KEYWORDS: *Activity-based sensing, hydrogen peroxide, redox signaling, boronate, molecular imaging, in vivo imaging, fluorescence imaging, photoacoustic imaging, labeling, neurodegeneration*

C hemical sensors are powerful tools to illuminate new
biology by enabling tracking of elemental species as well
as small and large biomolecules in space and time $1-3$ Indeed as small and large biomolecules in space and time.^{[1](#page-12-0)−[3](#page-13-0)} Indeed, cells orchestrate the many complex tasks required to maintain life by means of signaling pathways mediated by metal ions $(Ca^{2+}, Na^{+}, K^{+}, Cu^{1+/2+}, Fe^{2+/3+}, Zn^{2+})$, small-molecule and peptide/protein hormones and cytokines, lipids, glycans, and many other chemical signaling agents. $4-8$ $4-8$ $4-8$ In this context, reactive oxygen species (ROS) can also act as cellular messengers and play essential roles in redox signaling processes[.4,9](#page-13-0)[−][15](#page-13-0) ROS is an umbrella term used to denote a large array of small and transient molecular oxygen species, including the hydroxyl radical $(\bullet$ OH), ozone (O_3) , peroxynitrite (ONOO $^-$), superoxide $(O_2^{\bullet -})$, and hydrogen peroxide (H_2O_2) . Historically, ROS have been viewed as dangerous byproducts of respiration, and indeed redox misregulation and resulting oxidative stress and damage events are implicated in many pathologies such as neurodegeneration, cancer, and autoimmune disorders.[16](#page-13-0)−[18](#page-13-0) However, we now recognize that the chemistry and biology of ROS is much more sophisticated, as the generation of specific ROS is tightly regulated and also essential for normal signaling and metabolic functions.^{10,[12](#page-13-0),[13,19](#page-13-0)}

Along these lines, H_2O_2 is a particularly privileged redox signal produced from O_2 by specific enzymatic sources, including NADPH oxidases, superoxide dismutases, and mitochondrial electron transport chain complexes.[13](#page-13-0),[20](#page-13-0)−[22](#page-13-0) The relatively high stability of H_2O_2 , compared to other

ROS, allows it to traverse within and between cells and to regulate the activity of specific protein targets via cysteine or methionine oxidation, along with other emerging redox modifications.^{[11](#page-13-0),[23](#page-13-0)} As such, H_2O_2 has been identified as a vital mediator of biological processes spanning immune response, angiogenesis, and cell proliferation, differentiation, and migration.^{11-[13,24](#page-13-0)-[26](#page-13-0)} This broad biology motivates the development of new chemical tools that enable selective tracking of biological H_2O_2 fluxes and gradients.^{[9](#page-13-0)} Here, we provide an overview of the concept and application of activitybased sensing (ABS) as a general chemical approach for the study of biological messengers with molecular specificity. In particular, we focus on advances in the invention of boronatebased reagents by our laboratory and others that enable specific detection of hydrogen peroxide to illustrate the power of tailoring probe design to discover and decipher new biological principles. This Review provides a roadmap to inform future work and expand the ABS approach for a

broader range of biological and environmental chemical analytes for study.

■ **SOLVING THE SELECTIVITY CHALLENGE: ACTIVITY-BASED BORONATE PROBES FOR SELECTIVE H₂O₂ DETECTION**

Selectivity is the primary challenge in initiating and implementing successful bioimaging design strategies. In this context, synthetic small-molecule probes offer an attractive complement to large-molecule sensors based on proteins and nucleic acids, as the former can be rapidly deployed across multiple cellular and organismal models without further specimen manipulation. Indeed, in the context of selective ROS detection, fluorescent protein sensors, including the HyPer and roGFP2 series, have contributed to our understanding of cellular H_2O_2 trafficking,^{12,[27](#page-13-0)–[30](#page-13-0)} but these reagents require genetic encoding and additional technical expertise for introduction. Early molecular probes, such as 2′,7′-dichlorodihydrofluorescein (DCFH), suffered from nonselective reactivity within the complex biological milieu.^{[1](#page-12-0),[9](#page-13-0),[13,31](#page-13-0)} Additionally, the well-established and traditional binding-based approaches to fluorophore design, were not amenable for tracking small transient species such as ROS (Figure 1A).

As such, our laboratory initiated a research program focused on harnessing chemical reactivity as a platform to track small molecule transient analytes in biologically relevant settings, opening a field we term "activity-based sensing" (ABS) (Figure 1B). $1,32$ $1,32$ With the introduction of Peroxyfluor-1 (PF1), we

Figure 1. (A) Schematic cartoon depicting prototypical binding-based approaches for analyte sensing. (B) Schematic cartoon depicting activity-based sensing approaches which rely on chemical reactivity to enhance selectivity for transient species. (C) A primary example of activity-based sensing illustrated by the H_2O_2 -mediated uncaging of aryl boronate groups on Peroxyfluor-1 (PF1) to generate fluorescein, with a mechanism for boronate-to-phenol conversion.

established boronate uncaging as a viable design strategy for selective H_2O_2 sensing in biologically relevant settings (Figures 1C and [2](#page-3-0)). Inspired by organic chemistry reported in the 1950s showing that boronates could be converted to phenols by $H₂O₂$ -mediated oxidation, PF1 was based on the traditional fluorescein scaffold but modified with aryl boronate esters at the xanthenone 3′ and 6′ positions.^{[32](#page-13-0)−[34](#page-13-0)} In this form, the probe adopted the closed and nonfluorescent lactone form (Figure 1C). Oxidative deprotection of the aryl boronate esters to the corresponding phenolates generates the open quinoid and fluorescent form of fluorescein, thus enabling the selective detection of H_2O_2 in live-cell models.^{[32](#page-13-0)} Two key features of the boronate oxidation reaction mechanism are (1) its twoelectron nature, which distinguishes peroxide over radical ROS that act as single-electron oxidants, and (2) the elimination of water, which enables kinetic discrimination over alkyl peroxides, where alcohol would be the leaving group. When used in conjunction with appropriate controls such as nitric oxide synthase inhibitor to eliminate possibilities of peroxynitrite detection, which is generated at much lower levels with a much shorter lifetime if it is present, boronate probes are reliable activity-based reagents for selective H_2O_2 bioimaging.[1](#page-12-0)[,35,36](#page-13-0)

The success of PF1 and ease of aryl boronate ester installation onto virtually any type of fluorophore scaffold has facilitated the rapid adoption of this ABS strategy by the broader chemical biology community. Indeed, the field has witnessed an influx of highly creative fluorophore structures for $H₂O₂$ sensing that span the visible and near-infrared (near-IR) wavelength spectrum, afford ratiometric readouts, target specific organelles, and simultaneously monitor other important analytes [\(Figure](#page-3-0) 2). Importantly, each design advance in new chemical structures for ABS has unearthed new fundamental insights into biological H_2O_2 signaling, from the discovery of transmembrane proteins that facilitate H_2O_2 uptake intracellularly to identifying specific subcellular sources of ROS in conjunction with proteomic analysis. $37,38$ $37,38$ $37,38$ We direct the reader to other excellent reviews should they seek detailed historical contexts for ABS, extensive catalogues on photophysical properties of ABS probes, and/or discussions on ABS of other analytes.^{1[,39](#page-14-0)–[41](#page-14-0)}

