Study of Charge Transfer in Back-Bonding to Carbonyl and Nitrosyl Groups

STEVEN C. AVANZINO, ALBERT A. BAKKE, HSIANG-WEN CHEN, CRAIG J. DONAHUE,
WILLIAM L. JOLLY,* TING HO LEE, and ANTONIO J. RICCO

Received November 12, 1979

The carbon 1s, nitrogen 1s, and oxygen 1s binding energies of a wide variety of transition-metal carbonyl and nitrosyl compounds are subjected to correlative analysis. The carbon 1s and oxygen 1s binding energies of the carbonyls are linearly related to the C-O stretching force constants, and the nitrogen 1s and oxygen 1s binding energies of the nitrosyls are linearly related to the N-O stretching force constants. The data indicate that transfer of electron density to the CO and NO groups is accompanied by weakening of the C-O and N-O bonds. From the relative binding energy shifts it is calculated that, in back-bonding to CO groups, more charge is transferred to the carbon atoms than to the oxygen atoms, and, in back-bonding to NO groups, similar amounts of charge are transferred to the nitrogen and oxygen atoms.

Introduction

It has been established that the carbon 1s and oxygen 1s binding energies of metal carbonyl compounds are at least approximately linearly correlated with the corresponding C-O stretching force constants. Such correlations, for solid-state binding energies, have been observed by Barber et al.¹ for eight compounds and by Willemen et al.² for four compounds. In a recent paper we have shown that the oxygen 1s binding energies of 19 metal carbonyl compounds in the gas phase are linearly correlated with the degeneracy-weighted average C-O stretching frequencies.³ (The average frequencies were used as convenient stand-ins for C-O force constants.) In that paper we did not discuss carbon 1s binding energies because then we had measured only a few such energies and we feared that the binding energies of carbon atoms directly bonded to a variety of metal atoms might not be as well correlated with average stretching frequencies as the binding energies of the relatively isolated, terminal oxygen atoms. However, now we have both carbon 1s and oxygen 1s data for almost three times as many carbonyl compounds as were involved in our first study, including better data for several of the compounds studied earlier. Having both C 1s and O 1s binding energies, we can determine the relative amounts of electronic charge transferred to the carbon and oxygen atoms in $d\pi \rightarrow \pi^*$ back-bonding. We also now have nitrogen 1s and oxygen 1s binding energies for 15 metal nitrosyl compounds; with these data the relative charge transferred to the nitrogen and oxygen atoms can be determined, and the back-bonding in nitrosyl compounds can be compared with that in carbonyl compounds. We have calculated the C-O and N-O stretching force constants for all the carbonyl and nitrosyl compounds which we have studied and for which the necessary vibrational frequencies are known.

Results and Discussion

In Table I are listed the carbon 1s and oxygen 1s binding energies determined for 55 metal carbonyl compounds in the gas phase. For those compounds for which the necessary vibrational spectroscopic data are available, we have listed the degeneracy-weighted C-O stretching frequencies and the corresponding weighted C-O stretching force constants, calculated by the Cotton-Kraihanzel (CK) method.⁴ In Figure 1 the carbon 1s binding energies are plotted vs. the C-O force constants, and in Figure 2 the oxygen 1s binding energies are plotted vs. the same force constants (correlation coefficients 0.95 and 0.94, respectively). The linear correlations shown by these plots confirm the fact that transfer of electron density to the carbon and oxygen atoms of a CO group is accompanied

