Abstract

When do people say that they are moved, and does this experience constitute a unique emotion? We review theory and empirical research on being moved across psychology and philosophy. We examine feeling labels, elicitors, valence, bodily sensations, and motivations. We find that the English lexeme being moved typically (but not always) refers to a distinct and potent emotion that results in social bonding; often includes tears, piloerection, chills, or a warm feeling in the chest; and is often described as pleasurable, though sometimes as a mixed emotion. While we conclude that it is a distinct emotion, we also recommend studying it in a more comprehensive emotion framework, instead of using the ambiguous vernacular term being moved as a scientific term.

Keywords
being moved, chills, social emotion, tears

Then there are the emotions of being moved. Being moved too has control precedence. It intrudes on whatever one is doing. One falls silent. One is knocked over—bouleversé, as they say in French.

(Frijda, 2007, p. 38)

In his seminal work The Laws of Emotion Nico Frijda (2007) refers to a “class” of strong emotions he calls being moved. He argues that these “ambiguous” experiences (Frijda, 2001) are aesthetic emotions that “grip the body.” Later, Tan (2009) noted that being moved resembles a feeling of “being conquered.” First systematically discussed in psychology by McDougal (1919; he called it “the tender emotion”) and Claparède (1930; être ému), theorizations and empirical evidence concerning being moved are scattered across the emotion literature, often hiding in the shade of similar concepts. In sociology, Durkheim (1912) posited a similar concept, “collective effervescence.” While some scholars have followed Frijda in regarding the concept of being moved as part of a bigger construct or set of emotions (e.g., Batson, Fultz, & Schoenrade, 1987; Haidt, 2000), others have conceptualized it as a distinct emotion (Cova & Deonna, 2014; Menninghaus et al., 2015; Tan, 2009; Zickfeld et al., 2018). The experience has been categorized as purely...
positive (Cova & Deonna, 2014; Haidt, 2000; Seibt, Schubert, Zickfeld, & Fiske, 2017), occurring with mixed affect (Frijda, 2007; Menninghaus et al., 2015), and even as primarily negative (Bartsch, Kalch, & Oliver, 2014). In a recent national survey, about 51% of U.S. American adults reported being moved by media or something on the Internet at least several times a week (Raney et al., 2018).

A systematic review of the literature on the concept of being moved must address the following questions: What is being moved? Where do different conceptualizations of being moved converge and diverge? What are the strengths and weaknesses of the various conceptualizations? Does being moved constitute a distinct emotion? What evidence is there about the characteristics and causes of being moved? How is being moved experienced in different cultures? We focus on the psychological literature. Accounts in the anthropological, religious, and sociological literatures are certainly also relevant, but are beyond the scope of the present review. For the current review, we focus on literature that explicitly investigates being moved or measures its topic using the label being moved.

**Approach and Definitional Issues**

In order to review the literature on the concept of being moved, one must take a theoretical position about what emotions are in the first place. Unfortunately, there is little consensus on what exactly emotions are (Russell, 2014). However, most researchers see emotions and their labels as closely linked, if not interchangeable. That is, they assume that an emotion is whatever it is labeled, and often define “emotion” as the labeling of an experience. These assumptions run into basic problems as soon as one attempts to translate conceptual terms and measurement instruments. Different languages provide different and non-equivalent terms for emotions, similar to how color terms carve up the space of wavelength and brightness in visible light (Lucy & Shweder, 1979; Roberson, Davies, & Davidoff, 2000; Wierzbicka, 1999). Furthermore, even within a language community at one point in time, people use psychological terms ambiguously, and are inconsistent across contexts; further, different people use the same word differently (D. W. Fiske, 1981; S. T. Fiske, 1995). In addition, within every language, there are many overlapping but not completely synonymous emotion words (Orgakova, 2013).

The central debate in emotion literature is whether there is an equivalent to wavelength and brightness, or the rods and cones, when it comes to emotions, and if so, how many such dimensions there are. One school of thought argues that some basic, universal, and biologically grounded emotions exist across cultures (Ekman, 2016; Tracy, 2014). Another view posits that emotions are primarily social constructions that are specific to social and cultural contexts, while being informed by biological processes (Barrett, 2014; Mesquita & Boiger, 2014). The basic emotions view sees labels as capturing existing natural kinds. The constructionist view sees emotion labels as cultural and sociolinguistic construals of situations, with a few bodily processes (affect, arousal) only as one input among others (or even as an output of the labeling).

This debate is important for being moved because the lexemes used to denote it appear to be particularly broad in many languages, raising the question of whether there is a clear or consistent referent. For the purposes of the current review, we take no a priori stand in this debate, simply discussing work that identifies its topic using the English phrase being moved and a few additional sources that we deemed relevant. We will also report on the (limited) evidence—predicted on the basic emotions perspective—concerning cultural universality of the concept of being moved. In the conclusion of the review, we will come back to this issue, and present our own view on how to solve it.

Most emotion perspectives agree that an emotion can be understood as a set of components that emerge in a coordinated manner that are experienced as basically simultaneous and instantaneous. Those components are (a) an appraisal pattern or elicitor, (b) bodily reactions, (c) a feeling or affect (valence and arousal), (d) action tendency or motivation, and (e) expression and labels (facial or verbal; Coppin & Sander, 2016; Scherer, 2005). Therefore, we review the literature on being moved with regard to these five aspects.

**Linguistic Properties**

Etymologically, moved derives from Latin moveō via French émouvoir. Interestingly, the word emotion derives from the same Proto-Indo-European root (as do motive and motion). One could therefore think, as Claparède (1930) did, that being moved might represent a kind of proto-emotion. Analyses of linguistic properties within the German language have identified that moved is related to similar lexemes indicating some kind of passive action (Kuehnast, Wagner, Wassiliwizky, Jacobsen, & Menninghaus, 2014; Menninghaus et al., 2015). English lexemes such as moved, touched, and stirred are based on the same metaphors of passive displacement or contact that a number of other languages use to denote more or less the same emotion (e.g., Mandarin 感动 [gǎndòng], literally, “to feel movement”; see A. P. Fiske, Schubert, & Seibt, 2017a).