■ **RATIOMETRIC ACTIVITY-BASED SENSING PROBES ENABLE SELF-CALIBRATION BY TWO-COLOR RESPONSES**

Soon after the development of PF1, we sought to rapidly expand the scope and generality of activity-based probe design to enable ratiometric fluorescence imaging of H_2O_2 . Indeed, fluorescence quantification of a single emission component is challenging. In particular, potential variations in instrument hardware and parameters, photobleaching, probe aggregation, and variations (pH, polarity, temperature, etc.) in the surrounding probe microenvironment, among other factors, may lead to confounding and even irreproducible results. $42,43$ Ratiometric fluorescence imaging can bypass many of these challenges due to the internal referencing provided by simultaneously measuring changes in the fluorescence intensity between two emission bands and calculating their ratio.

In initial studies to achieve this goal, we developed Ratio-Peroxyfluor-1 (RPF1) as a Förster resonance energy transfer (FRET)-based approach toward ratiometric ABS imaging ([Figure](#page-4-0) 3A).⁴⁴ We drew inspiration from previous work by Nagano and co-workers, in which they employed FRET-based

Figure 2. Chronological overview detailing how advances in the development of activity-based sensing (ABS) probes in H_2O_2 detection lead to new biological discovery of redox signaling principles, emphasizing the synergy between ABS chemical probe design and biological experiments. fluorophore systems to measure protein tyrosine phosphatase (PTP) activity by tuning spectral overlap integrals.^{[45](#page-14-0)} RPF1 is composed of both coumarin and aryl boronate ester protected fluorescein scaffolds linked together by a short cyclohexane spacer ([Figure](#page-4-0) 3A).^{[44](#page-14-0)} In its protected form, fluorescein remains locked in the lactone form and does not exhibit an overlapping absorption band with the coumarin emission, effectively shutting off FRET-based fluorescence. H_2O_2 -mediated aryl boronate ester deprotection generates the open quinoid form of fluorescein thereby promoting spectral overlap between coumarin emission and fluorescein absorption thus enabling FRET-based fluorescence [\(Figure](#page-4-0) 3A). RPF1 was highly selective for H_2O_2 over other ROS and reactive nitrogen species (RNS) and enabled quantification of H_2O_2 production in isolated yeast mitochondria upon antimycin A stimulation.

In order to translate ratiometric activity-based imaging to live-cell models, we developed Peroxy Lucifer 1 (PL1, Figure 2), which leverages an intramolecular charge transfer (ICT) mechanism to generate a ratiometric fluorescence response.^{[46](#page-14-0)} The naphthalimide core is rendered electron-poor when the carbamate-tethered aryl boronate cage is intact with a maximum fluorescence emission centered at 475 nm. H_2O_2 mediated deprotection exposes the free amine, thus promoting greater electron donation into the core naphthalimide scaffold and resulting in a new fluorescence maximum at 540 nm. This

blue-to-green fluorescent response shift enabled the ratiometric analysis of endogenous H_2O_2 bursts produced and localization of these pools in PMA-stimulated RAW 264.7 macrophages.⁴⁶ In collaboration with Cho's laboratory, we also established Peroxy Naphthalene 1 (PN1) for deep tissue ratiometric imaging via two-photon microscopy, which provided the capability to monitor differences in basal H_2O_2 levels in distinct regions of rat hippocampal slices ([Figure](#page-4-0) 3B).⁴⁷

A particularly elegant ratiometric activity-based H_2O_2 sensor developed by Lin and co-workers couples both ICT and FRET mechanisms. The sensor dyad is composed of a coumarin scaffold linked to a boronate-modified napthalimide (CNBE) ([Figure](#page-4-0) 3C).^{[48](#page-14-0)} Deprotection of CNBE by H_2O_2 to generate CNOH activates ICT, resulting in a bathochromically shifted naphthalimide absorbance that overlaps with coumarin emission [\(Figure](#page-4-0) 3C). This strategy was capable of tracking H2O2 elevations in lipopolysaccharide (LPS)-stimulated HeLa cells and *in vivo* zebrafish models.^{[48](#page-14-0)} Other recent examples of ratiometric probes for activity-based peroxide sensing have been applied to monitor oxidative stress during ischemic brain injury or in Alzheimer's disease (AD) and Parkinson's models. $39,49,50$ $39,49,50$ $39,49,50$ As many of these systems utilize organelle targeting fragments or sense multiple analytes in addition to providing a ratiometric response, we elaborate on them in subsequent sections (*vide infra*).

Mono-boronate probes allow for visualization of endogenous H_2O_2

Figure 3. (A) Schematic detailing H_2O_2 -mediated uncaging of Ratio-Peroxyfluor-1 (RPF1), which relies on a fluorescence resonance energy transfer (FRET)-based mechanism for ratiometric signal generation. (B) Schematic depicting H_2O_2 -mediated uncaging of PN1. (C) CNBE generates CNOH in the presence of H_2O_2 which takes advantage of both internal charge transfer (ICT) and FRET mechanisms to produce a blue-to-yellow ratiometric signal. (D) Peroxy Green-1 (PG1) exhibits greatly enhanced sensitivity, thus enabling H_2O_2 imaging and deciphering of components of the peroxide signaling pathways during growth factor stimulation. The NADPH oxidase (Nox) inhibitor apocynin, PI3K inhibitor wortmannin, Rac1 inhibitor NSC23766, and epidermal growth factor (EGF) inhibitor PD153035 all diminish H_2O_2 signaling.