by a weakening of the C-O bond. The data strongly suggest that the carbon and oxygen core binding energies can be taken as measures of $d\pi \rightarrow \pi^*$ back-bonding in transition-metal carbonyl compounds. From Figures 1 and 2 it is obvious that the carbon 1s and oxygen 1s binding energies are linearly correlated with each other. Figure 3 is a plot of the oxygen 1s binding energies vs. the carbon 1s binding energies (correlation coefficient 0.97). The justifications for presenting this otherwise superfluous plot are that it includes points for five more compounds than are in Figures 1 and 2 and that it shows a significantly better linear correlation than shown in Figures 1 and 2. At least two explanations can be offered for the poorer correlations in Figures 1 and 2. First, the carbon 1s and oxygen 1s binding energies are not *solely* determined by the degree of back-bonding (which is presumably manifested as changes in atomic charge). On going from one compound to another there are changes in the electronic relaxation energy associated with core ionization and changes in the electrostatic potential due to the metal atom and other ligands.⁵ Although these changes in relaxation energy and potential are roughly linearly correlated with the changes in atomic charge,⁵ parts of these changes are unsystematic, that is, not so correlated. The unsystematic parts of the changes in relaxation energy and potential contribute to the scatter in the plots of binding energy vs. force constant. However, in the correlation of the 1s binding energies of carbon and oxygen atoms *in the same carbonyl groups*, the unsystematic parts of the changes in relaxation energy and potential would be expected to have about the same magnitude and sign and would be largely canceled. In addition, errors in spectrometer calibration cause scatter in the points of Figures 1 and 2 but tend to cancel when carbon 1s binding energies and oxygen 1s binding energies which were determined in the same runs are correlated. Even if we ascribe all the scatter of the points in Figures 1 and 2 to unsystematic changes in relaxation energy and potential, we conclude from the standard deviations that the average unsystematic change in the sum of these quantities on going from one compound to another is less than about 0.2 eV. This conclusion is important because it indicates that shifts in core binding energies greater than 0.2 eV in compounds of this type can be interpreted in terms of changes in atomic charge. In fact, the data suggest that even smaller shifts can be thus interpreted within sets of structurally similar molecules. For

Figure 1. Plot of carbon 1s binding energies for gas-phase metal carbonyl compounds vs. C-O stretching force constants. Correlation coefficient = 0.951; standard deviation = 0.23 eV.

Figure 2. Plot of oxygen 1s binding energies for gas-phase metal carbonyl compounds vs. C-O stretching force constants. Correlation coefficient = 0.944; standard deviation = 0.22 eV.

Figure 3. Plot of oxygen 1s binding energies vs. carbon 1s binding energies for gas-phase metal carbonyl compounds. Correlation coefficient = 0.970; standard deviations = 0.14 eV for $E_B(\text{O } 1s)$ and 0.17 eV for $E_B(\text{C } 1s)$.

example, in the correlations of the C 1s and O 1s binding energies with C-O force constants for the 12 penta-carbonylmanganese compounds, $\text{RMn}(\text{CO})_5$, the standard deviations are only 0.18 and 0.13 eV, respectively. Because a considerable part of these standard deviations is due to random experimental error, it seems reasonable to conclude that the average unsystematic changes in relaxation energy and potential in this set of compounds are no greater than about 0.1 eV.

From the slope of Figure 3 we can calculate the average relative amounts of electronic charge transferred to or from the oxygen and carbon atoms of carbonyl groups on going from one carbonyl compound to another. If we ignore changes in relaxation energy and potential, we can write $\Delta Q = \Delta E/k$, where ΔQ and ΔE are the changes in atomic charge and core binding energy and k is a constant inversely proportional to

Figure 4. Plot of nitrogen 1s binding energies for gas-phase metal nitrosyl compounds vs. N-O stretching force constants. Correlation coefficient = 0.73; standard deviation = 0.37 eV.

Figure 5. Plot of oxygen 1s binding energies for gas-phase metal nitrosyl compounds vs. N-O stretching force constants. Correlation coefficient = 0.81; standard deviation = 0.39 eV.

the radial distance of the valence electrons.^{6,7} Hence the ratio of the charge transferred to the oxygen and carbon atoms is calculated as

$$\frac{\Delta Q_O}{\Delta Q_C} = \frac{\Delta E_B(\text{O } 1s)}{\Delta E_B(\text{C } 1s)} \frac{k_C}{k_O} = 0.849 \left(\frac{23.0}{32.5} \right) = 0.601$$

In other words, on going from one carbonyl compound to another, most of the change in charge of a CO group occurs at the carbon atom. Now because of the close correlation of the binding energies with C-O force constants and the fact that changes in C-O force constants are usually interpreted in terms of changes in back-bonding,⁸⁻¹⁰ we believe that our data measure the relative atomic orbital contributions to the π^* orbitals of a coordinated CO group. Various high-quality molecular orbital calculations are in agreement that the CO groups of metal carbonyls are negatively charged;¹¹⁻¹³ in other words, considerably less negative charge is transferred from the CO to the metal by σ bonding than is transferred from the metal to the CO by π bonding. There is little question that the π^* orbitals of a free CO molecule reside more on the carbon atom than on the oxygen atom. Our results indicate that the same is true for a coordinated CO: as the interaction of the metal $d\pi$ orbitals with the CO π^* orbitals increases, the shift of electron density to the carbon atoms is greater than that to the oxygen atoms. There are calculations in accord with this result. Schreiner and Brown⁹ have calculated that