**Definitional Issues**

Being moved has sometimes been defined as belonging to a larger class of emotions (Frijda, 2007; Scherer & Zentner, 2001). One example is the research by Batson et al. (1987) who have treated being moved as a part of their empathy or empathic concern construct, which also consists of feelings of sympathy, compassion, tenderness, warmth, and soft-heartedness. Another conceptualization has been provided by Jon Haidt et al. with the elevation construct (Haidt, 2000, 2003). Haidt (2003, p. 281) noted “that the popular press and Oprah Winfrey talk about it (as being touched, moved, or inspired).” Scholars studying elevation have assessed their construct on multiple occasions with
items asking participants if they were **moved** (e.g., Schnall, Roper, & Fessler, 2010). However, Pohling and Diessner (2016) argue that **being moved** refers to an emotional state that can be elicited by a much broader range of stimuli than elevation (see also Thomson & Siegel, 2016). Both empathic concern and elevation emphasize an other-oriented feeling, which occurs only in response to witnessing or learning of others’ actions or feelings.

Although the elevation and empathic concern concepts might seem broader than **being moved**, they are included in the present review for two reasons: First, both concepts have often been assessed with items including the label **moved**. Second, there is some evidence that both concepts in fact mostly capture **being moved** (Cova, Deonna, & Sander, 2016, 2017; Zickfeld, Schubert, Seibt, & Fiske, 2017). Therefore, we include data primarily collected in the frameworks of the elevation or empathic concern constructs; we treat these data as probable evidence concerning the concept of **being moved**.

Cova and Deonna (2014) have argued that **being moved** is a distinct positive emotion, sometimes also labeled as **touched**, which is elicited by positive core values standing out. They assume that it is identical to what French speakers call *être ému*, “be moved.” Similarly, based on studies of the semantics of German lexemes that they used to translate **moved** (*bewegt, gerührt*; Kuehnast et al., 2014; cf. Schmidt-Atzert & Ströhm, 1983), Menninghaus et al. (2015) have proposed that **being moved** is a distinct emotion, which often occurs in response to significant relationship events or aesthetic stimuli. They integrate **being moved** in their recently proposed distancing–embracing model (Menninghaus, Wagner, Hanich, et al., 2017). According to the model, **being moved** helps integrating negative affect into pleasurable states in art reception. Research on aesthetics has produced a number of additional definitions. Schindler et al. (2017) define **being moved** as an aesthetic emotion that includes mixed affect. Konečni (2005, 2011, 2015) regards **being moved** as part of the aesthetic trinity, which also involves feelings of awe and thrills.

Bartsch et al. (2014) investigated **being moved** in the context of media enjoyment and argued that the feeling satisfies eudaimonic needs eliciting increased reflective thoughts. Interestingly, they define **being moved** as partly characterized by its negative valence. According to their definition, **being moved** can be regarded as a mixed emotion predicting enjoyment of aesthetic stimuli. **Being moved** as related to media enjoyment has sometimes been characterized as belonging to the class of self-transcendent emotions (Dale, Raney, Janicke, Sanders, & Oliver, 2017; Oliver et al., 2018; Stellar et al., 2017). According to Stellar et al. (2017), self-transcendent emotions are experienced as pleasant, other-oriented, and function to bind individuals together (typical examples include awe, compassion, gratitude, and elevation; see also van Cappellen, Saroglou, Iweins, Piovesana, & Fredrickson, 2013).

Finally, A. P. Fiske, Seibt, and Schubert (A. P. Fiske, Schubert, & Seibt, 2017a, 2017b; A. P. Fiske, Seibt, & Schubert, 2017) argue that the emotion that English speakers often (but by no means always) refer to as **being moved** is part of the concept they call **kama muta** (Sanskrit for “moved by love”). They note that vernacular labels are ambiguous and imprecise, therefore proposing the use of a scientific construct denoted by a formally defined lexeme. Thus, they indicate that while people often use **being moved** or **touched** to denote **kama muta**, they also use many other terms, depending on context and speaker, and sometimes use **being moved** or **touched** to denote other emotions distinct from **kama muta** (such as sadness or even anger/outrage). They note that in some contexts speakers of some languages have no accessible labels for their **kama muta** experiences—they experience the emotion, but cannot find a distinct name for it.

### Similar Concepts

Researchers studying **being moved** have identified a number of emotions that they regard as related but distinct (see Table 1). Among these have been awe and admiration (Haidt & Keltner, 2004); gratitude (Siegel, Thomson, & Navarro, 2014); inspiration (Algoe & Haidt, 2009); empathy (Batson, 2010); personal distress (Batson et al., 1987); sentimentality (Cova & Deonna, 2014); nostalgia, poignantness, elevation, and awe (Menninghaus et al., 2015); happiness, sadness, surprise, respect, empathy, and sympathy (Tokaji, 2003); aesthetic awe, thrills, and catharsis (Konečni, 2005); and awe, joy, admiration, pride, and sadness (Seibt, Schubert, Zickfeld, & Fiske, 2017). Awe and admiration are mentioned most frequently as sister emotions to the concept of **being moved**. While **being moved** experiences are often argued to be evoked by increased interpersonal closeness or

moral acts (e.g., Seibt, Schubert, Zickfeld, & Fiske, 2017), Keltner and Haidt (2003) posit that awe is evoked by perceived vastness. Algoe and Haidt (2009), and Onu, Kessler, and Smith (2016) posit that admiration is evoked by competence exceeding standards—which does not need to include moral acts or increased interpersonal closeness. There is also empirical evidence differentiating the label being moved from the labels of awe (Seibt, Schubert, Zickfeld, & Fiske, 2017; Zickfeld et al., 2018); admiration (Algoe & Haidt, 2009; Seibt, Schubert, Zickfeld, & Fiske, 2017); gratitude (Algoe & Haidt, 2009; Siegel et al., 2014); and sadness (Seibt, Schubert, Zickfeld, & Fiske, 2017; Zickfeld et al., 2018).