■ **MONOBORONATE ACTIVITY-BASED H₂O₂ PROBES FOR INCREASED SENSITIVITY AND MODULAR COLOR PALETTE TUNING**

Although PF1 and related bis-boronate protected probes developed subsequently provided an important foundation for the ABS of H_2O_2 with high ROS specificity, these reagents lacked the sensitivity required to monitor endogenous variations in H_2O_2 levels.^{[32](#page-13-0),[44,51](#page-14-0)} This situation arises because 2 equiv of H_2O_2 is necessary to generate one uncaged fluorophore. To overcome this limitation, our laboratory introduced the monoboronate Peroxy Green 1 (PG1) and Peroxy Crimson 1 (PC1) probes based on Tokyo Green and resorufin scaffolds, respectively (Figure 3D).^{35,[52](#page-14-0)} Both PG1 and PC1 exhibited greater fluorescence emission intensities upon uncaging than the previously reported diboronate analogues and retained high selectivity toward H_2O_2 over other ROS and RNS. Notably, these new monoboronate

protected analogues also outperformed the nonselective 2′,7′ dichlorodihydrofluorescein (DCFH) probe that was traditionally employed in cellular peroxide assays. These gains in sensitivity enabled the use of PG1 to monitor endogenous $H₂O₂$ elevations in growth factor signaling, as illustrated in live A431 cells stimulated by epidermal growth factor (EGF, Figure 3D). The high levels of epidermal growth factor receptors (EGFR) expressed on A431 cells provide a useful biological model for H_2O_2 signaling. Indeed, stimulation via EGF promotes H_2O_2 production via the Nox/phosphoinositide 3- κ indase (PI3K) pathway (Figure 3D).^{35,[53](#page-14-0)} Deployment of small molecule inhibitors of either the EGFR kinase domain (PD153035), phosphatidylinositol-3-OH kinase (wortmannin), or Nox (apocynin) attenuated the fluorescence intensity observed in PG1 stained A431 cells due to decreased H_2O_2 production (Figure 3D). Additionally, PG1 stained A431 cells treated with the NO synthase inhibitor $L-N^G$ -nitroarginine methyl ester (L-NAME) maintained similar fluorescence responses to EGF-stimulated cells, showing that the boronate probe is indeed detecting H_2O_2 and not peroxynitrite in this biological context. Taken together, these experiments provided the first direct imaging evidence for H_2O_2 -selective signaling in live cells. Importantly, PG1 staining enabled visualization of $H₂O₂$ in postnatal rat hippocampal neurons suggesting that similar pathways of ROS signaling are also active in brain systems.³

In addition to enhanced sensitivity, the monoboronate platform permitted a greater degree of flexibility in fluorophore design, as one-half of the molecule was now free to modify to introduce other functionalities. This characteristic enabled rapid incorporation of the monoboronate trigger into rhodolbased scaffolds constructed from aminophenol (Peroxy Emerald 1, PE1), diethylaminophenol (Peroxy Yellow 1, PY1), and julolidine (Peroxy Orange 1, PO1) components ([Figure](#page-3-0) 2). Facile access to this large color palette enabled dual-color imaging and simultaneous detection of two distinct ROS in RAW264.7 macrophages when coupled with the previously reported 2-[6-(4′-amino)phenoxy-3*H*-xanthen-3 on-9-yl]benzoic acid (APF) probe which responds predominately to HOCl, but also peroxynitrite and the hydroxyl radical.[54,55](#page-14-0) Notably, this study showed that the boronate reagents do not give a turn-on response to HOCl in cellular contexts.

■ **TARGETABLE AND TRAPPABLE ACTIVITY-BASED SENSING PROBE DERIVATIVES FOR SINGLE-CELL AND SUBCELLULAR H₂O₂ IMAGING**

Building on the high degree of tunability regarding photophysical properties and molecular selectivity toward H_2O_2 , a next set of advances have led to improvements in signal retention and/or spatial resolution through the introduction of organelle-targeting groups and/or cell-trapping mechanisms. Indeed, the ability to study perturbations in H_2O_2 production and trafficking in pathological contexts with organellar resolution remains an ongoing and critical challenge to meet in the redox biology field.

The accumulation of molecular cargo to specific cellular organelles can be promoted by the attachment of robust targeting scaffolds. For example, owing to their combination of positive charge and lipophilicity, triphenylphosphonium (TPP) groups are often used for mitochondrial targeting, while morpholino substitution as a basic amine enhances lysosomal accumulation, and methyl sulfonamide groups can target the

SNAP-Tag enables rapid measurement of H_2O_2 in subcellular compartments

endoplasmic reticulum (ER) ([Figure](#page-5-0) 4A).^{[56](#page-14-0)–[58](#page-14-0)} In this context, our laboratory developed MitoPY1, which harbors both a pendant TPP group and the aryl boronate ester trigger on a rhodol scaffold as a first-generation, organelle-targeting activity-based sensing probe ([Figure](#page-3-0) 2).⁵⁹ MitoPY1 imaging established its ability to monitor mitochondrial H_2O_2 pools across multiple cell types, including HeLa, HEK293T, Cos7, and CHO.K1. Moreover, the probe enabled H_2O_2 visualization in paraquat-stimulated HeLa cells, a commonly used *in vitro* Parkinson's disease model that induces mitochondrial oxidative stress.⁵⁹ Boron dipyrromethene (BODIPY) dyes have also found extensive use in mitochondrial H_2O_2 detection, as the BODIPY scaffold is highly tunable and relatively inert to pH and polarity fluctuations.^{[60](#page-14-0)} Li and co-workers tethered H_2O_2 responsive triggers onto the *meso*-position of BODIPY structures which rendered the probes nonfluorescent due to the electron-withdrawing nature of the triggers [\(Figure](#page-5-0) 4B, C). Uncaging in aqueous solutions generates the free *meso*carboxylate anion and a substantial increase in fluorescence quantum yield.^{[61](#page-14-0)} Multiple derivatives (P-HP-G, P-HP-O, P-HP-FR) spanning the visible wavelength spectrum were synthesized, including a TPP-modified mitochondria targeting derivative (P-HP-FR-tpp), which was able to visualize endogenous H_2O_2 fluxes in live-cell models [\(Figure](#page-5-0) 4B, C). Additionally, the highly tunable BODIPY scaffold also enabled the creation of H_2S and protease responsive analogues.⁶⁰ The TPP mitochondrial targeting strategy has also been used to develop two-photon fluorescent probes for ratiometric imaging of H_2O_2 in tissue specimens.^{[62](#page-14-0)} The Cho and Kim groups took advantage of a carbamate-linked aryl boronate trigger to synthesize SHP-Mito, which exhibited a fluorescence maximum at 470 nm. Akin to what is observed for PL1, more favorable ICT resulting from H_2O_2 -promoted uncaging shifts the fluorescence maximum to 540 nm, giving rise to a ratiometric response.⁴⁶ Two-photon microscopy of rat hippocampal slices incubated with SHP-Mito and treated with H_2O_2 show the ability to visualize H_2O_2 at 180 μ m depths.^{[62](#page-14-0)} The development of ABS fluorophores with greater two-photon absorption cross sections and increased sensitivity toward variations in endogenous H_2O_2 should enable further advances in activity-based imaging via two-photon microscopy.

