ABSTRACT

dL-tryptophane- $\beta$ -C<sup>14</sup> was administered to rabbits, dogs, and rats. The kynurenine and kynurenic acid, isolated from the urines were radioactive, the labeled carbon being the methylene carbon and the 3-position respectively. The N-methylnicotinamide was not radioactive, indicating that it was produced from tryptophane by some mechanism other than ring-closure to a quinoline derivative, followed by oxidation.

The metabolic conversion of tryptophane (I) into kynurenine (II) (2) (3), kynurenic acid (III) (4), and nicotinic acid (IV) (5) (6) has been demonstrated by feeding experiments in a variety of mammals. That kynurenine is an intermediate in the conversion of tryptophane into nicotinic acid by neurospora (7) has been established, and recently it has been shown that 3-hydroxyanthranilic acid is also an intermediate in the

neurospora (8) and probably in the rat (9). In animal experiments the nicotinic acid is excreted largely as the N-methyl amide (V), and it has been shown in experiments with  $C^{13}$  that when carboxyl-labeled nicotinic acid is fed to rats, the N-methylnicotinamide isolated from the urine retains a very high percentage of the initial label (10).

We have synthesized dl-tryptophane- $\beta$ - $C^{14}$  (11) and are studying the mechanism of these conversions:

The tryptophane was administered to rabbits, dogs, and rats, and from the urines kynurenine, kynurenic acid, and N-methylnicotinamide, respectively, were isolated by the usual methods (2), (4), (6). The

specific activities of the kynurenine and kynurenic acid were 37% and 29% of that expected for direct conversion, indicating dilution by the body pool of tryptophane.

The position of the label in the kynurenine (sp. act., 114 counts/min/mg.) was proved by its conversion by means of alkaline hypiodite to iodoform (sp. act., 81 counts/min/mg; calcd. 78), which could only have originated from the methylene carbon atom. The kynurenic acid (sp. act. 143 counts/min/mg.) was decarboxylated thermally to give inactive carbon dioxide. It was also oxidized to o-carboxyoxanilide (sp. act., 125 counts/min/mg. Calcd. 130)(12) which was hydrolyzed to give active oxalic acid (sp. act. as calcium oxalate, 188 counts/min/mg. Calc'd., 198) and was also decomposed thermally to give radioactive carbon dioxide (sp. act. as  $\text{BaCO}_3$  129 counts/min/mg. Calc'd., 128) and inactive carbon monoxide. Formyl-anthranilic acid, the probable intermediate in this decomposition, liberates carbon monoxide on heating. These reactions strongly indicate, but do not absolutely prove, that the labeled carbon atom is in the 3-position of kynurenic acid.

If the nicotinic acid were produced by oxidation of the benzenoid ring of a molecule such as kynurenic acid, which already contains a pyridine ring, it would be radioactive, following administration of the labeled tryptophane. If, however, hydroxyanthranilic acid is the intermediate (and we have shown that feeding this compound results in a substantial increase in N-methylnicotinamide excretion) the labeled carbon

would be lost, and the nicotinic acid would be inactive. Accordingly, the labeled tryptophane was fed to rats, and after carrier N-methylnicotinamide was added, it was isolated as the picrate (6) and a plate containing 12.3 mg. of picrate was completely devoid of activity. Fluorometric analysis of an aliquot of the Permutit eluate before the carrier was added, indicated the presence of 115  $\gamma$  (over three times the N-methylnicotinamide found in the urine of rats given no tryptophane). If the compound had been formed through a quinoline intermediate, the plate would have contained 103 counts/min. Less than 0.005% of this could easily be detected with the Nucleometer.

Thus, we have shown as formulated above that kynurenine is formed from tryptophane by direct opening of the pyrrole ring; kynurenic acid by direct ring-closure from kynurenine; and nicotinic acid by a mechanism, probably involving hydroxyanthranilic acid, which does not go through a quinoline intermediate.