Nostalgia is also in the same extended family of emotions (Batcho, 2013; Sedikides & Wildschut, 2017; Wildschut, Sedikides, Arndt, & Routledge, 2006). According to Wildschut and colleagues’ theory, nostalgia is often triggered by negative affect such as loneliness or separation, and generates positive affect and approach tendencies. Similar to being moved, it was found to include positive valence, approach orientations, and low arousal (van Tilburg, Wildschut, & Sedikides, 2017). While being moved is often regarded as an other-oriented emotion, nostalgia is primarily categorized as a self-relevant emotion. However, Menninghaus et al. (2015) found evidence that the lexemes bewegt (moved) and Nostalgie (nostalgia) cluster together when people rate emotional episodes, and A. P. Fiske, Schubert, et al. (2017a, 2017b) suggested that nostalgia may be what English speakers label kama muta when it is evoked by a memory of strong communal sharing.

Agents and even objects that are perceived as cute are often described with labels such as moving or touching (e.g., Aragón, Clark, Dyer, & Bargh, 2015; Sherman & Haidt, 2011; Steinnes, 2017). While some languages do have a precise term for the experience (e.g., Finnish, Estonian, Hungarian), English and most Germanic languages lack such a term. Some scholars have suggested calling this emotional reaction Aww, after the phatic exclamation that cute babies and animals often elicit in speakers of some languages (Buckley, 2016). Some findings have linked cuteness to the empathic concern concept (Lishner, Batson, & Huss, 2011; Lishner, Oceja, Stocks, & Zaspel, 2008). Two studies showed that the predominant emotion evoked by cute targets is kama muta, as assessed by appraisals of intensified communal sharing, positivity, desire to share the emotion, labels, sensations, and increased communal sharing motives (Steinnes, 2017).

Some researchers have argued that sadness and happiness or joy can be integral components of the being moved experience (Frijda, 2001, 2007; Menninghaus et al., 2015; Wassiliewzky, Wagner, Jacobsen, & Menninghaus, 2015), while others have treated being moved as distinct from these emotions, though positively valenced (Cova & Deonna, 2014; A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017).

**Appraisals or Elicitors**

A great deal of research has been conducted on elevation, sometimes also referred to as moral elevation (for reviews, see Pohling & Diessner, 2016; Thomson & Siegel, 2016). Elevation is posited to result from witnessing especially virtuous behavior—acts of “moral beauty” (Haidt, 2000). English speakers are said to typically label elevation as being moved or touched. Elevation is only evoked by observing moral beauty from a third-party perspective; the theory does not mention elevation ever resulting from actions directed at the self, or in response to the person’s self-initiated actions, sentiments, motives, or memories. So the experience of someone doing something morally beautiful towards/for oneself would not evoke “elevation.” Observing a stranger helping an old woman on the bus, for example, would qualify as evoking elevation if this action is appraised as morally beautiful. However, Janicke and Oliver (2017) have argued that elevation might also be evoked by connectedness, love, or kindness.

Empathic concern, a concept Batson and colleagues propose, is said to often be labeled being moved (Batson, Eklund, Chermok, Hoyt, & Ortiz, 2007; Batson et al., 1987). It is posited to be elicited by a combination of three appraisals: witnessing someone in need or distress, adopting the needy person’s perspective, and valuing the welfare of this person. Similar to elevation, empathic concern is primarily experienced as an other-oriented emotion; that is, one would not feel empathic concern for oneself. A meta-analysis of 16 studies found that empathic concern, as a trait measured by self-report of typical emotional responses to others’ suffering or distress, correlates .35 [95% CI: .29, .41] with self-reports of being moved or touched by a number of stimuli (Zickfeld et al., 2017).

Cova and Deonna (2014; Cova et al., 2017) argued that being moved is elicited by positive core values emerging and standing out from a negative background. More precisely, people are moved by events that manifest positive values, such as kindness or solidarity, despite negative circumstances. For Cova and Deonna, actively performing an action oneself or receiving a good deed may evoke being moved; it is not limited to events that one witnesses. According to this proposition, observing the stranger helping the old woman could move an observer if helping older ladies (or more broadly, helping) is a positive core value and there were negative circumstances, such as the woman struggling or falling down while trying to get on the bus. A recent study found that core values related to love, willpower, and beauty were rated as more moving when arising in unfavorable in contrast to favorable circumstances (Strick & van Soolingen, 2017), providing the first empirical support for Cova and Deonna’s theorization. Similarly related to core values, it has been argued that individuals are moved by other people surpassing standards with regard to virtue and success, but also music (Landmann, Cova, & Hess, 2019).

Based on studies that took the vernacular label being moved as their starting point, Menninghaus et al. (2015) theorized that this is a label for an emotion evoked by significant relationships or critical life events, such as weddings or reunions, especially if they are highly compatible with prosocial norms and self-ideals. In addition, they noted that aesthetic stimuli such as films or music often elicit feelings of being moved. So in this framework, observing the stranger helping the old woman might
elicit feelings of being moved if this is appraised as a critical event and compatible with one’s self-ideals or norms.

A. P. Fiske, Schubert, et al. (2017a; A. P. Fiske, Seibt, et al., 2017) argued that kama muta is evoked by the sudden intensification of a communal sharing (CS) relationship. The sudden CS intensification might occur between the participants and a target entity (e.g., a human being, group, deity, cute animal, the Earth) or by observing the intensification of CS between third parties. One of A. P. Fiske’s four fundamental relational models, CS is a social equivalence relation in a dyad or group perceived to have something essential in common (A. P. Fiske, 1991, 2004). CS relations typically involve feelings of belonging or identification, and altruistic behavior such as sharing and caring without keeping track, just giving what is needed. Need-based giving, hugging, kissing, sharing food, and touching are typical indicators of CS relations. Communal sharing generates the morality of kindness, compassion, and shared responsibility (Rai & Fiske, 2011).