Beyond TPP, mitochondrial-targeting of H_2O_2 ABS fluorophore systems based on quinolinium, indolinium, or pyridinium quaternary ammonium salt frameworks have been
reported.^{63−[69](#page-14-0)} Tang and co-workers have made use of both the indolinium quaternary ammonium salt and methyl sulfonamide groups to develop both mitochondria- and ER-directed probes, respectively.[58](#page-14-0) As each fluorophore exhibited distinct fluorescence emission maxima, the authors were able to concurrently track variations in H_2O_2 levels within each organelle. Applying these probes to live-cell models of apoptosis, the authors found that treatment with apoptotic stimulants such as L-buthionine sulfoximine (BSO), carbonyl cyanide *m*-chlorophenylhydrazone (CCCP), and Tm all increased organellar H_2O_2 levels at different rates, due to the different mechanisms of action for each stimulant. Notably, treatment of cells with CCCP, which directly targets the mitochondria, resulted in sustained H_2O_2 elevations in both organelles after an initial mitochondrial H_2O_2 burst, indicating the interplay between the two organelles. Whereas treatment of cells with Tm, an ER-targeting stimulant, demonstrated a sharp rise in ER H_2O_2 levels with a delayed sharp rise in mitochondrial H_2O_2 hinting toward a diffusive process.⁵⁸

Indeed, multianalyte measurement with subcellular-targeted probes can afford exciting new opportunities to further investigate mechanisms of interorganellar ROS communication. However, the simultaneous deployment of two singleanalyte responsive probes should be approached with caution, as differences in permeability and/or photophysical properties of individual probes can potentially confound results in the absence of proper control experiments.

Morpholine substitution is frequently utilized to enhance lysosomal accumulation of fluorescent dyes.[70](#page-14-0)−[72](#page-14-0) Indeed, systems developed for H_2O_2 sensing have found use in twophoton microscopy for deep tissue imaging of *ex vivo* rat liver tissue and in live-cell models of ischemia/reperfusion.^{[70,71](#page-14-0)} A pH-switchable spirobenzopyran-based fluorophore that elicits a turn on response only at low pH and in the presence of H_2O_2 (HP-L1) has also been reported[.73](#page-14-0) This probe does not contain a lysosomal-targeting group, but its response is only visible in lysosomes due to decreased pH within the organelle.

We have also identified Nuclear Peroxy Emerald 1 (NucPE1) to monitor H_2O_2 fluxes in cell nuclei, though the mechanism that promotes nuclear localization remains unclear[.74](#page-14-0) NucPE1 was applied to *in vivo* zebrafish models of aging by overexpressing Sir-2.1, which is an NAD-dependent histone deacetylase known to increase zebrafish lifespan. Using NucPE1, we demonstrated that Sir-2.1-overexpressing zebrafish exhibited lower basal levels of H_2O_2 and were less sensitive toward exogenous H_2O_2 treatment over their wild-type counterparts.[74](#page-14-0) The attachment of peptides to ABS probes also allows for facile tuning of targeting capabilities. Examples of this strategy include the Nuclear Localization Signal peptide for nuclear targeting, the KRGD peptide sequence to selectively target ovarian cancer cells, and octreotide for somatostatin receptor binding.^{[75](#page-14-0)-[77](#page-15-0)} Ester protection of carboxyl or phenolic hydroxyl groups on molecular cargo is known to increase lipophilicity, thereby enhancing cell permeability.[78](#page-15-0) Once inside the cell, deprotection via native intracellular esterases exposes the free carboxylic acid or phenol groups, effectively trapping the compound through polarity reversal. These features can be enhanced by increasing the number of ester-protected sites.^{[79](#page-15-0)} To leverage this strategy, we synthesized both Peroxy Yellow 1 Methyl-Ester (PY1-ME) and Peroxyfluor-6 acetoxymethyl ester (PF6-AM) concurrently ([Figure](#page-5-0) 4D, E).^{[37,](#page-13-0)[80](#page-15-0)} Deployment of PY1-ME in flow cytometry and confocal fluorescence imaging experiments enabled us to identify that specific aquaporin (AQP) isoforms, AQP3 and AQP8, are involved in shuttling H_2O_2 from the extracellular space to the intracellular cytosol [\(Figure](#page-5-0) 4D). This work demonstrates that H_2O_2 transport through membranes is not passive, as was previously believed. This belief was due to the ability of NO, another transient small-molecule signal, to pass freely through membranes. Instead, H_2O_2 transport is regulated via specific channels. Indeed, aquaporins are pervasive transmembrane channel proteins that facilitate the uptake of water and other small molecules intracellularly, and $H₂O₂$ can be viewed as a larger water-like substrate. Western blot analysis of Akt phosphorylation, coupled with complementary HyPer-based H_2O_2 imaging in EGF-stimulated cell models, established a biochemical pathway that links EGF activation of Nox to generate H_2O_2 , with subsequent intracellular uptake via AQP3 to the promotion of downstream Akt signaling cascades.

Tandem efforts from our laboratory were devoted toward applying PF6-AM imaging to elucidate the role of H_2O_2 in

redox-driven signaling pathways in the brain, with a focus on neural stem cells and neurogenesis ([Figure](#page-5-0) 4E). PF6-AM imaging, coupled with measurements of Akt and Erk phosphorylation, revealed that a related growth factor stimulation pathway involving Nox2-generated H_2O_2 promotes growth and proliferation of adult hippocampal stem/ progenitor cells (AHPs), leading to more neurogenesis. In this biochemical signaling cascade, Nox-derived H_2O_2 serves as a writer on the phosphatase PTEN, a key regulatory target that inhibits kinase Akt signaling. Cysteine oxidation of PTEN by the H_2O_2 signal results in temporary inactivation of its activity and reciprocal amplification of Akt signaling and growth/ proliferation pathways. Negative control experiments via chemical inhibition or shRNA knockout models of key components of this pathway strengthen these findings [\(Figure](#page-5-0) [4](#page-5-0)E). Additionally, *in vivo* mouse models using Nox2 knockout (Nox2[−]/[−]) mice and CL57BL/6J control mice established the pivotal role of Nox2-generated H_2O_2 in promoting neurogenesis, showing that peroxide production by this pathway represents a quarter to a third of the neurogenesis observed in the murine brain.^{[80](#page-15-0)} Thus, coupling the esterase-mediated cell trapping mechanism with highly sensitive ABS boronate probes enabled us to reveal key components in fundamental intracellular signaling mechanisms of H_2O_2 .

Our laboratory has also utilized SNAP-tag fusion protein technology to direct H_2O_2 -responsive probes to specific subcellular compartments [\(Figure](#page-5-0) 4F). ⁸¹ The SNAP-tag fusion technology pioneered by Johnsson and co-workers enables the transfer of molecular cargo to proteins of interest via the development of fusion proteins with *O*⁶ -alkylguanine-DNA alkyltransferase (hAGT), which undergoes covalent labeling with *O*⁶ -benzylguanine derivatized cargo [\(Figure](#page-5-0) 4F)[.82](#page-15-0),[83](#page-15-0) We appended a Peroxy Green analogue onto both a membranepermeable SNAP substrate for intracellular labeling and membrane-impermeable derivative for cell surface labeling (SNAP-PG, [Figure](#page-5-0) 4F). Application of SNAP-PG probes to live mammalian cells expressing the SNAP tag at the cell membrane, or in the nuclei, mitochondria, or endoplasmic reticulum facilitated the site-specific imaging of H_2O_2 at each location with high precision as measured in colocalization staining experiments.^{[81](#page-15-0)} Thus, this platform combines the significant targeting capabilities of genetic encoding with the high selectivity afforded by ABS approaches and offers a compelling approach to monitoring subcellular H_2O_2 distribution in pathological models.

