q^i s_*^2$, $\tilde{f}^i_{V,A} = (\widehat{g}' s_W c_W / e \cos \chi) f^i_{V,A}, \text{ and } s^2_W \text{ is identified to be the}$ $s_{M_Z}^2$ defined in the "Electroweak Model and Constraints on New Physics" review. Note that the value of the weak angle that appears in the vector coupling is shifted by the S and Toblique parameters:

$$s_*^2 = s_W^2 + \frac{1}{s_W^2 - c_W^2} \left(\frac{1}{4} \alpha S - c_W^2 s_W^2 \alpha T \right) . \tag{4}$$

Recall that $\rho = 1 + \alpha T$ defines the usual ρ parameter. In the presence of Z-Z' mixing, the oblique parameters receive contributions [4]:

$$\alpha S = 4\xi c_W^2 s_W \tan \chi$$

$$\alpha T = \xi^2 \left(\frac{M_{Z_2}^2}{M_{Z_1}^2} - 1 \right) + 2\xi s_W \tan \chi$$

$$\alpha U = 0$$
(5)

to leading order in small ξ . These contributions are in addition to those coming from top quark and Higgs boson loops in the Standard Model. (This is in contrast to the "Electroweak

Model and Constraints on New Physics" Review in which oblique parameters are defined to be zeró for reference values of m_t and M_H .) Note that nonzero Z-Z' contributions to S arise only in the presence of kinetic mixing.

The corresponding $Z_2\overline{\psi}\psi$ interaction Lagrangian is:

$$\mathcal{L}_{Z_2} = -\frac{e}{2s_W c_W} \overline{\psi}_i \gamma^{\mu} \left\{ \left(h_V^i - g_V^i \xi \right) - \left(h_A^i - g_A^i \xi \right) \gamma^5 \right\} \psi_i Z_{2\mu}$$
(6)

with the following definitions:

$$\begin{split} h_V^i &= \tilde{f}_V^i + \widetilde{s}(T_3^i - 2Q^i) \tan \chi \\ h_A^i &= \tilde{f}_A^i + \widetilde{s}T_3^i \tan \chi \\ \widetilde{s} &= s_W + \frac{s_W^3}{c_W^2 - s_W^2} \left(\frac{1}{4c_W^2} \alpha S - \frac{1}{2} \alpha T\right) \end{split} \tag{7}$$

where the last equation defines a weak angle appropriate for the \mathbb{Z}_2 interactions.

If the Z' charges are generation-dependent, there exist severe constraints in the first two generations coming from precision measurements such as the K_L - K_S mass splitting and $B(\mu \to 3e)$ owing to the lack of GIM suppression in the Z' interactions; however, constraints on a Z' which couples differently only to the third generation are somewhat weaker. (It will be assumed in the Z-pole constraint section that the Z' couples identically to all three generations of matter; all other results are general.) If the new Z' interactions commute with the Standard Model gauge group, then per generation, there are only five independent $Z'\bar{\psi}\psi$ couplings; we can choose them to be \tilde{f}_V^u , \tilde{f}_A^u , \tilde{f}_V^d , \tilde{f}_V^e , and \tilde{f}_A^e . All other couplings can be determined in terms of these, e.g., $\tilde{f}_V^v = (\tilde{f}_V^e + \tilde{f}_A^e)/2$.

Canonical models: One of the prime motivations for an additional Z' has come from string theory in which certain compactifications lead naturally to an E_6 gauge group, or one of its subgroups. E_6 contains two U(1) factors beyond the Standard Model, a basis for which is formed by the two groups U(1) χ and U(1) $_{\psi}$, defined via the decompositions $E_6 \to SO(10) \times U(1)_{\psi}$ and $SO(10) \to SU(5) \times U(1)_{\chi}$; one special case often encountered is U(1) $_{\eta}$ where $Z_{\eta} = \sqrt{\frac{3}{8}}Z_{\chi} + \sqrt{\frac{5}{8}}Z_{\psi}$. The charges of the SM fermions under these U(1)'s, and a discussion of their experimental signals, can be found in Ref. 5.

It is also common to express experimental bounds in terms of a toy Z' usually denoted $Z_{\rm SM}$. This $Z_{\rm SM}$, of arbitrary mass, couples to the SM fermions identically to the usual Z.

Almost all analyses of Z' physics have worked with one of these canonical models and have assumed zero kinetic mixing at the weak scale.

Experimental constraints: There are three primary sets of constraints on the existence of a Z' which will be considered here: precision measurements of neutral-current processes at low energies, Z-pole constraints on Z-Z' mixing, and direct search constraints from production at very high energies. In principle, one usually expects other new states to appear at the same scale as the Z', including its symmetry-breaking sector

and any additional fermions necessary for anomaly cancellation. However, because these states are highly model-dependent, we will not include searches for them, or Z^\prime decays to them, in the bounds that follow.

Low-energy constraints: After the breaking of the new gauge group and the usual electroweak breaking, the Z of the Standard Model can mix with the Z', with mixing angle ξ defined above. As already discussed, this Z-Z' mixing implies a shift in the usual oblique parameters [S,T,U] defined in Eq. (5). Current bounds on S and T translate into stringent constraints on the mixing angle, ξ , requiring $\xi \ll 1$; similar constraints on ξ arise from the LEP Z-pole data. Thus we will only consider the small- ξ limit henceforth.

Whether or not the new gauge interactions are parity violating, stringent constraints can arise from atomic parity violation (APV) and polarized electron-nucleon scattering experiments [6]. At low energies, the effective neutral-current Lagrangian is conventionally written:

$$\mathcal{L}_{\text{NC}} = \frac{G_F}{\sqrt{2}} \sum_{q=u,d} \left\{ C_{1q} (\bar{e} \gamma_\mu \gamma^5 e) (\bar{q} \gamma^\mu q) + C_{2q} (\bar{e} \gamma_\mu e) (\bar{q} \gamma^\mu \gamma^5 q) \right\} . \tag{8}$$

APV experiments are sensitive only to C_{1u} and C_{1d} (see the "Electroweak Model and Constraints on New Physics" Review for the nuclear weak charge, Q_W , in terms of the C_{1q}) where in the presence of the Z and Z':

$$C_{1q} = 2(1 + \alpha T)(g_A^e + \xi \tilde{f}_A^e)(g_V^q + \xi \tilde{f}_V^q) + 2r(h_A^e - \xi g_A^e)(h_V^q - \xi g_V^q)$$
(9)

where $r=(M_{Z_1}/M_{Z_2})^2$. The r-dependent terms arise from Z_2 exchange and can interfere constructively or destructively with the Z_1 contribution. In the limit $\xi=r=0$, this reduces to the Standard Model expression. Polarized electron scattering is sensitive to both the C_{1q} and C_{2q} couplings, again as discussed in the "Electroweak Model and Constraints on New Physics" Review. The C_{2q} can be derived from the expression for C_{1q} with the complete interchange $V \leftrightarrow A$.

Stringent limits also arise from neutrino-hadron scattering. One usually expresses experimental results in terms of the effective 4-fermion operators $(\overline{\nu}\gamma_{\mu}\nu)(\overline{q}_{L,R}\gamma^{\mu}q_{L,R})$ with coefficients $(2\sqrt{2}G_F)\epsilon_{L,R}(q)$. (Again, see the "Electroweak Model and Constraints on New Physics" Review.) In the presence of the Z and Z', the $\epsilon_{L,R}(q)$ are given by:

$$\begin{split} \epsilon_{L,R}(q) = & \frac{1 + \alpha T}{2} \left\{ (g_V^q \pm g_A^q) [1 + \xi (\tilde{f}_V^\nu \pm \tilde{f}_A^\nu)] + \xi (\tilde{f}_V^q \pm \tilde{f}_A^q) \right\} \\ & + \frac{r}{2} \left\{ (h_V^q \pm h_A^q) (h_V^\nu \pm h_A^\nu) - \xi (g_V^q \pm g_A^q) (h_V^\nu \pm h_A^\nu) - \xi (h_V^q \pm h_A^q) \right\} \; . \end{split}$$

$$(10)$$

Again, the r-dependent terms arise from Z_2 -exchange.

Z-pole constraints: Electroweak measurements made at LEP and SLC while sitting on the Z resonance are generally sensitive to Z' physics only through the mixing with the Z unless the Z and Z' are very nearly degenerate, a possibility we ignore.

Constraints on the allowed mixing angle and Z couplings arise by fitting all data simultaneously to the ansatz of Z-Z' mixing. For any observable, \mathcal{O} , the shift in that observable, $\Delta \mathcal{O}$, can be expressed (following the procedure of Ref. 7) as:

$$\frac{\Delta \mathcal{O}}{\mathcal{O}} = \mathcal{A}_{\mathcal{O}}^{S} \alpha S + \mathcal{A}_{\mathcal{O}}^{T} \alpha T + \xi \sum_{i} \mathcal{B}_{\mathcal{O}}^{(i)} \tilde{f}^{i}$$
 (11)

where i runs over the 5 independent $Z'\overline{\psi}\psi$ couplings listed earlier (assuming a Z' couplings commute with the generation and gauge symmetries of the Standard Model; this is the only place where we enforce such a restriction). The coefficients $\mathcal{A}_{\mathcal{O}}^{S,T}$ and $\mathcal{B}_{\mathcal{O}}^{(i)}$, which are functions only of the Standard Model parameters, are given in Table 1. The first 5 observables are directly measured at LEP and SLC, while \overline{A}_e , \overline{A}_b and \overline{A}_c are measured via the asymmetries $\overline{A}_{FB}^{(0,f)} = \frac{3}{4}\overline{A}_e\overline{A}_f$ and $A_{LR}^0 = \overline{A}_e$ as defined in the "Electroweak Model and Constraints on New Physics" Review. As an example, the shift in \overline{A}_e due to Z' physics is given by

$$\frac{\Delta \overline{A}_e}{\overline{A}_e} = -24.9 \,\alpha S + 17.7 \,\alpha T - 26.7 \,\xi \,\tilde{f}_V^e + 2.0 \,\xi \,\tilde{f}_A^e \ . \tag{12}$$

Table 1: Expansion coefficients for shifts in Z-pole observables normalized to the Standard Model value of the observable [7,3].

M_W^2	-0.93	1.43	0	0	0	0	0

High-energy indirect constraints: At $\sqrt{s} < M_{Z_2}$, but off the Z_1 pole, strong constraints on new Z' physics arise from measurements of deviations of asymmetries and leptonic and hadronic cross sections from their Standard Model predictions. These processes are sensitive not only to Z-Z' mixing but also to direct Z_2 exchange primarily through $\gamma-Z_2$ and Z_1-Z_2 interference; therefore information on the Z_2 couplings and mass can be extracted that is not accessible via Z-Z' mixing alone.

Far below the Z_2 mass scale, experiment is only sensitive to the scaled Z_2 couplings $(\sqrt{s}/M_{Z_2}) \cdot h_{V,A}^i$ so the Z_2 mass and overall magnitude of the couplings cannot both be extracted. However as \sqrt{s} approaches M_{Z_2} the Z_2 exchange can no longer be approximated by a contact interaction and the mass and couplings can be simultaneously extracted.

Z' studies done before LEP relied heavily on this approach; see, e.g., Ref. 8. LEP has also done similar work using data

collected above the Z peak; see, e.g., Ref. 9. For indirect Z' searches at future facilities, see, e.g. Refs. 10 and 11.

Direct-search constraints: Finally, high-energy experiments have searched for on-shell Z' (here Z_2) production and decay. Searches can be classified by the initial state off of which the Z' is produced, and the final state into which the Z' decays; we will not include here exotic decays of a Z'. Experiments to date have been sensitive to Z' production via their coupling to quarks $(p\bar{p}$ colliders), to electrons (e^+e^-) or to both (ep).

For a heavy Z' ($M_{Z_2}\gg M_{Z_1}$), the best limits come from $p\overline{p}$ machines via Drell-Yan production and subsequent decay to charged leptons. For $M_{Z_2}>600\,\mathrm{GeV}$, CDF [12] quotes limits on $\sigma(p\overline{p}\to Z_2X)\cdot B(Z_2\to \ell^+\ell^-)<0.04\,\mathrm{pb}$ at 95% C.L. for $\ell=e+\mu$ combined; DØ [13] quotes $\sigma\cdot B<0.025\,\mathrm{pb}$ for $\ell=e$. For $M_{Z_2}<600\,\mathrm{GeV}$, the mass dependence is complicated and one should refer to the original literature. For studies of the search capabilities of future facilities, see e.g. Ref. 10.

If the Z' has suppressed, or no, couplings to leptons (i.e., it is leptophobic) then experimental sensitivities are much weaker. In particular, searches for a Z' via hadronic decays at DØ [14] are able to rule out a Z' with quark couplings identical to those of the Z only in the mass range 365 GeV $< M_{Z_2} < 615$ GeV; CDF [15] cannot exclude even this range. Additionally, UA2 [16] finds $\sigma \cdot B(Z' \to jj) < 11.7$ pb at 90% C.L. for $M_{Z'} > 200$ GeV and more complicated bounds in the range 130 GeV $< M_{Z'} < 200$ GeV.

For a light Z' $(M_{Z'} < M_Z)$ direct searches in e^+e^- colliders have ruled out any Z' unless it has extremely weak couplings to leptons. For a combined analysis of the various pre-LEP experiments see Ref. 8.

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z_{SM}

Z'_M is assumed to have couplings with quarks and leptons which are identical to those of Z.

 38 ABE 97s limit is obtained assuming that Z' decays to known fermions only.

³⁹ LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t >$ 89 GeV used.

 40 LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0086 < \theta < 0.0005$.

41 ABE 95 limit is obtained assuming that Z^\prime decays to known fermions only.

 42 VILAIN 94B assume $m_t=150$ GeV.

 43 ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes B($Z^{\prime}
ightarrow q\overline{q}$)=0.7. See their Fig. 5 for ilmits in the $m_{Z^{\prime}}$ -B($q\overline{q}$) plane.

⁴⁴ ALLEN 93 limit is from total cross section for $\nu e \rightarrow \nu e$, where $\nu = \nu_e$, ν_μ , $\overline{\nu}_\mu$.

 $^{
m 45}\,{\rm RIZZO}$ 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to

the inclusion of the assumed K factor. ^46 ABE 910 give $\sigma(Z')$ B(e⁺ e⁻) < 1.31 pb (95%CL) for $m_{Z'}>$ 200 GeV at $E_{\rm CM}=1.8$ TeV. Limits ranging from 2 to 30 pb are given for $m_{Z'} = 100-200$ GeV.

⁴⁷GEIREGAT 91 limit is from comparison of g_V^e from $\nu_\mu e$ scattering with $\Gamma(Z
ightharpoonup ee)$ from LEP. Zero mixing assumed.