A. P. Fiske, Seibt, et al. (2017) note that “intensification” of CS may consist of a rapid temporal increase in a CS relation; the creation of a new CS relation; or a transformation of loss, separation, or longing into CS, whether the transition is remembered, anticipated, imagined, or actually experienced. These intensifications may be initiated by the participant, by a second person, by observed third parties, or result from collective action such as engaging in a protest or moving in rhythmic synchrony together. According to this proposition, observing the stranger helping the old woman would be experienced as moving if their communal sharing relationship is perceived to suddenly intensify—if the helper and the woman are suddenly perceived as closer and their relationship is perceived as warmer; or the helper is suddenly perceived as caring and kind because he feels compassion; or the perceiver suddenly feels closer to the woman and/or the helper.

Scholars have put forward more proposals on causes of being moved: forgiveness, selfless sacrifices, and generosity (Konečni, 2005); overcoming adverse circumstances (Tokaji, 2003); and fulfillment of a union in melodrama (Neale, 1986). Tan (2009) argued that easing the difficulty (such as separation) of a dear object (such as a close friend) elicits being moved. Similarly, Frijda (1988, p. 88) noted that there is a particular sequence of events that evokes being moved: “latent attachment concerns are awakened; expectations regarding their nonfulfillment are carefully evoked but held in abeyance; and then one is brusquely confronted with their fulfillment.” Judging by the phrase “carefully evoked but held in abeyance,” Frijda is apparently describing the evocation of this emotion by narrative or drama. In addition, being moved has been studied with regard to aesthetic stimuli such as films or music. In a survey study including 141 participants, feeling moved was identified as the fourth most common emotion in response to music (Juslin & Laukka, 2004; see also Eerola & Peltola, 2016; Gabrielsson, 2001; see Table 2 for a summary of the appraisals that have been proposed).

Eliciting Being Moved

Research has generally elicited being moved by either asking people to think of an episode involving positive tears and writing it down (e.g., Seibt, Schubert, Zickfeld, & Fiske, 2017; Zickfeld et al., 2018), or by presenting participants with stimuli such as short film clips (e.g., Schnall et al., 2010; Wassilwizky, Jacobsen, Heinrich, Schneiderbauer, & Menninghaus, 2017); music (e.g., Benedek & Kaernbach, 2011; Eerola, Vuoskoski, & Kautiainen, 2016; Strick, de Bruin, de Ruiter, & Jonkers, 2015; Vuoskoski & Eerola, 2017); short written narratives (e.g., Batson et al., 1987; Tokaji, 2003); or audio narratives (Zickfeld, 2015). These stimuli were either chosen by the researchers...
based on their judgment that they would evoke the targeted emotion (e.g., Schnall et al., 2010; Strick et al., 2015) or they were picked by the participants themselves (e.g., Benedek & Kaernbach, 2011). For example, to elicit elevation, Silvers and Haidt (2008) employed a video clip depicting a scene from The Oprah Winfrey Show. In this scene, a musician is surprisingly reunited with his old mentor and music teacher, who had helped him to overcome personal obstacles. This scene, and similar videos, have been used in other studies as well (e.g., Schnall et al., 2010; Seibt, Schubert, Zickfeld, Zhu, et al., 2017).

**Affect and Experience**

Researchers have distinguished between valence and arousal/activation in the feeling of an emotion (Larsen & Diener, 1992; Posner, Russell, & Peterson, 2005; Watson & Tellegen, 1985). With regard to the valence of *being moved*, most scholars have proposed that it is overall experienced as positive (Darwin, 1872; Batson et al., 1987; Cova & Deonna, 2014; A. P. Fiske, Seibt, et al., 2017; Frijda, 2001; Haidt, 2003; Menninghaus et al., 2015). Cova and Deonna (2014) theorize that *being moved* consists only of positive affect: they exclude from their *being moved* construct instances of experiences labeled as *being moved* that are reported as purely sad, saying that sad instances are only phenomenologically and semantically similar. However, in their opinion, the loss of something important might still trigger episodes of *being moved*. On the one hand, several researchers suggest that *being moved* includes aspects of happiness or joy together with sadness, positing that it is a mixture of positive and negative affect (Frijda, 2001; Hanich, Wagner, Shah, Jacobsen, & Menninghaus, 2014; Menninghaus et al., 2015; Pohling & Diessner, 2016; see also Aragón et al., 2015). For example, Frijda (2001, p. xi) noted that *being moved* includes “joy with a melancholy overtone” and also “sadness with a not unpleasant tone.” Similarly, Menninghaus and colleagues divide *being moved* into two different variants: one with joy as the main component, another one with sadness as the key ingredient (Menninghaus et al., 2015; Schindler et al., 2017; Wassiliwizky et al., 2015). In their study on appreciation of entertainment experiences, Bartsch et al. (2014) reported that *being moved* was primarily negatively valenced, though also including positive affect (see also Oliver & Bartsch, 2011). They characterized *being moved* as increasing reflective thoughts, that is, the tendency to meaningfully think about a given stimulus, thereby resulting in more positive evaluations and enjoyment of such film stimuli (cf. Hanich et al., 2014). However, although including both components of joy and sadness, most proponents of this positive and negative mixture conceptualization have highlighted that *being moved* is still experienced as overall positive.

The resolution of this issue may depend on the temporal resolution of the self-reports, where an extended experience often consists of distinct moments of positive affect and other moments of negative affect. In time series analysis of responses while viewing videos selected to evoke *being moved*, one set of participants’ continuous ratings of *being moved* or touched at each moment were consistently cross-correlated with another set of participants’ ratings of happiness at the same moments, but not cross-correlated with a third set of participants’ ratings of sadness at those moments (Schubert, Zickfeld, Seibt, & Fiske, 2016). However, when rating an entire episode, story, or video in the aggregate, participants may report feeling both sadness and happiness, though they probably felt the negative and positive affects at different moments (Seibt, Schubert, Zickfeld, & Fiske, 2017). Indeed, when concern about getting back together with loved ones evokes anxiety, fear, anger, or sadness, these negative affects may afford especially strong positive *kama muta* when the loved ones are ultimately reunited (A. P. Fiske, Schubert, et al., 2017b; see also Deonna, 2018; Frijda, 1988). Another issue here is that positive affect and negative affect are not polar opposites on a single dimension; they are often distinct aspects of the valence of an experience, so they need to be measured separately (Cacioppo & Berntson, 1994). In Schubert et al.’s (2016) time series analysis of means of separate sets of participants’ ratings while watching *kama muta*-evoking videos, the cross-correlations of happiness and sadness across moments was .03; after linear and quadratic temporal detrending, the cross-correlation was −.64. Similarly, Deonna (2018) argues that sadness is the opposite of *being moved* and the reason that they are sometimes regarded as the same might be either a mistake in labeling or that *being moved* is a rather ambiguous label.

