$\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^- \ell^+ \nu) / A(K^0 \to \pi^- \ell^+ \nu)$$
.

We list $Re\{x\}$ and $Im\{x\}$ for K_{e3} and $K_{\mu3}$ combined.

$x = A(\overline{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q)/A(\Delta S = \Delta Q)$

153 FRANZINI 65 gives x and θ for Re(x) and Im(x). See SCHMIDT 67.

CPT-VIOLATION PARAMETERS IN KO DECAY

if $\ensuremath{\textit{CP}}\xspace$ -violating interactions include a $\ensuremath{\textit{T}}\xspace$ conserving part then

$$\begin{split} |\kappa_S\rangle &= [|\kappa_1\rangle + (\epsilon + \Delta)|\kappa_2\rangle]/\sqrt{1 + |\epsilon + \Delta|^2} \\ |\kappa_L\rangle &= [|\kappa_2\rangle + (\epsilon - \Delta)|\kappa_1\rangle]/\sqrt{1 + |\epsilon - \Delta|^2} \\ \text{where} \\ |\kappa_1\rangle &= [|\kappa^0\rangle + |\overline{\kappa}^0\rangle]/\sqrt{2} \\ |\kappa_2\rangle &= [|\kappa^0\rangle - |\overline{\kappa}^0\rangle]/\sqrt{2} \\ \text{and} \\ |\overline{\kappa}^0\rangle &= \mathit{CP}|\kappa^0\rangle. \end{split}$$

The parameter Δ specifies the *CPT*-violating part.

Estimates of Δ are given below. See also THOMSON 95 for a test of $\it CPT$ -symmetry conservation in $\it K^0$ decays using the Bell-Steinberger relation.

REAL PART OF Δ

A nonzero value v	iolates <i>CP</i>	T invariance.

 $K^*(892)^0$ mass (MeV)

K*(892) MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = rac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4rac{\Gamma}{\sqrt{N}} \; .$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

$m_{K^{\bullet}(892)^{0}} - m_{K^{\bullet}(892)^{\pm}}$

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2=7.8$ for 11 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta p_i \delta p_j \right\rangle / \left\langle \delta p_i \cdot \delta p_j \right\rangle$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Mode	Rate (MeV)

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2=20.2$ for 24 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta p_i \delta p_j \right\rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2=2.9$ for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one

$$I(J^P) = \frac{1}{2}(2^-)$$

THE $K_2(1770)$ AND THE $K_2(1820)$

A partial-wave analysis of the $K^-\omega$ system based on about 100,000 $K^-p\to K^-\omega p$ events (ASTON 93) gives evidence for two $q\bar{q}$ D-wave states near 1.8 GeV. A previous analysis based on about 200,000 diffractively produced $K^-p\to K^-\pi^+\pi^-p$ events (DAUM 81) gave evidence for two $J^P=2^-$ states in this region, with masses \sim 1780 MeV and \sim 1840 MeV and widths \sim 200 MeV, in good agreement with the results of ASTON 93. In contrast, the masses obtained using a single resonance do not agree well: ASTON 93 obtains 1728 \pm 7 MeV, while DAUM 81 estimates \sim 1820 MeV. We conclude that there are indeed two K_2 resonances here.

We list under the $K_2(1770)$ other measurements that do not resolve the two-resonance structure of the enhancement.

 $^{^6}$ From energy-independent partial-wave analysis. 7 From a fit to Y_6^2 moment. $J^P={\bf 3}^-$ found.

 $^{^3}$ Confirmed by phase shift analysis of ESTABROOKS 78, yields $J^P=3^-.$ 4 From a partial wave amplitude analysis. 5 From a fit to the Y_0^6 moment.

 $K_3^*(1780), K_2(1820)$

 10 Errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

11 ESTABROOKS 78 find that BRANDENBURG 76D data are consistent with 175 MeV width. Not averaged.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=$ 0.0 for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ Γ_i/Γ_{total} . The fit constrains the x_i whose labels appear in this array to sum to one.

and in np and nA reactions by ALEEV 93. Not seen by BOEHN-LEIN 91. If due to strong decays, this state has exotic quantum numbers (B=0,Q=+1,S=-1 for $\varLambda \overline{p}\pi^+\pi^+$ and $I \geq 3/2$ for $\varLambda \overline{p}\pi^-$).

Needs confirmation.

Meson Particle Listings D MESONS, D^{\pm}

CHARMED MESONS

 $(C=\pm 1)$

 $D^+ = c\overline{d}$, $D^0 = c\overline{u}$, $\overline{D}{}^0 = \overline{c}u$, $D^- = \overline{c}d$, similarly for D^* 's

NOTE ON D MESONS

Written March 1998 by P.R. Burchat (Stanford University).

The new experimental results on charm meson decays reported in this edition are mostly from CLEO II at the e^+e^- storage ring CESR and from the Fermilab fixed-target experiments E687 and E791. A number of searches have been made for rare decays that are potentially sensitive to new physics, such as $D^0\overline{D}^0$ mixing (AITALA 96C and AITALA 98), CP-violating asymmetries in decay rates (AITALA 97B and AITALA 98C), and decays that would signal flavor-changing neutral currents (ADAMOVICH 97 and ALEXOPOULOS 97) or lepton-family number or lepton number violation (FRABETTI 97B). None of the searches has yielded evidence for new physics.

Significant progress has been made in the area of semileptonic charm decays. Five new results on rates for Cabibbo-suppressed semileptonic decays appear in this edition: $D^+ \to \rho \ell^+ \nu_\ell$ from E687 (FRABETTI 97) and E791 (AITALA 97), $D^0 \to \pi^- \ell^+ \nu_\ell$ from E687 (FRABETTI 96B), and $D^+ \to \pi^0 \ell^+ \nu_\ell$ and $\eta e^+ \nu_e$ from CLEO (BARTELT 97). Our knowledge of the inclusive semileptonic decay rate for the D^0 is greatly improved by new results from ARGUS (ALBRECHT 96C) and CLEO (KUBOTA 96B). The precision of the measurement of the form-factor ratios in the decay $D^+ \to \overline{K}^{*0} \ell^+ \nu_\ell$ has been improved by about a factor of two in a new analysis by E791 (AITALA 98B).

Many new studies of hadronic final states have been made, including measurements of singly and doubly Cabibbo-suppressed D^0 and D^+ decay rates and studies of resonant substructure.

New measurements of the \dot{D}_s^+ decay constant have been made by the L3 collaboration (ACCIARRI 97F) and the E653 collaboration (KODAMA 96). However, the statistical and systematic uncertainties are still on the order of (10–20)% each. Other new measurements on the D_s^+ front include two inclusive branching fractions by BES (BAI 97 and BAI 98), and the first observation of $D_s^+ \to \omega \pi^+$ by CLEO (BALEST 97).

$$I(J^P) = \frac{1}{2}(0^-)$$

D± MASS

The fit includes D^{\pm} , D^0 , D_s^{\pm} , $D^{*\pm}$, D^{*0} , and $D_s^{*\pm}$ mass and mass difference measurements.

 Γ_{160} A dummy mode used by the fit.

- (33 ±5)%
- [a] This is a weighted average of D^{\pm} (44%) and D^{0} (56%) branching fractions. See " D^+ and $D^0 \rightarrow (\eta \text{ anything}) / (\text{total } D^+ \text{ and } D^0)$ " under "D+ Branching Ratios" in these Particle Listings.
- [b] This value averages the e^+ and μ^+ branching fractions, after making a small phase-space adjustment to the μ^+ fraction to be able to use it as an e^+ fraction; hence our ℓ^+ here is really an e^+ .
- [c] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [d] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
- [e] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

CONSTRAINED FIT INFORMATION

An overall fit to 32 branching ratios uses 54 measurements and one constraint to determine 20 parameters. The overall fit has a $\chi^2 = 20.8$ for 35 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ Γ_i/Γ_{total} . The fit constrains the x_i whose labels appear in this array to sum to

one.

- ⁴ Isolates D^+ and $D^0 \to e^+ X$ and weights for relative production (44%–56%). ⁵ ALBRECHT 96C uses e^- in the hemisphere opposite to $D^{*+} \to D^0 \pi^+$ events.
- ⁶ ABE 93E also measures forward-backward asymmetries and fragmentation functions for c and b quarks.
- C and D quarks.

 7 ALBRECHT 92F uses the excess of right-sign over wrong-sign leptons in a sample of events tagged by fully reconstructed $D^*(2010)^+ \rightarrow D^0 \pi^+$ decays.

 8 Average BR for charm $\rightarrow e^+$ X. Unlike at $E_{\rm cm} = 3.77$ GeV, the admixture of charmed
- mesons is unknown.

 Not independent of BACINO 80 measurements of $\Gamma(e^+$ anything)/ Γ_{total} for the D^+ and D^0 separately.

 12 ALBRECHT 92F uses the excess of right-sign over wrong-sign leptons in a sample of events tagged by fully reconstructed $D^*(2010)^+\to~D^0~\pi^+$ decays.

Leptonic and semileptonic modes

$\Gamma(\mu^+\nu_\mu)/\Gamma_{\rm total}$

 Γ_7/Γ

See the "Note on Pseudoscalar-Meson Decay Constants" in the π^\pm Listings for the limit inferred on the D^+ decay constant from the limit here on $\Gamma(\mu^+\nu_\mu)/\Gamma_{\rm total}$.

CL% EVTS DOCUMENT ID TECN COMMENT 90 ADLER 888 MRK3 e+e- 3.77 GeV • • • We do not use the following data for averages, fits, limits, etc. • • • 0 13 AUBERT 83 SPEC μ^+ Fe, 250 GeV 90

¹³ AUBERT 83 obtains an upper limit 0.014 assuming the final state contains equal amounts of (D^+,D^-) , (D^+,\overline{D}^0) , (D^-,D^0) , and (D^0,\overline{D}^0) . We quote the limit they get under more general assumptions.

$\Gamma(K^0\ell^+\nu_\ell)/\Gamma_{\text{total}}$

 Γ_8/Γ

We average our $\overline{K}{}^0e^+\nu_e$ and $\overline{K}{}^0\mu^+\nu_\mu$ branching fractions, after multiplying the latter by a phase-space factor of 1.03 to be able to use it with the $\overline{K}{}^0\,e^+\nu_e$ fraction.

D^{\pm} PRODUCTION CROSS SECTION AT $\psi(3770)$

A compilation of the cross sections for the direct production of D^\pm mesons at or near the $\psi(3770)$ peak in e^+e^- production.

VALUE (nanobarns)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the	following data for average	s, fits, limit	s, etc. • • •
4.2 ±0.6 ±0.3			3 e ⁺ e ⁻ 3.768 GeV

9.1 ±2.0	⁷¹ PERUZZI	77 MRK	1 e ⁺ e ⁻ 3.774 GeV
68 This measurement con	nnares events with one de	terted D to	those with two detected D

 68 This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C measure the ratio of cross sections (neutral to charged) to be 1.36 \pm 0.23 \pm 0.14. This measurement does not include the decays of the $\psi(3770)$ not associated with charmed particle production.

69 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 \pm 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and we assume that the $\psi(3770)$ is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

may amount to a few percent correction.

70 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.

71 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross

to a few percent correction. 71 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

¹ PERUZZI 77 and SCHINDLER 81 errors do not include the 0.13% uncertainty in the absolute SPEAR energy calibration. TRILLING 81 uses the high precision $J/\psi(1.5)$ and $\psi(2.5)$ measurements of ZHOLENTZ 80 to determine this uncertainty and combines the PERUZZI 77 and SCHINDLER 81 results to obtain the value quoted. TRILLING 81 enters the fit in the D^{\pm} mass, and PERUZZI 77 and SCHINDLER 81 enter in the $m_{D^{\pm}} - m_{D^0}$, below.

² Error does not include possible systematic mass scale shift, estimated to be less than 5 MeV.

$m_{D^{\pm}} - m_{D^0}$

The flt includes D^{\pm} , D^{0} , D_{s}^{\pm} , $D^{*\pm}$, D^{*0} , and $D_{s}^{*\pm}$ mass and mass difference measurements.

$|m_{D_1^0} - m_{D_2^0}|$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson. To calculate the following limits, we use $\Delta m = [2r/(1-r)]^{1/2} \hbar/4.15 \times 10^{-13}$ s, where r is the experimental $D^0 \cdot \overline{D}{}^0$ mixing ratio.

- hing frac-⁰)" under
- making a o use it as
- [c] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
- [d] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [e] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [f] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [g] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.
- [h] The value is for the sum of the charge states of particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 51 branching ratios uses 122 measurements and one constraint to determine 28 parameters. The overall fit has a $\chi^2 = 64.8$ for 95 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

                                                  95 CLE2 < 0.156 (90% CL)
TTI 968 uses both e and \mu events, and makes a small correction to the \mu events to
nem effectively e events. This result gives \left| \frac{V_{cd}}{V_{cs}}, \frac{f_{r}^{\pi}(0)}{f_{r}^{\pi}(0)} \right|^2 = 0.050 \pm 0.011 \pm 0.002.
R 95 has 87 \pm 33 \pi^- e^+ \nu_e events. The result gives |\frac{V_{Cd}}{V_{Cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{\kappa}(0)}|^2 = 0.052 \pm
0.007.

II 88, DECAMP 911, AKERIB 93, ALBRECHT 94F, BARATE 97c, and AR-
98 use D^*(2010)^+ \rightarrow D^0 \pi^+ decays. The \pi^+ is both slow and of low p_T with
to the event thrust axis or nearest let (\approx D^{*+} direction). The excess number
\pi^+'s over background gives the number of D^*(2010)^+ \to D^0 \pi^+ events, and those with D^0 \to K^- \pi^+ gives the D^0 \to K^- \pi^+ branching fraction. ECHT 94 uses D^0 mesons from \overline B{}^0 \to D^{*+} \ell^- \overline{\nu}_\ell decays. This is a different set ts than used by ALBRECHT 94F.
(ERIB 93 value includes radiative corrections; without them the value is 0.0391 \pm
DLER 81 (MARK-2) measures \sigma(e^+e^-
                                                    \rightarrow \psi(3770)) \times branching fraction to
\pm 0.02 nb. We use the MARK-3 (ADLER 88C) value of \sigma = 5.8 \pm 0.5 \pm 0.6 nb.
ZI 77 (MARK-1) measures \sigma(e^+e^-\to \psi(3770)) \times branching fraction to be 0.05 nb. We use the MARK-3 (ADLER 88C) value of \sigma=5.8\pm0.5\pm0.6 nb.

D⁰ PRODUCTION CROSS SECTION AT \$\psi(3770)

A compilation of the cross sections for the direct production of D^0 mesons at or near the $\psi(3770)$ peak in $e^+\,e^-$ production.

- 112 This measurement compares events with one detected D to those with two detected D
- This measurement compares events with one detected D to those with two detected D mesons, to determine the the absolute cross section. ADLER 88C find the ratio of cross sections (neutral to charged) to be 1.36 ± 0.23 ± 0.14.
 This measurement comes from a scan of the ψ(3770) resonance and a fit to the cross section. PARTRIDGE 84 measures 6.4 ± 1.15 nb for the cross section. We take the phase space division of neutral and charged D mesons in ψ(3770) decay to be 1.33, and we assume that the ψ(3770) is an isosinglet to evaluate the cross sections. The noncharm decays (e.g. radiative) of the ψ(3770) are included in this measurement and may amount to a few percent correction.
 This measurement comes from a scan of the ψ(3770) resonance and a fit to the cross
- may amount to a few percent correction.
 114 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section.
 SCHINDLER 80 assume the phase space division of neutral and charged D mesons in $\psi(3770)$ decay to be 1.33, and that the $\psi(3770)$ is an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction.
- to a few percent correction. 115 This measurement comes from a scan of the $\psi(3770)$ resonance and a fit to the cross section. The phase space division of neutral and charged D mesons in $\psi(3770)$ decay is taken to be 1.33, and $\psi(3770)$ is assumed to be an isosinglet. The noncharm decays (e.g. radiative) of the $\psi(3770)$ are included in this measurement and may amount to a few percent correction. We exclude this measurement from the average because of uncertainties in the contamination from τ lepton pairs. Also see RAPIDIS 77.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2=$ 0.5 for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

 $D_s^+ = c\overline{s}, D_s^- = \overline{c}s$, similarly for D_s^* 's

$$I(J^P) = 0(0^-)$$

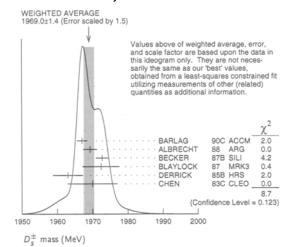

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a c3 ground state.