⁴⁸ ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W=80.49\pm0.43\pm0.24$ GeV and $m_7 = 91.13 \pm 0.03 \text{ GeV}.$

 49 HAGIWARA 90 perform a fit to e^+e^- data at PEP, PETRA, and TRISTAN including

 $\mu^+\mu^-$, $au^+ au^-$, and hadron cross sections and asymmetries. ⁵⁰ ALBAJAR 89 cross section limit at 630 GeV is $\sigma(Z')$ B(ee) < 4.2 pb (90% CL).

⁵¹ See Fig. 5 of ANSARI 87D for the excluded region in the $m_{Z^{\prime}}$ [$(g_{Z^{\prime}g})^2$ B(Z^{\prime} \rightarrow $e^+e^-)]$ plane. Note that the quantity $(g_{Z'q})^2$ B $(Z' \rightarrow e^+e^-)$ is normalized to unity for the standard Z couplings.

 52 ARNISON 86B find no excess e^+e^- pairs among 13 pairs from Z. Set limit $\sigma \times B(e^+e^-)$ <13 pb at CL = 90% at $E_{\rm cm}$ = 546 and 630 GeV.

Limits for Z_{LR} Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

 53 ABE 97s limit is obtained assuming that Z' decays to known fermions only. 54 LANGACKER 92B fit to a wide range of electroweak data including LEP results available

early '91. $m_t > 89$ GeV used.

 55 LANGACKER 92B give 95%CL limits on the Z-Z' mixing -0.0025 $< \theta < 0.0083$. 56 BARATE 97B gives 95% CL limits on Z-Z' mixing $-0.0017 < \theta < 0.0035$. The bounds are computed with $\alpha_s=0.120\pm0.003$, $m_t=175\pm6$ GeV, and $M_H=150^{+120}_{-90}$ GeV. See their Fig. 4 for the limit contour in the mass-mixing plane.

 57 ABE 95 limit is obtained assuming that Z^\prime decays to known fermions only. See their Fig. 3 for the mass bound of Z^\prime decaying to all allowed fermions and supersymmetric

58 VILAIN 94B assume $m_{
m f}=$ 150 GeV and $\theta=$ 0. See Fig. 2 for limit contours in the

mass-mixing plane. See rig. 2 for limit contours in the mass-mixing plane. So ADRIANI 93D give limits on the Z-Z' mixing $-0.002 < \theta < 0.015$ assuming the ABE 92B mass limit. So The LEP data available in summer '93 and is for $m_{\tilde{t}} = 110$

GeV. $m_H=$ 100 GeV and $lpha_{\it S}=$ 0.118 assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z- Z^\prime mixing angle is in Table 4.

61 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.
62 These limits assume that Z' decays to known fermions only.

 63 These limits assume that Z' decays to all E_6 fermions and their superpartners.

⁶⁴ See Fig. 7b and 8 in DELAGUILA 92 for the allowed region in $m_{Z^{\prime}}$ -mixing plane and $m_{Z'} - m_t$ plane from electroweak fit including '90 LEP data.

65 LAYSSAC 928 limit is from LEP data available spring '92. Specific Higgs sector is

assumed. See also LAYSSAC 92. 66 POLAK 92 limit is from m_{W_R} >477 GeV, which is derived from muon decay parameters assuming light ν_R . Specific Higgs sector is assumed.

⁶⁷ POLAK 928 limit is from a simultaneous fit to charged and neutral sector in $SU(2)_L \times SU(2)_R \times U(1)$ model using Z parameters, m_W , and low-energy neutral current data as of 1991. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Supersedes

POLAK 91.

68 RENTON 92 limits use LEP data taken up to '90 as well as m_W , νN , and atomic parity violation data. Specific Higgs structure is assumed.

69 ALTARELLI 918 is based on Z mass, widths, and A_{FB} . The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_t > 90$ GeV and $m_{H^0} < 1$ TeV assumed. For large m_t , the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the

70 DELAGUILA 91 bounds have extra assumption of superstring motivated Higgs sector. From ν N neutral current data with $m_Z=91.10\pm0.04$ GeV, $m_t>77$ GeV, $m_{H^0}<1$

From νN neutral current data with $m_Z = 2$. TeV assumed. 71 POLAK 91 limit is from a simultaneous fit to charged and neutral sector in SU(2)_L×SU(2)_R×U(1) model using m_W , m_Z , and low-energy neutral current data as of 1990. Light ν_R assumed and $m_t = m_H = 100$ GeV used. Superseded by POLAK 928. 72 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91. 73 HE 90B model assumes a specific Higgs sector. Neutral current data of COSTA 88 as well as m_Z is used. g_R is left free in the fit. 74 BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV. 75 DCLACIULA 90 limit is based on $\sigma(n_D \to Z')$ B($Z' \to e^+e^-$) < 1.8 pb at CERN p_D

⁷⁵ DELAGUILA 89 limit is based on $\sigma(p\bar{p}\to Z')$ ·B($Z'\to e^+e^-$) < 1.8 pb at CERN $p\bar{p}$ collider. 76 A wide range of neutral current data as of 1986 are used in the fit.

77 A wide range of neutral current data as of 1985 are used in the fit.

 78 ADEVA 858 measure asymmetry of μ -pair production, following formalism of RIZZO 81.

Gauge & Higgs Boson Particle Listings

Heavy Bosons Other than Higgs Bosons

Limits for Z_χ Z_χ is the extra neutral boson in SO(10) \to SU(5) \times U(1) χ . $g_\chi = e/\cos^2 W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. VALUE (GeV) CL% DOCUMENT ID TECN COMMENT

- $79\,\mathrm{ABE}$ 975 limit is obtained assuming that Z' decays to known fermions only.
- 80 LANGACKER 928 flt to a wide range of electroweak data including LEP results available early '91. m, >89 GeV used.
- 81 LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.0048~<~\theta<~0.0097$.
- $^{82}Z Z'$ mixing is assumed to be zero.
- 83 BARATE 978 gives 95% CL limits on Z-Z' mixing $-0.0016 < \theta < 0.0036$. The bounds are computed with $\alpha_s=0.120\pm0.003$, $m_t=175\pm6$ GeV, and $M_H=150^{+120}_{-90}$ GeV. See their Fig. 4 for the limit contour in the mass-mixing plane.
- 84 BUSKULIC 96N limit is from a combined fit to the hadronic cross sections measured at √s=130, 136 GeV (ALEPH) and √s=58 GeV (TOPAZ). Zero mixing is assumed.
- 85 ABE 95 limit is obtained assuming that Z^\prime decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric
- fermions. 86 ABREU 95M limit is for α_s =0.123, m_t =150 GeV, and m_H =300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.
- 87 NARDI 95 give 90%CL ilmits on $\it Z$ -Z $^{\prime}$ mixing $-0.0032 < \theta < 0.0031$ for $M_{Z^{\prime}} >$ 500 GeV, m_t =170 GeV, m_H =250 GeV, α_s =0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, $-0.0032 < \theta <$
- ⁸⁸ BUSKULIC 94 give 95%CL limits on the Z-Z' mixing $-0.0091 < \theta < 0.0023$.
- 89 VILAIN 948 assume $m_t=150$ GeV and $\theta=0$. See Fig. 2 for limit contours in the mass-mixing plane.
- 90 ADRIANI 93D give limits on the Z-Z' mixing $-0.004~<~\theta~<~0.015$ assuming the ABE 928 mass limit.
- 91 ALTARELLI 93B limit is from LEP data available in summer '93 and is for $m_{\tilde{t}}=110$ GeV. $m_H=100$ GeV and $\alpha_S=0.118$ assumed. The limit improves for larger m_t (see their Fig. 5). The 90%CL limit on the Z- Z^\prime mixing angle is in their Fig. 2.
- 92 These limits assume that Z^{\prime} decays to known fermions only.
- 93 These limits assume that Z^\prime decays to all E $_6$ fermions and their superpartners.
- 94 See Fig. 7a and 8 in DELAGUILA 92 for the allowed region in $m_{Z^{\rm I}}$ -mixing plane and $m_{Z'}-m_t$ plane from electroweak fit including '90 LEP data.
- 95 LAYSSAC 928 limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92. 96 LEIKE 92 is based on '90 LEP-data published in LEP 92.
- 97 RENTON 92 limits use LEP data taken up to '90 as well as m_W , ν N, and atomic parity
- violation data. Specific Higgs structure is assumed.
 98 ALTARELLI 918 is based on Z mass, widths, and A_{FB} . The limits are for superstring motivated models with extra assumption on the Higgs sector. $m_{t} > 90$ GeV and

- $m_{H^0} \, < \, 1$ TeV assumed. For large $m_{\, t^{*}}$ the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the paper.
- ⁹⁹BUCHMUELLER 91 limit is from LEP data. Specific assumption is made for the Higgs
- 100 Sector. DELAGUILA 91 bounds have extra assumption of superstring motivated Higgs sector. From νN neutral current data with $m_Z=91.10\pm0.04$ GeV, $m_t>77$ GeV, $m_{H^0}<1$ TeV assumed.
- 101 FARAGGG 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_{\nu}~<~0.5$ and is valid for $m_{\nu_R}~<~1$ MeV.
- 102 GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, Z mass and widths, m_W from ABE 906, 100 $<\!m_t<$ 200 GeV, $m_{H^0}=$ 100 GeV assumed. Dependence on m_t is shown in Fig. 7.
- $^{103}\,\mathrm{MAHANTHAPPA}$ 91 limit is from atomic parity violation in Cs with $m_W,\,m_Z$
- 104 ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$.
- 105 ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
- $106\,e^+\,e^-$ data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{c\overline{c}}$ below Z as well as ν_μ e scattering data of GEIREGAT 89 is used in the fit.
- 107 BARGER 908 limit is based on CDF limit $\sigma(p\bar{p}\to Z')$ B($Z'\to e^+e^-$) < 1 pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z^{\prime} decay.
- 108 GLASHOW 90 model assumes a specific Higgs sector. See GLASHOW 90B.
- These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{\nu} < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).
- 110 GRIFOLS 90 limit holds for $m_{\nu_R}\lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91. 111 HAGIWARA 90 perform a fit to $e^+\,e^-$ data at PEP, PETRA, and TRISTAN including $\mu^+\,\mu^-,\,\tau^+\,\tau^-,$ and hadron cross sections and asymmetries. The upper mass limit disappears at 2.7 s.d.
- ¹¹²DELAGUILA 89 limit is based on $\sigma(p\overline{p}\to Z')\cdot B(Z'\to e^+e^-)<1.8$ pb at CERN $p\overline{p}$
- 113 DORENBOSCH 89 obtain the limit $(g_\chi/g_Z)^2 \cdot (m_Z/m_{Z\chi})^2 < 0.11$ at 95% CL from the processes $\overline{\nu}_{\mu} \, e \to \ \overline{\nu}_{\mu} \, e$ and $\nu_{\mu} \, e \to \ \overline{\nu}_{\mu} \, e$.
- $^{114}\mbox{A}$ wide range of neutral current data as of 1986 are used in the fit.
- $^{115}Z'$ mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z^{\prime} decays only into light quarks and leptons.
- 116 MARCIANO 87 limit from unitarity of Cabibbo-Kobayashi-Maskawa matrix.
- $^{117}\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.

Limits for Z

 Z_{ψ} is the extra neutral boson in $E_6 \to SO(10) \times U(1)_{\psi}$. $g_{\psi} = e/\cos\theta_{W}$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 118 ABE 975 limit is obtained assuming that Z^\prime decays to known fermions only.
- 119 LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t > 89$ GeV used.
- 120 LANGACKER 92B give 95%CL limits on the Z-Z $^\prime$ mixing -0.0025 < heta < 0.013.
- 121 BARATE 978 gives 95% CL limits on Z-Z' mixing $-0.0020 < \theta < 0.0038$. The bounds are computed with $\alpha_5 = 0.120 \pm 0.003$, $m_t = 175 \pm 6$ GeV, and $M_H = 150 + \frac{120}{90}$ GeV. See their Fig. 4 for the limit contour in the mass-mixing plane.
- 122 BUSKULIC 96N limit is from a combined fit to the hadronic cross sections measured at √s=130, 136 GeV (ALEPH) and √s=58 GeV (TOPAZ). Zero mixing is assumed.
- 123 ABE 95 limit is obtained assuming that Z^\prime decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric
- 124 ABREU 95M limit is for α_s =0.123, m_t =150 GeV, and m_H =300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13. 125 NARDI 95 give 90%CL limits on Z-Z' mixing $-0.0056 < \theta < 0.0055$ for $M_{Z'}$ >500 GeV,
- m_t =170 GeV, m_H =250 GeV, α_s =0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, $-0.0066 < \theta <$

- 126 VILAIN 94B assume $m_{t}=$ 150 GeV and $\theta=$ 0. See Fig. 2 for limit contours in the mass-mixing plane.
- 127 ADRIANI 93D give limits on the Z-Z' mixing $-0.003 < \theta < 0.020$ assuming the ABE 928 mass limit.

 128 These limits assume that Z^I decays to known fermions only.
- 129 These limits assume that Z' decays to all E_6 fermions and their superpartners.
- 130 LEIKE 92 is based on '90 LEP data published in LEP 92.
- 131 ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$.
- $^{132} \rm{ABE}$ 90F ffx $m_{W} = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_{Z} = 91.13 \pm 0.03$ GeV.
- 133 e^+e^- data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{C\overline{C}}$ below Z as well as $\nu_{\mu}e$ scattering data of GEIREGAT 89 is used in the fit.
- 134 BARGER 908 limit is based on CDF limit $\sigma(p\overline{p}\to Z')$ B($Z'\to e^+e^-$) < 1 pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z^\prime decay.
- 135 These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{\nu} < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).
- 136 GRIFOLS 90D limit holds for $m_{\nu_R}\lesssim 1$ MeV. See also RIZZO 91. 137 HAGIWARA 90 perform a fit to ${\rm e^+\,e^-}$ data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries.
- 138 A wide range of neutral current data as of 1986 are used in the fit.
- $^{139}\,\mathrm{A}$ wide range of neutral current data as of 1985 are used in the fit.