In sum, there is some degree of consensus that *being moved* is a positive experience, though some scholars argue that the emotion often, or typically, also has a sad valence at the same time. In contrast, the arousal signature of *being moved* is not well characterized. Menninghaus et al. (2015) proposed that *being moved* consists of low to moderate arousal, while Bartsch et al. (2014) suggested that the experience is characterized by moderate levels of arousal. It seems reasonable to suppose that arousal levels may range from low to high, depending on the intensity of the emotion (Reisenzein, 1994). As noted in the next paragraph, both sympathetic and parasympathetic systems are activated during episodes of *being moved* (see Table 3 for a summary of proposed valences).

**Bodily Reactions**

There is considerable consensus in the literature on the bodily sensations and signs that characterize the emotion that English speakers often label *being moved*. Darwin (1872) and James (1890) mentioned tears in response to tender feelings. Later, Tan and Frijda (1999) described tears as typical of *being moved*. Nearly all conceptualizations have identified weeping or moist eyes as a common symptom of *being moved* (Cova & Deonna, 2014; A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017; Haidt, 2003; Konečný, 2005; Menninghaus et al., 2015; Miceli & Castelfranchi, 2003; Pohling & Diessner, 2016; Tan, 2009; Tan & Frijda, 1999; Thomson & Siegel, 2016). This theorization is supported by several studies that have found that people report moist eyes or tears when they have experiences they label *being moved* (e.g., Mori & Iwanaga, 2017; Schubert
The third bodily sensation that has been reported repeatedly across the literature is the experience of warmth, especially in the center of the chest (Cova & Deonna, 2014; A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017; Schnall et al., 2010; Schubert et al., 2016; Seibt, Schubert, Zickfeld, & Fiske, 2017; Tan & Frijda, 1999; Thomson & Siegel, 2016; Zickfeld, 2015). It seems to be the combination of all three sensations that uniquely indicates being moved (Schubert et al., 2016; Seibt, Schubert, Zickfeld, & Fiske, 2017; Tan & Frijda, 1999; Thomson & Siegel, 2016; Zickfeld, 2015). It is not clear whether there is an actual physical increase of warmth in the body, especially since many people experiencing kama muta on many occasions report a pleasant feeling in the center of the chest that they describe as something other than warmth, such as swelling or tingling or some kind of motion. In our own unpublished pilot work using thermal videography (resolution around 0.1 °C) with a small number of participants, we found no change in temperature on the surface of the chest at moments when participants reported subjective feelings of “warmth” there. Haidt (2003) speculated that the increase of warmth might be attributed to activity in the vagus nerve, which is involved in the parasympathetic nervous system, but research measuring core body temperature related to ostensibly moving stimuli has provided no consistent evidence (e.g., McFarland, 1985; Rimm-Kaufman & Kagan, 1996; Salimpoor, Benovoy, Larcher, Dagher, & Zatorre, 2011; Salimpoor, Benovoy, Longo, Cooperstock, & Zatorre, 2009). Also, there are multiple indications of sympathetic nervous system activation in episodes described as being moved (see following lines). Reviewing the same self-report studies as presented before (7,084 participants) resulted in a correlation of $r = .50$, 95% CI [0.46, 0.54], between felt warmth (in the chest) and being moved (see supplementary material).

Several studies have shown intercorrelations among tears or moist eyes, goosebumps or chills, and warmth in the chest (Mori & Iwanaga, 2017; Schubert et al., 2016; van de Ven, Meijis, & Vingerhoets, 2017; Wassiliwizky, Jacobsen, et al., 2017). However, it should be noted that each symptom on its own is not sufficient to indicate the concept of being moved (A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017). Tears might occur in response to sad events (Vingerhoets & Bylsma, 2015), to fear or anxiety, and to pain, as well as with intense laughter; chills or goosebumps in response to awe or fear (Maruskin, Thrash, & Elliot, 2012); and warmth in the body in response to positive affect in general (Fredrickson, 2001). It seems to be the combination of all three sensations that uniquely indicates being moved (Schubert et al., 2016; Seibt, Schubert, Zickfeld, & Fiske, 2017). However, while the three sensations are consistently and highly correlated within and across participants responding to the same situation, many people report being moved with only two, one, or none of the three sensations.

Based on interviews, participant observation, and many ethnographic and historical sources, A. P. Fiske, Schubert, et al. (2017a, 2017b) have observed that *kama muta* experiences often include taking and holding a deep breath, and also sensations of buoyancy (lightness, floating) and exhilaration (feeling refreshed, energized, and optimistic) that may endure for some time after the emotional moment.

Chills and goosebumps result from activation of the sympathetic nervous system. And studies have shown that episodes of *being moved*, as operationalized by the occurrence of piloerection or lachrymation, involve two other markers of sympathetic nervous system activation. There is an increase in heart rate (HR; Benedek & Kaernbach, 2011; Piper, Saslow, & Saturn, 2015; Salimpoor et al., 2011; Salimpoor et al., 2009; Sumpf, Jentschke, & Koelsch, 2015; Wassiliwizky, Jacobsen, et al., 2017; Wassiliwizky, Koelsch, et al., 2017), and a decreased pulse volume amplitude (Benedek & Kaernbach, 2011; Salimpoor et al., 2011; Salimpoor et al., 2009). In some studies, *being moved* episodes were marked by higher respiration rate than control events (Salimpoor et al., 2011; Salimpoor et al., 2009; Shiota, Neufeld, Yeung, Moser, & Perea, 2011; Wassiliwizky, Jacobsen, et al., 2017), while there were no differences in other studies (Benedek & Kaernbach, 2011; Sumpf et al., 2015). Benedek and Kaernbach (2011) observed differences from controls in respiratory depth at the moments when participants reported *being moved*. In addition, some evidence has been accumulated that *being moved* episodes involve (phasic) skin conductance responses (Benedek & Kaernbach, 2011; Salimpoor et al., 2011; Wassiliwizky, Jacobsen, et al., 2017; Wassiliwizky, Koelsch, et al., 2017), but not increased skin conductance levels (Benedek & Kaernbach, 2011).1 Finally, testing moral elevation, Piper et al. (2015) reported an increase in respiratory sinus arrhythmia. These findings suggest that both sympathetic and parasympathetic systems are activated during episodes of *being moved*.