■ **DUAL SENSING AND ALTERNATIVE IMAGING MODALITIES TO MAP PEROXIDE ACROSS MULTIPLE BIOLOGICAL LENGTH SCALES**

The development of single probes able to respond to multiple analytes was a significant advance in the activity-based sensing field.^{[84](#page-15-0),[85](#page-15-0)} Indeed, multianalyte sensing can generate new insights on the complex interplay between different biological phenomena, as cellular metabolic and signaling pathways rely on the synergy of multiple chemical species. In the context of H2O2 sensing, many probes have been designed that simultaneously respond to hypochlorite, $86-88$ $86-88$ $86-88$ nitrous oxide, 89 hydrogen sulfide,^{[90](#page-15-0),[91](#page-15-0)} thiols,⁹² pH,^{93–[95](#page-15-0)} enzymes,^{[96](#page-15-0)–[98](#page-15-0)} protein aggregates,^{[99,100](#page-15-0)} and viscosity.^{[101](#page-15-0)−[103](#page-15-0)} Indeed, structure design for multianalyte sensing has been applied to prepare duallocked prodrugs; these systems are beyond the scope of this review and covered extensively elsewhere.^{[39](#page-14-0),[104](#page-15-0)} Dual-responsive probes hold some general advantages over the

simultaneous use of single-analyte probes. Notably, differences in membrane permeability, localization, and metabolism of two probes can result in confounding results or data misinterpretation. Much like ratiometric reagents, dual-responsive probes often take advantage of modulating photoinduced electron transfer (PET), internal charge transfer (ICT), or Forster resonance energy transfer (FRET) processes, depend-ing on the type of system that is being investigated.^{[105](#page-15-0)}

Our first foray into dual-analyte sensing was the creation of a dendrimer-based system composed of both SNARF2 and PF1.⁹³ The fluorescence and emission exhibited by SNARF2 is modulated by pH, whereas PF1 provides an irreversible fluorescence turn-on response in the presence of H_2O_2 , thus enabling simultaneous multiplex imaging of both pH and redox status. Application of this dendrimer system to immune stimulated RAW264.7 macrophage models of phagocytosis elucidated the role of Nox in pH regulation as pharmacological Nox inhibition during oxidative bursts resulted in phagosomal acidification.^{[93](#page-15-0)} More recent examples of pH and H_2O_2 dualresponsive systems rely on single small-molecule probes and have been translated to in vivo LPS stimulated or H_2O_2 injected mouse models.^{[94,95](#page-15-0)}

HOCl is also an important target for sensor systems due to its involvement with H_2O_2 in immune response.^{[106](#page-15-0)} As such, dual-responsive single molecule fluorophore systems have been designed to monitor both analytes simultaneously.^{[87](#page-15-0)} Chen and co-workers devised a dual ICT and FRET-based strategy via the design of a thiocarbamate modified coumarin unit linked to an aryl boronate-modified naphthalimide (Geisha-1, [Figure](#page-8-0) [5](#page-8-0)A).^{[86](#page-15-0)} H₂O₂-mediated deprotection of the aryl boronate ester or thiocarbamate deprotection upon HOCl sensing results only in ICT with emission at distinct wavelengths (550 nm for $H₂O₂$ and 452 nm for HOCl). However, deprotection of both results in a FRET-based response with fluorescence emission at 550 nm.^{[86](#page-15-0)} The Cui group also devised an elegant ratiometric strategy for simultaneous monitoring of HOCl and H_2O_2 .^{[88](#page-15-0)} Instead of an aryl boronate approach for H_2O_2 sensing, their design involves the use of a ratiometric B-rhodamine core scaffold with a mercaptomethyl HOCl sensor (MMBR, [Figure](#page-8-0) [5](#page-8-0)B).^{[88](#page-15-0)} Sensing of HOCl results in the probe assuming an open zwitterionic form and fluorescence emission centered at 646 nm. Subsequent reaction with H_2O_2 results in the formation of a rhodamine structure with fluorescence emission hypsochromically shifted to 575 nm. Reaction with only H_2O_2 results in a closed and nonfluorescent rhodamine structure, thus MMBR can only be used to visualize HOCl or both H_2O_2 and HOCl. Notably, beyond visualizing endogenous fluxes of both HOCl and H_2O_2 in live cell models of oxidative stress, MMBR was also able to monitor wound induced myeloperoxidase catalyzed conversion of H_2O_2 into HOCl in zebrafish models.^{[88](#page-15-0)}

Particularly interesting are dual-responsive probes applied to neurodegenerative disease models. Elegant reports from the Lin and Liu groups established Mito-VH and Mito-NIRHV probes, respectively, to monitor mitochondrial changes in both $H₂O₂$ and viscosity, as increases in both have been linked to Alzheimer's disease (AD) pathology ([Figure](#page-8-0) 5C).^{101,102,[107](#page-15-0)} The intricate design of these probes utilize the mitochondrial targeting fragment as a strong electron acceptor, which when linked via an alkene tether to an electron donating group generates a donor-*π*-acceptor (D-*π*-A) system. Such a characteristic is commonplace in molecules using twisted intramolecular charge transfer (TICT) to modulate emission.

(D) CRANAD-88 responds to H_2O_2 to generate fluorescent CRANAD-58 which upon binding to A*β* plaques undergoes fluorescence amplification. (E) CRANAD-88 was applied to monitor both H_2O_2 and plaque formation in in vivo AD mouse models. Adapted with permission under a Creative Commons CC BY license from ref [100.](#page-15-0) Copyright 2016 Springer Nature.