- (6) Values of $(1/r)$ for carbon, nitrogen, and oxygen were taken from ref 7. For carbon and nitrogen, the value for an sp^3 hybrid orbital was used. For oxygen, the value for an orbital with 20% s character was used. The rounded k values in units of electronic charge per electronvolt are 23.0, 27.9, and 32.5, respectively.

the carbon π atomic orbitals contain more charge when CO is bonded to chromium, whereas the oxygen π charge is nearly unaffected. Electron density difference plots of Ziegler and Rauk¹³ indicate that, when $\text{Ni}(\text{CO})_3$ bonds to CO, most of the electron density is transferred from the carbons of the $\text{Ni}(\text{CO})_3$ to the carbon of the entering CO.

In Table II are listed the nitrogen 1s and oxygen 1s binding energies determined for 15 metal nitrosyl compounds in the gas phase. In all these compounds the nitrosyl groups are of the terminal, linear type, isostructural with terminal carbonyl groups. We know of no compounds with bent nitrosyl groups that have sufficient volatility for study in our spectrometer. In the table we have listed the degeneracy-weighted N-O stretching frequencies and the CK N-O stretching force constants. In Figure 4 the nitrogen 1s binding energies are plotted vs. the N-O force constants, and in Figure 5 the oxygen 1s binding energies are plotted vs. the same force constants. Although these plots show more scatter than those of Figures 1 and 2, they indicate that the nitrogen and oxygen core binding energies can be taken as measures of $d\pi \rightarrow \pi^*$ back-bonding in metal nitrosyl compounds. As in the case of the carbonyl compounds, the plot of the binding energies

Figure 6. Plot of oxygen 1s binding energies vs. nitrogen 1s binding energies for gas-phase metal nitrosyl compounds. Correlation coefficient = 0.914; standard deviations = 0.22 eV for $E_B(\text{O } 1s)$ and 0.18 eV for $E_B(\text{N } 1s)$.

against one another, shown in Figure 6, shows a better correlation. The results can be interpreted in essentially the same way as in the case of the carbonyl compounds. From the slope of Figure 6 we can calculate the average relative amounts of charge transferred to the oxygen and nitrogen atoms of nitrosyl groups on going from one nitrosyl compound to another:

$$\frac{\Delta Q_O}{\Delta Q_N} = \frac{\Delta E_B(\text{O } 1s)}{\Delta E_B(\text{N } 1s)} \frac{k_N}{k_O} = 1.257 \left(\frac{27.9}{32.5} \right) = 1.08$$

Apparently the oxygen and nitrogen atoms undergo comparable changes in charge, with perhaps slightly more change in charge occurring at the oxygen atom. To some extent this result is expected. An increase in the electronegativity of one atom in a diatomic molecule causes the contribution of that atom to the π^* MO to decrease. Thus, because nitrogen is more electronegative than carbon, one would expect that $d\pi \rightarrow \pi^*$ bonding would transfer relatively more charge to the oxygen atoms of NO groups than to the oxygen atoms of CO groups. However, in free NO^+ , the π^* orbital is located more on the nitrogen atom than on the oxygen atom,¹⁴ and thus it is at first sight surprising that a greater (or at least comparable) amount of charge is transferred to the oxygen atom of a coordinated NO^+ group than to the nitrogen atom. The explanation probably is to be found in the fact that the effective electronegativity of the nitrogen atom in a coordinated NO^+ group is much higher than it is in free NO^+ ; indeed it would not appear unreasonable if the nitrogen atom had a greater electronegativity than that of the oxygen atom. These changes in electronegativity can be understood in terms of the changes in formal charge. An increase in positive formal charge corresponds to an increase in electronegativity.¹⁵ In free NO^+ , the nitrogen atom has zero formal charge and the oxygen atom has a positive formal charge:

In coordinated NO^+ , the nitrogen atom has a positive formal charge, and the oxygen atom loses its positive formal charge in proportion to the extent of back-bonding:

In a carbonyl compound, even with strong back-bonding, the

formal charge of the oxygen atom is never more negative than that of the carbon atom, so the effective electronegativity of the oxygen atom is always greater than that of the carbon atom.