A few studies have explored the neurophysiology of *being moved* experiences. It has been theorized that emotions such as *being moved* involve activation of the hippocampus (Koelsch et al., 2015), though no evidence has been provided to date. In a recent study, Wassiliwizky, Koelsch, et al. (2017) explored the neurophysiological aspects of listening to poetry and experiencing chills. They found increased activity in subcortical areas of the basic reward system, but did not confirm previous studies showing greater activity in the nucleus accumbens when experiencing chills (Blood & Zatorre, 2001; Salimpoor et al., 2011). Although they did not design their study to evoke the particular emotion of *being moved*, Immordino-Yang, McColl, Damasio, and Damasio (2009) showed segments of videos that often *moved* their participants; these videos activated brain systems such as the insula that are involved in interoceptive representation and homeostatic regulation, as well as the default network that is involved in thinking about social relationships. Evoking elevation, Piper et al. (2015) identified medial prefrontal cortex activation. Exploring aesthetic engagement, the disposition to be *moved* by art or beauty, and employing resting state fMRI, Williams, Johnson, Curtis, King, and Anderson (2018) observed higher integration of the default mode network. In addition, a small study by Silvers and Haidt (2008) found that elevation can induce nursing in breastfeeding women. Based on this, Silvers and Haidt suggested that elevation involves the release of prolactin and perhaps oxytocin, but their results do not necessarily generalize to nonlactating women, or to males.

In sum, *being moved* experiences are often accompanied by self-reports of moist eyes or tears, goosebumps or chills, and subjective feelings of warmth in the body, especially in the center of the chest. However, the only objective evidence for any of these three types of bodily responses concerns goosebumps, and nothing is known about the physiology of the sensations in the center of the chest that are often described as warm (but sometimes described in other terms). In addition, increases in heart rate, respiration rate, and phasic skin conductance may occur along with reported chills during experiences that people may describe as *being moved* (see Table 4 for a summary of proposed sensations and signs of *being moved*).

**Action Tendencies or Motivation**

Most scholars have proposed that *being moved* results in affiliation with others and prosocial or altruistic behavior (Batson, 1991; Cova & Deonna, 2014; A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017; Haidt, 2003; Menninghaus et al., 2015; Pohling & Diessner, 2016; Tan, 2009; Thomson & Siegel, 2016). More precisely, the consequences of *being moved* have been posited to be love for others or moral action tendencies (Thomson & Siegel, 2016); the empathy–altruism hypothesis, which also includes the motivation to relieve the distress or need of another person (Batson, 1991, 2010); “reorganization of one’s hierarchy of values and priorities” (Cova & Deonna, 2014, p. 458); approaching, bonding, helping, as well as promoting social bonds (Menninghaus et al., 2015); signaling significance (Tan, 2009); and affective devotion and moral commitment to communal sharing relations (A. P. Fiske, Schubert, et al., 2017a; A. P. Fiske, Seibt, et al., 2017).

Early research by Frijda, Kuipers, and ter Schure (1989) corroborated the propositions that social relational motives emerge from this emotion. Participants classified the lexeme *being moved* as an emotion fostering approach tendencies. Scores of studies on the elevation concept have further supported this notion (see Pohling & Diessner, 2016; Thomson & Siegel, 2016). In addition, studies have provided evidence that *being moved* may reduce stereotypes and prejudice (Bartsch, Oliver, Nitsch, & Scherr, 2016; Krämer et al., 2016; Lai, Haidt, & Nosek, 2014; Oliver et al., 2015); increase altruistic helping behavior (Batson et al., 1988; Cova et al., 2016; Cox, 2010; Schnall et al., 2010; Strick et al., 2015; Thomson & Siegel, 2013); increase humanization of out-groups (Blomster, Seibt, & Thomsen, 2019); and foster interpersonal closeness and communal relations (Oliver et al., 2015; Steinnes, 2017; Zickfeld, 2015).

Other authors have argued that *being moved* might also lead to insight, meaning, and personal growth (Bartsch et al., 2014; Oliver & Bartsch, 2011; see also research on peak experiences
that people often describe as deeply moving: Keutzer, 1978; Maslow, 1962, 1970; Woodward, Findlay, & Moore, 2009; Wuthnow, 1978). Similarly, several studies have provided evidence that being moved plays a crucial part in the enjoyment of arts such as film (Hanich et al., 2014; Oliver & Raney, 2011); music (Vuoskoski & Eerola, 2017); and poetry (Menninghaus, Wagner, Wassiliwizky, Jacobsen, & Knoop, 2017). Sad music or films may lead to an increase in being moved, perhaps through empathic concern (compassionate caring), which in turn increases the enjoyment and pleasure ratings (Hanich et al., 2014; Vuoskoski & Eerola, 2017). Eerola, Vuoskoski, Peltola, Putkinen, and Schäfer, (2017) provided a comprehensive review on the enjoyment of music-induced sadness and discussed being moved as one possible aspect resulting in enjoyment. Finally, moving music has been found to increase the transportation moving music has been found to increase the transportation

