Summary:

A Green River Formation oil shale sample was crushed and extracted with refluxing methanol. The extract was analyzed by high performance liquid chromatography in combination with graphite furnace atomic absorption detection (HPLC-GFAA). The HPLC-GFAA analysis provided evidence for the identification of methyl- and phenylarsonic acids and arsenate. Further unequivocal evidence for the methyl- and phenylarsonic acids identification was provided by reaction of HPLC purified fractions of the total extract with excess 3-methylcatechol followed by capillary column gas chromatography - electron impact mass spectrometry (GC-EIMS) analysis. The GC-EIMS analysis demonstrated the presence of methyl- and phenylarsonic acids as there five-coordinate organoarsenic catecholates. The significant implication for the biogeochemical origin of these organoarsenic compounds will be discussed.

The molecular characterization of organometallic compounds which occur as natural products in fossil fuel precursors is becoming a significant area to research due to the importance of these compounds in emerging synthetic fuel processes as well as their impact on the environment.<sup>2</sup>

Recently, we identified, using a high performance liquid chromatograph coupled to a graphite furnace atomic absorption spectrometer as an element-selective detector (HPLC-GFAA), methyl- and phenylarsonic acids as well as arsenate in oil shale retort waters.<sup>3</sup> We also have analyzed the shale oils produced by pyrolysis of oil shale and have found that the above-mentioned organoarsenic acids also occur, but in association with iron-containing macro-molecules with molecular weights in the range of 2,000-4,000 daltons.<sup>4a,b</sup>

In order to discern whether these compounds were natural products in the precursor of the shale oil and the retort waters or were formed during pyrolysis, we examined a Green River Formation oil shale. Oil shale from the Green River Formation is a fine-grained sedimentary rock, which contains appreciable quantities of organic material. It consists of three fractions - kerogen, bitumen and an inert substance. Kerogen and bitumen, which constitutes the organic material, generally are regarded as biogeochemical fossil products, emanating largely from lipid fractions of ancient algae and forming the ubiquitous oil source matrix in shales.<sup>5</sup>

The Green River Formation oil shale sample (10 g) was crushed and Soxhlet extracted with 500 mL of methanol for 48 hours. This effectively removed about 20% of the total arsenic contained in this oil

shale.<sup>6</sup> Following evaporation (25 mL) and filtration, we speciated the extract by HPLC, using a Dionex anion exchange column with 0.2M ammonium carbonate in water/methanol (85:15) as the eluting solvent. The arsenic compounds were detected via automatic GFAA analysis at 197.3 nm.<sup>2,3</sup>

Figure 1 gives the arsenic-specific chromatogram of the compounds we identified as methylarsonic acid, phenylarsonic acid, and arsenate, based on retention times of the authentic arsenic compounds.<sup>7</sup> An unknown neutral organoarsenic compound eluted with the solvent front.<sup>8</sup>

We recently have studied the reactions of methyl- and phenylarsonic acids with substituted catechols, and established that they provide five-coordinate organoarsenic catecholates.<sup>9</sup> Since many of these organoarsenic catecholates could be gas chromatographed on fused silica capillary columns and characterized by electron impact mass spectroscopy (GC-EIMS), we decided to apply this derivitization technique for the unequivocal identification of methyl- and phenylarsonic acids present in the oil shale extract.

The methanol extract was purified by preparative HPLC (the area from 22 to 35 min. was collected, see Figure 1), lyophilized and dissolved in benzene. To this solution was added excess 3-methylcatechol and the reaction mixture was refluxed for 5 h and worked up to remove the excess 3-methylcatechol. A concentrated sample was subjected to GC-EIMS analysis<sup>10</sup> to provide spectra and scan numbers (retention times) that were identical to the known samples of the 3-methylcatecholates of both methyl- and phenylarsonic acids.

Figure 2(A) shows the reconstructed ion chromatogram of the two standards, 3-methylcatecholates of methyl- and phenylarsonic acids, and

the single ion chromatograms show pertinent fragments of interest at  $m/e$  197 and 212 for the methylarsonic acid derivative (Figure 2 B,C) and  $m/e$  197 and 274 for the phenylarsonic acid derivative (Figure 2 B,D). Figure 3(C) shows the region we purified by HPLC containing the organoarsenic acids, which were derivatized, and the expanded sections of this chromatogram containing the organoarsenic catecholates with the important ions,  $m/e$  197, 212 and 274, clearly evident for the 3-methylcatecholates of methyl- (Figure 3 A) and phenylarsonic (Figure 3 B) acids. Additionally, the inorganic anion, arsenate ( $AsO_4^{3-}$ ), was verified in a similar fashion (preparative HPLC of the region from 35.5-41 min) by preparation of the tris(trimethylsilyl-) derivative of the ammonium salt of arsenate and analyzing the purified extract by GC-EIMS for ions at  $m/e$  207, 343, and 358.<sup>11</sup> The organoarsenic compound(s) that elutes with the solvent front (Figure 1) has not been as yet identified and further work is in progress to verify its structure.<sup>8</sup>

We believe these identifications of the organoarsenic acids to be the first such molecular characterizations of trace organometallic compounds to be reported for any fossil fuel precursors and initiates the area of organometallic geochemistry, a field that has hithertofore been totally unexplored.

The implications are that these organoarsenic acids are natural products and hence have a biogeochemical origin in the oil shale taphonomy process. It is also interesting to note that no examples of biophenylation have been reported, whereas biomethylation of arsenic compounds is a well known reaction.<sup>12</sup> How the phenylarsonic acid forms will have to be answered with the examination of precursors to the oil

shale such as freshwater marine algal mats as well as other biogeochemical samples.

Finally, the fact that these organoarsenic acids are released upon oil shale pyrolysis has important implications in the various synthetic fuel processes where the role of organometallic compounds in poisoning process catalysts and contribute to environmental problems is paramount.