As such, TICT in these systems is regulated via rotation of the electron donating fragment which varies with solution viscosity (Figure 5C). Both H_2O_2 -mediated uncaging and increases in viscosity can be monitored through fluorescence turn-on responses at distinct wavelength regions, with H_2O_2 uncaging exhibiting blue-shifted emission in both instances.^{[101,102](#page-15-0)} The

addition of the thiophene spacer for Mito-NIRHV enabled NIR fluorescence emission for both sensors. As such, the Liu group applied Mito-NIRHV for the bioimaging of endogenous $H₂O₂$ and viscosity elevations in in vivo mouse models. Mice treated with LPS and genetic AD-model (APP/PS1 transgenic) mice demonstrated much stronger fluorescence responses over untreated and WT mice indicating the association between increased viscosity and H_2O_2 to AD pathology (Figure 5C).^{[101](#page-15-0)} Fluorophores that monitor protein aggregates such as amyloid *β* (A*β*) have also been developed as A*β* and oxidative stress are both hallmarks of AD pathology. Ran and co-workers synthesized CRANAD-88, which utilizes a self-immolative ABS trigger that liberates CRANAD-58, a compound with high affinity for $A\beta$, in the presence of H_2O_2 (Figure 5D). As such, both chemical reactivity and substrate affinity contribute to the functioning of this probe, leading to amplified near-IR fluorescent readouts upon dual H₂O₂ sensing and Aβ binding. Employing CRANAD-88 in mouse models of AD, the authors found increased levels of oxidative stress in AD mice brains compared to WT mice (Figure 5E). Additionally, toxic H_2O_2 levels could be regenerated in the presence of A*β* plaques even after scavenging with sodium pyruvate, thus indicating that treatment options should focus on the simultaneous removal of $A\beta$ and ROS (Figure 5E).^{[100](#page-15-0)}

In addition, there are many structural modifications in ABS fluorophore design that afford alternatives to fluorescence imaging and/or enable combining multiple imaging modalities. Systems making use of $PET₁₀₈¹⁰⁸ photocoustic_{109,110}$ $PET₁₀₈¹⁰⁸ photocoustic_{109,110}$ $PET₁₀₈¹⁰⁸ photocoustic_{109,110}$ $PET₁₀₈¹⁰⁸ photocoustic_{109,110}$ $PET₁₀₈¹⁰⁸ photocoustic_{109,110}$ or chemi/ bioluminescent[96](#page-15-0),[111](#page-15-0)−[113](#page-16-0) readouts tend to benefit *in vivo* bioimaging through greater tissue depth penetration though sometimes at the expense of resolution. Early reports exploring alternative imaging modalities from our group made use of $H₂O₂$ -responsive luminescent lanthanide compounds for timegated imaging as a strategy for decreasing autofluorescence in biological specimens.^{[114](#page-16-0)} We also developed PET-based approaches to H_2O_2 imaging in collaboration with the Wilson laboratory.^{[108](#page-15-0)}

As an introduction to bioluminescent-based H_2O_2 reporting strategies for use in animal models, our laboratory synthesized Peroxy Caged Luciferin-1 (PCL-1, [Figure](#page-9-0) 6A).^{[113](#page-16-0)} PCL-1 is a firefly luciferin analogue caged with a self-immolative benzyl boronic acid group. PCL-1 reports on endogenous H_2O_2 variations via a bioluminescent readout generated from the reaction of firefly luciferin with the luciferase enzyme in the presence of ATP and Mg²⁺. PCL-1 was able to monitor H_2O_2 production in both live luciferase expressing mice (FVB-luc+) and in a testosterone stimulated LNCap-luc tumor xenograft model in immunodeficient SCID hairless outbred (SHO) mice.^{[113](#page-16-0)} We also developed a dual-analyte responsive system composed of Peroxy Caged Luciferin-2 (PCL-2) which releases hydroxy-cyanobenzothiazole upon H_2O_2 sensing and the pentapeptide z-Ile-Glu-Thr-Asp-D-Cys (IETDC) that releases free D-cysteine upon reaction with caspase-8 [\(Figure](#page-3-0) [2](#page-3-0)).^{[96](#page-15-0)} Caspase-8 plays a prominent role in initiating apoptotic pathways during inflammatory signaling cascades. In situ formation of firefly luciferin via condensation of D-cysteine and hydroxy-cyanobenzothiazole in aqueous solutions provides a bioluminescent reporter when coupled with luciferase systems. Thus, this strategy reports on elevations in both caspase-8 and $H₂O₂$ but is effectively shut off in the presence of only one analyte or none, akin to a molecular AND-type logic gate. The PCL-2 and IETDC reporting strategy was enabled the *in vivo* detection of endogenous elevations of both H_2O_2 and caspase-

Figure 6. (A) H_2O_2 -mediated uncaging of PCL-1 and its use in testosterone stimulated LNCap-luc tumor xenograft mouse models. Adapted with permission from ref [113](#page-16-0). (C) Scheme depicting H_2O_2 -mediated uncaging of JW41 to JW35 which allows for photoacoustic and fluorescence dual-modal imaging in vivo and in excised fixed tissue.

8 in LPS treated mice modeling acute inflammatory responses⁹⁶ and has been expanded to other activity-based bioluminescent reporters.¹¹⁵

It is also worth noting chemiluminescent reporters which preclude the need for luciferase expressing systems.^{[116](#page-16-0)} Many such probes pioneered by the Shabat laboratory in particular, utilize Schaap's dioxetane fragments to generate bright luminescent readouts.^{[111](#page-15-0)[,112](#page-16-0),[117](#page-16-0)–[120](#page-16-0)} In a recent report, they synthesized both H_2O_2 -CL-510 and H_2O_2 -CL-B as chemiluminescent reporters on H_2O_2 fluxes (Figure 6B). H_2O_2 -CL-B makes use of the aryl boronate ester trigger but exhibits a much weaker turn-on response than H_2O_2 -CL-510 which contains a salicylaldehyde trigger that undergoes an H_2O_2 mediated Payne/Dakin reaction cascade to provide a highly emissive (\times 430) turn-on response (Figure 6B). As such, H_2O_2 - $CL-510$ was carried forward in studies monitoring H_2O_2 bursts due to cerebral ischemia-reperfusion injury in rat models (Figure $6B$).¹¹¹ While salicylaldehyde-based probes offer a promising alternative to aryl boronate triggers for H_2O_2 sensing, the need for a trichloroacetonitrile additive to promote uncaging may preclude its use in some biological models.

Photoacoustic (PA) imaging has garnered significant interest for *in vivo* imaging applications as it utilizes the detection of sound via probe excitation with longer wavelength deeper penetrating light.^{[121](#page-16-0)} Acoustic detection enables depth penetration at centimeter length scales as sound scatters significantly less than emitted light in biological tissues.^{[121](#page-16-0),[122](#page-16-0)} Photoacoustic probes are generally designed to minimize nonradiative decay processes thereby ensuring the majority of energy loss upon irradiation results in the generation of heat as opposed to fluorescence emission. The increase in temperature causes thermoelastic expansion in the surrounding tissues and the pressure changes result in the generation of sound waves which provide the image contrast.^{[121](#page-16-0)} Acoustogenic probes using the photoacoustic modality provide a promising direction for the activity-based sensing field. 123