Facial or Verbal Expression and Labels, Including Labels Used for Measurement

Many researchers have measured being moved by simply asking people to rate whether, or how much, they are moved (Batson et al., 1987; Cova & Deonna, 2014; Konečni, 2005; Menninghaus et al., 2015; Schnall et al., 2010; Schubert et al., 2016; Seibt, Schubert, Zickfeld, & Fiske, 2017). Some researchers have also asked people to rate how touched they are (Coke, Batson, & McDavis, 1978; Cova & Deonna, 2014; Konečni, 2005; Menninghaus et al., 2015; Schindler et al., 2017; Seibt, Schubert, Zickfeld, & Fiske, 2017; Silvers & Haidt, 2008). Menninghaus and colleagues, as well as Cova and Deonna, have indeed conceptualized their constructs as the denotation of the vernacular German and French cognates, respectively, of the English vernacular term moved. That is, they define their constructs as the ordinary language semantics of the lexemes—and assume that the semantics of the translated lexemes are essentially the same in at least these languages. They further assume that these vernacular lexemes correspond one-to-one with a distinct psychological system, so that psychology is simply lexicography: being moved is whatever people mean when they say that they, or someone else, is moved. Menninghaus et al. (2015) conducted a cluster analysis of German-speaking participants’ ratings of moving episodes. They identified im Innersten bewegt sein (being deeply moved), bewegt sein (being moved), berührt sein (being touched), gerührt sein (being stirred), and Nostalgie (nostalgia) as the being moved cluster. Schmidt-Atzert and Ströhm (1983) also identified a cluster containing Dankbarkeit (gratitude), Verehrung (adoration/worship), Wohlwollen (benevolence), Zuneigung (affection), Zutrauen (reliance), Mitgefühl (sympathy/compassion), and Rührung (the substantive of gerührt sein).

Research on elevation and on empathic concern have used quite a large set of lexemes to measure the constructs (Batson et al., 1987; Thomson & Siegel, 2016). On different occasions, elevation has been measured using ratings of touched, inspired (Silvers & Haidt, 2008); gratitude, love (Algoe & Haidt, 2009); compassion, admiration (Freeman, Aquino, & McFerran, 2009); moved, uplifted, optimistic about humanity (Schnall et al., 2010); emotional, meaningful, tender (Oliver, Hartmann, & Woolley, 2012); respect, inspiration, awe (Cappellen, Saroglou, Iweins, Piovesana, & Fredrickson, 2013); and emotionally, morally uplifted (Lai et al., 2014). These measures have not been convergently validated, so they may not measure the same thing. Weidman et al. (Weidman, Steckler, & Tracy, 2017) reviewed 10 years of self-report measurements of different emotions published in Emotion; they identified 65 emotion categories that the respective researchers purported to be distinct, although many of them overlap with each other conceptually or in the items used to measure them. Highlighting these discriminant validity issues, they found that self-ratings of moved were used in various studies to assess the concepts of sympathy (or empathic concern), empathy, and sadness.

Batson et al. (1987) have used a comparable arsenal of emotion words to measure the empathic concern construct. Their empathic concern measure includes ratings of sympathetic, moved, compassionate, tender, warm, and soft-hearted. An earlier version of this list also included touched, empathic, concerned, and intent (Coke et al., 1978).

To assess the kama muta concept, A. P. Fiske, Schubert, et al. (2017a) have used ratings of moved and touched on several occasions (Schubert et al., 2016; Seibt, Schubert, Zickfeld, & Fiske, 2017). They recently validated a scale assessing five aspects of kama muta; in the subscale of verbal labels, it includes items on moved, heart-warming, and touched (Zickfeld et al., 2018).

While there has been a lot of work on the verbal labeling of being moved, to our knowledge, there has been no research on any nonverbal expressions. Pohling and Diessner (2016) and Thomson and Siegel (2016) posit that no distinct facial expression exists for elevation, and A. P. Fiske, Schubert, et al. (2017a) posit that there is none for kama muta. Studies using facial EMG have provided evidence that being moved might involve a simultaneous activation of the zygomaticus and corrugator muscles (Wassiliwizky, Jacobsen, et al., 2017; Wassiliwizky, Koelsch, et al., 2017). Finally, A. P. Fiske, Schubert, et al. (2017a; A. P. Fiske, Seibt, et al., 2017) propose that kama muta sometimes includes putting one or both palms on the chest, and uttering a phatic exclamation such as “Awwww!”

See Table 6 for a summary of proposed verbal labels and whether nonverbal displays are distinctive. At this point, however, there exists no specific method for an observer to identify instances or degrees of being moved.

### Cross-Cultural Evidence

In the beginning we posed the question: what is an emotion? One might adopt the perspective that some emotions are universal natural kinds or, alternatively, that they are infinitely diverse, culturally constructed events. Most evidence regarding being moved, especially with regard to the elevation framework, has been collected using U.S. American participants (Thomson & Siegel, 2016). However, other studies have employed French-speaking Swiss (Cova & Deonna, 2014); German (Kuehnast et al., 2014; Menninghaus et al., 2015; Wassiliwizky, Jacobsen, et al., 2017); British (Schnall et al., 2010); Japanese (Tokaji, 2003); Dutch (Damen, 1999; Strick et al., 2015); Chinese, Israeli, Portuguese, Norwegian (Seibt, Schubert, Zickfeld, & Fiske, 2017); Finnish (Vuoskoski & Eerola, 2017); or Spanish (Casado, 2006) participants. Because each of these studies operationalized being moved differently, and measured it with items using vernacular lexemes that do not correspond one-to-one with the English lexeme be moved, nor with the other lexemes used in English scales, these findings cannot be directly compared. On the other hand, we are not aware of any major intercultural differences. When there is a term in a language that can be used as a measurement item, then similar findings seem to emerge. However, we note that some languages (e.g., Hindi/Urdu, Bikol, Ancient Greek) seem not to have a distinct, easily accessible lexeme for being moved, while others (e.g., Arabic)—

### Table 5. Action tendencies of being moved.
indeed, probably most languages—have labels for this emotion in some contexts, but none for it when it appears in other contexts.