Limits for Z_n

 Z_{η} is the extra neutral boson in E6 models, corresponding to $Q_{\eta}=\sqrt{3/8}~Q_{\chi}~ \sqrt{5/8}~Q_{\psi}.~g_{\eta}=e/\cos\! heta_{W}$ is assumed unless otherwise stated. We list limits with the assumption $\rho=1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 140 ABE 97s limit is obtained assuming that Z' decays to known fermions only.
- 141 LANGACKER 92B fit to a wide range of electroweak data including LEP results available early '91. $m_t >$ 89 GeV used.
- 142 LANGACKER 92B give 95%CL limits on the Z-Z' mixing $-0.038 < \theta < 0.002$.
- 143 BARATE 978 gives 95% CL limits on Z-Z' mixing $-0.021 < \theta < 0.012$. The bounds are computed with $\alpha_s = 0.120 \pm 0.003$, $m_t = 175 \pm 6$ GeV, and $M_H = 150 ^{+120}_{-90}$ GeV. See their Fig. 4 for the limit contour in the mass-mixing plane.
- 144 BUSKULIC 96N limit is from a combined fit to the hadronic cross sections measured at √s=130, 136 GeV (ALEPH) and √s=58 GeV (TOPAZ). Zero mixing is assumed.
- 145 ABE 95 limit is obtained assuming that Z^\prime decays to known fermions only. See their Fig. 3 for the mass bound of Z' decaying to all allowed fermions and supersymmetric
- 146 ABREU 95M limit is for $\alpha_{\rm S}$ =0.123, m_t =150 GeV, and m_H =300 GeV. For the limit contour in the mass-mixing plane, see their Fig. 13.

- 147 NARDI 95 give 90%CL limits on Z-Z' mixing $-0.0087 < \theta < 0.0075$ for $M_{Z^{I}} > 500$ GeV, m_t =170 GeV, m_H =250 GeV, α_s =0.12. The bound is relaxed under the simultaneous presence of the mixing of the known fermions with new heavy states, $-0.0087 < \theta <$
- 148 VILAIN 94B assume $m_f=150$ GeV and $\theta=0$. See Fig. 2 for limit contours in the
- 149 ADRIANI 93D give limits on the Z-Z $^\prime$ mixing $-0.029~<~\theta~<~0.010$ assuming the
- ABE 928 mass limit. 150 ALTARELLI 938 limit is from LEP data available in summer '93 and is for $m_{\tilde{t}}=110$ GeV. $m_H=100$ GeV and $\alpha_{\rm S}=0.118$ assumed. The 90%CL limit on the Z-Z $^{\prime}$ mixing angle is in Fig. 2.
- $^{151}\mathrm{These}$ limits assume that Z' decays to known fermions only.
- $^{152}\mathrm{These}$ limits assume that Z^\prime decays to all E_6 fermions and their superpartners.
- 153 See Fig. 7d in DELAGUILA 92 for the allowed region in $m_{\gamma l}$ -mixing plane from electroweak fit including '90 LEP data.
- 154 LAYSSAC 928 limit is from LEP data available spring '92. Specific Higgs sector is assumed. See also LAYSSAC 92.
- 155 LEIKE 92 is based on '90 LEP data published in LEP 92.
- 156 RENTON 92 limits use LEP data taken up to '90 as well as m_W, νN, and atomic parity violation data. Specific Higgs structure is assumed.
 157 ALTARELLI 918 is based on Z mass, widths, and A_{FB}. The limits are for superstring motivated models with extra assumption on the Higgs sector. m_t > 90 GeV and m_{HO} < 1 TeV assumed. For large m_t, the bound improves drastically. Bounds for Z-Z' mixing angle and Z mass shift without this model assumption are also given in the
- 158 GONZALEZ-GARCIA 91 limit is based on low-energy neutral current data, LEP Z mass and widths, m_W from ABE 90G. 100 $< m_t < 200$ GeV, $m_{H^0} = 100$ GeV assumed. Dependence on m_t is shown in Fig. 8.
- 159 ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$.
- ¹⁶⁰ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
- 161 e^+e^- data for R, $R_{\ell\ell}$, $A_{\ell\ell}$, and $A_{C\overline{C}}$ below Z as well as $\nu_{\mu}e$ scattering data of GEIREGAT 89 is used in the fit,
- 162 BARGER 908 limit is based on CDF limit $\sigma(p\bar{p}\to Z')\cdot B(Z'\to e^+e^-)<1$ pb (Nodulman, EPS Conf. '89). Assumes no new threshold is open for Z' decay.
- 163 These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_{\nu} < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV). 164 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.
- 165 HAGIWARA 90 perform a fit to e+e- data at PEP, PETRA, and TRISTAN including $\mu^+\mu^-$, $\tau^+\tau^-$, and hadron cross sections and asymmetries.
- 166 DELAGUILA 89 limit is based on $\sigma(p\vec{p}\to Z')$ -B($Z'\to e^+e^-$) < 1.8 pb at CERN $p\overline{p}$
- collider.
 167 A wide range of neutral current data as of 1986 are used in the fit.
- $^{168}Z_{\eta}$ mass limits obtained by combining constraints from non-observation of an excess of $t^+ t^-$ pairs at the CERN ho p collider and the global analysis of neutral current data by COSTA 88. Least favorable spectrum of three (E_6 27) generations of particles and their superpartners are assumed.
- ¹⁶⁹ Z' mass limits from non-observation of an excess of $\ell^+\ell^-$ pairs at the CERN $p\,\overline{p}$ collider [based on ANSARI 87D and GEER Uppsala Conf. 87]. The limits apply when Z^\prime decays only into light quarks and leptons.
- 170 BARGER 868 limit is based on UA1/UA2 limit on $p\bar{p} \to Z'$, $Z' \to e^+e^-$ (Lepton Photon Symp., Kyoto, '85). Extra decay channels for Z' are assumed not be open.
- $^{171}\mathrm{A}$ wide range of neutral current data as of 1985 are used in the flt.

Limits for other Z'

LEPTOQUARK QUANTUM NUMBERS

Written December 1997 by M. Tanabashi (Tohoku U.).

Leptoquarks are particles carrying both baryon number (B)and lepton number (L). They are expected to exist in various extensions of the Standard Model (SM). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary SM fermions are dimensionless and invariant under the SM gauge group. Table 1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. Naming conventions of leptoquark states are taken from Ref. 1. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

Table 1: Possible leptoquarks and their quantum numbers.

Leptoquarks	Spin	3B + L	$SU(3)_c$	$\mathrm{SU}(2)_W$	$\mathrm{U}(1)_Y$
$\overline{S_1}$	0	-2	3	1	1/3
$ ilde{S}_1$	0	-2	$\bar{3}$	1	4/3
S_3	0	-2	3	3	1/3
V_2	`1	-2	3	2	5/6
$ ilde{V}_2$	1	- 2	3	2	-1/6
R_2	0	0	3	2	7/6
$ ilde{R}_2$	0	0	3	2	1/6
U_1	1	0	3	1	2/3
$ ilde{U}_1$	1	0	3	1	5/3
U_3	1	0	3	3	2/3

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible.

The Pati-Salam model [2] is an example predicting the existence of a leptoquark state. In this model a vector leptoquark appears at the scale where the Pati-Salam SU(4) "color" gauge group breaks into the familiar QCD $SU(3)_C$ group (or $SU(3)_C \times U(1)_{B-L}$). The Pati-Salam leptoquark is a weak isosinglet and its hypercharge is 2/3 (U₁ leptoquark in Table 1). The coupling strength of the Pati-Salam leptoquark is given by the QCD coupling at the Pati-Salam symmetry breaking scale.

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from the bounds on the leptoquark induced four-fermion interactions which are obtained from low energy experiments.

The pair production cross sections of leptoquarks are evaluated from their interactions with gauge bosons. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 1. The magneticdipole-type and the electric-quadrupole-type interactions of a vector leptoquark are, however, not determined even if we fix its gauge quantum numbers as listed in the table [3]. We need extra assumptions about these interactions to evaluate the pair production cross section for a vector leptoquark.

If a leptoquark couples to fermions of more than a single generation in the mass eigenbasis of the SM fermions, it can induce four-fermion interactions causing flavor-changing-neutralcurrents and lepton-family-number violations. Non-chiral leptoquarks, which couple simultaneously to both left- and righthanded quarks, cause four-fermion interactions affecting the $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio [4]. Indirect limits provide stringent constraints on these leptoquarks. Since the Pati-Salam leptoquark has non-chiral coupling with both e and μ , indirect limits from the bounds on $K_L \to \mu e$ lead to severe bounds on the Pati-Salam leptoquark mass. For detailed bounds obtained in this way, see the Boson Particle Listings for "Indirect Limits for Leptoquarks" and its references.

It is therefore often assumed that a leptoquark state couples only to a single generation in a chiral interaction, where indirect limits become much weaker. This assumption gives strong constraints on concrete models of leptoquarks, however. Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first (second, third) generation leptoquarks in this section.

180 ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, eejj, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively.

¹⁸¹ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. The quoted limit is for scalar leptoquark with $B(\tau b)=1$.

182 ABE 95U search for scalar leptoquarks of charge $Q\!\!=\!\!2/3$ and $-1/3$ using $\mu\mu JJ$ events
in $p\bar{p}$ collisions at $E_{cm}=1.8$ TeV. The limit is for $B(\mu q)=1$. For $B(\mu q)=B(\nu q)=1$
0.5, the limit is > 96 GeV.

183 Limit is for charge -1/3 isospin-0 leptoquark with $B(\ell q)=2/3$.

184 First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

185 Limits are for charge -1/3, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks. 186 ADRIANI 93M limit for charge -1/3, isospin-0 leptoquark decaying to au b.

187 ABBOTT 97B, ABE 97x search for scalar leptoquarks using eejj events in $p\overline{p}$ collisions at E_{cm} =1.8 TeV. The limit is for B(eq)=1.

188 ABACHI 95G search for scalar leptoquarks using $\mu\mu$ +jets and $\mu\nu_{\mu}$ +jets events in $p\overline{p}$

collisions at $E_{\rm Cm}=1.8$ TeV. The limit is for B(μq) = 1. For B(μq) = 0.5, the limit is > 97 GeV. 189 ABACHI 948 search for ee[j] and $e\nu[j]$ events in $p\bar{p}$ collisions at $E_{\rm Cm}=1.8$ TeV. ABACHI 948 obtain the limit >120 GeV for B(eq)=B(νq)=0.5 and >133 GeV for B(eq)=1. A change in the DØ luminosity monitor constant reduces the first bound to >116 GeV quoted above (see FERMILAB-TM-1911). This limit does not depend on the electroweak quantum numbers of the leptoquark.

190 ABE 93) search for $\ell\ell j j$ events in $p \bar p$ collisions at $E_{\rm CM} = 1.8$ TeV. The limit is for B(eq) = B(νq) = 0.5 and improves to >113 GeV for B(eq) = 1. This limit does not depend on electroweak quantum numbers of the leptoquark.

191 ABREU 92F limit is for charge -1/3 isosin-0 leptoquark with $B(\mu q) = 2/3$. If first and second generation leptoquarks are degenerate, the limit is 43.0 GeV, and for a charge 2/3 second generation leptoquark 43.4 GeV. Cross-section limit for pair production of tates decaying to ℓq is given in the paper.

192 ALITTI 92E search for $\ell\ell j j$ and $\ell\nu j j$ events in $\rho \bar{\rho}$ collisions at $E_{\rm cm}=$ 630 GeV. The limit is for ${\rm B}(eq)=1$ and is reduced to 67 GeV for ${\rm B}(eq)={\rm B}(\nu q)=0.5$. This limit does not depend on electroweak quantum numbers of the leptoquark.

193 KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange.

The decay of the first (second) generation leptoquark is assumed to be any mixture of $d\,e^+$ and $u\overline{
u}$ ($s\,\mu^+$ and $c\,\overline{
u}$). See paper for limits for specific branching ratios.

 194 BARTEL 878 limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint $B(X \to c \overline{\nu}_{\mu}) + B(X \to c \overline{\nu}_{\mu})$

 195 BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ , decays either into $s\mu^+$ or $c\overline{\nu}$: $B(X \to s\mu^+) + B(X \to c\overline{\nu}) = 1$.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q- ℓ -leptoquark coupling g_{LQ} . It is often assumed that $g_{LQ}^2/4\pi$ =1/137. Limits shown are for a scalar, weak isoscalar, charge -1/3 lepto-

 $^{196}\mathrm{The}$ quoted limit is for a left-handed scalar leptoquark which solely couples to the first generation with electromagnetic strength. AID 96B also search for leptoquarks with lepton-flavor violating couplings. For limits on states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 2, Fig. 3, and Table 2. AID 96B

197 Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(\ell q)=2/3$. The limit is 77 GeV if first and cond leptoquarks are degenerate.

198 DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

their Figs. 3-8 and Table 1 for detailed limits.

199 AHMED 94B limit is for the left-handed leptoquark decaying to eq and νq with B(eq)

= B(νq)=1/2. Electromagnetic coupling strength is assumed for the scalar leptoquark interaction. For limits on states with different quantum numbers and the limits in the coupling-mass plane, see their Table 2 and Fig. 6.

 $^{200}\,\mathrm{ABT}$ 93 search for single leptoquark production in ep collisions with the decays eq and

 νq . The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit is for a leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit for B(eq) = 1 is 178 GeV. For limits on states with different quantum numbers, see their Fig. 2. ABT 93 superseded by AHMED 94B. 2^{01} DERRICK 93 search for single leptoquark production in ep collisions with the decay eq and νq . The limit is for leptoquark coupling of electromagnetic strength and assumes $B(eq) = B(\nu q) = 1/2$. The limit for B(eq) = 1 is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

 202 DEANDREA 97 limit is for \tilde{R}_2 leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

²⁰³ DERRICK 97 search for lepton-flavor violation in ep collision. See their Tables 2-5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

204 GROSSMAN 97 estimate the upper bounds on the branching fraction $B\to \tau^+\tau^-({\rm X})$ from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

205 JADACH 97 limit is from $e^+e^- \to q\bar{q}$ cross section at \sqrt{s} =172.3 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

206 AID 95 limit is for the weak isotriplet spin-1 leptoquark with the electromagnetic coupling strength. For the limits of leptoquarks with different quantum number, see their Table 2. AID 95 limits are from the measurements of the Q^2 spectrum measurement of ep

207 E/X.

207 E/X.

207 E/X.

E/X. quoted limit is from $K_L \to \mu e$ decay assuming zero mixing. See also KUZNETSOV 94, DESHPANDE 83, and DIMOPOULOS 81.

208 MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

²⁰⁹BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. m_H =250 GeV, $\alpha_S(m_Z)$ =0.12, m_t =180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\overline{e}_L t_R$, $\overline{\mu} t$, and $\overline{\tau} t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.

210 DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion insteractions from π , K, D, B, μ , τ decays and meson mixings, etc. See Table 15 of

DAVIDSON 94 for detail.
211 KUZNETSOV 94 gives mixing independent bound of the Patl-Salam leptoquark from the cosmological limit on $\pi^0 \to \overline{\nu}\nu$.

212 LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound. See also SHANKER 82. 213 MAHANTA 94 gives bounds of P- and T-violating scalar-leptoquark couplings from

atomic and molecular experiments.

214 DESHPANDE 83 used upper limit on $K_L^0 \rightarrow \mu e$ decay with renormalization-group equations to estimate coupling at the heavy boson mass. See also DIMOPOULOS 81.