D_s^{\pm} MASS

The fit includes D^{\pm} , D^0 , D_s^{\pm} , $D^{\pm\pm}$, D^{*0} , and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the D_s^{\pm} mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a]	For now, we average togeth branching fractions. This is				d X $\mu^+ u_\mu$

- [b] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
- [c] This branching fraction includes all the decay modes of the final-state
- [d] This value includes only K^+K^- decays of the $f_J(1710)$, because branching fractions of this resonance are not known.
- [e] This value includes only $\pi^+\pi^-$ decays of the $f_0(1500)$, because branching fractions of this resonance are not known.
- [f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 24 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 17.8$ for 15 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

D*+ DECAY MODES

 $D_{\rm S}^{*-}$ modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_I/Γ)	
$\overline{\Gamma_1}$	$D_5^+ \gamma$	(94.2±2.5) %	
Γ_2	$\begin{array}{c}D_s^+\gamma\\D_s^+\pi^0\end{array}$	(5.8±2.5) %	

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 1 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2=$ 0.0 for 0 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

$D_{s1}(2536)^{\pm}$

 $I(J^P) = 0(1^+)$ J, P need confirmation.

Seen in $D^*(2010)^+ K^0$. Not seen in $D^+ K^0$ or $D^0 K^+$. $J^P = 1^+$ assignment strongly favored.

B Meson Production and Decay, b-flavored hadrons

BOTTOM MESONS

 $(B=\pm 1)$

 $B^+ = u\overline{b}$, $B^0 = d\overline{b}$, $\overline{B}{}^0 = \overline{d}b$, $B^- = \overline{u}b$, similarly for $B^{\bullet *}$'s

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^{\pm} section, but because of their importance we have created two new sections: " B^{\pm}/B^0 Admixture" for T(4S) results and " $B^{\pm}/B^0/B_s^0/b$ -baryon Admixture" for results at higher energies. Most inclusive decay branching fractions are found in the Admixture sections. $B^0.\overline{B}^0$ mixing data and B- \overline{B} mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP-violation data are found in the B^0 section. D-baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF b-FLAVORED HADRONS

Written March 1998 by K. Honscheid (Ohio State University, Columbus).

In 1997 we celebrated the 20th anniversary of the discovery of the b quark. What started out as a bump in the dimuon invariant mass spectrum has turned into the exciting field of heavy flavor physics. Weak decays of heavy quarks provide access to fundamental parameters of the Standard Model, in particular the weak mixing angles of the Cabibbo-Kobayashi-Maskawa matrix. There is great hope that experiments with B mesons may lead to the first precise determination of the fourth CKM parameter, the complex phase. While the underlying decay of the heavy quark is governed by the weak interaction, it is the strong force that is responsible for the formation of the hadrons that are observed by experimenters. Although this complicates the extraction of the Standard Model parameters from the experimental data it also means that decays of B mesons provide an important laboratory to test our understanding of the strong interaction

New results that were added to this edition fall into two categories. Arguably the most exciting development since the last edition of this review is the progress in b-quark decays beyond the tree level. Gluonic penguin decays such as $B \to K^-\pi^+$ have been measured for the first time providing us with new opportunities to search for physics beyond the Standard Model and/or to probe the phase structure of the CKM matrix.

At tree level, i.e. for $b \to c$ transitions, the CLEO collaboration used a sample of more than 6 million B decays to update branching fractions for many exclusive hadronic decay channels. New results on semileptonic decays have been reported by CLEO and the LEP collaborations. Lifetime measurements improved steadily and now have reached a precision of a few percent.

Heavy flavor physics is a very dynamic field and in this brief review it is impossible to do justice to all recent theoretical and experimental developments. I will highlight a few new results but otherwise refer the interested reader to several excellent reviews [1-4].

Production and spectroscopy: Elementary particles are characterized by their masses, lifetimes and internal quantum numbers. The bound states with a b quark and a \overline{u} or \overline{d} antiquark are referred to as the B_d $(\overline{B^0})$ and the B_u (B^-) mesons, respectively. The first excitation is called the B^* meson. B^{**} is the generic name for the four orbitally excited (L=1) B-meson states that correspond to the P-wave mesons in the charm system, D^{**} . Mesons containing an s or a c quark are denoted B_s and B_c , respectively.

Experimental studies of b decay are performed at the $\Upsilon(4S)$ resonance near production threshold as well as at higher energies in proton-antiproton collisions and Z decays. Most new results from CLEO are based on a sample of $\approx 3.1 \times 10^6$ $B\overline{B}$ events. At the Tevatron, CDF and DØ have collected 100

pb⁻¹ of data. Operating at the Z resonance each of the four LEP collaborations recorded slightly under a million $b\bar{b}$ events while the SLD experiment collected about 0.2 million hadronic Z decays.

For quantitative studies of B decays the initial composition of the data sample must be known. The $\Upsilon(4S)$ resonance decays only to $B^0\overline{B}^0$ and B^+B^- pairs, while at high-energy collider experiments heavier states such as B_s or B_c mesons and b-flavored baryons are produced as well. The current experimental limit for non- $B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level [5]. CLEO has measured the ratio of charged to neutral $\Upsilon(4S)$ decays using semileptonic B decays and found [6]

$$\frac{f_{+}}{f_{0}} = \frac{\mathcal{B}(\Upsilon(4S) \to B^{+}B^{-})}{\mathcal{B}(\Upsilon(4S) \to B^{0}\overline{B}^{0})} = 1.13 \pm 0.14 \pm 0.13 \pm 0.06 \quad (1)$$

where the last error is due to the uncertainties in the ratio of B^0 and B^+ lifetimes. Assuming isospin symmetry an independent value can be obtained from $\mathcal{B}(B^- \to J/\psi K^{(*)-})$ and $\mathcal{B}(\overline{B}^0 \to J/\psi \overline{K}^{(*)0})$ [7]:

$$\frac{f_{+}}{f_{0}} = 1.11 \pm 0.17 \ . \tag{2}$$

This is consistent with equal production of B^+B^- and $B^0\overline{B}^0$ pairs and unless explicitly stated otherwise we will assume $f_+/f_0=1$. This assumption is further supported by the near equality of the B^+ and B^0 masses.

At high-energy collider experiments b quarks hadronize as $\bar{B}^0, B^-, \bar{B}^0_s$, and B_c^- mesons or as baryons containing b quarks. The b-hadron sample composition is not very precisely known although over the last few years significant improvements have been achieved, in particular thanks to B^0 oscillation measurements. The fractions $f_{B^0}, f_{B^+}, f_{B_s}$, and f_{A_b} of B^0, B^+, B_s^0 , and b baryons in an unbiased sample of weakly decaying b hadrons produced at the b resonance are shown in Table 1. They have been estimated by the LEP b oscillations working group [8] using the assumptions b and b and b are the b summarized below.

An estimate of f_{B_s} is obtained from the measurements of the product branching fraction $f_{B_s} \times \mathcal{B}(B_s \to D_s^- \ell^+ \nu_{\ell} X)$. Under the assumption of equal semileptonic partial widths for b-flavored hadrons, results from the $\Upsilon(4S)$ experiments and the b-hadron lifetimes (Table 2) are combined to obtain an estimate for $\mathcal{B}(B_s \to D_s^- \ell \nu_\ell X)$. Together these are used to extract $f_{B_s} =$ $(12.0^{+4.5}_{-3.4})$ %. A similar procedure is followed to obtain $f_{A_b} =$ $(10.1^{+3.9}_{-3.1})\%$ from measurements of $f_{\Lambda_b} \times \mathcal{B}(\Lambda_b \to \Lambda_c^+ \ell^- \overline{\nu}_\ell X)$. A statistically independent estimate $f_{B_s} = (10.1^{+2.0}_{-1.9})\%$ is then derived from measurements of B^0 oscillations. This is done using measurements of the mixing parameters $\chi_d = (1/2)$. $x_d^2/(1+x_d^2)$, in which $x_d=\Delta m_d \tau_{B^0}$, and $\overline{\chi}=f_{B_s}' \chi_s + f_{B^0}' \chi_d$. Here f'_{B_s} and f'_{B^0} are the fractions of B^0_s and B^0 mesons among semileptonic b decays. The dependence on the lifetimes is taken into account and $\chi_s = 1/2$ is assumed. This estimation is performed simultaneously with the Δm_d averaging described

in the mixing section below. An average of the two estimates of f_{B_s} , taking the correlated systematic effects into account, yields $f_{B_s} = (10.5^{+1.8}_{-1.7})\%$ and hence the fractions of Table 1.

Table 1: Fractions of weakly decaying b-hadron species in $Z \to b\bar{b}$ decay.

\overline{b} hadron	Fraction [%]
$\overline{B^-}$	$39.7^{+1.8}_{-2.2}$
$ ilde{B}^0$	$39.7^{+1.8}_{-2.2}$
$ar{B}^0_s$	$10.5_{-1.7}^{+1.8}$
b baryons	$10.1^{+3.9}_{-3.1}$

To date, the existence of four b-flavored mesons $(B^-, \overline{B}^0, B^*, B_s)$ as well as the Λ_b baryon has been established. Using exclusive hadronic decays such as $B_s^0 \to J/\psi \phi$ and $\Lambda_b \to J/\psi \Lambda$ the masses of these states are now known with a precision of a few MeV. The current world averages of the B_s and the Λ_b mass are 5369.6 ± 2.4 MeV/ c^2 and 5624 ± 9 MeV/ c^2 , respectively.

The B_c is the last weakly decaying bottom meson to be observed. Potential models predict its mass in the range 6.2–6.3 GeV/ c^2 . At the 1998 La Thuile conference CDF presented an analysis providing clear evidence for semileptonic $B_c \rightarrow J/\psi \ell X$ decays with $20.4^{+6.2}_{-5.5}$ observed events [13]. CDF reconstructs a B_c mass of $6.4 \pm 0.39 \pm~0.13$ MeV/ c^2 and a B_c lifetime of $0.46^{+0.18}_{-0.16} \pm 0.03$ ps.

First indications of Σ_b and Ξ_b production have been presented by the LEP collaborations [14]. DELPHI has measured the $\Sigma_b^* - \Sigma_b$ hyperfine splitting to 56 ± 16 MeV [15].

Excited B-mesons states have been observed by CLEO, CUSB, and LEP. Evidence for B^{**} production has been presented by ALEPH, OPAL, and DELPHI [3]. Inclusively reconstructing a bottom hadron candidate combined with a charged pion from the primary vertex they see the B^{**} as broad resonance in the $M(B\pi)$ M(B) mass distribution. The LEP experiments have also provided preliminary evidence for excited B_s^{**} states and DELPHI [16] has reported a possible observation of the B', the first radial excitation in the B meson system.

Lifetimes: In the naive spectator model the heavy quark can decay only via the external spectator mechanism and thus the lifetimes of all mesons and baryons containing b quarks would be equal. Nonspectator effects such as the interference between contributing amplitudes modify this simple picture and give rise to a lifetime hierarchy for b-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variation in the b system should be significantly smaller, of order 10% or less [17]. For the b system we expect

$$\tau(B^-) \geq \tau(\overline{B}^0) \approx \tau(B_s) > \tau(\Lambda_b^0) . \tag{3}$$

Measurements of lifetimes for the various b-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector. Precise lifetimes are

b-flavored hadrons

important for the determination of V_{cb} . They also enter in $B\overline{B}$ mixing measurements.

Over the past years the field has matured and advanced algorithms based on impact parameter or decay length measurements exploit the potential of silicon vertex detectors. However, in order to reach the precision necessary to test theoretical predictions, the results from different experiments need to be averaged. This is a challenging task that requires detailed knowledge of common systematic uncertainties and correlations between the results from different experiments. The average lifetimes for b-flavored hadrons given in this edition have been determined by the LEP B Lifetimes Working Group [19]. The papers used in this calculation are listed in the appropriate sections. A detailed description of the procedures and the treatment of correlated and uncorrelated errors can be found in [20]. The new world average b-hadron lifetimes are summarized in Table 2. Lifetime measurements have reached a precision that the average b-hadron lifetime result becomes sensitive to the composition of the data sample. The result listed in Table 2 takes into account correlations between different experiments and analysis techniques but does not correct for differences due to different admixtures of b-flavored hadrons. In order to estimate the size of this effect the available results have been divided into three sets. LEP measurements based on the identification of a lepton from the *b* decay yield $\tau_{b \text{ hadron}} = 1.537 \pm 0.020 \text{ ps}^{-1}$ [21–23]. The average b-hadron lifetime based on inclusive secondary vertex techniques is $\tau_{b \text{ hadron}} = 1.576 \pm 0.016 \text{ ps}^{-1}$ [24–29]. Finally, CDF [30] used ψ mesons to tag the b vertex resulting in $\tau_{b \text{ hadron}} = 1.533 \pm 0.015^{+0.035}_{-0.031} \text{ ps}^{-1}.$

Table 2: Summary of inclusive and exclusive b-hadron lifetime measurement.

	·
Particle	Lifetime [ps]
$\overline{B^0}$	1.56 ± 0.04
B^+	1.65 ± 0.04
B_s	1.54 ± 0.07
\boldsymbol{b} baryon	1.22 ± 0.05
b hadron	1.564 ± 0.014

For comparison with theory lifetime ratios are preferred. Experimentally we find [19]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.04 \pm 0.04 \; , \; \; \frac{\tau_{B_s}}{\tau_{B^0}} = 0.99 \pm 0.05 \; , \; \; \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.79 \pm 0.06 \; \; (4)$$

while theory makes the following predictions [1]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1 + 0.05 \left(\frac{f_B}{200 \text{ MeV}}\right)^2 , \quad \frac{\tau_{B_{\bullet}}}{\tau_{B^0}} = 1 \pm 0.01 , \quad \frac{\tau_{A_b}}{\tau_{B^0}} = 0.9 .$$
 (5)

In conclusion, the pattern of measured B-mesons lifetimes follows the theoretical expectations and non-spectator effects are observed to be small. However, the Λ_b -baryon lifetime is unexpectedly short. As has been noted by several authors, the observed value of the Λ_b lifetime is quite difficult to accommodate

theoretically [31–33]. This apparent breakdown of the heavy-quark expansion for inclusive, non-leptonic B decays could be caused by violations of local quark-hadron duality. Neubert, however, argues that this conclusion is premature because a reliable field-theoretical calculation is still lacking. Exploring a reasonable parameter space for the unknown hadronic matrix elements he demonstrated that within the experimental errors theory can accommodate the measured lifetime ratios [1].

 $B\overline{B}$ mixing: In production processes involving the strong or the electromagnetic interaction neutral B and \overline{B} mesons can be produced. These flavor eigenstates are not eigenstates of the weak interaction which is responsible for the decay of neutral mesons containing b quarks. This feature and the small difference between the masses and/or lifetimes of the weak interaction eigenstates give rise to the phenomenon of $B-\overline{B}$ mixing. The formalism which describes B-meson mixing closely follows that used to describe $K^0-\overline{K}^0$ mixing, although the time scale characteristic of $B^0-\overline{B}^0$ oscillations is much shorter [34].