In the context of activity-based H_2O_2 sensing, Bohndiek and co-workers developed JW41 which leverages a heptamethine carbocyanine core scaffold with 2-deoxyglucose targeting groups and a centrally linked aryl boronate cage, for dual modal photoacoustic and fluorescence imaging (Figure $6C$).^{[110](#page-15-0)} The pendant glucose groups enhance uptake in cancerous tissues which generally exhibit higher levels of oxidative stress. Caged JW41 displays an absorption maximum at 730 nm that shifts to 790 nm upon uncaging to JW35. Though the fluorescence maximum centered at 825 nm is identical in both forms, there is a significant 100% increase in the fluorescence quantum yield of the uncaged dye. This dye was amenable to *in vitro* fluorescence imaging of H_2O_2 in MDA-MB-231 and MCF7 cells. Importantly, intravenous injection of JW41 enabled PA imaging of H_2O_2 elevations in subcutaneous MDA-MB-231 tumors in nude mice. While JW41 localized to both the tumors and liver, oxidative uncaging was substantially higher in tumors. *Ex vivo* fluorescence imaging of fixed tumor sections was also carried out and demonstrated cytosolic probe localization with substantially decreased accumulation in necrotic tumor regions.^{[110](#page-15-0)} Additionally, the Hai group has also developed an elegant strategy for mitochondrial-targeted dual photoacoustic and fluorescence imaging applied to *in vivo* mouse models of inflammation.¹⁰⁹

Hyp-L probes reveal elevated H₂O₂ levels within autophagosomes and provide a facile workflow for analysis via SDS-PAGE, fluorescence microscopy, and conditional proteomics

■ **TANDEM ACTIVITY-BASED SENSING AND LABELING PROBES TO ENABLE CELL-SPECIFIC PROFILING**

The development of tandem activity-based sensing and labeling strategies to create cell-trappable molecular probes has recently garnered significant research interest. Probes described in this section undergo H_2O_2 -mediated uncaging to release either a molecule or reactive intermediate capable of labeling proximal internal cellular structures. Such probes

greatly enhance signal-to-noise responses, preserve spatial information, and offer key insights into transcellular signaling processes. The new biological information revealed by such chemical reagents contrasts with many of the fluorophores discussed in previous sections, which have significantly advanced our understanding of intracellular H_2O_2 signaling. We also differentiate tandem ABS and labeling probes from previously described organelle-targeting fluorophores in that the localization of the probe is dictated by reactivity as

opposed to an orthogonal specialized targeting group and/or esterase-mediated uncaging.

The first tandem ABS and labeling strategy for H_2O_2 developed in our laboratory relied on immunodetection of the aminonucleoside puromycin as a histochemical readout[.124,125](#page-16-0) Puromycin is an aminoacylated-tRNA analogue that inhibits protein translation at the ribosome and is terminally incorporated into nascent peptides and proteins. Taking inspiration from a previously reported collaboration with the Renslo group, we synthesized Peroxymycin-1, a puromycin caged with an aryl boronate ester trigger at the *α*-amino position necessary for peptide bond formation [\(Figure](#page-10-0) [7A](#page-10-0)).^{[124](#page-16-0),[126](#page-16-0)} H₂O₂-mediated uncaging results in a selfimmolation cascade generating free puromycin that, when incorporated into nascent biomolecules, results in a permanent and dose-dependent label that can be visualized through immunofluorescence using puromycin-specific antibodies ([Figure](#page-10-0) 7A). Notably, the amenability of this strategy toward biological fixation complements the many existing ABS fluorophores discussed in this review, which may degrade under conditions necessary for sample fixation.

The covalent nature of the cell-trapping mechanism inherent to the puromycin-based approach allows for significantly increased sensitivity over previously reported ABS and organelle-targeted ABS fluorophore derivatives. The considerable sensitivity facilitated the profiling of basal H_2O_2 levels across a panel of cancer and nontumorigenic breast cell lines and revealed heightened H_2O_2 levels in metastatic cancer cells compared to less invasive and nontumorigenic cells. This work reveals a correlation between basal H_2O_2 levels and cellular metastatic potential. Deployment of this puromycin-based strategy in mouse tissue models of diet-induced nonalcoholic fatty liver disease displayed increased levels of oxidative stress in liver tissue lysates from mice fed a high-fat diet vs a normal diet. These results agreed with similar experiments employing 4-hydroxy-2-nonenal (4-HNE) immunostaining indicating the complementarity of puromycin-based approaches to more widely used methods, however we note that 4-HNE is not a selective reporter of H_2O_2 but an indirect proxy for oxidative stress[.124,125](#page-16-0),[127](#page-16-0)

As the *α*-amino group on puromycin is a general synthetic handle that can undergo modification with a range of specialized ABS triggers, we envision a wide range of opportunities to employ puromycin and other histochemical scaffolds to monitor other dynamic biological analytes. In this context, our laboratory is actively engaged in expanding ABSmediated intracellular fluorophore trapping strategies to include proximity labeling via the generation reactive intermediates upon analyte detection. Such methods complement the puromycin-based platforms that harness cellular machinery to become intracellularly trapped. Indeed, metaldirected acyl-imidazole (MDAI) chemistry as an intracellular trapping strategy has advanced our understanding of cellular signaling processes mediated by redox active and labile transition metals.[128](#page-16-0)−[130](#page-16-0) In this design, an acyl imidazole fragment bridges both a metal-sensing motif and a fluorophore. Reversible metal chelation enhances the electrophilicity of the acyl imidazole unit thereby driving biomolecular labeling forward.[128](#page-16-0)[−][130](#page-16-0)

In another example of tandem activity-based sensing and labeling, we were inspired by recent reports from Urano and co-workers, where they utilized *o*-quinone methide chemistry to promote cell retention of $β$ -galactosidase substrates.^{131,[132](#page-16-0)}

We reasoned that *o*-quinone methide chemistry provides an excellent blueprint for the H_2O_2 -driven proximity labeling and cell trapping of fluorophores. To this end, we developed PeroxyGreen-1 Fluoro Methyl (PG1-FM) as a first-generation analogue for tandem ABS and labeling ([Figure](#page-10-0) 7B, C). 133 133 133 Key to this strategy is the installment of a fluoromethylene unit proximal to the aryl boronate ester trigger on the fluorescein core scaffold. H_2O_2 -mediated uncaging and subsequent fluoride elimination results in the generation of a highly reactive *o*-quinone methide intermediate that undergoes nucleophilic biomolecule labeling to produce a trapped
fluorecent readout $(\overline{\text{Ui}mna} \overline{B} \overline{C})^{133}$ fluorescent readout [\(Figure](#page-10-0) 7B, C).¹

PG1-FM enabled visualization of endogenous H_2O_2 elevations in live-cell models of oxidative stress and redox signaling. Notably, unlike parent analogues, a strong fluorescence signal is retained in PG1-FM stained cells after multiple washing steps.^{[55](#page-14-0)[,133](#page-16-0)} Additionally, in-gel fluorescence analysis from sodium dodecyl sulfate−polyacrylamide gel electrophoresis (SDS-PAGE) of PG1-FM stained cell lysate treated with H_2O_2 revealed proteome-wide labeling.