Similarly, Fernández-Dols and Russell (2003) have discussed the Spanish expression of *emocionado*, which literally means to be emotional and can be best translated as *being moved* or *being touched*. Casado (2006) provided qualitative reports from Spanish speakers showing evidence that *emocionado* is represented distinctively from happiness. The authors also suggested that the concept of *emocionado* could be culture specific, as the full meaning in Spanish is not easily translatable to English vernacular.

A recent many-labs investigation including 19 different countries from five continents tested how *kama muta* is experienced cross-culturally (Zickfeld et al., 2018). In general, the study revealed few systematic differences among the countries and provided cross-cultural support for the *kama muta* concept in every sample, as well as for the Kama Muta Multiplex Scale (KAMMUS; Zipfel, Koelsch, et al., 2017) or qualitative approaches (Menninghaus et al., 2015). Cova and Deonna (2014) concluded after a series of thought experiments that some uses of the label moving (or *émouvant*) are theoretically irrelevant. While vernacular lexemes can be studied to address linguistic and lexicographic questions, vernacular labels are not likely to denote valid psychological mechanisms (A. P. Fiske, Schubert, et al., 2017). Hence, we view the vernacular lexeme *being moved* as a culturally situated term that is not well suited for use as a scientific concept, which is why we have italicized it throughout the text. We prefer to use a conceptually defined technical label for our scientific concept, such as elevation, empathic concern, or *kama muta*.

A closely related limitation has been the employment of self-report ratings of emotion labels as operational definitions of *being moved* (see Paulhus & Vazire, 2007). As reviewed earlier, these self-report measures have employed a number of different sets of emotion labels, which complicates the ability to reliably assess distinct emotion categories (Weidman et al., 2017). In addition, most studies have often only assessed feeling labels, while neglecting other aspects of the emotional concept such as the appraisal, bodily sensations, or action tendencies. Coppin and Sander (2016) recommend that for a valid assessment of an emotion concept all of these aspects should be measured. Scholars have also recommended assessing emotions using multiple methods in addition to self-report, such as observational, neurophysiological, physiological, or behavioral measures (Coppin & Sander, 2016; Scherer, 2005). However, very few studies of *being moved* have employed neurophysiological or physiological measurements (for an exception, see Benedek & Kaernbach, 2011; Wassiliwizky, Jacobsen, et al., 2017; Wassiliwizky, Koelsch, et al., 2017) or qualitative approaches.
to study it among young children, and also in people who are atypical in their sociality, especially people on the autism spectrum, people who have Williams syndrome, who have early-stage fronto-temporal dementia, and who are highly sociopathic, narcissistic, or socially avoidant.

**There Is an Emotion that English Speakers May Label Being Moved—But There Is No Consensus on What Causes It, What Its Valence Is, or How to Measure It**

We have systematically reviewed the evidence on appraisal patterns, valence, bodily sensations, motivation and action tendencies, feeling labels, measures, and methods for research on the concept of being moved, including the literature on intersecting constructs such as elevation and empathic concern.

We are well aware that there is a certain irony in the fact that we offer a comprehensive review of the literature on being moved, only to conclude that this term is ill-suited as a scientific concept. Theories should be constructed around scientific constructs that are precisely and explicitly defined, and measured using multiple indicators. Constructs such as cognitive dissonance, projection, releasing stimulus, reinforcement, and elevation, or DSM and ICD diagnoses, are useful because (or to the extent that) their meanings are explicitly defined and consistently used. The purpose of this review was not to promote the use of kama muta theory, but to survey the literature as it has developed by using the term being moved. Any theory of being moved should explicate what metatheory of emotions it is using, and how it understands the relations between specific languages’ vernacular labels for emotional states and the emotions themselves (if it distinguishes between labels and psychological states).

In any case, this review shows that a large number of theoretical and empirical proposals converge in the claim that there is an emotion, which English speakers often call being moved, that has an identifiable pattern of components and can be operationalized precisely enough to be studied. This is in and by itself an important conclusion, because the label being moved is sometimes used broadly to label a variety of emotions, and many other lexemes in English are often used to denote the same emotion in particular contexts.

Researchers differ in their conceptualization and measurement of being moved—differ regarding elicitors and appraisal patterns, valence, and labels. Menninghaus et al. (2015) have included both positive and negative German vernacular lexemes indicative of the concept that they call being moved. Bartsch et al.’s (2014) conceptualization of being moved comprises mostly negative experiences. Not focusing on the labels per se, Haidt (2000) has argued that the concept of elevation might be called moved, and posits that it is a very positive experience. However, a recent review (Pohling & Diessner, 2016) of the elevation concept argues that being moved is broader than elevation and includes negative cases. Batson et al. (1987) identify moved as part of the empathic concern concept, which also...
contains labels of sympathetic and tenderness. Finally, kama muta theory has argued that there is an emotion that English speakers often label moved, but this emotion has many other English labels, and that people sometimes use the term being moved to label awe, sadness, or even outrage.

Based on the converging evidence with regard to bodily sensations, motivation, and valence, we think that there is a distinct emotion that has often been referred to as being moved. However, we think that calling this emotion being moved or operationalizing it purely by asking about moving experiences (or any other set of labels) should be avoided. In order to get a more valid idea of the concept, we should measure several of its aspects, including appraisals, bodily sensations, valence and arousal, motivation, bodily expressions (if any), and labels.

The study of the concept that is often referred to as being moved may help inform a number of research areas. It may be a major source of social solidarity, and it may be crucial to processes such as prejudice and discrimination, and fostering connectedness among groups (Oliver et al., 2015). It also seems to play a major role in the appreciation and enjoyment of arts, psychotherapy, support groups, addiction-recovery groups, market
ing polities, and religion. There is much promising ground to explore.

Declaration of Conflicting Interests
The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Note
1 It should be noted that except for Benedek and Kaernbach (2011), and Wassiliwizky, Jacobsen, et al. (2017), none of these studies explicitly measured being moved. Most of the studies used aesthetic stimuli such as music or poetry to induce goosebumps or chills. In most of these studies, participants were not asked about tears and warm feelings, and some of the people reporting goosebumps or chills may have felt awed by the stimuli, but not moved.