The ALEPH, DELPHI, L3, OPAL, SLD, and CDF experiments have performed explicit measurements of $\operatorname{Prob}(B^0 \to \overline{B}^0)$ as a function of proper time to extract the oscillation parameter $\Delta m_d = x_d \Gamma_d$ [3]. The flavor of the final state b quark is tagged using the charge of a lepton, a fully or partially reconstructed charmed meson, or a charged kaon, from $b \to \ell^-$, $b \to c$ or $b \rightarrow c \rightarrow s$ decays respectively. For fully inclusive analyses, final state tagging techniques include jet charge and charge dipole methods. The initial state flavor is either tagged directly (same-side tag) or indirectly by tagging the flavor of the other b hadron produced in the event (opposite-side tag). Same-side tagging can be performed with a charged hadron produced in association with the B meson (possibly through a B^{**} state), and opposite-side tagging can be performed with a lepton or a kaon from the decay of the other b hadron. Jet charge techniques have also been used on both sides. If the B meson is produced with polarized beams, its polar angle with respect to the incoming beam axis can also be used to construct an initial

The LEP B oscillations working group has combined all published measurements of Δm_d to obtain an average of $0.470 \pm 0.019 \ \mathrm{ps^{-1}}$ [8]. The averaging procedure takes into account all correlated uncertainties as well as the latest knowledge on the b-hadron production fractions (Table 1), lifetimes (Table 2) and time-integrated parameters. Including the data from the time-integrated measurements performed by ARGUS and CLEO at the $\Upsilon(4S)$ resonance yields a combined result of $\Delta m_d = 0.464 \pm 0.018 \ \mathrm{ps^{-1}}$. Averaging time-dependent results from LEP and CDF and time-integrated measurements from CLEO and ARGUS the time-integrated mixing parameter χ_d is determined to 0.172 ± 0.010 . As stated earlier, Δm_d and the b-hadron fractions are determined simultaneously, providing a self-consistent set of results.

The measurement of the oscillation parameter $\Delta m_s = x_s \Gamma_s$ for the B_s^0 meson combined with the results from the $B^0-\overline{B}^0$

Meson Particle Listings b-flavored hadrons

oscillations allows the determination of the ratio of the CKM matrix elements $|V_{td}|^2/|V_{ts}|^2$ with significantly reduced theoretical uncertainties. For large values, as expected for the B_s^0 meson, time-integrated measurements of B_s^0 mixing become insensitive to Δm_s and one must make time-dependent measurements in order to extract this parameter. The observation of the rapid oscillation rate of the B_s^0 meson is an experimental challenge that is still to be met. The ALEPH, DELPHI, and OPAL experiments have provided lower limits on Δm_s [3]. The most sensitive analyses use inclusive leptons or fully reconstructed D_s^- mesons. All published data have been combined by the LEP B oscillations working group to yield the limit $\Delta m_s > 9.1 \, \mathrm{ps}^{-1}$ at 95% C.L. [8].

For the B_s meson, the quantity $\Delta\Gamma$ may be large enough to be observable [18]. Parton model calculations [9] and calculations with exclusive final states [10] suggest that the width difference may be 10–20%. This lifetime difference could be determined experimentally by using decays to final states with different CP. For example, a measurement of a difference in the lifetimes between $\overline{B}_s^0 \to J/\psi K_s$ and $\overline{B}_s^0 \to D_s^- \ell^+ \nu_\ell$ would yield $\Delta\Gamma/\Gamma^2$. It has also been suggested that such measurements could be used to constrain $|V_{ts}/V_{td}|^2$ if parton model calculations are reliable [11].

Semileptonic B decays: Measurements of semileptonic B decays are important to determine the weak couplings $|V_{cb}|$ and $|V_{ub}|$. In addition, these decays can be used to probe the dynamics of heavy quark decay. The leptonic current can be calculated exactly while corrections due to the strong interaction are restricted to the $b \to c$ and $b \to u$ vertices, respectively.

Experimentally, semileptonic decays have the advantage of large branching ratios and the characteristic signature of the energetic charged lepton. The neutrino, however, escapes undetected so a full reconstruction of the decaying B meson is impossible. Various techniques which take advantage of production at threshold or the hermiticity of the detector have been developed by the ARGUS, CLEO, and LEP experiments to overcome this difficulty.

Three different approaches have been used to measure the inclusive semileptonic rate $B \to X \ell \nu_{\ell}$. These are measurements of the inclusive single lepton momentum spectrum, measurements of dilepton events using charge and angular correlations, and measurements of the separate B^- and \overline{B}^0 branching ratios by using events which contain a lepton and a reconstructed B meson. The dilepton method has the least model-dependency and the current averages based on this method are listed in Table 3 [2]. Differences in \mathcal{B}_{sl} measured at the $\Upsilon(4S)$ and the Z are expected due to the different admixture of b-flavored hadrons. Given the short Λ_b lifetime, however, the LEP value should be lower than the $\Upsilon(4S)$ result. While the experimental errors are still too large to draw any conclusions a potential systematic effect in the LEP results has been pointed out by Dunietz [12]. He noted that the LEP analyses have not yet been corrected for the recently observed production of \overline{D} mesons in \overline{B} decay.

A few new results on exclusive semileptonic B decays have been reported. The current world averages are listed in Table 3. It is interesting to compare the inclusive semileptonic branching fraction to the sum of branching fractions for exclusive modes. At the 2–3 σ level the exclusive modes saturate the inclusive rate leaving little room for extra contributions.

Table 3: Inclusive and exclusive semileptonic branching fractions of B mesons. $\mathcal{B}(\overline{B} \to X_u \ell^- \overline{\nu}_\ell) = 0.15 \pm 0.1\%$ has been included in the sum of the exclusive branching fractions.

Mode		Branching fraction [%]
$\overline{\overline{B}} \to X \ell^- \overline{\nu}_{\ell}(\Upsilon(4S))$		10.18 ± 0.39
$b \to X \ell^- \overline{\nu}_{\ell}(Z)$		10.95 ± 0.32
$\overline{\overline{B}} \to D\ell^-\overline{\nu}_{\ell}$		1.95 ± 0.27
$\overline{B} o D^* \ell^- \overline{ u}_\ell$		5.05 ± 0.25
$\overline{B} \to D^{(*)} \pi \ell^- \overline{\nu}_{\ell}$		2.3 ± 0.44
with $\overline{B} \to D_1^0(2420) \ell^- \overline{\nu}_{\ell}$	0.65 ± 0.11	
$\overline{B} \to D_2^{\stackrel{\bullet}{*}\stackrel{\circ}{0}}(2460)\ell^{-}\overline{\nu}_{\ell}$	$<0.8~90\%~\mathrm{CL}$	
$\Sigma \mathcal{B}_{ ext{exclusive}}$		9.45 ± 0.58

Dynamics of semileptonic B decay: Since leptons are not sensitive to the strong interaction, the amplitude for a semileptonic B decay can be factorized into two parts, a leptonic and a hadronic current. The leptonic factor can be calculated exactly while the hadronic part is parameterized by form factors. A simple example is the transition $B \to D\ell\nu_{\ell}$. The differential decay rate in this case is given by

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2}{24\pi^3} |V_{cb}^2| P_D^3 f_+^2(q^2) \tag{6}$$

where q^2 is the mass of the virtual W $(\ell \nu_{\ell})$ and $f_{+}(q^2)$ is the single vector form factor which gives the probability that the final state quarks will form a D meson. Since the leptons are very light the corresponding $f_{-}(q^2)$ form factor can be neglected. For $B \to D^* \ell \nu_\ell$ decays there are three form factors which correspond to the three possible partial waves of the $B \rightarrow$ $D^*\widehat{W}$ system (here \widehat{W} is the virtual W boson which becomes the lepton-antineutrino pair). Currently, form factors cannot be predicted by theory and need to be determined experimentally. Over the last years, however, it has been appreciated that there is a symmetry of QCD that is useful in understanding systems containing one heavy quark. This symmetry arises when the quark becomes sufficiently heavy to make its mass irrelevant to the nonperturbative dynamics of the light quarks. This allows the heavy quark degrees of freedom to be treated in isolation from the the light quark degrees of freedom. This is analogous to the canonical treatment of hydrogenic atoms, in which the spin and other properties of the nucleus can be neglected. The behavior and electronic structure of the atom are determined by the light electronic degrees of freedom. Heavy quark effective theory (HQET) was created by Isgur and Wise [35] who define

b-flavored hadrons

a single universal form factor, $\xi(v\cdot v')$, known as the Isgur-Wise function. In this function v and v' are the four velocities of the initial and final state heavy mesons. The Isgur-Wise function cannot be calculated from first principles but unlike the hadronic form factors mentioned above it is universal. In the heavy quark limit it is the same for all heavy meson to heavy meson transitions and the four form factors parameterizing $B \to D^*\ell\nu_\ell$ and $B \to D\ell\nu_\ell$ decays can be related to this single function ξ .

In this framework the differential semileptonic decay rates as function of $w=v_B\cdot v_{D^{(\bullet)}}=(m_B^2+m_{D^{(\bullet)}}^2-q^2)/2m_Bm_{D^{(\bullet)}}$ are given by [1]

$$\begin{split} \frac{d\Gamma(\overline{B} \to D^* \ell \overline{\nu}_{\ell})}{dw} &= \frac{G_F^2 M_B^5}{48\pi^3} r_*^3 (1 - r_*)^2 \sqrt{w^2 - 1} (w + 1)^2 \\ & \times \left[1 + \frac{4w}{w + 1} \frac{1 - 2w r_* + r_*^2}{(1 - r_*)^2} \right] |V_{cb}|^2 \mathcal{F}^2(w) \\ \frac{d\Gamma(\overline{B} \to D \ell \overline{\nu}_{\ell})}{dw} &= \frac{G_F^2 M_B^5}{48\pi^3} r^3 (1 + r)^2 (w^2 - 1)^{3/2} |V_{cb}|^2 \mathcal{G}^2(w) \quad (7) \end{split}$$

where $r_{(\star)} = M_{D^{(\star)}}/M_B$ and q^2 is the invariant momentum transfer. For $m_Q \to \infty$, the two form factors $\mathcal{F}(w)$ and $\mathcal{G}(w)$ coincide with the Isgur-Wise function $\xi(w)$.

Both CLEO [36] and ALEPH [37] have measured the differential decay rate distributions and extracted the ratio $\mathcal{G}(w)/\mathcal{F}(w)$ which is expected to be close to unity. As can be seen from the ALEPH result shown in Fig. 1, the data are compatible with a universal form factor $\xi(w)$

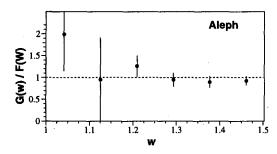

Figure 1: Ratio of the two form factors $\mathcal{G}(w)$ and $\mathcal{F}(w)$ in semileptonic B decay [37].

CLEO has also performed a direct measurement of the three form factors that are used to parameterize $B \to D^*\ell\nu_\ell$ decays [38]. These are usually expressed in terms of form factor ratios R_1 and R_2 [39]. At zero recoil, i.e. w=1, CLEO finds $R_1=1.24\pm0.26\pm0.12$ and $R_2=0.72\pm0.18\pm0.07$. While the errors are still large, this is in good agreement with a theoretical prediction of $R_1=1.3\pm0.1$ and $R_2=0.8\pm0.2$ [1].

Extraction of $|V_{cb}|$: The universal form factor $\xi(w)$ describes the overlap of wavefunctions of the light degrees of freedom in the initial and final heavy meson. At zero recoil, *i.e.* when the two mesons move with the same velocity, the overlap is

perfect and the form factor is absolutely normalized, $\xi(1)=1$. In principle, all that experimentalists have to do to extract a model-independent value for $|V_{cb}|$ is to measure $d\Gamma(B \to D^{(*)}\ell\nu_{\ell})/dw$ for $w\to 1$. However, in the real world the b and c quarks are not infinitely heavy so corrections to the limiting case have to be calculated. After much theoretical effort, the current results are [1]:

$$\mathcal{F}(1) = 0.924 \pm 0.027$$
,
 $\mathcal{G}(1) = 1.00 \pm 0.07$. (8)

Furthermore, the shape of the form factor has to be parameterized because at zero recoil the differential decay rate actually vanishes. Experimentally, the decay rate is measured as function of w and then extrapolated to zero recoil using an expansion of form

$$\mathcal{F}(w) = \mathcal{F}(1) \left(1 - \widehat{\rho}^2(w - 1) \right) . \tag{9}$$

The slope $\hat{\rho}^2$ of the form factor and $|V_{cb}|$ are correlated. The current world averages for $|V_{cb}|$ and $\hat{\rho}$ as extracted from exclusive semileptonic B decays have been compiled by Drell [2]. This value of $|V_{cb}|$ is in good agreement with independent determinations of $|V_{cb}|$ from inclusive B decays.

Table 4: Current world averages.

Mode	$ V_{cb} $	$\widehat{ ho}^2$
$\overline{\overline{B}} \to D^* \ell^- \overline{\nu}_{\ell}$	0.0387 ± 0.0031	0.71 ± 0.11
$\overline{B} \to D\ell^- \overline{\nu}_\ell$	0.0394 ± 0.0050	0.66 ± 0.19

Hadronic B decays: In hadronic decays of B mesons the underlying weak transition of the b quark is overshadowed by strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements from experimental results it also turns the B meson into an ideal laboratory to study our understanding of perturbative and non-perturbative QCD, of hadronization, and of Final State Interaction (FSI) effects.

The precision of the experimental data has steadily improved over the past years. In 1997 CLEO updated most branching fractions for exclusive $B \to (n\pi)^- D^{(*)}$ and $B \to J/\psi K^{(*)}$ transitions. New, tighter limits on color suppressed decays such as $\overline{B} \to D^0 \pi^0$ have been presented [41] and a new measurement of the polarization in $B \to J/\psi K^*$ resolved an outstanding discrepancy between theory and experiment [40]. Progress has been made in experimental techniques. Last summer CLEO presented several analyses based on partial reconstruction [48,49]. In this method, D^* mesons are not fully reconstructed but rather tagged by the presence of the characteristic slow pion from the $D^* \to D^0\pi$ decay. This results in substantially increased event yields, e.g., $281 \pm 56 \ D^{**}(2420)$ candidates have been reconstructed. The preliminary results are

$$\mathcal{B}(\overline{B}^0 \to D^{*+}\pi^-) = (2.81 \pm 0.11 \pm 0.21 \pm 0.05) \times 10^{-3}$$

$$\mathcal{B}(B^- \to D^{*0}\pi^-) = (4.81 \pm 0.42 \pm 0.40 \pm 0.21) \times 10^{-3}$$

$$\mathcal{B}(B^- \to D_1(2420)\pi^-) = (1.17 \pm 0.24 \pm 0.16 \pm 0.03) \times 10^{-3}$$

$$\mathcal{B}(B^- \to D_2(2460)\pi^-) = (2.1 \pm 0.8 \pm 0.3 \pm 0.05) \times 10^{-3}. (10)$$

b-flavored hadrons

The second systematic error reflects the uncertainty in the D^* branching fractions.

