ABSTRACT

Water, weather, and climate affect everyone. However, their impacts on various communities can be very different based on who has access to essential services and environmental knowledge. Structural discrimination, including racism and other forms of privileging and exclusion, affects people's lives and health, with ripples across all sectors of society. In the United States, the need to equitably provide weather, water, and climate services is uplifted by the Justice40 Initiative (Executive Order 14008), which mandates 40% of the benefits of certain federal climate and clean energy investments flow to disadvantaged communities. To effectively provide such services while centering equity, systemic reform is required. Reform is imperative given increasing weather-related disasters, public health impacts of climate change, and disparities in infrastructure, vulnerabilities, and outcomes. It is imperative that those with positional authority and resources manifest responsibility through (1) recognition, inclusion, and prioritization of community exper-

tise; (2) the development of a stronger and more representative and equitable workforce; (3) communication about climate risk in equitable, relevant, timely, and culturally responsive ways; and (4) the development and implementation of new models of relationships between communities and the academic sector.

Keywords: Justice40, climate justice, weather, water, environmental justice, climate change

INTRODUCTION

IN AN INTERVIEW AT COP26 (26th UN Climate Change Conference of the Parties), when asked what climate change looked and felt like, Brianna Fruean, a young Pacific Islander who advocates for climate justice on behalf of her fellow Samoans, described the smell of thick mud she had to wade through and shovel out of houses after a flood.¹ The multiple human dimensions of climate change are inescapable. *Anthropogenic climate change* is the disruptive response of our planet's weather and water cycles to human activity and development—largely emissions and land surface changes—that directly and indirectly affect energy balance in the Earth System.

Yet, what that definition does not name are the tangible and inequitably distributed consequences of this anthropogenic problem. *Climate injustice* refers to the role of structural discrimination in saddling communities of color and low-income communities with disproportionately high burdens of the harmful risks and impacts of climate change.² In the United States and around the world, when climate disasters occur—whether extreme weather leading to floods, tornadoes, hurricanes, fires, or droughts—black, Indigenous, and other people of color (BIPOC) and frontline communities are disproportionately vulnerable to environmental and climate injustices.^{3–10}

Structural racism and segregation are intrinsically linked to this vulnerability.¹¹ Although no one is insulated from the climate crisis, BIPOC communities are most at risk. As equity gaps increase, skewed vulnerabilities and repeated disasters can destabilize families and communities for generations. For example, high concentrations of BIPOC communities live in flood-prone and/or water-poor areas.^{12,13} Racist U.S. Federal urban planning policies, including redlining, have resulted in a lack of trees and parks in areas of BIPOC communities, contributing to urban heat islands and higher mortality rates during heat waves.^{14,15}

The nation's weather, water, and climate services, such as disaster risk management, community outreach, water resource assessment, swift and accurate information dissemination, hazard monitoring, education, workforce preparation, and more, play a key role in communities' well-being. Yet BIPOC communities often experience delays in response to climate emergencies and receive fewer resources for recovery,^{4,16,17} which can cascade into disasters of greater and longer magnitude, and intersect with other crises. For example, in Louisiana's "Cancer Alley," delayed emergency response in the wake of Hurricane Ida further increased residents' risk of exposure to carcinogenic materials and increased transmission of coronavirus through seeking the same limited shelter accommodations.¹⁸

In the southeast United States, the National Weather Service (NWS) radar networks leave wide swaths of black communities without radar coverage.¹⁹ During and after Hurricane Katrina and other events, inequitable and racist policies and practices associated with risk management, service management, disaster response, and redevelopment contributed to reduced community resiliency and entrenching of health and wealth disparities through the loss of home, family, networks, and educational access and reform.¹⁰ Loss of relationship to place due to migration and forced displacement can cascade into a loss of culture, sovereignty (particularly for Indigenous communities), and autonomy, and into threats to civil liberties.^{1,20}

Another dimension of this problem is that there is little representation from BIPOC communities in the geosciences.^{21–23} Less than 10% of National Oceanic and Atmospheric Administration (NOAA's) senior executive service members or NWS employees are from BIPOC communities, and 91% of NWS meteorologists and hydrologists are white based on March 2022 data from the NWS Equal Opportunity and Diversity Management Division. In contrast, over 42% of the U.S. population is nonwhite.²⁴

This inadequate representation of BIPOC scientists means there is a lack of workers who understand the issues most relevant to BIPOC communities, which cascades into the development of inequitable policies, services, outreach, planning, and resource deployments that devalue and deprioritize the needs of BIPOC communities.^{25–27} These concerns are further heightened given the strengths of Indigenous and local knowl-

edges for climate adaptation and resilience, and for safeguarding biodiversity.²⁸ Both the Intergovernmental Panel on Climate Change²⁹ and the White House³⁰ have affirmed that Indigenous peoples hold diverse Science, Technology, Engineering, and Mathematics (STEM) knowledges that can guide natural resources stewardship, water management, fire management, soil and water health, disaster response, and decision making.