215 From $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2$ (\overline{v}_{eL} u_R) ($\overline{d}_L e_R$)with g=0.004 for spin-0 leptoquark and g^2/M^2 ($\overline{\nu}_{eL} \ \gamma_{\mu} u_L$) ($\overline{d}_R \ \gamma^{\mu} e_R$) with $g \simeq 0.6$ for spin-1 leptoquark.

Gauge & Higgs Boson Particle Listings

Heavy Bosons Other than Higgs Bosons

- 218 ABE 97G search for new particle decaying to dijets.
- 219 ABE 95N assume axigluons decaying to quarks in the Standard Model only.
- 220 ABE 93G assume $\Gamma(g_A) = N\alpha_S m_{g_A}/6$ with N=10.
- ²²¹CUYPERS 91 compare $lpha_{\mathcal{S}}$ measured in \mathcal{T} decay and that from R at PEP/PETRA
- ²²² ABE 90H assumes $\Gamma(g_A) = N\alpha_S m_{g_A}/6$ with N = 5 ($\Gamma(g_A) = 0.09 m_{g_A}$). For N = 10, the excluded region is reduced to 120–150 GeV.
- 223 ROBINETT 89 result demands partial-wave unitarity of J=0 $t\bar{t}\to t\bar{t}$ scattering amplitude and derives a limit $m_{g_A}>0.5$ m_t . Assumes $m_t>56$ GeV.
- $^{\rm O,A}$ ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A)<0.4~m_{g_A}$ assumed. See also BAGGER 88.
- 225 CUYPERS 88 requires $\Gamma(\Upsilon \to gg_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by DONCHESKI 88.
- 226 DONCHESKI 88 requires $\Gamma(T \to g q \overline{q})/\Gamma(T \to g g g) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to mg_A > 21 GeV.

X^0 (Heavy Boson) Searches In Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

- ²²⁷ See Fig. 4 of ACCIARRI 97Q for the upper limit on B(Z $\rightarrow \gamma X^0$; $E_{\gamma} > E_{\min}$) as a function of E_{min} .
- ²²⁸ ACTON 93E give $\sigma(e^+e^- \rightarrow X^0\gamma)$ -B($X^0 \rightarrow \gamma\gamma$)< 0.4 pb (95%CL) for m_{X^0} =60 ± 2.5 GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0)$ -B($X^0\to\gamma\gamma$)² <20 MeV for $m_{X^0}=60\pm 1$ GeV.
- ²²⁹ABREU 92D give σ_Z · B($Z \rightarrow \gamma X^0$) · B($X^0 \rightarrow$ hadrons) <(3–10) pb for m_{X^0} = 10–78 GeV. A very similar limit is obtained for spin-1 X^0 .
- ²³⁰ ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z + \mathsf{B}(Z \to \gamma X^0)$ \cdot B($X^0 \rightarrow \text{ hadrons}$) <(2–10) pb (95%CL) is given for $m_{X^0} = 25-85$ GeV.
- 231 ACTON 91 searches for $Z \to Z^* X^0$, $Z^* \to e^+ e^-$, $\mu^+ \mu^-$, or $\nu \overline{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM ... Higgs boson.
- ²³² ACTON 918 limits are for $m_{\chi^0}=$ 60–85 GeV.
- ²³³ ADEVA 91D limits are for $m_{\chi^0} = 30$ -89 GeV.
- ²³⁴ADEVA 91D limits are for $m_{\chi^0}=$ 30–86 GeV.
- 235 AKRAWY 901 give $\Gamma(Z \to \gamma X^0)$ -B($X^0 \to \text{hadrons}) < 1.9 \text{ MeV } (95\%\text{CL}) \text{ for } m_{\chi^0} = 32\text{-80 GeV}$. We divide by $\Gamma(Z) = 2.5 \text{ GeV}$ to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \to \gamma q \bar{q}) < 8.2 \text{ MeV}$ assuming three-body phase space distribution.

- 236 ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \rightarrow \text{hadrons}$ at E_{cm} = 55.0-60.8 GeV.
- 237 DERRICK 86 found no deviation from the Standard Model Bhabha scattering at E_{cm} = 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 o e^+ e^-)$ - m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0 , in which case the limit applies for $\Gamma(X^0 \to e^+e^-) =$
- 238 ADEVA 85 first limit is from 2γ , $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. $E_{\rm cm}=40$ –47 GeV. Supersedes ADEVA 84.
- 239 BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \rightarrow e^+e^-$ and $\mu^+\mu^$ at $E_{\rm cm}=34.7$ GeV. See Fig. 5 for excluded region in the $m_{\chi 0}-\Gamma(\chi^0)$ plane.

 240 ADEVA 84 and BEHREND 84C have $E_{\rm cm}=39.8$ –45.5 GeV. MARK-J searched X^0 in $e^+e^- \rightarrow \text{ hadrons, } 2\gamma, \ \mu^+\mu^-, \ e^+e^- \text{ and CELLO in the same channels plus } \tau \text{ pair.}$ No narrow or broad X^0 is found in the energy range. They also searched for the effect of χ^0 with $m_{\chi} > E_{\rm cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0\to e^+e^-)=2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

ı

The limit is for $\Gamma(X^0 \to e^+e^-) \cdot \mathsf{B}(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0 .

248 ADAM 96C DLPH X⁰ decaying invisibly

²⁴⁸ ADAM 96C is from the single photon production cross at \sqrt{s} =130, 136 GeV. The upper bound is less than 3 pb for X^0 masses between 60 and 130 GeV. See their Fig. 5 for the exact bound on the cross section $\sigma(e^+e^- \rightarrow \gamma X^0)$.

CL%

VALUE (MeV)

Search for X^0 Resonance in $Z \to f\overline{f}X^0$ The limit is for $B(Z \to f\overline{f}X^0) \cdot B(X^0 \to F)$ where f is a fermion and F is the specified final state. Spin 0 is assumed for X^0 .

- $^{250}\mathrm{Limit}$ is for m_{χ^0} around 60 GeV.
- $^{251} \, \mathrm{ABREU}$ 96T obtain limit as a function of $m_{\chi^0}.$ See their Fig. 15.
- ²⁵² ADRIANI 92F give σ_Z · B($Z \to q \overline{q} \, X^0$) · B($X^0 \to \gamma \gamma$)<(0.75–1.5) pb (95%CL) for $m_{X^0} = 10$ –70 GeV. The limit is 1 pb at 60 GeV.

Search for X^0 Resonance in $p\bar{p} \rightarrow WX^0$

DOCUMENT ID TECN COMMENT 253 ABE 97W CDF $X^0 \rightarrow b\bar{b}$

²⁵³ ABE 97w search for X^0 production associated with W in $p\overline{p}$ collisions at $E_{\rm cm}$ =1.8 TeV. The 95%CL upper limit on the production cross section times the branching ratio for $X^0 \to b\bar b$ ranges from 14 to 19 pb for X^0 mass between 70 and 120 GeV. See their Fig. 3 for upper limits of the production cross section as a function of m_{X^0} .

Search for Resonance X, Y in $e^+e^- \rightarrow XY$ DOCUMENT ID TECN COMMENT ²⁵⁴ ALEXANDER 978 OPAL $X \rightarrow 2$ jets, $Y \rightarrow 2$ jets 255 BUSKULIC,D 96 ALEP $X \rightarrow 2$ Jets, $Y \rightarrow 2$ Jets ²⁵⁴ ALEXANDER 97B search for the associated production of two massive particles decaying into quarks in e^+e^- collisions at \sqrt{s} =130-136 GeV. The 95%CL upper limits on $\sigma(e^+e^-\to XY)$ range from 2.7 to 4.5 pb for 95< $m_X+m_Y<$ 120 GeV. 255 BUSKULIC,D 96 observed an excess of four-jet production cross section in e⁺e⁻ collisions at \sqrt{s} =130–136 GeV and find an enhancement in the sum of two dijet masses around 105 GeV.

Heavy Particle Production in Quarkonium Decays

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

Axions (A^0) and Other Very Light Bosons, Searches for

AXIONS AND OTHER VERY LIGHT BOSONS

Written October 1997 by H. Murayama (University of California, Berkeley) Part I; April 1998 by G. Raffelt (Max-Planck Institute, München) Part II; and April 1998 by C. Hagmann, K. van Bibber (Lawrence Livermore National Laboratory), and L.J. Rosenberg (Massachusetts Institute of Technology) Part III.

This review is divided into three parts:

Part I (Theory)

Part II (Astrophysical Constraints)

Part III (Experimental Limits)

AXIONS AND OTHER VERY LIGHT BOSONS, PART I (THEORY)

(by H. Murayama)

In this section we list limits for very light neutral (pseudo) scalar bosons that couple weakly to stable matter. They arise if there is a global continuous symmetry in the theory that is spontaneously broken in the vacuum. If the symmetry is exact, it results in a massless Nambu–Goldstone (NG) boson. If there is a small explicit breaking of the symmetry, either already in the Lagrangian or due to quantum mechanical effects such as anomalies, the would-be NG boson acquires a finite mass; then it is called a pseudo-NG boson. Typical examples are axions (A^0) [1], familons [2], and Majorons [3,4], associated, respectively, with spontaneously broken Peccei-Quinn [5], family, and lepton-number symmetries. This Review provides brief descriptions of each of them and their motivations.

One common characteristic for all these particles is that their coupling to the Standard Model particles are suppressed by the energy scale of symmetry breaking, *i.e.* the decay constant f, where the interaction is described by the Lagrangian

$$\mathcal{L} = \frac{1}{f} (\partial_{\mu} \phi) J^{\mu}, \tag{1}$$

where J^{μ} is the Noether current of the spontaneously broken global symmetry.

An axion gives a natural solution to the strong CP problem: why the effective θ -parameter in the QCD Lagrangian $\mathcal{L}_{\theta} = \theta_{eff} \frac{\alpha_s}{8\pi} F^{\mu\nu a} \widetilde{F}^a_{\mu\nu}$ is so small $(\theta_{eff} \lesssim 10^{-9})$ as required by the current limits on the neutron electric dipole moment, even though $\theta_{eff} \sim O(1)$ is perfectly allowed by the QCD gauge invariance. Here, θ_{eff} is the effective θ parameter after the diagonalization of the quark masses, and $F^{\mu\nu a}$ is the gluon field strength and $\widetilde{F}^a_{\mu\nu} = \frac{1}{2} \epsilon_{\mu\nu\rho\sigma} F^{\rho\sigma a}$. An axion is a pseudo-NG boson of a spontaneously broken Peccei–Quinn symmetry, which is an exact symmetry at the classical level, but is broken quantum mechanically due to the triangle anomaly with the gluons. The definition of the Peccei–Quinn symmetry is model dependent. As a result of the triangle anomaly, the axion acquires an effective coupling to gluons

$$\mathcal{L} = \left(\theta_{eff} - \frac{\phi_A}{f_A}\right) \frac{\alpha_s}{8\pi} F^{\mu\nu a} \widetilde{F}^a_{\mu\nu} , \qquad (2)$$

where ϕ_A is the axion field. It is often convenient to define the axion decay constant f_A with this Lagrangian [6]. The QCD nonperturbative effect induces a potential for ϕ_A whose minimum is at $\phi_A = \theta_{\it eff} f_A$ cancelling $\theta_{\it eff}$ and solving the strong $\it CP$ problem. The mass of the axion is inversely proportional to f_A as

$$m_A = 0.62 \times 10^{-3} \text{eV} \times (10^{10} \text{GeV}/f_A)$$
. (3)

The original axion model [1,5] assumes $f_A \sim v$, where $v = (\sqrt{2}G_F)^{-1/2} = 247$ GeV is the scale of the electroweak symmetry breaking, and has two Higgs doublets as minimal ingredients. By requiring tree-level flavor conservation, the axion mass and its couplings are completely fixed in terms of one parameter $(\tan \beta)$: the ratio of the vacuum expectation values of two Higgs fields. This model is excluded after extensive experimental searches for such an axion [7]. Observation of a narrow-peak structure in positron spectra from heavy ion collisions [8] suggested a particle of mass 1.8 MeV that decays into e^+e^- . Variants of the original axion model, which keep $f_A \sim v$, but drop the constraints of tree-level flavor conservation, were proposed [9]. Extensive searches for this particle, $A^0(1.8 \text{ MeV})$, ended up with another negative result [10].

The popular way to save the Peccei-Quinn idea is to introduce a new scale $f_A \gg v$. Then the A^0 coupling becomes weaker, thus one can easily avoid all the existing experimental limits; such models are called invisible axion models [11,12]. Two classes of models are discussed commonly in the literature. One introduces new heavy quarks which carry Peccei-Quinn charge while the usual quarks and leptons do not (KSVZ axion or "hadronic axion") [11]. The other does not need additional quarks but requires two Higgs doublets, and all quarks and leptons carry Peccei-Quinn charges (DFSZ axion or "GUTaxion") [12]. All models contain at least one electroweak singlet scalar boson which acquires an expectation value and breaks Peccei-Quinn symmetry. The invisible axion with a large decay constant $f_A \sim 10^{12}$ GeV was found to be a good candidate of the cold dark matter component of the Universe [13](see Dark Matter review). The energy density is stored in the lowmomentum modes of the axion field which are highly occupied and thus represent essentially classical field oscillations.

The constraints on the invisible axion from astrophysics are derived from interactions of the axion with either photons, electrons or nucleons. The strengths of the interactions are model dependent (i.e., not a function of f_A only), and hence one needs to specify a model in order to place lower bounds on f_A . Such constraints will be discussed in Part II. Serious experimental searches for an invisible axion are underway; they typically rely on axion-photon coupling, and some of them assume that the axion is the dominant component of our galactic halo density. Part III will discuss experimental techniques and limits.

Gauge & Higgs Boson Particle Listings Axions (A⁰) and Other Very Light Bosons

Familons arise when there is a global family symmetry broken spontaneously. A family symmetry interchanges generations or acts on different generations differently. Such a symmetry may explain the structure of quark and lepton masses and their mixings. A familon could be either a scalar or a pseudoscalar. For instance, an SU(3) family symmetry among three generations is non-anomalous and hence the familons are exactly massless. In this case, familons are scalars. If one has larger family symmetries with separate groups of left-handed and right-handed fields, one also has pseudoscalar familons. Some of them have flavor-off-diagonal couplings such as $\partial_{\mu}\phi_{F}\bar{d}\gamma^{\mu}s/F_{ds}$ or $\partial_{\mu}\phi_{F}\bar{e}\gamma^{\mu}\mu/F_{\mu e}$, and the decay constant F can be different for individual operators. The decay constants have lower bounds constrained by flavor-changing processes. For instance, $B(K^+ \to \pi^+ \phi_F) < 3 \times 10^{-10}$ [14] gives $F_{ds} > 3.4 \times 10^{11} \text{ GeV } [15]$. The constraints on familous primarily coupled to third generation are quite weak [15].