Gronau and Wyler [50] first suggested that decays of the type $B \to DK$ can be used to extract the angle γ of the CKM unitarity triangle, $\gamma \approx \arg(V_{ub})$. The first example of such a Cabibbo suppressed mode has recently been observed by CLEO [51]:

$$\frac{\mathcal{B}(B^- \to D^0 K^-)}{\mathcal{B}(B^- \to D^0 \pi^-)} = 0.055 \pm 0.014 \pm 0.005 \ . \tag{11}$$

Measurements of exclusive hadronic B decays have reached sufficient precision to challenge our understanding of the dynamics of these decays. It has been suggested that in analogy to semileptonic decays, two-body hadronic decays of B mesons can be expressed as the product of two independent hadronic currents, one describing the formation of a charm meson and the other the hadronization of the remaining $\overline{u}d$ (or $\overline{c}s$) system from the virtual W^- . Qualitatively, for a B decay with a large energy release, the $\overline{u}d$ pair, which is produced as a color singlet, travels fast enough to leave the interaction region without influencing the second hadron formed from the c quark and the spectator antiquark. The assumption that the amplitude can be expressed as the product of two hadronic currents is called "factorization" in this paper. By comparing exclusive hadronic B decays to the corresponding semileptonic modes the factorization hypothesis has been experimentally confirmed for decays with large energy release [40]. Note that it is possible that factorization will be a poorer approximation for decays with smaller energy release or larger q^2 . For internal spectator decays the validity of the factorization hypothesis is also questionable and requires experimental verification. The naive color transparency argument used in the previous sections is not applicable to decays such as $B \to J/\psi K$, and there is no corresponding semileptonic decay to compare to. For internal spectator decays one can only compare experimental observables to quantities predicted by models based on factorization. Two such quantities are the production ratio

$$\mathcal{R} = \frac{\mathcal{B}(B \to J/\psi K^*)}{\mathcal{B}(B \to J/\psi K)} \tag{12}$$

and the amount of longitudinal polarization Γ_L/Γ in $B \rightarrow$ $J/\psi K^*$ decays. Previous experimental results, $\mathcal{R}=1.68\pm0.33$ and $\Gamma_L/\Gamma = 0.78 \pm 0.04$, were inconsistent with all model predictions. The theory had difficulties in simultaneously accommodating a large longitudinal polarization and a large vector-to-pseudoscalar production ratio. Non-factorizable contributions that reduce the transverse amplitude were proposed to remedy the situation. New experimental results, however, make this apparent breakdown of the factorization hypothesis less likely. The CLEO collaboration published new data on $B \to \text{charmonium transitions}$ [7]. Their values,

$$\mathcal{R} = 1.45 \pm 0.20 \pm 0.17$$
, $\Gamma_L/\Gamma = 0.52 \pm 0.07 \pm 0.04$, (13)

are now consistent with factorization-based models.

In the decays of charm mesons, the effect of color suppression is obscured by the effects of FSI or reduced by nonfactorizable effects. Because of the larger mass of the b quark, a more consistent pattern of color-suppression is expected in the B system, and current experimental results seem to support that color-suppression is operative in hadronic decays of B mesons. Besides $B \to \text{charmonium transitions no other color-suppressed}$ decay has been observed experimentally [41]. The current upper limit on $\mathcal{B}(\overline{B}^0 \to D^0 \pi^0)$ is 0.012% at 90% C.L.

By comparing hadronic B^- and \overline{B}^0 decays, the relative contributions from external and internal spectator decays have been disentangled. For all decay modes studied the B^- branching ratio was found to be larger than the corresponding \overline{B}^0 branching ratio indicating constructive interference between the external and internal spectator amplitudes. In the BSW model [42] the two amplitudes are proportional to effective coefficients, a_1 and a2, respectively. A least squares fit using the latest branching ratio measurements and a model by Neubert et al. [43] gives

$$a_2/a_1 = 0.22 \pm 0.04 \pm 0.06$$
, (14)

where we have ignored uncertainties in the theoretical predictions. The second error is due to the uncertainty in the B-meson production fractions (f_+, f_0) and lifetimes (τ_+, τ_0) that enter into the determination of a_1/a_2 in the combination $(f_+\tau_+/f_0\tau_0)$. As this ratio increases, the value of a_2/a_1 decreases. Varying $(f_+\tau_+/f_0\tau_0)$ in the allowed experimental range $(\pm 20\%)$ excludes a negative value of a_2/a_1 . Other uncertainties in the magnitude of the decay constants f_D and f_{D^*} as well as in the hadronic form factors can change the magnitude of a_2/a_1 but not its sign.

The magnitude of a_2 determined from this fit to the ratio of B^- and \overline{B}^0 branching fractions is consistent with the value of $|a_2|$ determined from the fit to the $B \to J/\psi$ decay modes which only via the color suppressed amplitude. The coefficient a_1 also shows little or no process dependency.

The observation that the coefficients a_1 and a_2 have the same relative sign in B^- decay came as a surprise, since destructive interference was observed in hadronic charm decay. The sign of a_2 disagrees with the theoretical extrapolation from the fit to charm meson decays using the BSW model. It also disagrees with the expectation from the $1/N_c$ rule [44]. The result may be consistent with the expectation of perturbative QCD [45]. B. Stech proposed that the observed interference pattern in charged B and D decay can be understood in terms of the running strong coupling constant α_s [46]. A solution based on PQCD factorization theorems has been suggested by B. Tseng and H.N. Li [47].

Although constructive interference has been observed in all the B^- modes studied so far, these comprise only a small fraction of the total hadronic rate. It is conceivable that higher multiplicity B^- decays demonstrate a very different behaviour.

It is intriguing that $|a_1|$ determined from $B \to D^{(*)}\pi$, $D^{(*)}\rho$ modes agrees well with the value of a_1 extracted from $B \to DD_s$ decays. The observation of color-suppressed decays such as

b-flavored hadrons

 $\overline{B}^0 \to D^0 \pi^0$ would give another measure of $|a_2|$ complementary to that obtained from $B \to$ charmonium decays.

In summary, experimental results on exclusive B decay match very nicely with theoretical expectations. Unlike charm the b quark appears to be heavy enough so that corrections due to the strong interaction are small. Factorization and color-suppression are at work. An intriguing pattern of constructive interference in charged B decays has been observed.

Inclusive hadronic decays: Over the last years inclusive B decays have become an area of intensive studies, experimentally as well as theoretically. Since the hadronization process to specific final state mesons is not involved in inclusive calculations the theoretical results and predictions are generally believed to be more reliable.

CLEO and the LEP collaborations presented new measurements of inclusive $b \rightarrow c$ transitions that can be used to extract n_c , the number of charm quarks produced per b decay. Naively we expect $n_c = 115\%$ with the additional 15% coming from the decay of the W boson to $\bar{c}s$. This expectation can be verified experimentally by adding all inclusive $b \rightarrow c$ branching fractions. Using CLEO and LEP results we can perform the calculation shown in Table 5. Modes with 2 charm quarks in the final state are counted twice. For the unobserved $B \to \eta_c X$ decay we take the experimental upper limit. B_s mesons and bbaryons produced at the Z but not at the $\Upsilon(4S)$ cause the increase in D_s and Λ_c production rates seen by LEP. To first order, however, this should not affect the charm yield and it should be compensated by reduced branching fractions for D mesons. This is not reflected in the current data but the errors are still large. In addition, there are significant uncertainties in the D_s and Λ_c absolute branching fractions.

Table 5: Charm yield per B decay.

Channel	Branching fraction [%] $\Upsilon(4S)$ [40] LEP [2]
$B \to D^0 X$	63.6 ± 3.0 57.6 ± 2.6
$+ B \rightarrow D^+X$	$23.5 \pm 2.7 22.4 \pm 1.9$
$+ B \rightarrow D_s^+ X$	12.1 ± 1.7 19.1 ± 5.0
$+ B \rightarrow \Lambda_c^+ X$	2.9 ± 2.0 11.4 ± 2.0
$+ B \rightarrow \Xi_c^{+,0} X$	2.0 ± 1.0 6.3 ± 2.1
$+ 2 \times B \rightarrow J/\psi_{\text{direct}} X$	0.8 ± 0.08
$+ 2 \times B \rightarrow \psi(2S)_{\text{direct}} X$	0.35 ± 0.05
$+ 2 \times B \rightarrow \chi_{c1} X$	0.37 ± 0.07
$+ 2 \times B \rightarrow \chi_{c2} X$	0.25 ± 0.1
$+ 2 \times B \rightarrow \eta_c X$	< 0.9 (90%C.L.)
$+ 2 \times b \rightarrow (c\overline{c})X$	3.4 ± 1.2
n_c	110 ± 5 120 ± 7

Inclusive $b \to c\overline{c}s$ transitions: It was previously assumed that the conventional $b \to c\overline{u}d \to DX$ and $b \to c\overline{c}s \to D\overline{D}_sX$ mechanisms account for all D meson production in B decay. Buchalla et al. [57] suggested that a significant fraction of D mesons could also arise from $b \to c\overline{c}s$ transitions with light quark pair production at the upper vertex, i.e. $b \to c\overline{c}s$

 $c\overline{c}s \to D\overline{D}X_s$. The two mechanisms can be distinguished by the different final states they produce. In the first case the final state includes only D mesons whereas in the second case two D mesons can be produced, one of which has to be a \overline{D} .

Table 6: CLEO results on $B \to DDK$ decays (preliminary).

Mode	Branching fraction [%]
$\overline{\mathcal{B}(\overline{B}^0 \to D^{*+} \overline{D}^0 K^-)}$	$0.45^{+0.25}_{-0.19} \pm 0.08\%$
$\mathcal{B}(B^- \to D^{*0}\overline{D}^0K^-)$	$0.54^{+0.33}_{-0.24} \pm 0.12\%$
$\mathcal{B}(\overline{B}^0 \to D^{*+} \overline{D}^{*0} K^-)$	$1.30^{+0.61}_{-0.47} \pm 0.27\%$
$\mathcal{B}(B^- \to D^{*0}\overline{D}^{*0}K^-)$	$1.45^{+0.78}_{-0.58} \pm 0.36\%$

Two routes to search for this addition to $\Gamma(b \to c\bar{c}s)$ have been pursued experimentally. In an exclusive search for $B \to D\overline{D}K$ decays CLEO required the final state to include a D and a \overline{D} meson. Statistically significant signals are observed for several $D^{(*)}\overline{D}^{(*)}$ combinations. The preliminary CLEO results are listed in Table 6 [52]. While the observation of these decays proves the existence of \overline{D} -meson production at the upper vertex, a more inclusive measurement is needed to estimate the overall magnitude of this effect. A recent CLEO analysis exploits the fact that the flavor of the final state D-meson tags the decay mechanism. A high momentum lepton $(p_{\ell} > 1.4 \text{ GeV/}c)$ from the second B meson is used to classify the flavor of the decaying B meson. $b \to c\overline{u}d$ transitions lead to $D\ell^+$ combinations while the observation of $\overline{D}\ell^+$ identifies the new $b \to c\overline{c}s$ mechanism. Angular correlations are used to remove combinations with both particles coming from the same B meson. CLEO finds [53]

$$\frac{\Gamma(\overline{B} \to \overline{D}X)}{\Gamma(\overline{B} \to DX)} = 0.100 \pm 0.026 \pm 0.016 , \qquad (15)$$

which implies

$$\mathcal{B}(\overline{B} \to \overline{D}X) = 0.079 \pm 0.022 \ . \tag{16}$$

 $b \to D\overline{D}X$ decays have also been observed at LEP. ALEPH [54] finds

$$\mathcal{B}(B \to D^0 \overline{D}^0 X + D^0 D^{\mp} X) = 0.078^{+0.02}_{-0.018} {}^{+0.017}_{-0.004} {}^{+0.05}_{,,}$$
(17)

where the last error reflects the uncertainty in D meson branching fractions. DELPHI reports the observation of $D^{*+}D^{*-}$ production [55]

$$\mathcal{B}(\overline{B} \to D^{*+}D^{*-}X) = 0.01 \pm 0.002 \pm 0.003$$
. (18)

These results are still preliminary. We can now calculate $n_{cc} = \mathcal{B}(b \to c\bar{c}s)$. Using the data listed in Table 5 and the new result, $\mathcal{B}(\overline{B} \to \overline{D}X) = 0.079 \pm 0.022$, we find

$$n_{cc} = 23.9 \pm 3.0\%$$
 (19)

The contribution from $B \to \Xi_c^0 X$ was reduced by 1/3 to take into account the fraction that is not produced by the $b \to c\bar{c}s$ subprocess but by $b \to c\bar{u}d + s\bar{s}$ quark pair production.

This result is consistent with theoretical predictions, $\mathcal{B}(b \to c \bar{c}s) = 22 \pm 6\%$ [31,56]. n_{cc} is related to n_c , the number of charm quarks produced per b decay. We expect $n_c = 1 + n_{cc} - n_{B \to \text{no charm}}$ which is consistent with the LEP result reported above. If the smaller value of n_c observed by CLEO is confirmed it could indicate a problem with $\Gamma(b \to c \bar{u} d)$ or a very large $\mathcal{B}(b \to sg)$.

Charm counting and the semileptonic branching fraction: The charm yield per B-meson decay is related to an intriguing puzzle in B physics: the experimental value for the semileptonic branching ratio of B mesons, $\mathcal{B}(B \to X \ell \nu_{\ell}) = 10.18 \pm 0.39\%$ ($\Upsilon(4S)$), is significantly below the theoretical lower bound $\mathcal{B} > 12.5\%$ from QCD calculations within the parton model [58]. Since the semileptonic and hadronic widths are connected via

$$1/\tau = \Gamma = \Gamma_{\text{semileptonic}} + \Gamma_{\text{hadronic}} \tag{20}$$

an enhanced hadronic rate is necessary to accommodate the low semileptonic branching fraction. The hadronic width can be expressed as

$$\Gamma_{\text{hadronic}} = \Gamma(b \to c\overline{c}s) + \Gamma(b \to c\overline{u}d) + \Gamma(b \to sg + \text{no charm})$$
 (21)

Several explanations of this $n_c/\mathcal{B}_{\rm sl}$ discrepancy have been proposed:

- 1. Enhancement of $b \to c\overline{c}s$ due to large QCD corrections or a breakdown of local duality;
- 2. Enhancement of $b \rightarrow c\overline{u}d$ due to non-perturbative effects;
- 3. Enhancement of $b \to sg$ and/or $b \to dg$ due to new physics;
- 4. Systematic problem in the experimental results;

or the problem could be caused by some combination of the above. Arguably the most intriguing solution to this puzzle would be an enhanced $b \to sg$ rate but as we will see in the next section, new results from CLEO and LEP show no indication for new physics and place tight limits on this process.

 $\mathcal{B}(b \to c\overline{u}d)$ has been calculated to next-to-leading order. Bagan *et al.* [59] find:

$$r_{ud} = \frac{\mathcal{B}(b \to c\overline{u}d)}{\mathcal{B}(b \to c\ell\nu_{\ell})} = 4.0 \pm 0.4 \to \mathcal{B}(b \to c\overline{u}d)_{\text{theory}} = 41 \pm 4\%$$
 (22)

Experimentally, we can extract this quantity in the way shown in Table 7.

Table 7: Experimental extraction of $\mathcal{B}(b \to c\overline{u}d)$.

$\mathcal{B}(b \to c\overline{u}d)_{\text{exp.}} = \mathcal{B}(B \to (D + \overline{D})X)$	$87.1 \pm 4.0\%$
$+ \mathcal{B}(B o D_s X)_{\mathrm{lower vertex}}$	$1.8 \pm 0.9\%$
$+ \mathcal{B}(B \to \text{baryons}X)$	$4.6\pm2.1\%$
$-2 \times \mathcal{B}(B \to \overline{D}X)_{\text{upper vertex}}$	$2\times(7.9\pm2.2\%)$
$-\mathcal{B}(B o D_sX)$	$12.1\pm1.7\%$
$-$ 2.25 $ imes$ $\mathcal{B}(b o c\ell u_\ell)$	$22.9\pm0.9\%$
	$43 \pm 6\%$

Here upper vertex refers to the W decay while lower vertex refers to the $b \to c$ transition. For the total semileptonic branching fraction we assumed $\mathcal{B}(b \to c\tau\nu_{\tau}) = 0.25 \times \mathcal{B}(b \to ce\nu_e)$. There is good agreement between theory and experiment but the errors are still too large to completely rule out an enhanced $b \to c\overline{u}d$ rate.