Su and Faller¹⁶ observed that the difference between the oxygen 1s and the nitrogen 1s binding energies for crystalline complexes containing linear nitrosyl groups was 132 ± 1 eV, i.e.

$$E_B(\text{O } 1s) \approx E_B(\text{N } 1s) + 132$$

The equation of the least-squares line through the points in Figure 6 is

$$E_B(\text{O } 1s) = 1.257 E_B(\text{N } 1s) + 27.06$$

However the standard deviation of the slope (1.257) is 0.16, and the data only marginally justify fitting to an equation with two adjustable parameters rather than to a one-parameter equation. Indeed, the average difference between $E_B(\text{O } 1s)$ and $E_B(\text{N } 1s)$ in Table II is 131.91 eV, with a standard deviation of 0.24 eV, and therefore our gaseous nitrosyl data are consistent with the solid-state data of Su and Faller.¹⁶ It would be of considerable interest to obtain gas-phase data for bent nitrosyls to see if the $E_B(\text{O } 1s) - E_B(\text{N } 1s)$ difference for these compounds is significantly lower than 132 eV, as was found for the crystalline compounds. The standard deviation of the slope (0.849) of the line in the plot of $E_B(\text{O } 1s)$ vs. $E_B(\text{C } 1s)$ (Figure 3) is only 0.03; in this case the data strongly justify fitting to a two-parameter equation rather than a one-parameter equation.

Experimental Section

The unreferenced binding energies in Tables I and II were determined by using procedures previously described.¹⁷ A few of the data are redeterminations of values reported earlier.³ In general, the binding energies given to two decimal places are known to ± 0.05 eV; those given to one decimal place have uncertainties of ± 0.1 eV. It was not possible to resolve the oxygen 1s spectra of the carbonyl nitrosyl compounds, except $\text{Mn}(\text{NO})_2\text{CO}$, into separate peaks. In these cases the full widths at half-maximum for the O 1s lines were significantly greater (1.60-eV average) than those of the other nitrosyl compounds (1.40-eV average), and the reported O 1s binding energies are weighted averages for the NO and CO oxygens. Therefore we believe the reported nitrosyl O 1s binding energies of the carbonyl nitrosyl compounds are uncertain by 0.2–0.3 eV. If the points involving these data are deleted from Figure 6, the slope of the least-squares line is increased only from 1.257 to 1.321, and our conclusions are not changed significantly.

The C–O and N–O stretching frequencies are from the literature in those cases in which the infrared measurements were carried out by using nonpolar hydrocarbon solvents. The unreferenced values are based on our measurements, using either hexane or pentane solvent.

The force constants are those obtained by the CK procedure,⁴ which, although approximate, gives reasonable relative force constants for comparing bond strengths.¹⁸ Even though more accurate force constants have been calculated for some of the compounds, we have not used these because we believe it is important that all the constants used in a correlation be calculated by a consistent procedure. It can be easily shown, by using the "exact" secular equations involved in the CK method, that a force constant can be simply obtained from the familiar equation

$$k = 4\pi^2 c^2 \mu \nu^2$$

if one uses the degeneracy-weighted stretching frequency, $\langle \nu \rangle$, for ν . For example, the degeneracy-weighted C–O stretching force

- (14) The π^* orbital of CO is localized 68% on the carbon atom and 32% on the oxygen atom. (See: Snyder, L. C.; Basch, H. "Molecular Wave Functions and Properties"; Wiley-Interscience: New York, 1972.) The π^* orbital of O_2^{2+} is symmetrically distributed between the two atoms. Undoubtedly the delocalization of the π^* orbital of the intermediate isoelectronic species NO^+ is intermediate between that of CO and O_2^{2+} .

constant¹⁹ of an octahedral carbonyl $M(\text{CO})_6$ is evaluated as $\langle\nu_{\text{CO}}\rangle = \frac{1}{6}\nu_{\text{A}_{1g}} + \frac{2}{6}\nu_{\text{E}_g} + \frac{3}{6}\nu_{\text{T}_{1u}}$. For calculating the C–O and N–O stretching force constants, we used the relations

$$k_{\text{CO}} = 4.0423 \times 10^{-6} \langle\nu_{\text{CO}}\rangle^2 \quad k_{\text{NO}} = 4.4004 \times 10^{-6} \langle\nu_{\text{NO}}\rangle^2$$

In the case of carbonyls having more than one structural type of CO group, we calculated the overall weighted average k_{CO} values.