If there is a global lepton-number symmetry and if it breaks spontaneously, there is a Majoron. The triplet Majoron model [4] has a weak-triplet Higgs boson, and Majoron couples to Z. It is now excluded by the Z invisible-decay width. The model is viable if there is an additional singlet Higgs boson and if the Majoron is mainly a singlet [16]. In the singlet Majoron model [3], lepton-number symmetry is broken by a weak-singlet scalar field, and there are right-handed neutrinos which acquire Majorana masses. The left-handed neutrino masses are generated by a "seesaw" mechanism [17]. The scale of lepton number breaking can be much higher than the electroweak scale in this case. Astrophysical constraints require the decay constant to be $\gtrsim 10^9$ GeV [18].

There is revived interest in a long-lived neutrino, to improve Big-Bang Nucleosynthesis [19] or large scale structure formation theories [20]. Since a decay of neutrinos into electrons or photons is severely constrained, these scenarios require a familion (Majoron) mode $\nu_1 \rightarrow \nu_2 \phi_F$ (see, e.g., Ref. 15 and references therein).

Other light bosons (scalar, pseudoscalar, or vector) are constrained by "fifth force" experiments. For a compilation of constraints, see Ref. 21.

It has been widely argued that a fundamental theory will not possess global symmetries; gravity, for example, is expected to violate them. Global symmetries such as baryon number arise by accident, typically as a consequence of gauge symmetries. It has been noted [22] that the Peccei-Quinn symmetry, from this perspective, must also arise by accident and must hold to an extraordinary degree of accuracy in order to solve the strong CP problem. Possible resolutions to this problem, however, have been discussed [22,23]. String theory also provides sufficiently good symmetries, especially using a large compactification radius motivated by recent developments in M-theory [24].

AXIONS AND OTHER VERY LIGHT BOSONS: PART II (ASTROPHYSICAL CONSTRAINTS)

(by G.G. Raffelt)

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, etc.) are produced in hot plasmas and thus represent an energy-loss channel for stars. The strength of the interaction with photons, electrons, and nucleons can be constrained from the requirement that stellar-evolution time scales are not modified beyond observational limits. For detailed reviews see Refs. [1,2].

The energy-loss rates are steeply increasing functions of temperature T and density ρ . Because the new channel has to compete with the standard neutrino losses which tend to increase even faster, the best limits arise from low-mass stars, notably from horizontal-branch (HB) stars which have a helium-burning core of about 0.5 solar masses at $\langle \rho \rangle \approx 0.6 \times 10^4 \, \mathrm{g \ cm^{-3}}$ and $\langle T \rangle \approx 0.7 \times 10^8 \, \mathrm{K}$. The new energy-loss rate must not exceed about 10 ergs $\mathrm{g^{-1} \, s^{-1}}$ to avoid a conflict with the observed number ratio of HB stars in globular clusters. Likewise the ignition of helium in the degenerate cores of the preceding red-giant phase is delayed too much unless the same constraint holds at $\langle \rho \rangle \approx 2 \times 10^5 \, \mathrm{g \ cm^{-3}}$ and $\langle T \rangle \approx 1 \times 10^8 \, \mathrm{K}$. The white-dwarf luminosity function also yields useful bounds.

The new bosons X^0 interact with electrons and nucleons with a dimensionless strength g. For scalars it is a Yukawa coupling, for new gauge bosons (e.g., from a baryonic or leptonic gauge symmetry) a gauge coupling. Axion-like pseudoscalars couple derivatively as $f^{-1}\bar{\psi}\gamma_{\mu}\gamma_{5}\psi$ $\partial^{\mu}\phi_{X}$ with f an energy scale. Usually this is equivalent to $(2m/f)\bar{\psi}\gamma_{5}\psi$ ϕ_{X} with m the mass of the fermion ψ so that g=2m/f. For the coupling to electrons, globular-cluster stars yield the constraint

$$g_{Xe} \lesssim \begin{cases} 0.5 \times 10^{-12} & \text{for pseudoscalars [3]} \\ 1.3 \times 10^{-14} & \text{for scalars [4]} \end{cases}, \tag{1}$$

if $m_X \lesssim 10 \, \text{keV}$. The Compton process $\gamma + {}^4\text{He} \to {}^4\text{He} + X^0$ limits the coupling to nucleons to $g_{XN} \lesssim 0.4 \times 10^{-10}$ [4].

Scalar and vector bosons mediate long-range forces which are severely constrained by "fifth-force" experiments [5]. In the massless case the best limits come from tests of the equivalence principle in the solar system, leading to

$$g_{B,L} \lesssim 10^{-23} \tag{2}$$

for a baryonic or leptonic gauge coupling [6].

In analogy to neutral pions, axions A^0 couple to photons as $g_{A\gamma}\mathbf{E}\cdot\mathbf{B}\,\phi_A$ which allows for the Primakoff conversion $\gamma\leftrightarrow A^0$ in external electromagnetic fields. The most restrictive limit arises from globular-cluster stars [2]

$$g_{A\gamma} \lesssim 0.6 \times 10^{-10} \,\text{GeV}^{-1}$$
 (3)

The often-quoted "red-giant limit" [7] is slightly weaker.

The duration of the SN 1987A neutrino signal of a few seconds proves that the newborn neutron star cooled mostly by neutrinos rather than through an "invisible channel" such as right-handed (sterile) neutrinos or axions [8]. Therefore,

$$3 \times 10^{-10} \lesssim g_{AN} \lesssim 3 \times 10^{-7} \tag{4}$$

is excluded for the pseudoscalar Yukawa coupling to nucleons [2]. The "strong" coupling side is allowed because axions then escape only by diffusion, quenching their efficiency as an energy-loss channel [9]. Even then the range

$$10^{-6} \lesssim g_{AN} \lesssim 10^{-3} \tag{5}$$

is excluded to avoid excess counts in the water Cherenkov detectors which registered the SN 1987A neutrino signal [11].

In terms of the Peccei-Quinn scale f_A , the axion couplings to nucleons and photons are $g_{AN} = C_N m_N/f_A$ (N=n or p) and $g_{A\gamma} = (\alpha/2\pi f_A) (E/N-1.92)$ where C_N and E/N are model-dependent numerical parameters of order unity. With $m_A = 0.62 \, \mathrm{eV} \, (10^7 \, \mathrm{GeV}/f_A)$, Eq. (3) yields $m_A \lesssim 0.4 \, \mathrm{eV}$ for E/N = 8/3 as in GUT models or the DFSZ model. The SN 1987A limit is $m_A \lesssim 0.008 \, \mathrm{eV}$ for KSVZ axions while it varies between about 0.004 and 0.012 eV for DFSZ axions, depending on the angle β which measures the ratio of two Higgs vacuum expectation values [10]. In view of the large uncertainties it is good enough to remember $m_A \lesssim 0.01 \, \mathrm{eV}$ as a generic limit (Fig. 1).

In the early universe, axions come into thermal equilibrium only if $f_A \lesssim 10^8 \, {\rm GeV}$ [12]. Some fraction of the relic axions end up in galaxies and galaxy clusters. Their decay $a \to 2\gamma$ contributes to the cosmic extragalactic background light and to line emissions from galactic dark-matter haloes and galaxy clusters. An unsuccessful "telescope search" for such features yields $m_a < 3.5 \, {\rm eV}$ [13]. For $m_a \gtrsim 30 \, {\rm eV}$, the axion lifetime is shorter than the age of the universe.

For $f_A \gtrsim 10^8\,\mathrm{GeV}$ cosmic axions are produced nonthermally. If inflation occurred after the Peccei-Quinn symmetry breaking or if $T_{\mathrm{reheat}} < f_A$, the "misalignment mechanism" [14] leads to a contribution to the cosmic critical density of

$$\Omega_A h^2 \approx 1.9 \times 3^{\pm 1} (1 \,\mu\text{eV}/m_A)^{1.175} \,\Theta_i^2 F(\Theta_i)$$
 (6)

where h is the Hubble constant in units of $100\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$. The stated range reflects recognized uncertainties of the cosmic conditions at the QCD phase transition and of the temperature-dependent axion mass. The function $F(\Theta)$ with F(0)=1 and $F(\pi)=\infty$ accounts for anharmonic corrections to the axion

Gauge & Higgs Boson Particle Listings Axions (A⁰) and Other Very Light Bosons

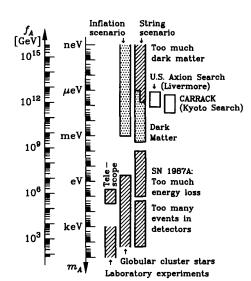

Figure 1: Astrophysical and cosmological exclusion regions (hatched) for the axion mass m_A or equivalently, the Peccei-Quinn scale f_A . An "open end" of an exclusion bar means that it represents a rough estimate; its exact location has not been established or it depends on detailed model assumptions. The globular cluster limit depends on the axion-photon coupling; it was assumed that E/N = 8/3 as in GUT models or the DFSZ model. The SN 1987A limits depend on the axion-nucleon couplings; the shown case corresponds to the KSVZ model and approximately to the DFSZ model. The dotted "inclusion regions" indicate where axions could plausibly be the cosmic dark matter. Most of the allowed range in the inflation scenario requires fine-tuned initial conditions. In the string scenario the plausible dark-matter range is controversial as indicated by the step in the low-mass end of the "inclusion bar" (see main text for a discussion). Also shown is the projected sensitivity range of the search experiments for galactic dark-matter axions.

potential. Because the initial misalignment angle Θ_i can be very small or very close to π , there is no real prediction for the mass of dark-matter axions even though one would expect $\Theta_i^2 F(\Theta_i) \sim 1$ to avoid fine-tuning the initial conditions.

A possible fine-tuning of Θ_i is limited by inflation-induced quantum fluctuations which in turn lead to temperature fluctuations of the cosmic microwave background [15,16]. In a broad class of inflationary models one thus finds an upper limit to m_A where axions could be the dark matter. According to the most recent discussion [16] it is about 10^{-3} eV (Fig. 1).

If inflation did not occur at all or if it occurred before the Peccei-Quinn symmetry breaking with $T_{\rm reheat} > f_A$, cosmic axion strings form by the Kibble mechanism [17]. Their motion is damped primarily by axion emission rather than gravitational waves. After axions acquire a mass at the QCD phase transition they quickly become nonrelativistic and thus form a cold dark

matter component. Battye and Shellard [18] found that the dominant source of axion radiation are string loops rather than long strings. At a cosmic time t the average loop creation size is parametrized as $\langle \ell \rangle = \alpha t$ while the radiation power is $P = \kappa \mu$ with μ the renormalized string tension. The loop contribution to the cosmic axion density is [18]

$$\Omega_A h^2 \approx 88 \times 3^{\pm 1} \left[(1 + \alpha/\kappa)^{3/2} - 1 \right] (1 \,\mu\text{eV}/m_A)^{1.175} ,$$
 (7)

where the stated nominal uncertainty has the same source as in Eq. (6). The values of α and κ are not known, but probably $0.1 < \alpha/\kappa < 1.0$ [18], taking the expression in square brackets to 0.15–1.83. If axions are the dark matter, we have

$$0.05 \lesssim \Omega_A h^2 \lesssim 0.50 , \qquad (8)$$

where it was assumed that the universe is older than 10 Gyr, that the dark-matter density is dominated by axions with $\Omega_A \gtrsim 0.2$, and that $h \gtrsim 0.5$. This implies $m_A = 6-2500~\mu\text{eV}$ for the plausible mass range of dark-matter axions (Fig. 1).

Contrary to Ref. 18, Sikivie et al. [19] find that the motion of global strings is strongly damped, leading to a flat axion spectrum. In Battye and Shellard's treatment the axion radiation is strongly peaked at wavelengths of order the loop size. In Sikivie et al.'s picture more of the string radiation goes into kinetic axion energy which is redshifted so that ultimately there are fewer axions. In this scenario the contributions from string decay and vacuum realignment are of the same order of magnitude; they are both given by Eq. (6) with Θ_i of order one. As a consequence, Sikivie et al. allow for a plausible range of dark-matter axions which reaches to smaller masses as indicated in Fig. 1.

The work of both groups implies that the low-mass end of the plausible mass interval in the string scenario overlaps with the projected sensitivity range of the U.S. search experiment for galactic dark-matter axions (Livermore) [20] and of the Kyoto search experiment CARRACK [21] as indicated in Fig. 1. (See also Part III of this Review by Hagmann, van Bibber, and Rosenberg.)

In summary, a variety of robust astrophysical arguments and laboratory experiments (Fig. 1) indicate that $m_A \lesssim 10^{-2}$ eV. The exact value of this limit may change with a more sophisticated treatment of supernova physics and/or the observation of the neutrino signal from a future galactic supernova, but a dramatic modification is not expected unless someone puts forth a completely new argument. The stellar-evolution limits shown in Fig. 1 depend on the axion couplings to various particles and thus can be irrelevant in fine-tuned models where, for example, the axion-photon coupling strictly vanishes. For nearly any m_A in the range generically allowed by stellar evolution, axions could be the cosmic dark matter, depending on the cosmological scenario realized in nature. It appears that our only practical chance to discover these "invisible" particles rests with the ongoing or future search experiments for galactic dark-matter.

AXIONS AND OTHER VERY LIGHT BOSONS, PART III (EXPERIMENTAL LIMITS)

(by C. Hagmann, K. van Bibber, and L.J. Rosenberg)

In this section we review the experimental methodology and limits on light axions and light pseudoscalars in general. (A comprehensive overview of axion theory is given by H. Murayama in the Part I of this Review, whose notation we follow [1].) Within its scope are searches where the axion is assumed to be dark matter, searches where the Sun is presumed to be a source of axions, and purely laboratory experiments. We restrict the discussion to axions of mass $m_A < O(eV)$, as the allowed range for the axion mass is nominally $10^{-6} < m_A < 10^{-2}$ eV. Experimental work in this range predominantly has been through the axion-photon coupling $g_{A\gamma}$, to which the present review is confined. As discussed in Part II of this Review by G. Raffelt, the lower bound derives from a cosmological overclosure argument, and the upper bound from SN1987A [2]. Limits from stellar evolution overlap seamlessly above that, connecting with accelerator-based limits which ruled out the original axion. There it was assumed that the Peccei-Quinn symmetry-breaking scale was the electroweak scale, i.e., $f_A \sim 250$ GeV, implying axions of mass $m_A \sim O(100\,\mathrm{keV})$. These earlier limits from nuclear transitions, particle decays, etc., while not discussed here, are included in the Listings.