The theoretically preferred solution calls for an enhancement of the $b\to c\bar cs$ channel [31,59]. Increasing the $b\to c\bar cs$ component, however, would increase the average number of c quarks produced per b-quark decay as well as n_{cc} , the number of b decays with 2 charm quarks in the final state. Figure 2 taken from Ref. 1 shows the theoretical range together with experimental values from LEP and CLEO/ARGUS.

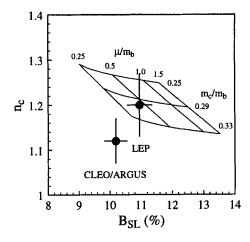

Figure 2: Charm yield (n_c) versus semileptonic branching fraction.

While the experimental value of n_{cc} is consistent with this scenario, the value of n_c measured at the $\Upsilon(4S)$ appears to be too low at the few σ -level. Systematic problems with D meson branching fractions have been pointed out as a potential solution [12] but new results from ALEPH [60] and CLEO [61] on $\mathcal{B}(D^0 \to K^-\pi^+)$ make this less likely.

After years of experimental and theoretical efforts the missing charm/ \mathcal{B}_{sl} problem has begun to fade away. There is still a discrepancy between the charm yield measured by CLEO and the theoretical prediction. More data are needed to either resolve this issue or to demonstrate that the problem persists.

Rare B decays: All B-meson decays that do not occur through the usual $b \to c$ transition are known as rare B decays. These include semileptonic and hadronic $b \to u$ decays that—although at tree level—are suppressed by the small CKM matrix element V_{ub} as well as higher order processes such as electromagnetic and gluonic penguin decays. Branching fractions are typically around 10^{-5} for exclusive channels and sophisticated background suppression techniques are essential for these analyses.

b-flavored hadrons

Arguably the most exciting new experimental results since the last edition of this review are in the field of rare B decays. For many charmless B-decay modes the addition of new data and the refinement of analysis techniques allowed CLEO to observe signals where previously there have been upper limits. For other channels new tighter upper limits have been published [62].

Semileptonic $b \to u$ transitions: The simplest diagram for a rare B decay is obtained by replacing the $b \to c$ spectator diagram a CKM suppressed $b \to u$ transition. These decays probe the small CKM matrix element V_{ub} , the magnitude of which sets bounds on the combination $\rho^2 + \eta^2$ in the Wolfenstein parameterization of the CKM matrix. Measurements of the magnitude of V_{ub} have been obtained from both inclusive and exclusive semileptonic B decays [63,65]. Inclusive analyses at the $\Upsilon(4S)$ focus on leptons in the endpoint region of the single lepton spectrum which are kinematically incompatible with coming from a $b \to c$ transition. Models are used to extrapolate to the full spectrum from which $|V_{ub}| = (3.7 \pm 0.6) \times 10^{-3}$ is extracted [64]. The error is dominated by uncertainties in the models.

Exclusive semileptonic $b \to u$ transitions have been observed by the CLEO Collaboration [63]. Using their large data sample and employing the excellent hermiticity of the CLEO II detector they were able to measure $\mathcal{B}(B^0 \to \pi^- \ell^+ \nu_\ell) = (1.8 \pm 0.4 \pm 0.3 \pm 0.2) \times 10^{-4}$ and $\mathcal{B}(B^0 \to \rho^- \ell^+ \nu_\ell) = (2.5 \pm 0.4^{+0.5}_{-0.7} \pm 0.5) \times 10^{-4}$ which can be used to extract $|V_{ub}| = (3.3 \pm 0.2^{+0.3}_{-0.4} \pm 0.7) \times 10^{-3}$. The last error in these results reflects the model-dependence.

While the consistency of the two methods is encouraging, the errors, in particular the theoretical uncertainties, are still large.

Hadronic $b \to u$ transitions: Exclusive hadronic $b \to u$ transitions still await experimental discovery. Using 3.3×10^6 $B\overline{B}$ decays CLEO searched for exclusive charmless final states such as $\pi^+\pi^-$ and $\rho^+\pi^-$. No significant excess has been observed and some of the new upper limits are listed in Table 8 [66]. The mode $B^0 \to \pi^+\pi^-$ is of particular interest for CP-violation studies in the B-meson system. The branching fraction is smaller than initial expectations and extracting $\sin(2\alpha)$, i.e. one of the angles in the unitarity triangle, will become increasingly more difficult. Assuming factorization we can use CLEO's measurement of $B^0 \to \pi^-\ell^+\nu_\ell$ and the ISGW II form factors [67] to predict $\mathcal{B}(B^0 \to \pi^+\pi^-) = (1.2 \pm 0.4) \times 10^{-5}$ and $\mathcal{B}(B^+ \to \pi^+\pi^0) = (0.6 \pm 0.2) \times 10^{-5}$.

Electromagnetic penguin decays: The observation of the decay $B \to K^*(892)\gamma$, reported in 1993 by the CLEO II experiment, provided first evidence for the one-loop penguin diagram [69]. Using a larger data sample the analysis was re-done in 1996 yielding [69]

$$\mathcal{B}(B \to K^* \gamma) = (4.2 \pm 0.8 \pm 0.6) \times 10^{-5}$$
 (23)

The observed branching fractions were used to constrain a large class of Standard Model extensions [72]. However, due to the

Table 8: Summary of new CLEO results on $B \to \pi\pi, K\pi$ and KK branching fractions. The branching fractions and the 90% C.L. upper limits are given in units of 10^{-5} . Using the notation of Gronau *et al.* [68] the last column indicates the dominant amplitudes for each decay (T, C, P, E denote tree, color suppressed, penguin, and exchange amplitudes and the unprimed (primed) amplitudes refer to $\bar{b} \to \bar{u}u\bar{d}$ ($\bar{b} \to \bar{u}u\bar{s}$) transitions, respectively.)

$\begin{array}{c} \hline \text{Mode} \\ (B \rightarrow) \end{array}$	В	Amplitude	Theoretical expectation
$\pi^+\pi^-$	< 1.5	-(T+P)	0.8-2.6
$\pi^{+}\pi^{0}$	< 2.0	$-(T+C)/\sqrt{(2)}$	0.4 - 2.0
$\pi^0\pi^0$	< 0.93	$-(C-P)/\sqrt{(2)}$	0.006-0.1
$K^+\pi^-$	$1.5^{+0.5}_{-0.4} \pm 0.1 \pm 0.1$	-(T'+P')	0.7-2.4
$K^+\pi^0$	< 1.6	$-(T'+C'+P')/\sqrt{(2)}$	0.3-1.3
$K^0\pi^-$	$2.3^{+1.1}_{-1.0} \pm 0.3 \pm 0.2$	P'	0.8 - 1.5
$K^0\pi^0$	< 4.1	$-(C'-P')/\sqrt{(2)}$	0.3-0.8
$\overline{K^+K^-}$	< 0.43	E

uncertainties in the hadronization, only the inclusive $b \to s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. CLEO [70] found

$$\mathcal{B}(b \to s\gamma) = (2.32 \pm 0.57 \pm 0.35) \times 10^{-4} \text{ (CLEO)}$$
. (24)

ALEPH used a lifetime tagged sample of $Z \to b\bar{b}$ events to search for high-energy photons in the hemisphere opposite to the tag. This allows them to measure the photon spectrum from B decays which ultimately leads to [71]

$$\mathcal{B}(b \to s\gamma) = (3.11 \pm 0.80 \pm 0.72) \times 10^{-4} \,(\text{ALEPH}) \,.$$
 (25)

Our theoretical understanding of inclusive $b \to s\gamma$ transitions has been significantly enhanced by two new calculations that now include all terms to next-to-leading order [73]. The expected Standard Model rate, while slightly larger now, is still consistent with both the CLEO and ALEPH results. The substantially reduced uncertainties result in tighter constraints on new physics such as double Higgs models [2].

Gluonic penguin decays: A larger total rate is expected for gluonic penguins, the counterpart of $b \to s\gamma$ with the photon replaced by a gluon.

Experimentally, it is a major challenge to measure the inclusive $b\to sg$ rate. The virtual gluon hadronizes as a $q\overline{q}$ pair without leaving a characteristic signature in the detector. CLEO extended $D-\ell$ correlation measurements described in the section on hadronic B decays to obtain the flavor specific decay rate $\Gamma(\overline{B}\to DX)_{\text{lower vertex}}/\Gamma_{\text{total}}$. This quantity should be 1 minus corrections for charmonium production, $b\to u$ transitions, $B\to \text{baryons}$, and D_s production at the lower vertex. Most importantly, the $b\to sg$ rate must also be subtracted. To remove uncertainties due to $\mathcal{B}(D^0\to K^-\pi^+)$

CLEO normalizes to $\Gamma(\overline{B}\to DX\ell\nu_\ell)/\Gamma(\overline{B}\to X\ell\nu_\ell)$. Their preliminary result is

$$\frac{\Gamma(\overline{B} \to DX)_{\text{lower vertex}}/\Gamma_{\text{total}}}{\Gamma(\overline{B} \to DX\ell\nu_{\ell})/\Gamma(\overline{B} \to X\ell\nu_{\ell})} = 0.901 \pm 0.034 \pm 0.014 \quad (26)$$

whereas $0.903 \pm 0.018 - \mathcal{B}(b \to sg)$ was expected. This corresponds to an upper limit of $\mathcal{B}(b \to sg) < 6.8\%$ [53]. DELPHI [55] studied the the p_T spectrum of charged kaons in B decays and found a model-dependent limit $\mathcal{B}(b \to sg) < 5\%$ (95% C.L.). These results agree well with the Standard Model prediction of $\mathcal{B}(\overline{B} \to \text{no charm}) = (1.6 \pm 0.8)\%$ [74] and there is little experimental support for new physics and an enhanced $b \to sg$ rate [75]. However, experimental uncertainties are still large and it is too early to draw final conclusions. Last summer, the SLD collaboration reported an excess in the kaon spectrum at high p_T [76].

Exclusive decays such as $B^0 \to K^+\pi^-$ are strongly suppressed to first order and are expected to proceed via loop processes. CLEO studied these decay modes and last summer reported the first observation of $B^0 \to K^+\pi^-$ and $B^+ \to K^0\pi^+$ decays. The results are listed in Table 8. $\mathcal{B}(B^+ \to K^0\pi^+)$ is of particular interest since it directly measures the strength of the gluonic penguin amplitude (Table 8). The smaller rate measured for $B^0 \to K^+\pi^-$ could indicate that the two amplitudes contributing to this channel interfere destructively. This observation has been extended by Fleischer and Mannel [77] to place some constraints on γ , the phase of V_{ub} .

CLEO extended their search of charmless B decay to modes including light meson resonances such as ρ , K^* , ω , η , and η' [78]. Statistically significant signals have been seen in several channels; the results are summarized in Table 9.

Table 9: Summary of new CLEO results on rare B decays involving light meson resonances.

Mode	Branching fraction (×10 ⁻⁵)
$B \to \omega K^+$ $B \to \eta' K^+$ $B \to \eta' K^0$ $B \to \eta' X_s$	$\begin{array}{c} 1.5^{+0.7}_{-0.6} \pm 0.3 \\ 7.1^{+2.5}_{-2.1} \pm 0.9 \\ 5.3^{+2.8}_{-2.2} \pm 1.2 \\ 62 \pm 16 \pm 13 \\ (2.0 < p_{\eta'} < 2.7 \text{GeV/c}) \end{array}$

A surprisingly large signal has been observed for $B \to \eta' K$ (see Fig. 3) while no evidence for ηK or $\eta' K^*$ final states has been found [79].

The interpretation of these results is subject of an ongoing discussion. It has been suggested that interference between different penguin amplitudes causes $\mathcal{B}(B \to \eta' K)$ to be larger than $\mathcal{B}(B \to \eta K)$ [80,81]. Other proposals try to explain the large $\eta' K$ rate by the anomalous coupling of the η' to glue [82,83], a $c\bar{c}$ component in the η' [84] or by an enhanced $b \to sg$ rate due to some new physics [85]. Additional experimental input to this puzzle comes from a CLEO measurement of inclusive η' production. At high momenta the η' spectrum is dominated by

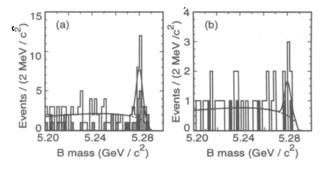

Figure 3: Beam-constrained mass for (a) $B^+ \to \eta' h^+$ with $h^+ = K^+$ or π^+ and (b) $B^0 \to \eta' K^0$. A likelihood analysis shows that the $B^+ \to \eta' h^+$ channel is dominated by $\eta' K^+$. (CLEO)

 $B \to \eta' X_s$ decays and a study of the system recoiling against the η' shows that large masses $m(X_s)$ are preferred [86].

In summary, gluonic penguin decays have been established. Many decay modes have been observed for the first time and the emerging pattern is full of surprises. The observed penguin effects are large and while old favorites such as $B^0 \to \pi^+\pi^-$ might be less useful for CP-violation studies there is hope that new opportunities will open up.

Outlook: With the next Fermilab collider run still years away and LEP running at higher energies it is not likely that the B-meson lifetimes presented in this edition will change substantially over the next two years. Nor should we expect many new results on b-hadron spectroscopy. In the short term, CLEO is still taking data and so is SLD. The SLD collaboration expects to collect half a million hadronic Z events. Combining this with the excellent resolution of the SLD vertex detector could push the sensitivity on B_s mixing up to $\Delta m_s = 15 \text{ ps}^{-1}$. We have just began to observe rare B decays and already now we see many intriguing patterns: Why is $B \to \eta' K$ so large? Where are the $B^0 \to \pi^+\pi^-$ events? The size of the CLEO data sample will soon reach the 10 fb⁻¹ mark and many results, answers and new questions should be expected.

In the long term, which is actually only a year away, the next generation of B experiments will come on line: BaBar, BELLE, CLEO III, as well as HERA-B. So there is hope that in two years when the next edition of this *Review* will be written we have reached another milestone in our understanding of B mesons and b baryons.

 B^0

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the B^{\pm}/B^0 ADMIXTURE and $B^{\pm}/B^0/B_s^0/b$ -baryon AD-MIXTURE sections.

See the Notes "Experimental Highlights of B Meson Production and Decay" and "Semileptonic Decays of B Mesons" at the beginning of the B^{\pm} Particle Listings and the Note on " B^0 - \overline{B}^0 Mixing and CPViolation in B Decay" near the end of the B⁰ Particle Listings.

BO MASS

The fit uses m_{B^+} , $(m_{B^0}-m_{B^+})$, $m_{B^0_c}$, and $(m_{B^0_c}-(m_{B^+}+m_{B^0})/2)$ to determine m_{B^+} , m_{B^0} , m_{B^0} , and the mass differences. m_{B^0} data are excluded from the fit because they are not independent.