Dicarbonyl(η^5 -cyclopentadienyl)cobalt was obtained from Pressure Chemical Co. The compound was twice purified by chromatography in petroleum ether on a silica gel column. After solvent removal, the compound was purified on the vacuum line; the pure compound was collected in a -30°C trap. The infrared data were in precise agreement with the literature values²⁰ ($\nu_{\text{CO}} = 2028$ and 1967 cm^{-1}).

Methyldinitricobalt nonacarbonyl, prepared by the method of Nestle et al.,²¹ melted at $105\text{--}106^\circ\text{C}$ (lit. mp $105\text{--}106^\circ\text{C}$) and showed infrared absorptions (pentane solution) at 2028, 2042, 2058, and 2100 cm^{-1} (C–O stretching) (lit.²¹ IR (CCl_4 solution): $\nu_{\text{CO}} = 2025, 2045, 2060, 2105\text{ cm}^{-1}$).

(Chloromethyldiene)tricobalt nonacarbonyl, prepared by the method of Nivert et al.,²² melted at $131\text{--}133^\circ\text{C}$ (lit. mp $131\text{--}133^\circ\text{C}$) and showed infrared absorptions (pentane solution) at 2112, 2064, 2048, 2032, and 1993 cm^{-1} (lit.²² IR (CCl_4 solution): $\nu_{\text{CO}} = 2112, 2065, 2045, 2020, 1985\text{ cm}^{-1}$).

(Methylmethyldiene)tricobalt nonacarbonyl was kindly provided by L. Stuhl. The compound was sublimed just prior to use.

(Bromomethyldiene)tricobalt nonacarbonyl, prepared by the method of Ercoli et al.,²³ melted at $119\text{--}120^\circ\text{C}$ (lit. mp $130\text{--}132^\circ\text{C}$) and showed infrared absorptions (pentane solution) at 2108, 2061, 2045, and 2032 cm^{-1} (C–O stretching) (lit.²⁴ IR (hexane solution): $\nu_{\text{CO}} = 2108.7, 2064.4, 2046.6, 2031\text{ cm}^{-1}$).

Dicarbonyl(η^5 -cyclopentadienyl)(thiocarbonyl)manganese, prepared by the method of Fenster and Butler,²⁵ melted at $51\text{--}52^\circ\text{C}$ (lit. mp $51\text{--}53^\circ\text{C}$) and showed infrared absorptions (pentane solution) at 2010 and 1965 cm^{-1} (C–O stretching) and 1275 cm^{-1} (C–S stretching) (lit.²⁵ IR (CS_2 solution): $\nu_{\text{CO}} = 2006, 1954\text{ cm}^{-1}$; $\nu_{\text{CS}} = 1266\text{ cm}^{-1}$).

Dicarbonyl(η^5 -cyclopentadienyl)(thionitrosyl)chromium, prepared by the method of Kolthammer and Legzdins,²⁶ melted at $68.5\text{--}69.5^\circ\text{C}$ (lit. mp $68\text{--}69^\circ\text{C}$) and showed infrared absorption (pentane solution) at 2025 and 1966 cm^{-1} (C–O stretching) and 1180 cm^{-1} (N–S stretching). (lit.²⁶ IR (hexane solution): $\nu_{\text{CO}} = 2033, 1962\text{ cm}^{-1}$; $\nu_{\text{NS}} = 1180\text{ cm}^{-1}$).

Manganese pentacarbonyl iodide was prepared by the addition of I_2 to a solution of $\text{NaMn}(\text{CO})_5$ in tetrahydrofuran at room temperature. After removal of the solvent, the product was obtained by sublimation at room temperature to a 0°C trap. The infrared spectrum of $\text{IMn}(\text{CO})_5$ agreed with the literature.²⁷

Manganese pentacarbonyl chloride was prepared by the method of Abel and Wilkinson.²⁸ Many attempts were made to characterize this compound by its infrared spectrum in cyclohexane solution,²⁷ but peaks attributable to $\text{Mn}_2(\text{CO})_8\text{Cl}_2$ were always present, along with the bands from the monomer. This is consistent with the findings of Bamford et al.²⁹ that $\text{Mn}(\text{CO})_5\text{Cl}$ easily undergoes conversion to $\text{Mn}_2(\text{CO})_8\text{Cl}_2$ in solution with loss of CO. Consequently, the $\text{Mn}(\text{CO})_5\text{Cl}$ sample was characterized by means of its mass spectrum,^{30,31} from which any sign of $\text{Mn}_2(\text{CO})_8\text{Cl}_2$ impurity was absent.