To move beyond exploring the intracellular signaling landscape, we sought to harness tandem ABS and labeling approaches to map cell-to-cell redox signaling processes. In collaboration with the Swanson group, we deployed PG1-FM to study transcellular redox signaling in a microglia-neuron coculture system. This system models neuronal injury mediated by microglial activation, which is the hallmark of neural degenerative disorders such as Alzheimer's and Parkinson's. Microglia can be activated to produce H_2O_2 via treatment with lipopolysaccharide (LPS) and interferongamma (IFN-*γ*); however, LPS and IFN-*γ* do not have any effect on ROS production in neurons ([Figure](#page-10-0) 7C). We showed that neurons cocultured with microglia and treated with LPS and IFN- γ exhibited elevations in H_2O_2 whereas neuron monocultures treated under the same conditions do not. Additional coculture studies employing p47^{pho} knockout (p47^{phox−/−}) microglia cells exhibit attenuated H_2O_2 production when treated with LPS and IFN-*γ*, thus indicating that PG1-FM is selectively capturing H_2O_2 fluxes that are produced in microglia and travel to neighboring neurons. Taken together, these experiments establish that PG1-FM is capable of identifying transcellular H_2O_2 redox signaling with singlecell resolution in complex coculture models, opening the door to studies of ROS-mediated cell−cell communication [\(Figure](#page-10-0) $7C$ $7C$).¹³³

In parallel to our investigations, the Hamachi group reported a similar H₂O₂-responsive *o*-quinone methide labeling strategy.^{[38](#page-13-0)} This impressive work introduced both coumarin (Hyp-L-1) and fluorescein (Hyp-L-2) derivatives in which the ABS and labeling fragment was tethered to the dye as opposed to attached directly onto the main fluorophore scaffold [\(Figure](#page-10-0) [7](#page-10-0)D). Intracellular biomolecule labeling under oxidative conditions using the Hyp-L workflow enabled analysis via SDS-PAGE, fluorescence confocal microscopy, and conditional proteomics. Hyp-L-2 was used for their key studies which involved fluorescence confocal imaging of fixed hippocampal slices from mouse brain tissues under 2-thenoyltrifluoroace-tone (TTFA) stimulated conditions ([Figure](#page-10-0) $7D$).^{[38](#page-13-0)} TMTbased quantitative proteomic analysis of mouse brain tissues either treated with TTFA or not and incubated with Hyp-L-2 revealed H_2O_2 -induced proximity labeling of predominately mitochondrial proteins which correlates with the pharmacological mechanism of TTFA which promotes oxidative stress

workflow.[38](#page-13-0)

■ **OUTLOOK AND FUTURE DIRECTIONS**

Activity-based sensing (ABS) provides a general and versatile platform for chemistry-enabled advances in biology. In particular, small-molecule probes offer a number of advantages for bioimaging, including their ease of use, highly tunable nature, and amenability to rapid screening across multiple biological models. Indeed, the swift development of synthetic small-molecule ABS fluorophores parallels that of genetically encodable protein redox sensors, which often demonstrate unrivaled site specificity and sensitivity. The prevailing spirit of the field is not one of competition but instead the bolstering of available resources and tools that enhance our abilities to draw the most valid conclusions from the model being studied, especially when such tools are deployed in tandem. Thus, there exists plenty of opportunities for expansion and improvements on both fronts.

phages utilizing the Hyp-L-2 microscopy and proteomic

There is an ongoing need to discover new triggers that exhibit more rapid uncaging kinetics relative to the archetypical aryl boronate ester scaffold. 1 Exciting work by Vauzeilles and colleagues on borinic-acid-based coumarin dyes shows an impressive second-order rate constant of $1.9 \times 10^4 \ \text{M}^{-1} \cdot \text{s}^{-1}$ toward H_2O_2 -mediated oxidation.¹³⁴ The replacement of one oxygen linkage with carbon decreases electron donation into the empty boron p-orbital, thereby increasing electrophilicity at that position.^{[135](#page-16-0)} This substitution results in an observed 10 000-fold rate enhancement over aryl boronic ester triggers and showcases the effect that seemingly subtle synthetic manipulations have on ABS fluorophore systems. The reported borinic-acid-based coumarin was selective for H_2O_2 over other ROS and exhibited a significantly faster turn-on response in live COS7^{gp91/p22}.^{[134](#page-16-0)} Recent follow-up work detailed the synthesis of a more general trigger derivative that was further modified to overcome challenges related to the regioselectivity of oxidative deprotection[.136](#page-16-0) Another direction is in catalytic activity-based sensing where one uncaging event can lead to multiple signal outputs. This strategy is highlighted by elegant work from Shabat and colleagues on self-immolative polymer scaffolds that can be uncaged by a single boronate oxidation or systems by Phillips that self-sustain peroxide consumption and
generation for continuous detection.^{[137](#page-16-0)−[139](#page-16-0)} Indeed, the development of ABS triggers with faster uncaging kinetics holds potential for offering enhanced spatial resolution. When coupled with new tandem sensing and labeling approaches, such ABS tools provide a platform for activity-based proximity labeling and profiling of key redox regulators akin to the activity-based protein profiling (ABPP) approaches pioneered by the Cravatt and Bogyo laboratories and many other prominent groups.[140](#page-16-0)−[142](#page-16-0) The trade-off for heightened reactivity is often diminished ROS selectivity, and thus great care should be taken when designing experiments and when attributing the tandem ABS and labeling process to a specific $ROS.9,143$ $ROS.9,143$ $ROS.9,143$ $ROS.9,143$

In parallel, improvements in small-molecule H_2O_2 sensors can also rely on the application of constantly evolving design principles of the parent fluorophore structures responsible for photophysical and chemical characteristics.^{[144](#page-16-0)−[146](#page-16-0)} The introduction of new dyes with specially tailored equilibrium constants between emissive "open" and nonemissive "closed" forms that are amenable to emergent single-molecule localization microscopy (SMLM) techniques provides extensive starting points to explore ABS systems with drastically enhanced resolution over diffraction limited microscopy techniques.^{146,[147](#page-16-0)} Additionally, the development of far-red (700−780 nm) and short-wave infrared (SWIR, 1000−2000 nm) shifted dyes is of extreme importance as the longer wavelength absorption/emission profiles enhance depth penetration and minimize background autofluorescence from biological structures thus greatly enhancing *in vivo* bioimaging.[148](#page-16-0)−[153](#page-17-0) As such, ample opportunities remain to leverage the rapidly growing toolbox of ABS triggers with synthetic advances in fluorophore structure design. The continued evolution of which coupled with translation into increasingly complex biological models will open new and exciting avenues to further our understanding of basic biology and translation to diagnostics and medicines. Indeed, the area of activity-based diagnostics is an exciting direction in this burgeoning field.^{[154](#page-17-0)}