While the axion mass is well determined by the Peccei-Quinn scale, i.e., $m_A = 0.62$ eV $(10^7 \text{ GeV}/f_A)$, the axionphoton coupling $g_{A\gamma}$ is not: $g_{A\gamma} = (\alpha/\pi f_A) g_{\gamma}$, with $g_{\gamma} =$ (E/N-1.92)/2, where E/N is a model-dependent number. It is noteworthy however, that two quite distinct models lead to axion-photon couplings which are not very different. For the case of axions imbedded in Grand Unified Theories, the DFSZ axion [3], $g_{\gamma} = 0.37$, whereas in one popular implementation of the "hadronic" class of axions, the KSVZ axion [4], $g_{\gamma} = -0.96$. The Lagrangian $L = g_{A\gamma} \mathbf{E} \cdot \mathbf{B} \phi_A$, with ϕ_A the axion field, permits the conversion of an axion into a single real photon in an external electromagnetic field, i.e., a Primakoff interaction. In the case of relativistic axions, $k_{\gamma} - k_{A} \sim m_{A}^{2}/2\omega \ll \omega$, pertinent to several experiments below, coherent axion-photon mixing in long magnetic fields results in significant conversion probability even for very weakly coupled axions [5].

Below are discussed several experimental techniques constraining $g_{A\gamma}$, and their results. Also included are recent but yet-unpublished results, and projected sensitivities for experiments soon to be upgraded.

III.1. Microwave cavity experiments: Possibly the most promising avenue to the discovery of the axion presumes that axions constitute a significant fraction of the dark matter halo of our galaxy. The maximum likelihood density for the Cold Dark Matter (CDM) component of our galactic halo is $\rho_{\text{CDM}} = 7.5 \times 10^{-25} \text{g/cm}^3 (450 \, \text{MeV/cm}^3)$ [6]. That the CDM halo is in fact made of axions (rather than e.g. WIMPs) is in principle an independent assumption, however should very light axions exist they would almost necessarily be cosmologically

abundant [2]. As shown by Sikivie [7], halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q cavity permeated by a strong magnetic field. The cavity is tunable and the signal is maximum when the frequency $\nu = m_A(1 + O(10^{-6}))$, the width of the peak representing the virial distribution of thermalized axions in the galactic gravitational potential. The signal may possess ultra-fine structure due to axions recently fallen into the galaxy and not yet thermalized [8]. The feasibility of the technique was established in early experiments of small sensitive volume, V = O(1 liter) [9,10] with High Electron Mobility Transistor (HEMT) amplifiers, which set limits on axions in the mass range $4.5 < m_A < 16.3 \,\mu\text{eV}$, but at power sensitivity levels 2-3 orders of magnitude too high to see KSVZ and DFSZ axions (the conversion power $P_{A\to\gamma}\propto g_{A\gamma}^2$). A recent large-scale experiment ($B \sim 7.5 \, \mathrm{T}, V \sim 200 \, \mathrm{liter}$) has achieved sensitivity to KSVZ axions over a narrow mass range $2.77 < m_A < 3.3 \,\mu\text{eV}$, and continues to take data [11]. The exclusion regions shown in Fig. 1 for Refs. [9-12] are all normalized to the best-fit Cold Dark Matter density $\rho_{\rm CDM} = 7.5 \times 10^{-25} {\rm g/cm^3 (450 \, MeV/cm^3)}$, and 90% CL. Recent developments in DC SQUID amplifiers [12] and Rydberg atom single-quantum detectors [13] promise dramatic improvements in noise temperature, which will enable rapid scanning of the axion mass range at or below the DFSZ limit. The region of the microwave cavity experiments is shown in detail in Fig. 2.

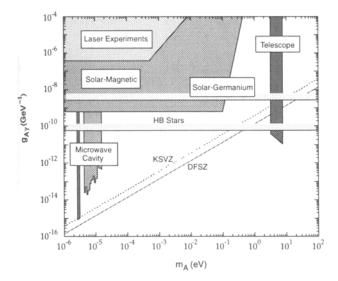

Figure 1: Exclusion region in mass vs. axion-photon coupling $(m_A, g_{A\gamma})$ for various experiments. The limit set by globular cluster Horizontal Branch Stars ("HB Stars") is shown for Ref. 2.

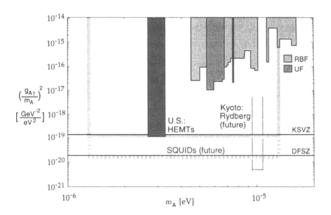

Figure 2: Exclusion region from the microwave cavity experiments, where the plot is flattened by presenting $(g_{A\gamma}/m_A)^2$ vs. m_A . The first-generation experiments (Rochester-BNL-FNAL, "RBF" [9]; University of Florida, "UF" [10]) and the US large-scale experiment in progress ("US" [11]) are all HEMT-based. Shown also is the full mass range to be covered by the latter experiment (shaded line), and the improved sensitivity when upgraded with DC SQUID amplifiers [12] (shaded dashed line). The expected performance of the Kyoto experiment based on a Rydberg atom single-quantum receiver (dotted line) is also shown [13].

III.2. Telescope search for eV axions: For axions of mass greater than about 10^{-1} eV, their cosmological abundance is no longer dominated by vacuum misalignment or string radiation mechanisms, but rather by thermal production. Their contribution to the critical density is small, $\Omega \sim 0.01 \, (m_A/\text{eV})$. However, the spontaneous-decay lifetime of axions, $\tau(A \rightarrow$ $(2\gamma) \sim 10^{25} \text{sec}(m_A/\text{eV})^{-5}$ while irrelevant for μeV axions, is short enough to afford a powerful constraint on such thermally produced axions in the eV range, by looking for a quasimonochromatic photon line from galactic clusters. This line, corrected for Doppler shift, would be at half the axion mass and its width would be consistent with the observed virial motion, typically $\Delta \lambda/\lambda \sim 10^{-2}$. The expected line intensity would be of the order $I_A \sim 10^{-17} (m_A/3 \, \text{eV})^7 \text{erg cm}^{-2} \text{arcsec}^{-2} \text{Å}^{-1} \text{sec}^{-1}$ for DFSZ axions, comparable to the continuum night emission. The conservative assumption is made that the relative density of thermal axions fallen into the cluster gravitational potential reflects their overall cosmological abundance. A search for thermal axions in three rich Abell clusters was carried out at Kitt Peak National Laboratory [14]; no such line was observed between 3100-8300 Å ($m_A = 3-8$ eV) after "on-off field" subtraction of the atmospheric molecular background spectra. A limit everywhere stronger than $g_{A\gamma} < 10^{-10} \text{GeV}^{-1}$ is set, which is seen from Fig. 1 to easily exclude DFSZ axions throughout the mass range.

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

III.3. A search for solar axions: As with the telescope search for thermally produced axions above, the search for solar axions was stimulated by the possibility of there being a "1 eV window" for hadronic axions (i.e., axions with no treelevel coupling to leptons), a "window" subsequently closed by an improved understanding of the evolution of globular cluster stars and SN1987A [2]. Hadronic axions would be copiously produced within our Sun's interior by a Primakoff process. Their flux at the Earth of $\sim 10^{12} \text{cm}^{-2} \text{sec}^{-1} (m_A/\text{eV})^2$, which is independent of the details of the solar model, is sufficient for a definitive test via the axion reconversion to photons in a large magnetic field. However, their average energy is ~ 4 keV, implying an oscillation length in the vacuum of $2\pi (m_A^2/2\omega)^{-1} \sim O(\text{mm})$, precluding the mixing from achieving its theoretically maximum value in any practical magnet. It was recognized that one could endow the photon with an effective mass in a gas, $m_{\gamma} = \omega_{\rm ph}$ thus permitting the axion and photon dispersion relationships to be matched [15]. A first simple implementation of this proposal was carried out using a conventional dipole magnet with a conversion volume of variable-pressure helium gas and a xenon proportional chamber as the x-ray detector [16]. The magnet was fixed in orientation to take data for $\sim 1000 \sec/day$. Axions were excluded for $g_{A\gamma} < 3.6 \times 10^{-9} {\rm GeV^{-1}}$ for $m_A <$ $0.03\,\mathrm{eV}, \ \mathrm{and} \ g_{A\gamma} < 7.7 \times 10^{-9} \mathrm{GeV}^{-1} \ \mathrm{for} \ 0.03\,\mathrm{eV} < m_A < 0.11$ eV (95% CL). A more ambitious experiment has recently been commissioned, using a superconducting magnet on a telescope mount to track the Sun continuously. A preliminary exclusion limit of $g_{A\gamma} < 6 \times 10^{-10} \text{GeV}^{-1}$ (95% CL) has been set for $m_A < 0.03 \text{ eV } [17].$

Another search for solar axions has been carried out, using a single crystal germanium detector. It exploits the coherent conversion of axions into photons when their angle of incidence satisfies a Bragg condition with a crystalline plane. Analysis of 1.94 kg-yr of data from a 1 kg germanium detector yields a bound of $g_{A\gamma} < 2.7 \times 10^{-9} {\rm GeV}^{-1}$ (95% CL), independent of mass up to $m_A \sim 1$ keV [18].

III.4. Photon regeneration ("invisible light shining

through walls"): Photons propagating through a transverse field (with E||B) may convert into axions. For light axions with $m_A^2 l/2\omega \ll 2\pi$, where l is the length of the magnetic field, the axion beam produced is colinear and coherent with the photon beam, and the conversion probability Π is given by $\Pi \sim (1/4)(g_{A\gamma}Bl)^2$. An ideal implementation for this limit is a laser beam propagating down a long, superconducting dipole magnet like those for high-energy physics accelerators. If another such dipole magnet is set up in line with the first, with an optical barrier interposed between them, then photons may be regenerated from the pure axion beam in the second magnet and detected [19]. The overall probability $P(\gamma \to A \to \gamma) = \Pi^2$. Such an experiment has been carried

out, utilizing two magnets of length l=4.4 m and B=3.7 T.

Axions with mass $m_A < 10^{-3}$ eV, and $g_{A\gamma} > 6.7 \times 10^{-7} \text{GeV}^{-1}$

were excluded at 95% CL [20,21]. With sufficient effort, limits

comparable to those from stellar evolution would be achievable. Due to the $g_{A\gamma}^4$ rate suppression however, it does not seem feasible to reach standard axion couplings.

III.5. Polarization experiments: The existence of axions can affect the polarization of light propagating through a transverse magnetic field in two ways [22]. First, as the E_{\parallel} component, but not the E_{\perp} component will be depleted by the production of real axions, there will be in general a small rotation of the polarization vector of linearly polarized light. This effect will be a constant for all sufficiently light m_A such that the oscillation length is much longer than the magnet $(m_A^2 l/2\omega \ll 2\pi)$. For heavier axions, the effect oscillates and diminishes with increasing m_A , and vanishes for $m_A > \omega$. The second effect is birefringence of the vacuum, again because there can be a mixing of virtual axions in the E_{\parallel} state, but not for the E_{\perp} state. This will lead to light which is initially linearly polarized becoming elliptically polarized. Higher-order QED also induces vacuum birefringence, and is much stronger than the contribution due to axions. A search for both polarizationrotation and induced ellipticity has been carried out with the same magnets described in Sec. (III.4) above [21,23]. As in the case of photon regeneration, the observables are boosted linearly by the number of passes the laser beam makes in an optical cavity within the magnet. The polarization-rotation resulted in a stronger limit than that from ellipticity, $g_{A\gamma}$ < $3.6 \times 10^{-7} {\rm GeV^{-1}}$ (95% CL) for $m_A < 5 \times 10^{-4}$ eV. The limits from ellipticity are better at higher masses, as they fall off smoothly and do not terminate at m_A . There are two experiments in construction with greatly improved sensitivity which while still far from being able to detect standard axions, should measure the QED "light-by-light" contribution for the first time [24,25]. The overall envelope for limits from the laser-based experiments in Sec. (III.4) and Sec. (III.5) is shown schematically in Fig. 1.

 3 ADLER 97 bound is for massless $A^0.$ 4 KITCHING 97 limit is for B(K+ $\rightarrow \ \pi^+A^0$)·B($A^0 \rightarrow \gamma\gamma$) and applies for $m_{A^0} \simeq 50$ MeV, $\tau_{A^0} < 10^{-10}\,\mathrm{s}$. Limits are provided for $0 < m_{A^0} < 100$ MeV, $\tau_{A^0} < 10^{-8}\,\mathrm{s}$.

⁵ ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable A^0 particles and extends to m_{A^0} =80 MeV at the same level. See paper for dependence on finite lifetime.

⁶ AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.

⁷ The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0) > 10^{-23}$ sec.

 8 ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable 40 of m_{A^0} =150-250 MeV, and the limit becomes stronger (10⁻⁸) for m_{A^0} =180-240 MeV.

MeV. 9 NG 93 studled the production of X^0 via $\gamma\gamma \to \pi^0 \to \gamma X^0$ in the early universe at $T \simeq 1$ MeV. The bound on extra neutrinos from nucleosyntheis $\Delta N_{\nu} < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0 .

10 ALLIEGRO 92 limit applies for m_{A^0} =150-340 MeV and is the branching ratio times the decay ptobability. Limit is < 1.5 × 10⁻⁸ at 99%CL.

11 ATIYA 92 looked for a peak in missing mass distribution. The limit applies to $m_{\chi 0}$ =0-130 MeV in the narrow resonance limit. See paper for the dependence on

lifetime. Covariance requires X^0 to be a vector particle.

12 MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}$ – 10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for $m_{X^0} = 25$ –120 MeV. Angular momentum conservation requires that X^0 has snin > 1.

requires that X^0 has spin ≥ 1 . 13 ATIYA 90B limit is for B($K^+ \to \pi^+ A^0$)·B($A^0 \to \gamma \gamma$) and applies for $m_{A^0} = 50$ MeV, $\tau_{A^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{A^0} < 100$ MeV, $\tau_{A^0} < 10^{-8}$ s.

¹⁴ KORENCHENKO 87 limit assumes $m_{A^0} = 1.7$ MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and B($A^0 \rightarrow a^+a^-$) = 1

15 EICHLER 86 looked for $\pi^+ \to e^+ \nu A^0$ followed by $A^0 \to e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of A^0 . The quoted limits are valid when $\tau(A^0) \gtrsim 3. \times 10^{-10} \mathrm{s}$ if the decays are kinematically allowed.

16 YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

 17 ASANO 82 at KEK set limits for B(K+ $\to ~\pi^+ A^0$) for $m_{A^0} <$ <100 MeV as BR $< 4. \times 10^{-8}$ for $\tau (A^0 \to ~n\gamma$'s) $> 1. \times 10^{-9}$ s, BR $< 1.4 \times 10^{-6}$ for $\tau < 1. \times 10^{-9}$ s.