It is critical to center equity if we are going to address intersecting climate, environmental, and social justice crises. Although these topics and related issues have been highlighted for decades, there has been insufficient action. In light of Executive Order 14008 and the Justice40 Initiative,^{31,32} this comment is intended as a resource and call to action for the services and science community.

“THE FIERCE URGENCY OF NOW”

Given the current and future importance of the nation's weather, water, and climate services to the well-being of communities, it is imperative to apply an equity and justice framework to ensure these services serve everyone. The moral and public health imperatives of the climate crisis, and the continued human, social, and environmental costs of inaction, drive, to paraphrase Dr. Martin Luther King, Jr.,³³ a “fierce urgency of now” around equitable and just action. We have a mandate to accelerate society's response to climate change, while simultaneously moving beyond good intentions and toward action.

The nation's services have an essential role to play in dismantling discriminatory structures and the building of new systems, informed by community knowledge. Without urgent and targeted action in response to the accelerating rate of climate change and extreme weather

events, we will continue to see a widening of disparities, and we will continue to see inadequate, unequal, and unjust responses. The *No Time for Silence* call to action³⁴ cast down a gauntlet for change and laid out a road map to move beyond recognizing the injustices, to taking specific actions, and has been endorsed by professional geoscience societies and departments representing >60,000 geoscientists.

CENTERING EQUITY, NOT JUST DIVERSITY OR INCLUSION

The nation's weather, water, and climate services need equity-minded leaders who have resources, positional authority, and institutional agency to heed and respond to multiple calls for change.^{34–37} Correcting the effects of systemic discrimination requires changing cultures and sharing power, not solely increasing diversity that often results in bringing BIPOC individuals into hostile environments. Equity must be built in from the outset by identifying clear indicators and metrics with which to evaluate justice and equity outcomes^{38–40} (i.e., who will benefit and how, who will be included in decision making).

Environmental justice efforts must go beyond identifying disproportionate impacts, and directly engage with why certain communities were discriminated against.⁴¹ Equity in and of itself cannot be adequately addressed

without recognizing and addressing systemic racism as a root cause of environmental inequities, and go beyond colorblind ideological frameworks and explicitly address institutionalized racism.⁴²

Smart and intentional action planning can move levers of change in transformative ways. If the issues are taken to heart by forward-thinking leaders across the policy-making, corporate, academic, philanthropic, and non-profit sectors, major steps can be taken to address these issues in the geosciences in the next decade. Leaders can drive institutional change now by modifying practices; bylaws; and local, state, and federal policies, to support more inclusive, equitable, and just organizations.

ACTIONS TO ADVANCE EQUITY IN THE NATION'S WEATHER, WATER, AND CLIMATE SERVICES

Intentional and deliberate progress toward an equity framework will require leaders to prioritize four action areas: (1) recognizing and prioritizing community expertise; (2) building a stronger and more equitable workforce; (3) communicating about climate risk in equitable, timely, and culturally responsive ways; and (4) developing new models of relationship between communities and academia. Our goal is to identify current shortcomings and propose strategies to improve implementation.

Recognizing and prioritizing community expertise

Communities need to be key partners in how scientists and policy-makers respond and adapt to weather, water, and climate issues, with a seat at the table.^{38,43} A close and authentic relationship between communities and services will facilitate effective and sustainable solutions that are culturally sensitive, timely, and relevant. Authenticity requires from the outset a sustained commitment to relational accountability and an in-person approach grounded in equity; justice; reciprocity; mutual trust; respect; and sharing of information, resources, and power.

Effective partnerships should respect the realities of communities, with a social, historical, and present-day trauma-informed context. Services and justice in BIPOC communities have been adversely impacted by institutional barriers and generations of disempowerment, which continue to limit all aspects of physical, mental, ecological, economic, and social health, as well as cultural life and community resilience. Research and engagement with communities need to be reimagined given that many BIPOC individuals, families, and communities—including people who are immigrants or undocumented—have

significant reasons to distrust government or higher education entities,^{3,44} with a desire to avoid continuation of exploitation. This presents a difficult, yet not insurmountable challenge.