$\text{Mn}(\text{CO})_5\text{Br}$ (Strem) was shown to be pure by its infrared spectrum.²⁷

$\text{F}_3\text{SiMn}(\text{CO})_5$ was prepared and characterized as described in the literature.³²

$\text{CF}_3\text{COMn}(\text{CO})_5$ was prepared by the reaction of trifluoroacetic anhydride with $\text{NaMn}(\text{CO})_5$ in tetrahydrofuran; the melting point agreed with the literature.²⁰ $\text{CF}_3\text{Mn}(\text{CO})_5$ was made by the decarbonylation of the trifluoroacetyl derivative.²⁰

(σ -Allyl)manganese pentacarbonyl was prepared according to the literature³³ and purified by fractional condensation in vacuo. The product was trapped at 0°C ; volatile impurities and solvent were trapped (along with a small amount of product) at -196°C , and nonvolatile impurities remained in the original flask at 20°C . The product was shown to be pure by its NMR spectrum, using CDCl_3 solvent.

All the $\text{Cr}(\text{CO})_5\text{PX}_3$ and $\text{Mo}(\text{CO})_5\text{PX}_3$ complexes were prepared by the same general procedure,³⁴ which involves the reaction of the iodopentacarbonylmetalate $\text{M}(\text{CO})_5\text{I}^-$ with an equimolar amount of the ligand in the presence of a Lewis acid. The complex $[\text{n-Bu}_4\text{N}][\text{Mo}(\text{CO})_5\text{I}]$ ³⁵ and the Lewis acid Et_3OBF_4 ³⁶ were prepared by literature methods. The complexes were purified by vacuum distillation ($\text{Mo}(\text{CO})_5\text{PF}_3$, mp $4.5\text{--}5.5^\circ\text{C}$ (lit.³⁷ mp 5°C)), sublimation ($\text{Mo}(\text{CO})_5\text{PCl}_3$, mp 31°C (lit.³⁸ mp 30°C); $\text{Mo}(\text{CO})_5\text{PMe}_3$; $\text{Mo}(\text{CO})_5\text{P}(\text{NMe}_2)_3$, mp $150\text{--}153^\circ\text{C}$ dec (lit.³⁹ mp $152\text{--}154^\circ\text{C}$ dec)), or recrystallization ($\text{Mo}(\text{CO})_5\text{P}(\text{OMe})_3$, mp $7\text{--}8^\circ\text{C}$ (lit.⁴⁰ mp 8°C); $\text{Mo}(\text{CO})_5\text{P}(\text{OEt})_3$).

The complex $\text{cis-Mo}(\text{CO})_3(\text{PF}_3)_3$ was prepared by reaction of $\pi\text{-C}_9\text{H}_7\text{Mo}(\text{CO})_3$ with PF_3 at an elevated temperature and pressure.⁴¹ Sublimation of the crude product yielded a pure sample, mp $63\text{--}64^\circ\text{C}$ (lit.³⁷ mp 64°C).

$\text{Cr}(\text{CO})_5\text{CS}$ and $\text{W}(\text{CO})_5\text{CS}$ were prepared by treating the reduced carbonyls (prepared from the hexacarbonyls and sodium amalgam in refluxing tetrahydrofuran) with thiophosgene at room temperature.⁴² Pure ($>95\%$) $\text{Cr}(\text{CO})_5\text{CS}$ was obtained from the $\text{Cr}(\text{CO})_6/\text{Cr}(\text{CO})_5\text{CS}$ product mixture by repeated recrystallization from hexane. Pure ($>95\%$) $\text{W}(\text{CO})_5\text{CS}$ was obtained by converting the $\text{W}(\text{CO})_6/\text{W}(\text{CO})_5\text{CS}$ product mixture to $\text{W}(\text{CO})_6/\text{trans-W}(\text{CO})_4\text{CSI}^-$, isolating the thiocarbonyl salt and then substituting I^- with CO in the presence of a Ag^+ salt. Purity was established by comparison of the experimental and published infrared spectra and by GLC using a 10% SE-30 column.