¹⁸ ASANO 81B is KEK experiment. Set B($K^+ \to \pi^+ A^0$) < 3.8 × 10⁻⁸ at CL = 90%. ¹⁹ ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 (3 < m <40 MeV) contradicts experimental muon anomalous magnetic moments.

A⁰ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

²⁰ BALEST 95 tooked for a monochromatic γ from T(1.5) decay. The bound is for $m_{A0} < 5.0$ GeV. See Fig. 7 in the paper for bounds for heavier m_{A0} . They also quote a bound on branching ratios 10⁻³-10⁻⁵ of three-body decay $\gamma X \overline{X}$ for $0 < m_X < 3.1$ GeV.

²¹ The combined limit of ANTREASYAN 90c and EDWARDS 82 excludes standard axion with $m_{A^0} < 2m_e$ at 90% CL as long as $C_T C_{J/\psi} > 0.09$, where $C_V \ (V = T, J/\psi)$ Is the reduction factor for $\Gamma(V \to A^0 \gamma)$ due to QCD and/or relativistic corrections. The same data excludes 0.02 < x < 260 (90% CL) if $C_T = C_{J/\psi} = 0.5$, and further combining with ALBRECHT 86D result excludes $5 \times 10^{-5} < x < 260$. x is the ratio of the vacuum expectation values of the two Higgs fields. These limits use conventional assumption $\Gamma(A^0 \to ee) \propto x^{-2}$. The alternative assumption $\Gamma(A^0 \to ee) \propto x^2$ gives a somewhat different excluded region 0.00075 < x < 44. 22 The first DRIZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3 \times 10^{-13}$ s/MeV and

 m_{A^0} < 20 MeV.

²³ The second DRUZHININ 87 limit is valid when au_{A0}/m_{A^0} < 5 × 10 $^{-13}$ s/MeV and m_{A^0} < 20 MeV.

²⁴ The third DRUZHININ 87 limit is valid when $au_{A^0}/m_{A^0} > 7 imes 10^{-12}$ s/MeV and m_{A^0} < 200 MeV.

 $^{25}\tau_{A^0}<1\times10^{-13}{\rm s}$ and $m_{A^0}<1.5$ GeV. Applies for $A^0\to\gamma\gamma$ when $m_{A^0}<100$ MeV. $^{26}\tau_{A^0}>1\times10^{-7}{\rm s}.$

27 Independent of TAO.

²⁸ BOWCOCK 86 looked for A^0 that decays into e^+e^- in the cascade decay $\Upsilon(25) \rightarrow$ $\Upsilon(1S)\pi^+\pi^-$ followed by $\Upsilon(1S)\to A^0\gamma$. The limit for B($\Upsilon(1S)\to A^0\gamma$)B($A^0\to$ e^+e^-) depends on m_{A^0} and τ_{A^0} . The quoted limit for m_{A^0} =1.8 MeV is at $\tau_{A^0}\sim$ 2. \times 10⁻¹²s, where the limit is the worst. The same limit 2. \times 10⁻³ applies for all lifetimes for masses $2m_e < m_{A^0} < 2m_{\mu}$ when the results of this experiment are combined with the results of ALAM 83.
29 MAGERAS 86 looked for $\mathcal{T}(15) \to \gamma A^0$ ($A^0 \to e^+e^-$). The quoted branching fraction limit is for $m_{A^0} = 1.7$ MeV, at $\tau(A^0) \sim 4. \times 10^{-13}$ s where the limit is the worst

worst. 30 ALAM 83 is at CESR. This limit combined with limit for B($J/\psi \to A^0\gamma$) (EDWARDS 82)

excludes standard axion. 31 NICZYPORUK 83 is DESY-DORIS experiment. This limit together with lower limit 9.2×10^{-4} of B($\Upsilon \to A^0 \gamma$) derived from B($J/\psi(15) \to A^0 \gamma$) limit (EDWARDS 82) excludes standard axion

³² EDWARDS 82 looked for $J/\psi \rightarrow \gamma A^0$ decays by looking for events with a single γ [of energy \sim 1/2 the $J/\psi(15)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

³³ SIVERTZ 82 is CESR experiment. Looked for $au o \gamma A^0$, A^0 undetected. Limit for 15 (35) is valid for $m_{A^0} < 7$ GeV (4 GeV).

A⁰ (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT

		39 AMALDI 40 CARRONI	85	CNTR	

 $^{^{34}}$ The ASAI 94 limit is based on inclusive photon spectrum and is independent of ${\it A}^{0}$ decay

- 38 ORITO 89 limit translates to $g_{A^0\,e\,e}^2/4\pi~<6.2 imes10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0} : $B < 7.6 \times 10^{-6}$ at 100 keV. ³⁹ AMALDI 85 set limits $B(A^0\gamma) / B(\gamma\gamma\gamma) < (1-5) \times 10^{-6}$ for $m_{A^0} = 900$ –100 keV
- which are about 1/10 of the CARBONI 83 limits.
- 40 CARBONI 83 looked for orthopositronium $\rightarrow A^0 \gamma$. Set limit for A^0 electron coupling squared, $g(e e A^0)^2/(4\pi) < 6 \times 10^{-10} 7 \times 10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from g-2 experiments.

A⁰ (Axion) Search in Photoproduction

DOCUMENT ID COMMENT

⁴¹ BASSOMPIE... 95 $m_{A^0} = 1.8 \pm 0.2 \text{ MeV}$

TECN COMMENT

41 BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of e^+e^- pairs in the region $m_{e^+e^-}=1.8\pm0.2$ MeV. They obtained bounds on the production rate A^0 for $\tau(A^0)=10^{-18}-10^{-9}$ sec. They also found an excess of events in the range $m_{e^+e^-}=2.1$ -3.5 MeV.

73 VYSOTSKII 78 42 AHMAD 97 reports a result of APEX Collaboration which studied positron production in $^{238} \rm U + ^{232} \rm Ta$ and $^{238} \rm U + ^{181} \rm Ta$ collisions, without requiring a coincident electron. No narrow lines were found for 250 <E $_{e^+}$ < 750 keV.

⁷² MICELMAC... 78

78

780 WIRE Beam dump

71 DONNELLY

HANSL

 $< 0.5 \times 10^{-8}$

- 43 LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy e^+e^- -line at \sim 635 keV in 238 U+ 181 Ta collision. Limits on the production probability bility for a narrow sum-energy e^+e^- line are set. See their Table 2.
- 44 GANZ 96 (EPos II Collaboration) has placed upper bounds on the production cross section of e^+e^- pairs from 238 U+ 181 Ta and 238 U+ 232 Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of ${\it e^+\,e^-}$ pairs. These limits rule out the existence of peaks in the e^+e^- sum-energy distribution, reported by an earlier version of this experiment.
- earlier version of this experiment. 45 KAMEL 96 looked for e^+e^- pairs from the collison of 32 5 (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{ee} > 2$ MeV.
- ⁴⁶ BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0 target to induce x. See Fig. 5 for the excluded region in m_{A0} -x plane. For the standard axion, 0.3 < x<25 is excluded at 95% CL. If combined with BLUEMLEIN 91, 0.008 < x<32 is excluded.

³⁵ The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0} < 10^{-13}~m_{A^0}$ [keV] s. 36 ASAI 91 limit translates to $g_{A^0}^2 e^+ e^-/4\pi < 1.1 \times 10^{-11}$ (90%CL) for $m_{A^0} < 800$

 $^{^{37}\,\}text{The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of$ A⁰ decay modes.

- 47 MEIJERDREES 92 give $\Gamma(\pi^- p \rightarrow nA^0)$ B($A^0 \rightarrow e^+ e^-$)/ $\Gamma(\pi^- p \rightarrow all)$ < 10^{-5} (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11} - 10^{-23}$ sec. Limits ranging from 2.5 × 10^{-3} to 10^{-7} are given for $m_{A^0} = 25$ -136 MeV.
- 48 BLUEMLEIN 91 Is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \rightarrow e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0} -x plane (x= $\tan \beta = v_2/v_1$). Standard axion is excluded for 0.2 $< m_{A^0} < 3.2$ MeV for most
- x>1, 0.2–11 MeV for most x<1. ⁴⁹ FAISSNER 89 searched for $A^0\to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass 2m-20 MeV is excluded. Lower limit on f_{A0} of $\simeq 10^4$ GeV is given for $m_{A0} = 2m_e$ -20 MeV.
- 50 DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass \sim 1.1, \sim 2.1, and \sim 9 MeV, lifetimes 10^{-16} - 10^{-15} s decaying to $e^+e^$ and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A A22 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B Is a reply which contests the criticism.
- 51 EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 \pm 0.59 MeV, lifetime (0.15 \pm 0.01) \times 10⁻¹⁴ s, which is produced in heavy ion interactions with emulsion nuclei at \sim 4 GeV/c/nucleon.
- 52 FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma \gamma$. A standard axion decaying to 2γ is excluded except for a region $x\!\!\simeq 1$. Lower limit on f_{A^0} of 10^2 – 10^3 GeV is given for $m_{A^0}=0.1$ –1 MeV.
- 53 BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range $m_{A^0}=$ (20–200) MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60-600) GeV. See their figure 6 for excluded region on $f(A^0)$ - m_{Δ^0} plane.
- ⁵⁴BERGSMA 85 look for $A^0 \rightarrow 2\gamma$, e^+e^- , $\mu^+\mu^-$. First limit above is for $m_{A^0}=1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on $f_{A0} - m_{A0}^{(1)}$ plane, where t_{A0} is A^0 decay constant. For Peccel-Quinn PECCEI 77 A^0 , m_{A0} <180 keV and τ >0.037 s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.
- 55 FAISSNER 83 observed 19 1-7 and 12 2-7 events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if Iron wall is set in front of the decay region.
- 56 FAISSNER 838 extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ 's are not at variance with LAMPF upper limit of 450 γ 's. Derived from LAMPF limit that $\left[d\sigma(A^0)/d\omega$ at 90° $M_{A^0}/\tau_{A^0} < 14 \times 10^{-35} \text{ cm}^2 \text{ sr}^{-1} \text{ MeV ms}^{-1}$. See comment on FRANK 83B.
- 57 FRANK 838 stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-AO are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ 's. See comment on FAISSNER 838. 58 HOFFMAN 83 set CL = 90% limit $d\sigma/dt$ B(e^+e^-) < 3.5 × 10⁻³² cm²/GeV² for 140
- < m_{A^0} < 160 MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.
- 59 FTSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay
- 60 FAISSNER 81 see excess μe events. Suggest axion interactions.
- 61 FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 \pm 5.0 events of 2 γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim$ 1 MeV. Axion interpretation with η - A^0 mixing gives $m_{A^0}=250\pm25$ keV, $\tau_{\{2\gamma\}}=(7.3\pm3.7)\times10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEK-SEEV 82, CAVAIGNAC 83, and ANANEV 85. 62 KIM 81 analyzed 8 candidates for $A^0\to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86\sim5.6)\times10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.
- 63 FAISSNER 80 Is SIN beam dump experiment with 590 MeV protons looking for $A^0 \rightarrow e^+e^-$ decay. Assuming $A^0/\pi^0=5.5\times 10^{-7}$, obtained decay rate limit $20/(A^0$ mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to m_{A0} <2m_e-
- 64 JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobserva tion of excess neutral-current-type events $[\sigma({
 m production})\sigma({
 m interactaction}) < 7. imes 10^{-68}$ cm⁴, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ 's or e+e-, and for axion mass a few MeV.
- 65 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
- ⁶⁶BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^- . No signal found. CL = 90% limits for model parameter(s) are given.
- 67 COTEUS 79 is a beam dump experiment at BNL.
- 68 DISHAW 79 is a calorimetric experiment and looks for low energy tall of energy distri-
- butions due to energy lost to weakly interacting particles.

 69 BELLOTTI 78 first value comes from search for $A^0 \rightarrow e^+e^-$. Second value comes from search for $A^0 \rightarrow e^+e^-$. For any mass satisfying this, limit is above value × (mass - 4). Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{Interaction}) < 10^{-67} \text{ cm}^4.$
- ⁷⁰ BOSETTI 78B quotes σ(production)σ(interaction) $< 2. \times 10^{-67}$ cm⁴.
- 71 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
- 72 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
- 73 VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red superglants.

A⁰ (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use th	e following data for averag	es, fit	s, limits,	etc. • • •
	74 ALTMANN	95	CNTR	Reactor; $A^0 \rightarrow e^+e^-$
	⁷⁵ KETOV	86	SPEC	Reactor, $A^0 \rightarrow \gamma \gamma$
	⁷⁶ косн	86	SPEC	Reactor; $A^0 \rightarrow \gamma \gamma$
	77 DATAR	82	CNTR	Light water reactor
	78 VUILLEUMIE	R 81	CNTR	Reactor, $A^0 \rightarrow 2\gamma$

- ⁷⁴ ALTMANN 95 looked for A^0 decaying into e^+e^- from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma) \times \mathbb{B}(A^0 \to 0)$ e^+e^-)< 10^{-16} for $m_{A^0}=1.5$ MeV at 90% CL. The limit is weaker for heavier A^0 . In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.
- 75 KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 [100 keV/ m_{A^0}] $^6\times 10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0} > 150$ keV. Not valid for $m_{A^0} \gtrsim$
- 76 1 MeV. 76 KOCH 86 searched for $A^0 \rightarrow \gamma \gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$
- 77 Rev. DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture $(np \to dA^0)$ at Tarapur 500 MW reactor. Sensitive to sum of I=0 and I=1 amplitudes. With ZEHNDER 81 [(I=0)]- (I = 1)] result, assert nonexistence of standard A^0 .
- 78 VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0} <$ 280 keV.