- ²⁴ Combined result of $D/D^*\ell X$ analysis and fully reconstructed B analysis.

 au_{B^+}/ au_{B^0} (Inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+ . We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

BO DECAY MODES

 $\overline{B}{}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE

The branching fractions listed below assume 50% $B^0 \overline{B}{}^0$ and 50% $B^+ B^$ production at the $\Upsilon(45)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(45)$ production ratio to 50:50 and their assumed $D,\ D_s,\ D^*$, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

- ³⁶ ACKERSTAFF 97G assumes fraction (B^+) = fraction (B^0) = $(37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and branching ratio of D^* and D decays.
- 37 BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 \pm 2.2)% and PDG 96 values for B lifetime and D^* and D branching fractions.
- 38 ABREU 96P result is the average of two methods using exclusive and partial D^{st} recon-
- ³⁹ BARISH 95 use B($D^0 \rightarrow K^- \pi^+$) = (3.91 ± 0.08 ± 0.17)% and B($D^{*+} \rightarrow D^0 \pi^+$) $= (68.1 \pm 1.0 \pm 1.3)\%.$
- ⁴⁰ ALBRECHT 94 assumes B($D^{*+} \rightarrow D^0 \pi^+$) = 68.1 ± 1.0 ± 1.3%. Uses partial reconstruction of D^{*+} and is independent of D^{0} branching ratios.
- 41 ALBRECHT 93 reports $0.052 \pm 0.005 \pm 0.006$. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \rightarrow K^-\pi^+$). We have taken their average e and μ value. They also obtain $\alpha = 2*\Gamma^0/(\Gamma^- + \Gamma^+) 1 = 1.1 \pm 0.4 \pm 0.2$. $A_{AF}=3/4*(\Gamma^--\Gamma^+)/\Gamma=0.2\pm0.08\pm0.06$ and a value of $|V_{cb}|=0.036$ -0.045 depending on model assumptions.
- 42 We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 \pm 0.005 \pm 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). The measurement suggests a D^* polarization parameter value $lpha=0.65\pm0.66\pm0.25$.
- ⁴³ BUSKULIC 95N assumes fraction (B^+) = fraction (B^0) = 38.2 \pm 1.3 \pm 2.2% and au_{B^0} = 1.58 \pm 0.06 ps. $\Gamma(D^{*-}\ell^{+}\nu_{\ell})/\text{total} = [5.18 - 0.13(\text{fraction}(B^{0}) - 38.2) - 1.5(\tau_{B^{0}} - 1.5)$
- 44 Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test V-A structure and fit the decay angular distributions to obtain $A_{FB}=3/4*(\Gamma^--\Gamma^+)/\Gamma=0.14\pm0.06\pm0.03$. Assuming a value of V_{CD} , they measure V, A_1 , and A_2 , the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.
- 45 ANTREASYAN 90B is average over B and \overline{D}^* (2010) charge states.
- ⁴⁶ The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 \pm 0.45.
- or $\alpha = 0.7 \pm 0.9$. 47 ALBRECHT 89,1 is ALBRECHT 87,1 value rescaled using B($D^*(2010)^- \rightarrow D^0 \pi^-$) = 0.57 \pm 0.04 \pm 0.04. Superseded by ALBRECHT 93.
- ⁴⁸ ALBRECHT 87J assume μ -e universality, the B($\Upsilon(4S) \rightarrow B^0 \overline{B}{}^0$) = 0.45, the B($D^0 \rightarrow$ $K^-\pi^+)=(0.042\pm0.004\pm0.004)$, and the B($D^*(2010)^-\to D^0\pi^-)=0.49\pm0.08$. Superseded by ALBRECHT 89J.