(η^5 -Cyclopentadienyl)nitrosylnickel, prepared by the method of King,²⁰ melted at -40 to -39°C (lit. mp -41°C) and showed an infrared absorption (pentane solution) at 1825 cm^{-1} (N–O stretching) (lit.⁴³ IR (liquid): $\nu_{\text{NO}} = 1810\text{ cm}^{-1}$).

(η^3 -Allyl)dicarbonylnitrosyliron, prepared by the method of Chaudhari et al.,⁴⁴ melted at -19 to -18°C and showed infrared absorptions (pentane solution) at 2040 and 1984 cm^{-1} (C–O stretching) and 1760 cm^{-1} (N–O stretching) (lit.⁴⁵ IR (petroleum ether): $\nu_{\text{CO}} = 2038, 1983\text{ cm}^{-1}$; $\nu_{\text{NO}} = 1761\text{ cm}^{-1}$).

Dicarbonyl(η^5 -cyclopentadienyl)nitrosylchromium, prepared by the method of Crease and Legzdins,⁴⁶ melted at $66\text{--}67^\circ\text{C}$ and showed infrared absorptions at 2024 and 1960 cm^{-1} (C–O stretching) and 1715 cm^{-1} (N–O stretching) (lit.⁴⁷ IR (CH_2Cl_2 solution): $\nu_{\text{CO}} = 2020, 1945\text{ cm}^{-1}$; $\nu_{\text{NO}} = 1680\text{ cm}^{-1}$). Dicarbonyl(η^5 -cyclopentadienyl)nitrosylmolybdenum, prepared by the method of Seddon et al.,⁴⁸ melted

(19) An early, perhaps the first, use of degeneracy-weighted stretching frequencies (although not for calculating force constants) was by Schreiner and Brown.⁹

at 83–84.5 °C and showed infrared absorptions (pentane solution) at 2018 and 1950 cm^{-1} (C–O stretching) and 1688 cm^{-1} (N–O stretching) (lit.⁴⁷ IR (CH_2Cl_2 solution): ν_{CO} = 2020, 1937; ν_{NO} = 1663).

Dicarbonyl(η^5 -cyclopentadienyl)nitrosyltungsten, prepared by the method of Crease and Legzdins,⁴⁶ melted at 107–108.5 °C and showed infrared absorptions at 2010 and 1938 cm^{-1} (C–O stretching) and 1683 cm^{-1} (N–O stretching) (lit.⁴⁷ IR (CH_2Cl_2 solution): ν_{CO} = 2010, 1925 cm^{-1} ; ν_{NO} = 1655 cm^{-1}).

Trinitrosyl(trimethylphosphine)manganese was prepared by the reaction of $\text{Mn}(\text{NO})_3\text{CO}^{49}$ and trimethylphosphine in xylene solution. After the reaction, the solvent was removed in vacuo. The green residue was sublimed at 50 °C to obtain dark green crystals. The infrared spectrum (pentane solution) showed nitrosyl bands at 1792 and 1680 cm^{-1} .

$\text{W}(\text{Cp})(\text{NO})_2\text{H}$ was kindly furnished by Prof. Legzdins of the University of British Columbia.

Chloro(η^5 -cyclopentadienyl)dinitrosylchromium, prepared by the method of Hoyano et al.,⁴⁷ melted and decomposed at 144–145 °C (lit. mp 144 °C).

Dinitrosyliron iodide dimer, prepared by the method of Haymore and Feltham,⁵⁰ melted at 95–96 °C and showed infrared absorptions (pentane solution) at 1810 and 1768 cm^{-1} (N–O stretching) (lit.⁵¹ IR (CCl_4 solution): ν_{NO} = 1810, 1769 cm^{-1}).

Dinitrosyliron bromide dimer was prepared by a method analogous to that used for dinitrosyliron iodide. The compound melted at 94–96 °C and showed infrared absorptions (pentane solution) at 1817 and

1767 cm^{-1} (lit.⁵¹ IR (CCl_4 solution): ν_{NO} = 1818.5, 1767 cm^{-1}).

Acknowledgment. This work was supported by the Division of Chemical Sciences, Office of Basic Energy Sciences, U.S. Department of Energy, under Contract No. W-7405-Eng-48. We are grateful to Drs. J. W. Koepke and W. B. Perry for assistance with some of the spectroscopic runs.