- $^{79}\, extsf{DEBOER}$ 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into e^+e^- would explain the excess of events with large opening
- 80 TSUNODA 95 looked for axion emission when ²⁵²Cf undergoes a spontaneous fission, with the axion decaying into e^+e^- . The bound is for $m_{A0}=40$ MeV. It improves to 2.5×10^{-5} for $m_{\ensuremath{A^0}}{=}200$ MeV.
- 81 MINOWA 93 studied chain process, 139 Ce \rightarrow 139 La* by electron capture and M1 transition of 139 La* to the ground state. It does not assume decay modes of A^0 . The bound applies for $m_{A^0}<$ 166 keV.
- ⁸² HICKS 92 bound is applicable for au_{χ^0} < 4 × 10⁻¹¹ sec.
- 83 The ASANUMA 90 limit is for the branching fraction of 20 emission per 241 Am $_{lpha}$ decay and valid for τ_{χ^0} < 3 × 10⁻¹¹ s.
- ⁸⁴ The DEBOER 90 limit is for the branching ratio 8 Be* (18.15 MeV, $^{1+}$) \rightarrow 8 Be 40 , $A^0 \rightarrow e^+ e^-$ for the mass range $m_{A^0} = 4$ –15 MeV.
- ⁸⁵The BINI 89 limit is for the branching fraction of $^{16}O^*(6.05 \text{ MeV}, 0^+) \rightarrow ^{16}OX^0$, $X^0
 ightharpoonup e^+ e^-$ for $m_X = 1.5$ -3.1 MeV. $au_{X^0} \lesssim 10^{-11} \, \mathrm{s}$ is assumed. The spin-parity of X is restricted to 0+ or 1-.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

- ⁸⁶ AVIGNONE 88 looked for the 1115 keV transition C* \rightarrow Cu A^0 , either from $A^0 \rightarrow$ 2γ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0}\,<\,1.1$ MeV.
- 87 DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \rightarrow e^+e^$ in the mass range 1.02-2.5 MeV and lifetime range 10^{-13} - 10^{-8} s. The above limit is for $\tau=5\times 10^{-13}$ s and m=1.7 MeV; see the paper for the τ -m dependence of the
- ⁸⁸The limit is for the branching fraction of $^{16}\text{O}^*$ (6.05 MeV, $^{+}$) \rightarrow ^{16}O 0 , 0 \rightarrow ${
 m e^+e^-}$ against internal pair conversion for $m_{\chi 0}=1.7$ MeV and $au_{\chi 0}~<~10^{-11}\,{
 m s}.$ Similar limits are obtained for $m_{\chi 0} = 1.3-3.2$ MeV. The spin parity of X^0 must be either 0+ or 1-. The limit at 1.7 MeV is translated into a limit for the X^0 -nucleon coupling constant: $g_{X^0NN}^2/4\pi < 2.3\times 10^{-9}$.
- ⁸⁹The DOEHNER 88 limit is for $m_{A^0}=1.7$ MeV, $\tau(A^0)<10^{-10}$ s. Limits less than
- 90 SAVAGE 88 looked for 0 40 that decays into e⁺ e⁻ in the decay of the 9.17 MeV P = 2 + state in 14 N, 17.64 MeV state J = 1 + in 8 Be, and the 18.15 MeV state J = 2 1+ In $^8\mathrm{Be}$. This experiment constrains the isovector coupling of A^0 to hadrons, if m_{A^0} = (1.1 \rightarrow 2.2) MeV and the isoscalar coupling of A^0 to hadrons, if m_{A^0} = (1.1 \rightarrow 2.6) MeV. Both limits are valid only if $au(A^0) \lesssim 1 imes 10^{-11}$ s.
- 91 Limits are for $\Gamma(A^0(1.8~\text{MeV}))/\Gamma(\pi M1);$ i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0}~<~2\times 10^{-11}\text{s.}^{~6}\text{Li}$ Isovector decay data strongly disfavor PECCEI 86 model I, whereas the 10B and 14N
- isoscalar decay data strongly reject PECCEI 86 model II and III. 92 SAVAGE 868 looked for 40 that decays into e^+e^- in the decay of the 9.17 MeV $J^P=$ 2^+ state in 14 N. Limit on the branching fraction is valid if $au_{A^0}\lesssim 1. imes 10^{-11} {
 m s}$ for m_{A^0} = (1.1-1.7) MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.
- 93 ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (LI* decay) and below $2m_e$ for deuteron* decay.
- 94 CAVAIGNAC 83 at Bugey reactor exclude axion at any m_{97} Nb*decay and axion with $m_{\Delta0}$ between 275 and 288 keV (deuteron* decay).
- 95 ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges m_{A^0} <400 keV (LI* decay) and 330 keV < m_{A^0} <2.2 MeV. (deuteron* decay).
- 96 LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5}/\text{s}$ (CL = 95%) excluding m_{A^0}
- between 100 and 1000 keV.

 97 ZEHNDER 82 used Goesgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0 . Set limit m_{A^0} <60 keV for any
- 98 ZEHNDER 81 looked for Ba* \rightarrow A⁰ Ba transition with A⁰ \rightarrow 2 γ . Obtained 2 γ coincidence rate $< 2.2 \times 10^{-5}/s$ (CL = 95%) excluding $m_{A^0} >$ 160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- ⁹⁹ CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A⁰ (Axion) Limits from its Electron Coupling

VALUE (s)	CL%	DOCUMENT ID		TECN	COMMENT
 • • We do not use the follow 	wing d	ata for averages, fits	i, limi	ts, etc. •	• •

- ¹⁰⁰ The listed BROSS 91 limit is for $m_{A^0}=1.14$ MeV. B($A^0\to e^+e^-$) = 1 assumed. Excluded domain in the τ_{A^0} - m_{A^0} plane extends up to $m_{A^0}\approx 7$ MeV (see Fig. 5). Combining with electron g-2 constraint, axions coupling only to e^+e^- ruled out for $m_{A^0}<4.8$ MeV (90%CL).
- $101\,\mathrm{GUO}$ 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with g – 2 constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0}~<~2.7$ MeV (90% CL).
- 102 BJORKEN 88 reports limits on axion parameters (f_A , m_A , τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.
- tors. 103 BLINOV 88 assume zero spin, m=1.8 MeV and lifetime $<5\times10^{-12}$ s and find $\Gamma(A^0\to\gamma\gamma)\mathrm{B}(A^0\to e^+e^-)<2$ eV (CL=90%). 104 Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0}<15$ MeV.
- 105 Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.
- $106\,m_{A^0}^2=1.8$ MeV assumed. The excluded domain in the $au_{A^0}-m_{A^0}$ plane extends up to $m_{A0}^{\gamma} \approx 14$ MeV, see their figure 4.

 $107\,\mathrm{The}$ limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma-A^0\,\mathrm{e}^+\,\mathrm{e}^-$ coupling plane by assuming Primakoff production.

Search for A⁰ (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$.

- 108 HALLIN 92 quote limits on lifetime, 8×10^{-14} 5×10^{-13} sec depending on mass, assuming B($A^0 \rightarrow e^+e^-$) = 100%. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.
- 109 HENDERSON 92C exclude axion with lifetime au_{A0} =1.4 imes 10 $^{-12}$ -4.0 imes 10 $^{-10}$ s, as- $\rightarrow e^+e^-)=100\%$. HENDERSON 92C also exclude a vector boson with $r=1.4 \times 10^{-12} - 6.0 \times 10^{-10}$ s.
- 110 WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming B($A^0 \rightarrow e^+e^-$)=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13}$ s.
- ¹¹¹WIDMANN 91 bound applies exclusively to the case B($A^0 \rightarrow e^+e^-$)=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{total}$ changes. See their Fig. 6.
- ¹¹² JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13} s $< \tau(A^0)$ $< 7.5 \times 10^{-12} \, \mathrm{s}$ (95% CL) at $m_{A^0} = 1.832$ MeV. Comparable limits can be set for m_{A0} = 1.776-1.856 MeV.
- 113 See also TSERTOS 88B in references.
 114 The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B,
- ¹¹⁵ VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$ – 10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.
- 116 MAIER 87 obtained limits $R\Gamma\lesssim 60$ eV (100 eV) at $m_{A^0}\simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\rm Cm}\simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma_{ee}^2/\Gamma_{total}$. For a discussion implying that $\Delta E_{\rm cm} \simeq 10 \, {\rm keV}$, see TSERTOS 89.
- 117 VONWIMMERSPERG 87 measured Bhabha scattering for $E_{\rm cm}=1.37$ –1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{\rm cm}=14.5\pm6.8$ keV-b. For a comment and a reply, see VANKLINKEN 888 and VONWIMMERSPERG 88. Also see CONNELL 88.

Search for A^0 (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for $\Gamma(A^0 \to e^+e^-) \cdot \Gamma(A^0 \to \gamma\gamma)/\Gamma_{\text{total}}$

- 130 BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2 \times 10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e (G_F/8\pi\sqrt{2})^{1/2}$.
- ¹³¹ALBRECHT 90E limits are for B($au o \ell X^0$)/B($au o \ell
 u \overline{
 u}$). Valid for $m_{\chi 0} < 100$
- MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for $m_{\chi^0}=500$ MeV. ¹³² ATIYA 90 limit is for $m_{\chi^0}=0$. The limit B < 1 × 10⁻⁸ holds for $m_{\chi^0}<95$ MeV. For the reduction of the limit due to finite lifetime of x^0 , see their Fig. 3.
- 133 BOLTON 88 limit corresponds to $F>3.1\times10^9$ GeV, which does not depend on the chirality property of the coupling.
- 134 CHANDA 88 find $v_{\mathcal{T}}~<$ 10 MeV for the weak-triplet Higgs vev. in Gelmini-Roncadelli model, and $v_{\rm S}~>~5.8\times10^6$ GeV in the singlet Majoron model.
- 135 CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2\times 10^{-5} < h < 3\times 10^{-4}$ for the

- interaction $L_{\rm int}=\frac{1}{2}lh\overline{\psi}_{\nu}^{c}\gamma_{5}\psi_{\nu}\phi_{\rm X}.$ For several families of neutrinos, the limit applies for $(\Sigma h_I^4)^{1/4}$.
- 136 PICCIOTTO 88 limit applies when $m_{\chi 0}~<$ 55 MeV and $au_{\chi 0}~>$ 2ns, and it decreases to 4×10^{-7} at $m_{\chi^0} = 125$ MeV, beyond which no limit is obtained.
- 137 GOLDMAN 87 limit corresponds to $F > 2.9 \times 10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int}=(1/F)\overline{\psi}_{\mu}\gamma^{\mu}$ $(a+b\gamma_5)$ $\psi_e\partial_{\mu}\phi_{\chi^0}$ with $a^2+b^2=1$. This is not as sensitive as the limit $F > 9.9 \times 10^9$ GeV derived from the search for $\mu^+ \rightarrow$ $e^+ \, \chi^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.
- 138 Limits are for $\Gamma(\mu \to e X^0)/\Gamma(\mu \to e \nu \overline{\nu})$. Valid when $m_{\chi^0}=0$ –93.4, 98.1–103.5
- 139 EICHLER 86 looked for $\mu^+ \to e^+ X^0$ followed by $X^0 \to e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0 . The quoted limits are valid when $\tau_{X^0} \lesssim 3. \times 10^{-10}$ s if the decays are kinematically allowed.
- ¹⁴⁰ JODIDIO 86 corresponds to $F > 9.9 \times 10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int}=(1/F)~\overline{\psi}_{\mu}\gamma^{\mu}\psi_{e}\partial^{\mu}\phi_{\chi^{0}}$
- ¹⁴¹BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95%
- limits are $B(\tau \to \mu^+ X^0)/B(\tau \to \mu^+ \nu \nu)$ < 0.125 and $B(\tau \to e^+ X^0)/B(\tau \to e^+ \nu \nu)$ < 0.04. Inferred limit for the symmetry breaking scale is m > 3000 TeV.

 142 The primordial heavy neutrino must decay into ν and familion, f_A , early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \infty$ πf_A and $\mu \to -e f_A$ are unseen. Combining these excludes $m_{
 m heavy}
 u$ between 5 imes 10 $^{-5}$ and 5 \times 10 $^{-4}$ MeV (μ decay) and $m_{\rm heavy}\nu$ between 5 \times 10 $^{-5}$ and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. Previous Indications for neutrinoless double beta decay with majoron emission have been superseded. No experiment currently claims any such evidence. For a review, see

- 143 BERNATOWICZ 92 studied double-eta decays of 128 Te and 130 Te, and found the ratio $(1^{30}\text{Te})/r(1^{20}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of 128 Te of $(7.7\pm0.4)\times10^{24}$ year. We calculated 90% CL limit as $(7.7-1.28 \times 0.4=7.2) \times 10^{24}$.

- 144 See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models. 145 TANAKA 93 also quote limit 5.3 \times 10¹⁹ years on two Majoron emission. 146 VERGADOS 82 sets limit $g_H < 4 \times 10^{-3}$ for (dimensionless) lepton-number violating coupling, g_H , of scalar boson (Majoron) to neutrinos, from analysis of data on double β decay of ⁴⁸Ca.

Invisible A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

 $v_1=v_2$ is usually assumed ($v_i=$ vacuum expectation values). For a review of these limits, see RAFFELT 90C and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

147 BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-13}$ from the photoproduction of axions off of electric fields in the outer layers of neutron stars. 148 KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1 \times 10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9 \times 10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.

149 KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and plon-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.

150 RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red glant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).

151 ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5 \times 10^{-13}$, from energy

loss via axion emission.

152 BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2 γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

153 KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an upperbound rather than a lowerbound.

154 RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung process

155 RESSELL 91 uses absence of any Intracluster line emission to set limit.

 156 ENGEL 90 rule out $10^{-10}\lesssim g_{AN}\lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to 2.5 \times 10⁻³ eV $\lesssim m_{A^0} \lesssim$ 2.5 \times 10⁴ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

157 RAFFELT 90D is a re-analysis of DEARBORN 86.

 158 The region $m_{A^0} \gtrsim 2$ eV is also allowed.

159 ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

160 MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2-4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 888.

161 RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium burning stars $\epsilon <$ 100 erg g $^{-1}$ s $^{-1}$, which gives a firmer basis for the axion limits based on red glant cooling.

 162 RAFFELT 87 also gives a limit $g_{A\gamma}~<~1\times 10^{-10}~{\rm GeV}^{-1}.$

 163 DEARBORN 86 also gives a limit $g_{A\gamma}~<~1.4 \times 10^{-11}~{\rm GeV}^{-1}.$

 164 RAFFELT 86 gives a limit $g_{A\gamma} < 1.1 \times 10^{-10}~{\rm GeV}^{-1}$ from red glants and $< 2.4 \times 10^{-9}$

GeV $^{-1}$ from the sun. 165 KAPLAN 85 says $m_{A^0} <$ 23 eV is allowed for a special choice of model parameters.

 $^{166}\,\mathrm{FUKUGITA}$ 82 gives a limit $g_{A\gamma}~<~2.3\times10^{-10}~\mathrm{GeV}^{-1}.$

167 HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

168 WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A0}]^2$ = 2×10^{-14} MeV $^{-4}$ (the three generation DFSZ model) and $\rho_A=300$ MeV/cm 3 that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\,\rho_A=4\times 10^{-44}.$ Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A⁰ (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L=G_{A\gamma\gamma}\phi_A {\bf E}\cdot {\bf B}$. Related limits from astrophysics can be found in the "Invisible A⁰ (Axion) Mass Limits from Astrophysics and Cosmology" section.

174 These experiments measured induced magnetization of a bulk material by the spindependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.

These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either

176 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

Axion Limits from T-violating Medium-Range Forces

The limit is for the coupling g in a T-violating potential between nucleons or nucleon and electron of the form $V = \frac{g\hbar^2}{8\pi m_g} (\sigma \dot{\Phi}) \left(\frac{1}{f^2} + \frac{m_A c}{\hbar r} \right) e^{-m_A c r/\hbar}$