                                            <sup>49</sup> ALEXANDER 96T CLE2 e + e^- \rightarrow T(4S)
• • • We do not use the following data for averages, fits, limits, etc. • • •
                                           <sup>50</sup> BEAN
                                 90
                                                                     938 CLE2 e^+e^- \rightarrow T(45)
 ^{49} ALEXANDER 96T gives systematic errors ^{+0.5}_{-0.7}\pm 0.5 where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin
     symmetry: \Gamma(B^0 \to \rho^- \ell^+ \nu_\ell) = 2 \times \Gamma(B^+ \to \rho^0 \ell^+ \nu_\ell) \sim 2 \times \Gamma(B^+ \to \omega \ell^+ \nu_\ell).
 <sup>50</sup> BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine
    \Gamma(\rho^0\ell^+\nu_\ell) and \Gamma(\omega\ell^+\nu_\ell) with this result, they obtain a limit <(1.6-2.7)\times 10^{-4} at
     90% CL for B^+ \to (\omega \, {\rm or} \, \, \rho^0) \ell^+ \nu_\ell. The range corresponds to the ISGW, WSB, and
     K5 models. An upper limit on |V_{ub}/V_{cb}| < 0.08–0.13 at 90% CL is derived as well.

```

 51 ALEXANDER 96T gives systematic errors $\pm 0.3\,\pm\,0.2$ where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: $\Gamma(B^0 \to \pi^- \ell^+ \nu_\ell) = 2 \times \Gamma(B^+ \to \pi^0 \ell^+ \nu_\ell)$. Γ_6/Γ $\Gamma(\pi^-\mu^+\nu_\mu)/\Gamma_{\text{total}}$

$B^0-\overline{B}^0$ MIXING

Revised December 1997 by H. Quinn (SLAC)

There are two neutral B meson systems which are like the neutral kaon system, in that two CP-conjugate states exist: the states $B^0 = \overline{b}d$, and $\overline{B}^0 = \overline{d}b$, which we will call the B_d system; and the states $B_s^0 = \overline{b}s$, and $\overline{B}_s^0 = \overline{s}b$, which we call the B_s system. For early work on CP violation in the B systems, chiefly the B_d system, see Ref. 1. In both these systems the mass eigenstates are not CP eigenstates, but are mixtures of the two CP-conjugate quark states. The fact that the mixing, due to box diagrams, shown in Fig. 1, produces non-CP eigenstates means that there is a CP-violating phase that enters in the amplitude for these diagrams. The two mass eigenstates can be written, for example for the B_d system,

$$|B_L\rangle = p|B^0\rangle + q|\overline{B}^0\rangle ,$$

 $|B_H\rangle = p|B^0\rangle - q|\overline{B}^0\rangle .$ (1)

Here H and L stand for Heavy and Light, respectively.

The complex coefficients p and q obey the normalization condition

$$|q|^2 + |p|^2 = 1. (2)$$

 B^0

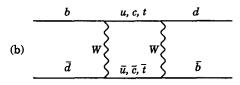

Figure 1: Mixing Diagrams.

We define the mass difference ΔM and width difference $\Delta \Gamma$ between the neutral B mesons:

$$\Delta M \equiv M_H - M_L ,$$

$$\Delta \Gamma \equiv \Gamma_H - \Gamma_L ,$$
(3)

so that ΔM is positive by definition. Finding the eigenvalues of the mass-mixing matrix, one gets

$$(\Delta M)^2 - \frac{1}{4}(\Delta \Gamma)^2 = 4(|M_{12}|^2 - \frac{1}{4}|\Gamma_{12}|^2) \tag{4}$$

and

$$\Delta M \Delta \Gamma = 4 \operatorname{Re} \left(M_{12} \Gamma_{12}^* \right) \,, \tag{5}$$

where the off-diagonal term of the mixing matrix is written as $M_{12} + i\Gamma_{12}$. Note that both M_{12} and Γ_{12} may be complex quantities; the separation is defined by the fact that Γ_{12} is given by the absorbtive part of the diagrams (cut contributions). The ratio q/p is given by

$$\frac{q}{p} = -\frac{\Delta M - \frac{i}{2}\Delta\Gamma}{2(M_{12} - \frac{i}{2}\Gamma_{12})} = -\frac{2(M_{12}^* - \frac{i}{2}\Gamma_{12}^*)}{\Delta M - \frac{i}{2}\Delta\Gamma}.$$
 (6)

Whereas in the kaon case the lifetimes of the two eigenstates are significantly different and the difference in masses between them is small, in the B_d system it is the mass differences that dominate the physics, and the two states have nearly equal predicted widths (and thus lifetimes). We define, for q = d, s

$$x_q = \frac{\Delta M_q}{\Gamma_q}$$
, $y_q = \frac{\Delta \Gamma_q}{\Gamma_q}$. (7)

The value of x_d is about 0.7, not very different from the similar quantity for the K^0 which is 0.48. The difference between the widths of the two B_d eigenstates is produced by the contributions from channels to which both B^0 and \overline{B}^0 can decay. These have branching ratios of $\mathcal{O}(10^{-3})$ [2]. Furthermore there are contributions of both signs to the difference, so there is no reason that the net effect should be much larger than the individual terms. Conservatively, one expects $y_d \leq 10^{-2}$ and thus also $|q/p|_d$ equal to 1 to a very good approximation. Experimentally no effect of a difference in lifetimes has been observed.

For B_s there is currently only a lower bound on the value of x_s . Theoretical expectation is that it may be as large as 20 or more, which makes it quite difficult to measure. A significant difference in widths is possible, due to the fact that a number of the simplest two-body channels contribute only to a single CP (like the two-pion state which dominates K-decays and is the source of the large width difference in that system). The difference in widths could be as much as 20% of the total width in the B_s system [3]. Note that this still gives a small ratio, of order a few percent, for $\Delta\Gamma/\Delta M$.

The proper time evolution of an initially (t=0) pure B^0 or $\overline{B}{}^0$ is given by

$$|B_{\text{phys}}^{0}(t)\rangle = g_{+}(t)|B^{0}\rangle + (q/p)g_{-}(t)|\overline{B}^{0}\rangle ,$$

$$|\overline{B}_{\text{phys}}^{0}(t)\rangle = (p/q)g_{-}(t)|B^{0}\rangle + g_{+}(t)|\overline{B}^{0}\rangle .$$
(8)

where

$$g_{\pm} = \frac{1}{2} \exp(-\Gamma t/2) \exp(-iMt)$$

$$\times \left\{ e^{-(\Delta \Gamma/2 - \Delta M)t} \pm e^{+(\Delta \Gamma/2 - \Delta M)t} \right\} . \tag{9}$$

The rate at which an initial B_q^0 (\overline{B}_q^0) decays as a \overline{B}_q^0 (B_q^0) is thus

$$R_q(t) = q/p \text{ (or } p/q)\Gamma |g_-(t)|^2$$
 (10)

The quantity χ_q measures the total probability that a created B^0 decays as a \overline{B}^0 ; it is given by

$$\chi_q = \int_0^\infty R_q(t) dt = \frac{1}{2} |q/p|^2 \frac{x_q^2 - y_q^2/4}{(1 + x_q^2)(1 - y_q^2/4)} , \qquad (11)$$

Time-dependent mixing measurements are now being done for the B_d system; earlier experiments measured only the time-integrated mixing, which is parameterized by a parameter χ_d . In this case to a good approximation we can set |q/p|=1 and $|y_d| \ll x_d < 1$ so that the simpler form $\chi_d = \frac{1}{2} \frac{x_d^2}{1+x_d^2}$ applies, and a measurement of χ_d implies a value of x_d .

In the B^0 – \overline{B}^0 mixing section of the B^0 Particle Listings, we list the χ_d measurements, most of which come from $\Upsilon(4S)$ data, and the Δm_{B^0} measurements, which come from Z data. We average these sections separately, but then include the results from both sections in "OUR EVALUATION" of χ_s and $\Delta M_{B^0_s}$. We convert both of these sets of measurements and list them in the χ_d section. The χ_d values obtained from Δm_{B^0} measurements have a common systematic error due to the error on τ_{B^0} . The averaging takes this common systematic error into account.

Because of the large value of x_s the quantity χ_s will be close to its upper limit of 0.5. This means that one cannot determine x_s accurately by measuring χ_s . It will require excellent time resolution to resolve the time-dependent mixing of the B_s^0 system, and thereby determine $\Delta M_{R_s^0}$.

In the $B_s^0 - \overline{B}_s^0$ mixing section of the B_s^0 Particle Listings, we give measurements of χ_B , the mixing parameter for a high-energy admixture of b-hadrons

$$\chi_B = f_d \frac{\mathcal{B}_d}{\langle \mathcal{B} \rangle} \chi_d + f_s \frac{\mathcal{B}_s}{\langle \mathcal{B} \rangle} \chi_s . \tag{12}$$

Here f_d and f_s are the fractions of b hadrons that are produced as B^0 and B^0_s mesons respectively, and \mathcal{B}_d , \mathcal{B}_s , and $\langle \mathcal{B} \rangle$ are branching fractions for B_d , B_s , and the b-hadron admixture respectively decaying to the observed mode. If we assume that $\chi_s = 0.5$ and $\mathcal{B}_d/\langle \mathcal{B} \rangle = \mathcal{B}_s/\langle \mathcal{B} \rangle = 1$, Eq. (12) can be used to determine f_s as discussed in the note on "Production and Decay of b-Flavored Hadrons."

B⁰-B⁰ MIXING PARAMETERS

or a discussion of $B^0 ext{-}\overline{B}{}^0$ mixing see the note on " $B^0 ext{-}\overline{B}{}^0$ Mixing" in the For a discussion of B^--B^- B Particle Listings above.

 x_d is a measure of the time-integrated $B^0 \overline{B}{}^0$ mixing probability that a produced $B^0(\overline{B}^0)$ decays as a $\overline{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$x_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L}) \, \tau_{B^0} \; .$$

where H,L stand for heavy and light states of two B^0 CP eigenstates and $au_{B^0} = \frac{1}{0.5(\Gamma_{B_H^0 + \Gamma_{B_L^0}}^0)}$.

This B^0 - \overline{B}^0 mixing parameter is the the probability (integrated over time) that a produced B^0 (or \overline{B}^0) decays as a \overline{B}^0 (or B^0), e.g. for inclusive lepton decays

$$X_d = \Gamma(B^0 \to \ell^+ X \text{ (via } \overline{B}^0))/\Gamma(B^0 \to \ell^{\pm} X)$$

$$= \Gamma(\overline{B}^0 \to \ell^{\pm} X \text{ (via } B^0))/\Gamma(\overline{B}^0 \to \ell^{\pm} X)$$

 $= r(\overline{B}^0 \to \ell^{\pm} X \text{ (via } B^0))/r(\overline{B}^0 \to \ell^{\pm} X)$ Where experiments have measured the parameter r = X/(1-X), we have converted to X. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated x_d from x_s where the subscripts indicate $B^0(\overline{b}d)$ or $B^0_s(\overline{b}s)$. They are listed in the $B_s^0 - \overline{B}_s^0$ MIXING section.

The experiments at $\Upsilon(45)$ make an assumption about the $B^0\overline{B}{}^0$ fraction and about the ratio of the B^{\pm} and B^{0} semileptonic branching ratios (usually that it equals one).

OUR EVALUATION, provided by the LEP B Oscillation Working Group, includes X_d calculated from Δm_{B^0} and au_{B^0} .

VIOLATION IN B DECAY **STANDARD** MODEL PREDICTIONS

Revised February 1998 by H. Quinn (SLAC).

The study of CP violation in B decays [1] offers an opportunity to test whether the Standard Model mechanism for CP violation, due to the phase structure of the CKM matrix, is the only source of such effects [2]. The known CP-violation effects in K decays can be accommodated by this mechanism, but do not provide a critical test of it.

The Unitarity conditions (see our Section on "The Cabibbo-Kobayashi-Maskawa mixing matrix")

$$V_{uq}V_{ub}^* + V_{cq}V_{cb}^* + V_{tq}V_{tb}^* = 0 , (1)$$

with q = s or q = d where V_{ij} is an element of the CKM matrix can be represented as triangles in the complex plane. The three interior angles of the q = d triangle are labeled

$$\alpha \equiv \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right) , \quad \beta \equiv \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right) ,$$

$$\gamma \equiv \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right) . \tag{2}$$

In terms of the Wolfenstein parameters [3] we can also write

$$\tan \alpha = \frac{\eta}{\eta^2 - \rho(1 - \rho)}$$
, $\tan \beta = \frac{\eta}{1 - \rho}$,
 $\tan \gamma = \frac{\eta}{\rho}$. (3)

Notice that the sign as well the magnitude of these angles is meaningful and can be measured.

A major aim of CP-violation studies of B decays is to make enough independent measurements of the sides and angles that the Unitarity triangle is overdetermined and thereby to check the validity of the Standard Model predictions that relate various measurements to aspects of this triangle. Constraints can be made on the basis of present data on the B-meson masses and lifetimes, on the ratio of charmless decays to decays with charm (V_{ub}/V_{cb}) , and on ϵ [4] in K decays. These constraints have been discussed in many places in the literature; for a recent summary see Ref. 5. The range of allowed values depends on matrix element estimates, these are difficult to calculate hadronic physics effects. Improved methods to calculate such quantities, and understand the uncertainties in them, are needed to further sharpen tests of the Standard Model. Because of the uncertainties in these quantities, any given "Standard Model allowed range," for example for (ρ, η) , cannot be interpreted as a statistically-based error range.

The phases in decay amplitudes which arise because of the phase in the CKM matrix, are called weak phases; the phases which arise from final state rescattering effects are referred to as strong phases. When one compares the amplitude for decay to a CP eigenstate to that for the related CP-conjugate process, the weak phase ϕ_i of each contribution changes sign, while the strong phase δ_i is unchanged:

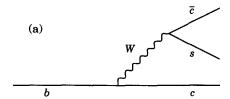

$$\mathcal{A} = \Sigma_i \mathcal{A}_i e^{i(\delta_i + \phi_i)} , \overline{\mathcal{A}} = \Sigma_i \mathcal{A}_i e^{i(\delta_i - \phi_i)} .$$
 (4)

Direct CP violation is a difference in the direct decay rate between $B \to f$ and $\overline{B} \to \overline{f}$ without any contribution from mixing effects. This requires $|A| \neq |\overline{A}|$, which occurs only if there is more than one term in the sum Eq. (4), and then only if the two terms have both different weak phases and different strong phases. A nonzero result for $Re(\epsilon'/\epsilon)$ in K decay is a direct CP-violation effect. Direct CP violation can occur both in charged channels and in neutral channels in B decays [4].

In the Standard Model direct CP violation occurs because there are two major classes of diagrams that contribute to weak decays, tree diagrams, and penguin diagrams, examples of which are shown in Fig. 1. Tree diagrams are those in which the W does not reconnect to the quark line from which it was emitted. Penguin diagrams are loop diagrams in which the W is re absorbed on the same quark line, producing a net change of flavor, and a gluon (for a strong penguin) or a photon or Z (for an electroweak penguin) is emitted from the loop. There may be several different tree diagrams for a given process, namely Wemission and decay, W decay, W exchange between the initial valence quarks, and/or valence quark-antiquark annihilation to produce the W. However all such contributions which enter a given transition do so with the same CKM (weak) phase. Direct CP violation occurs because of interference between tree diagrams and those penguin diagrams which have different weak phases than the trees. In channels where there are no tree contributions, direct CP violation can arise because of interference between different penguin contributions.

To calculate the size of expected CP-violation effects one begins from the relevant quark decay diagrams. We divide the amplitudes into two factors: a CKM factor given by the CKMmatrix elements that enter at each W vertex, and a Feynman amplitude from evaluating the remainder of the diagram. The Feynman amplitude of the penguin diagram is suppressed relative to tree diagrams by a factor of order $\alpha_s(m_b)/4\pi$. Firm predictions based on this argument for the strength of the CP-violating effects in particular exclusive charged B-decay channels are not possible because the relationship between the free-quark decay diagrams and the exclusive meson-decay amplitudes depends on operator matrix elements and thus estimates are model dependent. Furthermore one cannot reliably predict the strong phases that contribute to the asymmetry.

There is one interesting exception to this last statement that gives a possible way to find large direct CP-violation effects with known strong phase differences. This is any situation where two or more resonance channels contribute to the same final state

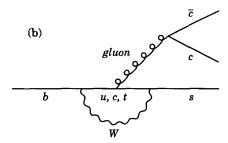

Figure 1: Quark level processes for $b \to c\bar{c}s$: (a) Tree diagram; (b) Penguin diagram. In the case of electroweak penguin contributions, the gluon is replaced by a Z or a γ .

set of particles in overlapping kinematic regions. The dominant contributions to the strong phases are then the resonant decay phases, which are known from measurements that determine the resonance mass and width. These give a known strong phase contribution which varies with the kinematics of the final particles and overlays the fixed strong phase of the resonanceproduction process. If two such resonant channels interfere, then there is a large and kinematically-varying known contribution to the strong phase difference between the contributions of the two channels. Examples include the interference of the different ρ - π charge combinations in the three pion final states [6] or interference between different $K^*\pi$ combinations in $K\pi\pi$ states. Detailed exploration of possible applications of these ideas can be found in Ref. 7.

A second type of CP violation, referred to as indirect CPviolation, or CP violation in the mixing, would arise from any difference in the widths $\Delta\Gamma$ of the two mass eigenstates, or more precisely from complex mixing effects $Arg(\Gamma_{12}M_{12}^*) \neq 0$, that would give $|q/p| \neq 1$ and also give a nonvanishing lifetime difference for the two B mass eigenstates [8]. Indirect CPviolation in the K system is responsible for Re $\epsilon \neq 0$, which give CP-violating asymmetries in leptonic decay rates. Such effects are expected to be tiny in the B_d system, where both |q/p|-1 and the difference of lifetimes $\Delta\Gamma/\Gamma$ are expected to be of order 10^{-2} [8]. For B_s a difference in the widths is possible, due to the fact that a number of the simplest two-body channels contribute only to a single CP. The difference in widths could be as much as 20% of the total width in the B_s system [9]. However the quantity |q/p|-1 is expected to be even smaller in the B_s system than in the B_d system. An indirect CPviolating asymmetry would be seen as an charge asymmetry in the same-sign dilepton events produced via mixing from an incoherent state that initially contains a $B^0\overline{B}{}^0$ pair. This asymmetry vanishes with $\Delta\Gamma$; it is expected to be no larger than 1% in B_d decays [10].

There are additional CP-violating effects in neutral B decays which arise from interference between the two paths to a given final state f

$$B \to f \text{ or } B \to \overline{B} \to f$$
 (5)

This effect, an interference between decay with and without mixing, is seen also in K decays where it contributes to the parameter Im ϵ . This interference can produce rate differences between B decay to a CP-eigenstate and the CP-conjugate \overline{B} decay. Such asymmetries can be directly related to the CKM phases, provided there is no direct CP violation in addition to this effect. In channels where there is also direct CP violation, the relationship between the measured asymmetry and the CKM parameters is more complicated.

A simple way to distinguish the three types of CP violation is to note that direct CP violation occurs when $|\overline{A}/A| \neq 1$ while indirect CP violation requires $|q/p| \neq 1$ (see the review on B^0 \overline{B}^0 Mixing). CP violation due to the interference between direct decay and decay after mixing can occur when both quantities have unit absolute value; it requires only that their product have a nonzero weak phase [11].

Neutral B decays to CP eigenstates: The decays of neutral B mesons into CP eigenstates are of particular interest because many of these decays allow clean theoretical interpretation in terms of the parameters of the Standard Model [12]. We denote such a state by f_{CP} , for example $f_{CP} = J/\psi(1S)K_S$ or $f_{CP} = \pi \pi$, and define the amplitudes

$$\mathcal{A}_{f_{CP}} \equiv \langle f_{CP} | B^0 \rangle, \quad \overline{\mathcal{A}}_{f_{CP}} \equiv \langle f_{CP} | \overline{B}^0 \rangle .$$
 (6)

For convenience let us introduce the quantity $\lambda_{f_{CP}}$

$$\lambda_{f_{CP}} \equiv \frac{q}{p} \frac{\overline{\mathcal{A}_{f_{CP}}}}{\mathcal{A}_{f_{CP}}} \ . \tag{7}$$

In the limit of no CP violation, $\lambda_{f_{CP}} = \pm 1$, where the sign is given by the CP eigenvalue of the particular state f_{CP} .

When the small difference in width of the two B_d states is ignored we can write

$$(q/p)_{B_d} = \frac{(V_{tb}^* V_{td})}{(V_{tb} V_{td}^*)} = e^{-2i\phi_M} ,$$
 (8)

where $2\phi_M$ denotes the CKM phase of the $B-\overline{B}$ mixing diagram (see the review on $B^0 - \overline{B}{}^0$ Mixing). The time-dependent decay width for an initial $B^0(\overline{B}^0)$ state to decay to a state f is then given by

$$\begin{split} &\Gamma(B^0_{\rm phys}(t) \to f_{CP}) = \\ &|\mathcal{A}_{f_{CP}}|^2 e^{-\Gamma t} \bigg[\frac{1 + |\lambda_{f_{CP}}|^2}{2} + \frac{1 - |\lambda_{f_{CP}}|^2}{2} \\ &\quad \times \cos(\Delta M t) - \operatorname{Im} \, \lambda_{f_{CP}} \sin(\Delta M t) \bigg], \end{split}$$

$$B^0$$

$$\Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP}) =$$

$$|\mathcal{A}_{f_{CP}}|^{2} e^{-\Gamma t} \left[\frac{1 + |\lambda_{f_{CP}}|^{2}}{2} - \frac{1 - |\lambda_{f_{CP}}|^{2}}{2} \right] \times \cos(\Delta M t) + \operatorname{Im} \lambda_{f_{CP}} \sin(\Delta M t) . \tag{9}$$

The time-dependent CP asymmetry is thus

$$\begin{split} a_{f_{CP}}(t) &\equiv \frac{\Gamma(B_{\text{phys}}^{0}(t) \to f_{CP}) - \Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP})}{\Gamma(B_{\text{phys}}^{0}(t) \to f_{CP}) + \Gamma(\overline{B}_{\text{phys}}^{0}(t) \to f_{CP})} \\ &= \frac{(1 - |\lambda_{f_{CP}}|^{2})\cos(\Delta M t) - 2\text{Im} \; (\lambda_{f_{CP}})\sin(\Delta M t)}{1 + |\lambda_{f_{CP}}|^{2}} \; . \; (10) \end{split}$$

Further, when there is no direct CP violation in a channel, that is when all amplitudes that contribute have the same CKM decay-phase, ϕ_D , then $|\mathcal{A}_{f_{CP}}/\overline{\mathcal{A}_{f_{CP}}}|=1$. In that case $\lambda_{f_{CP}}$ depends on CKM-matrix parameters only, without hadronic uncertainties, and can be written $\lambda_{f_{CP}}=\pm e^{-2i(\phi_D+\phi_M)}$. Then Eq. (10) simplifies to

$$a_{f_{CP}}(t) = \mp \text{Im} (\lambda_{f_{CP}}) \sin(\Delta M t)$$
$$= \pm \sin(2(\phi_M + \phi_D)) \sin(\Delta M t) . \tag{11}$$

where the overall sign is given by the CP eigenvalue, ± 1 , of the final state f_{CP} . The mixing phase ϕ_M and the decay phase ϕ_D are each convention dependent, that is their value can be changed by redefining the phases of some of the quark fields. However Im $\lambda_{f_{CP}}$ depends on convention-independent combinations of CKM parameters only. From Eq. (11) one can directly relate the measured CP-violating asymmetry to the phase of particular combination of CKM-matrix elements in the Standard Model.

Extracting CKM parameters from measured asymmetries: In order make this relationship one looks at the CKM elements that appear in the relevant decay amplitudes and in the mixing diagrams. If the final state of the decay includes a K_S , an additional contribution from the K-mixing phase must be included in relating the measured asymmetry to the CKM parameters.

Table 1: $B \rightarrow q\overline{q}s$ decay modes

Whenever a penguin amplitude can contribute there are three separate diagrams, corresponding to the three flavors of up-type quarks in the loop. Each of these has a different CKM coefficient. We use the Unitarity condition Eq. (1) to express one coefficient as minus the sum of the other two. This regroups the three terms as a sum of two terms each of which involves a difference of two penguin diagrams (and thus is an ultra-violet finite quantity). As we will see below, the most convenient regrouping is different for $b \to q\bar{q}s$ decays and for $b \to q\bar{q}d$ decays.

When there is a tree diagram one of the two penguin terms will have the same CKM coefficient (and hence the same weak phase) as the tree diagram. Terms with the same weak phase can always be treated as a single contribution, from the perspective of looking for CP violations, although one must be sure to include all the relevant operators when estimating the expected size of such a term. In what follows we use the term "tree-dominated contribution" to describe a tree contribution plus any penguin contribution with the same weak phase. We label the second penguin term, which has a different CKM coefficient from the tree diagram as a "pure penguin contribution." Where no tree diagrams contribute there are two pure penguin terms. With this convention there are at most two terms with different weak decay phases that contribute for any decay in the Standard Model. It is instructive to note that any beyond-Standard-Model contribution, whatever its weak phase, can always be written as a sum of two terms with the weak phases of the two Standard Model terms, thus it is the pattern of relative strengths, and isospin structure, of the two terms that is peculiar to the Standard Model. (Care should be taken when comparing the terms defined by this grouping with statements in the literature about the sizes of terms made using definitions that do not include this regrouping.)

Table 1 gives the CKM factors for the various $b \to q \overline{q}'s$ quark decay channels. Here we choose to group penguin terms
by eliminating the coefficient $V_{ts}V_{tb}^*$. Note that the two penguin
terms in this arrangement are each the difference between a top
quark contribution and a lighter (c or u) quark contribution, so
they differ only by the mass dependent factors in this second

Quark process	Leading term	Secondary term	$\begin{array}{c} {\rm Sample} \\ B_d \ {\rm modes} \end{array}$	B_d angle	Sample B_s modes	B_s angle
$b \rightarrow c\overline{c}s$	$V_{cb}V_{cs}^* = A\lambda^2$ tree + penguin $(c-t)$	$V_{ub}V_{us}^* = A\lambda^4(\rho - i\eta)$ penguin only $(u - t)$	$J/\psi \ K_S$	β	$\psi\eta \ D_s\overline{D}_s$	0
$b o s \overline{s} s$	$V_{cb}V_{cs}^* = A\lambda^2$ penguin only $(c-t)$	$V_{ub}V_{us}^* = A\lambda^4(\rho - i\eta)$ penguin only $(u - t)$	ϕK_S	β	$\phi\eta^{t}$	0
$b \to u\overline{u}s$ $b \to d\overline{d}s$	$V_{cb}V_{cs}^* = A\lambda^2$ penguin only $(c-t)$	$V_{ub}V_{us}^* = A\lambda^4(\rho - i\eta)$ tree + penguin $(u - t)$	$\pi^0 K_S$ $ ho K_S$	competing terms	$\phi\pi^0 \ K_S \overline{K}_S$	competing terms

contribution and by their overall sign and the CKM factors. One is suppressed by the CKM factor $\lambda^2(\rho - i\eta)$ compared to the other.

The columns labeled "Sample B_d Modes" and "Sample B_s Modes" list some of the simplest CP-study modes for each case. (These are either CP eigenstates, or modes from which CP-eigenstate contributions can be isolated, for example by angular analysis.) The columns labeled "Angle" show the angle of the unitarity triangle measured by $\phi_M + \phi_D$ where ϕ_M is the weak phase due to mixing, and ϕ_D that of the dominant decay amplitude (only the sum of these quantities is convention independent). Any Cabibbo-suppressed pure-penguin terms gives a negligible correction to this result. For the decay $b \to s\overline{s}s$ there is no tree contribution so the angle given is that due to the dominant penguin term, ignoring the Cabibbo-suppressed penguin term.

The quark decays to $u\overline{u}s$ and $d\overline{d}s$ contribute to the same set of final state hadrons and so must be combined. Here the tree diagram contributes to the Cabibbo-suppressed amplitude, so that the net result is that the two terms are expected to give comparable contributions with different CKM phases. For these decays, as with other direct CP-violating processes, there is no simple relationship between the measured asymmetry and a CKM phase, and thus no entry in the "Angle" columns in Table 1.

In addition to the neutral CP-eigenstate methods to determine the angles of the unitarity triangle listed in the tables, there are a number of other methods that involve decays that self-tag B-flavor, such as $DK^*(892)$ in either neutral [13] or charged [14] B decays. Further methods to measure γ in charged $B \to DK$ or $B \to D\pi$ have been suggested [15], which use interferences between a suppressed B decay followed by an allowed D decay and an allowed B decay followed by a suppressed D decay. However the relationship between the decay asymmetry and the angle is not as simple as Eq. (11) in this case. These methods require accurate measurements of several branching ratios, including a number that are quite small.

Table 2: $B \rightarrow q\overline{q}d$ decay modes

In Table 2 we list decays $b \to q\overline{q}'d$ decays. Here we choose to eliminate whichever of the two terms $V_{ud}V_{ub}^*$ or $V_{cd}V_{cb}^*$ is not present in the tree diagrams, so that the two penguin terms are one with the same weak phase as the tree and a second with CKM coefficient $V_{td}V_{tb}^*$ which has the opposite weak phase as the dominant mixing term in the Standard Model and hence a known value, zero, for $\phi_M + \phi_D$.

Here the competition between the tree-dominated and purepenguin amplitudes is stronger because there is no Cabibbo suppression of the latter. The pure-penguin contributions are expected to be somewhat smaller because of the $\alpha(m_b)/\pi$ suppression factor. Table 2 lists the angle $\phi_M + \phi_D$, using ϕ_D for the tree-dominated terms as the angle measured. However the measured angle may be significantly shifted from this value if the pure-penguin terms turn out to be large. In certain cases one still may be able to extract a measurement of an angle, for example of $\sin(2\alpha)$ from the $\pi^+\pi^-$ asymmetry by measuring the rates in several isospin-related channels and using a multiparameter fit to separate a tree-only contribution [16]. The impact of electroweak penguins, which will not be removed by this analysis [17] is quite small in this channel [18]. This isospin analysis requires measuring the decay rate for channel $\pi^0\pi^0$, which will be a challenge. For the $\rho\pi$ decays the restrictions due to isospin can again be used to make a multiparameter fit to the ρ -regions of the Dalitz plot for $\pi^+\pi^-\pi^0$ distribution [6]. The interference between different p-charge channels is significant and may provide sufficient information to allow the separation of tree-dominated and pure-penguin effects and thus extraction of the parameter α . Isospin analyses at the very least can be used to test whether the penguin contributions are indeed small enough to be neglected in the determination of α .

In the case $b \to s\overline{s}d$ there are no tree graph contributions. The phase of the dominant penguin contribution is such that, combined with mixing effects, it gives a zero asymmetry for B_d decays and an asymmetry proportional to β for B_s decays. However, Gérard and Hou [19] have pointed out that interference with the sub-dominant penguin terms, proportional to

Quark process	Leading term	Secondary term	$\begin{array}{c} {\rm Sample} \\ B_d \ {\rm modes} \end{array}$	B_d angle	Sample B_s modes	B_s angle

^{*}Leading terms only.

B^0

 $V_{ub}V_{ud}^*$ can give significant direct CP-violation asymmetries for such channels. Fleischer [20] has estimated that this asymmetry is possibly as large as 50%. While the sub-dominant term in this case would vanish if the masses of the up quark and the charm quark were equal, these estimates, which are based on the actual quark mass values and extreme values of operator matrix elements estimated using models, cannot be excluded. Thus, contrary to some comments in the literature, observation of CP-violating asymmetries in channels such as $B_d \to \phi \pi^0$ or $K^0\overline{K}^0$ would not necessarily require beyond-Standard-Model effects to explain them.

The entry for $b \to c\overline{u}d$ where the D^0 decays to a CP eigenstate ignores the small effect of doubly-Cabibbo-suppressed D-decays [21]. In contrast, the last entry indicates that one can select modes reached only by doubly-Cabibbo-suppressed decays from $D^0\pi$ and observe their interference with unsuppressed decays to the same channel from $\overline{D}^0\pi$ states, and thereby obtain a measurement of gamma [22].

There are some decay channels which are common to the B^0 and $\overline{B}{}^0$ but which are not CP eigenstates. For example the channel $J/\psi(1S)K^*(892)$ where the $K^*(892) \to K_S\pi^0$, the final state is not a CP eigenstate because both even and odd relative angular momenta between the $J/\psi(1S)$ and the $K^*(892)$ are allowed. One can use angular analysis to separate the different CP final states and measure the asymmetry in each [23]. The method applies in many quasi-two-body decays, such as other vector-vector channels, or those with higher-spin particles in final states. The branching ratio to these channels may be significantly larger than the CP-eigenstate (vector-scalar or scalar-scalar) channels with the same quark content. Such angular analyses may therefore be important in achieving accurate values for the parameters α and β .

Additional ways to extract CKM parameters by relationships between rates for channels such as $\pi\pi$, πK that can be extracted using SU(3) invariance have received considerable attention in the literature [24]. While these relationships will be interesting to investigate, the uncertainties introduced by SU(3) corrections may be significant. The review by Buras [5] gives a good summary of these ideas.

CP VIOLATION PARAMETERS

Re(cgo)

 \overline{CP} impurity in B_0^0 system. It is obtained from $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events at the T(4S).

$$\mathrm{Re}(\epsilon_{B^0}) \simeq \tfrac{1}{4} \mathsf{a}_{\ell\ell} = \tfrac{1}{4} \; \tfrac{N(\ell^+\ell^+) - N(\ell^-\ell^-)}{N(\ell^+\ell^+) + N(\ell^-\ell^-)} \; .$$

315 ACKERSTAFF 970 assumes CPT and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and $Q_{\rm hem}$ tags. If CPT is not invoked, Re(ϵ_B) = -0.006 ± 0.006 is found. The indirect CPT violation parameter is determined to ${\rm Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$.

316 BARTELT 93 finds $s_{\ell\ell}=0.031\pm0.096\pm0.032$ which corresponds to $|s_{\ell\ell}|<0.18$, which yields the above ${\rm Re}(\epsilon_{\rm B0})$.

B^{\pm}/B^{0} ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibilty would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

 $\overline{\cal B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

B±/B0/B0/b-baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Lifetime Working Group as described in our review "Production and Decay of b-flavored Hadrons" in the B^\pm Section of these Listings. The averaging procedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

1		

- ¹ Measured using inclusive $J/\psi(1S) \rightarrow \mu^{+}\mu^{-}$ vertex.
- 2 ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.
- eter.

 3 ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.
- ⁴ BUSKULIC 96F analyzed using 3D impact parameter.
- ⁵ ABE,K 95B uses an inclusive topological technique.
- ⁶ ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
- ⁷ ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.
- ⁸ BUSKULIC 930 analyzed using dipole method.
- 9 Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
- 10 From proper time distribution of $b o J/\psi(15)$ anything.
- 11 ABE 93J analyzed using $J/\psi(1S)
 ightarrow ~\mu \mu$ vertices.
- ¹² ABREU 93D data analyzed using $D/D^*\ell$ anything event vertices.
- 13 ABREU 93G data analyzed using charged and neutral vertices.
- 14 ACTON 93C analysed using $D/D^*\ell$ anything event vertices.
- 15 ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
- 16 ACTON 92 is combined result of muon and electron impact parameter analyses.
- ¹⁷ BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991
- run. ¹⁸ BUSKULIC 92G use $J/\psi(15)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(15)$ branching fractions of the different b-flavored hadrons are in the same ratio.
- hadrons are in the same ratio. 19 Using $Z\to \,{\rm e^+X}$ or $\mu^+{\rm X}$, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
- ²⁰ Using $Z \to J/\psi(1S)$ X, $J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.

- 21 Using $Z\to e X$ or $\mu X,$ DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
- 22 HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
- 23 LYONS 90 combine the results of the B lifetime measuresments of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
- 24 We have combined an overall scale error of 15% in quadrature with the systematic error of ± 0.7 to obtain ± 2.1 systematic error.
- ²⁵ Statistical and systematic errors were combined by BROM 87.

 $^{^{28}}$ ADAM 95 data analyzed using vertex-charge technique to tag b-hadron charge.

b PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $Sp\bar{p}S$) are used in the branching fraction averages. The production fractions give our best current estimate of the admixture at

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical when only one of the specified particles is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

The modes below are listed for a \overline{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode Fraction (Γ_I/Γ) Confidence level

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at the Z have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the LEP B Oscillation Working Group as described in the note "Production and Decay of b-Flavored Hadrons" in the B^\pm Particle Listings. Values assume

$$\begin{array}{ll} B(\overline{b} \rightarrow B^+) = B(\overline{b} \rightarrow B^0) \\ B(\overline{b} \rightarrow B^+) + B(\overline{b} \rightarrow B^0) + B(\overline{b} \rightarrow B^0_s) + B(b \rightarrow \Lambda_b) = 100 \ \%. \end{array}$$

The notation for production fractions varies in the literature $(f_{B^0}, f(b \to \overline{B}^0))$, $Br(b \to \overline{B}^0))$. We use our own branching fraction notation here, $B(\overline{b} \to B^0)$.

32 BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This beautiful properties to the production of the properties o depends primarily on the ratio of dileptons to single leptons at high p_T , but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ± 0.0026 and is included in the systematic error.

33 AKERS 93B analysis performed using single and dilepton events.

 35 Assumes Standard Model value for R_B .

 36 ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.

37 AKERS 93B analysis performed using single and dilepton events.

38 ADEVA 91c measure the average $B(b\to eX)$ branching ratio using single and double tagged b enhanced Z events. Combining e and μ results, they obtain $0.113\pm0.010\pm0.006$. Constraining the initial number of b quarks by the Standard Model prediction $(378\pm3$ MeV) for the decay of the Z into $b\bar{b}$, the electron result gives $0.112\pm0.004\pm0.008$. They obtain $0.119\pm0.003\pm0.006$ when e and μ results are combined. Used to measure the $b\bar{b}$ width itself, this electron result gives $370\pm12\pm24$ MeV and combined with the muon result these $388\pm7.4\pm23$ MeV. with the muon result gives 385 \pm 7 \pm 22 MeV.

39 ABE 932 experiment also measures forward-backward asymmetries and fragmentation functions for b and c.

 $\Gamma(\mu^+\nu_\mu {
m anything})/\Gamma_{{
m total}}$ These branching fraction values are model dependent. See the note on "Semileptonic "Se Decays of D and B Mesons, Part II" at the beginning of the B^+ Particle Listings.

B^* , $B_J^*(5732)$

 2 These papers report E_{γ} in the B^* center of mass. The $m_{B^*}-m_B$ is 0.2 MeV higher. $E_{\rm cm} = 10.61-10.7$ GeV. Admixture of $B^{\rm O}$ and B^{+} mesons, but not $B_{\rm S}$.

 3 LEE-FRANZINI 90 value is for an admixture of B^0 and B^+ . They measure 46.7 \pm 0.4 \pm 0.2 MeV for an admixture of B^0 , B^+ , and B_s , and use the shape of the photon line to separate the above value. ⁴ HAN 85 is for $E_{\rm cm}=10.6$ –11.2 GeV, giving an admixture of B^0 , B^+ , and B_s .

$|(m_{B^{*+}}-m_{B^+})-(m_{B^{*0}}-m_{B^0})|$

 3 Measured using fully reconstructed $B_S \to J/\psi(1S)\phi$ decay.

 4 ACKERSTAFF 98F use fully reconstructed $D_s^+ o \phi \pi^-$ and $D_s^- o K^{*0} K^-$ in the inclusive B_s^0 decay.

⁵ Measured using $D_s^- \ell^+$ vertices.

 6 Measured using D_{s}^{-} hadron vertices.

⁷ Measured using $\phi \ell$ vertices.

⁸ Measured using inclusive D_S vertices.

 9 Combined results from $D_{s}^{-}\ell^{+}$ and D_{s} hadron.

 $^{10}\,\mathrm{ABE}$ 96N uses 58 \pm 12 exclusive $B_{\mathrm{S}} \to ~J/\psi(1S)\phi$ events.

 11 Combined result for the four ABREU 96F methods. 12 Exclusive reconstruction of $B_{\rm S} \to ~\psi \, \phi.$

 13 ABREU 94E uses the flight-distance distribution of $D_{_{S}}$ vertices, ϕ -lepton vertices, and $D_S \mu$ vertices.

BO DECAY MODES

These branching fractions all scale with B($\overline{b} \rightarrow B_s^0$), the LEP B_s^0 production fraction. The first four were evaluated using $B(\overline{b} \rightarrow B_s^0) =$ $(10.5^{+1.8}_{-1.7})\%$ and the rest assume B($\bar{b} \to B_s^0$) = 12%.

The branching fraction B($B_s^0 o D_s^- \ell^+
u_\ell$ anything) is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times$ ${\sf B}(B_0^0\to D_0^-\ell^+\nu_\ell$ anything) was used to determine ${\sf B}(\overline{b}\to B_0^0)$, as described in the note on "Production and Decay of b-Flavored Hadrons."

	Mode	Fraction (Γ_I/Γ)	Confidence level

BO-BO MIXING

For a discussion of $B^0_S - \overline B^0_S$ mixing see the note on " $B^0 - \overline B^0$ Mixing" in the \mathcal{B}^{0} Particle Listings above.

 x_s is a measure of the time-integrated $\mathcal{B}_s^0 - \overline{\mathcal{B}}_s^0$ mixing probability that produced $B^0_s(\overline{B}^0_s)$ decays as a $\overline{B}^0_s(B^0_s)$. Mixing violates $\Delta B \neq 2$ rule.

$$X_S = \frac{x_S^2}{2(1+x_s^2)}$$

$$x_{s} = \frac{\Delta m_{B_{s}^{0}}}{\Gamma_{B_{s}^{0}}} = (m_{B_{sH}^{0}} - m_{B_{sL}^{0}}) \tau_{B_{s}^{0}},$$

where \emph{H} , \emph{L} stand for heavy and light states of two $\emph{B}^0_\emph{s}$ \emph{CP} eigenstates and $\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{sH}^0} + \Gamma_{B_{sL}^0})}$

x_B at high energy

This is a B-B mixing measurement for an admixture of B^0 and B^0_s at high energy. $X_B = r'_d X_d + r'_s X_s$ where r'_d and r'_s are the branching ratio times production fractions of B^0_d and B^0_s mesons relative to all b-flavored hadrons which decay weakly. Mixing violates $\Delta B \neq 0$

 44 Uses di-muon events. 45 ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \rightarrow Z \rightarrow b\overline{b}$ and $c\overline{c}$.

 46 This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.

 $^{47}\, \rm BUSKULIC$ 94G data analyzed using e.e, e.u, and $\mu\mu$ events.

48 BUSKULIC 92B uses a jet charge technique combined with electrons and muons.

 $^{49}\,\mathrm{ABE}$ 91G measurement of χ is done with $e\,\mu$ and $e\,e$ events.

50 ALBAJAR 91D measurement of X is done with dimuons.
51 UENO 96 extracted X from the energy dependence of the forward-backward asymmetry. ⁵² AREU 94F uses the average electric charge sum of the Jets recoiling against a *b*-quark jet tagged by a high p_T muon. The result is for $\overline{X} = f_d X_d + 0.9 f_s X_s$.

53 This ABREU 941 result combines ££, \$\Lambda\$£, and jet-charge £ (ABREU 94F) analyses. It is for $\overline{X} = f_d X_d + 0.96 f_s X_s$.

54 ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.

 $^{55} \text{ABREU}$ 93C data analyzed using e.e., e.u., and $\mu\mu$ events.

56 AKERS 93B analysis performed using dilepton events.

57 ACTON 92C uses electrons and muons. Superseded by AKERS 93B.

58 ADEVA 92c uses electrons and muons.
59 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 928. 60 ADEVA 90P measurement uses e.e, $\mu\mu$, and e. μ events from 118k events at the Z. Superseded by ADEVA 92C.

 61 These experiments are not in the average because the combination of $B_{\rm S}$ and $B_{\rm d}$ mesons which they see could differ from those at higher energy.

62 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL

are 0.06 and 0.38. 63 ALBAJAR 87c measured $x=(\overline{B}^0\to B^0\to \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.

 64 Limit is average probability for hadron containing ${\it B}$ quark to produce a positive lepton.

 $\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$ $\Delta m_{B_s^0}$ is a measure of 2π times the $B_s^0 - \overline{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is an average of the data listed below performed by the LEP B Oscillation Working Group as described in our review "Production and Decays of B-flavored Hadrons" in the B^\pm Section of these Listings. The averaging procedure takes into account correlations between the measurements.

THE CHARMONIUM SYSTEM

The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.