Although Western STEM and policy institutions are increasingly recognizing these exploitative outcomes and pledged to be more equitable and inclusive, much work is needed. Support is needed for communities to have the space, time, and resources to organize the involvement of their knowledge keepers, scientists, and knowledge systems in science and policy. This includes crafting inclusion in ways that reflect what it takes for communities to mobilize.

Institutions need to recognize the diverse forms of knowledge that communities may choose to invoke in particular circumstances. Indigenous people have used traditional knowledge systems to not only track environmental change over time, but also to take action to address climate change through efforts such as community-based planning for resettlement, the rebuilding of institutions, and actions to engage in self-determination and self-governance.⁴⁰ In island communities, local and Indigenous knowledge systems serve critical roles in climate resilience, including by providing food security and architectural integrity in the face of increasing hurricane activity.^{45–47}

Communities need updated time-relevant information on potential risks and available services to effectively plan and manage impacts, and should be included, non-exploitably, and in ways that build community capacity, in determining what those services are. Community-based assessments are effective in determining what services are available, what is needed, and how they should be provided.

Direct payment for community member service on boards and committees are places where relationships can start to form and become long standing, in the same way that scientists' and policy-makers' salaries empower them to serve. Support is needed to ensure there is continuity of relationship, resources to complete the work, and a focus on building community capacity and centering community priorities.

In addition to providing resources, entities that provide services must update their processes to be more supportive of communities. They must share updates and

results through briefings and communications to community members, and create agreements on governance and who holds authority throughout processes (e.g., establishing questions, collecting data, accessing findings, receiving credit, determining intellectual property rights, and guaranteeing meaningful outputs for communities).

Transparency and accountability mechanisms should be incorporated throughout, to ensure there are opportunities for determining what constitutes healthy and ethical interactions, and shifting course. A central goal should be rebuilding practices, rules, and organizational cultures so that communities are involved nonexploitably from the outset. For services, this includes planning, education, research, operations, communications, and infrastructure development.

Building a stronger and more equitable workforce

Equity indicators provide evidence of high rates of discrimination in geoscience training and workforce settings.^{37,48–51} Exclusion from educational opportunities, workforce rights, policy development, and leadership and decision-making roles perpetuates systemic racism, and ultimately protects the exclusionary nature of the status quo. This cycle is fundamental to the entrenchment of systemic racism in the academic and nonacademic workforce, and in individual institutions and organizations. As the climate crisis grows, current deficits in diversity and retention in the workforce and academy will continue to impede the development of effective and relevant weather, water, and climate services, priorities, and policies.

Equity in the workforce. Professionally, the representation of people of color in the federal STEM workforce lags behind the civilian workforce, which in turn significantly lags behind the nation's demographic profile.^{20,47} In the atmospheric science and meteorological workforce, there are ~96,000 people working as post-secondary teachers, faculty, and instructors, yet fewer than 10 black full professors in atmospheric sciences and meteorology, and less than 15 in tenure-track positions.^{20,47} The private sector represents the fastest segment of growth in the weather, water, and climate enterprise and also has low levels of diversity.^{23,52}

Thus there is a major need for representation in the nonacademic and academic workforce and in leadership

that reflects the nation's demographics. Some companies work to directly recruit in and provide scholarship support to BIPOC students, minority-serving institutions (MSIs), and/or to programs for diverse workforce development at colleges and universities. Others use an equity lens to evaluate human resource policies on hiring and assessment, drawing on rubrics, and to evaluate whether applicants have meaningful engagement and experience with equity work.

Organizations and companies serious about centering equity and justice work should affirm their rationale for making these and other changes (e.g., to better the institution, to improve services, and/or to correct past unfair practices) and collaborate with community experts, whom they should recruit as employees, advisory board members, and consultants. In addition to necessitating the involvement of community experts, initiatives benefit from federal oversight to ensure data and programs are reliable and adherent to standards.

A recent RAND Corporation collaboration focused on reducing vulnerability while retaining resilience and involved company scientists partnering on a community-based participatory research project to catalog chemicals in maritime industrial areas and the risk of release in severe weather events. On issues that matter to impacted communities, companies and organizations should support advocacy to policy-makers and translate findings into action.

Recognizing that centering equity is challenging, strategies and programs should be evaluated to determine whether they are "easy," or equity-avoidant strategies that are economically expedient, or whether they are in fact meaningful. Planning must address both immediate needs and long-term solutions, and consider cumulative long-term impacts on communities. There are opportunities to draw on principles of Indigeneity and focus on integrative life cycle analyses, which address water, climate, ecological, health, and equity impacts over multiple timescales, instead of only immediate costs.

Equity in education and training. Youth and students are future planners and climate leaders. From curiosity in the geosciences and STEM, a passion for addressing climate injustice and community engagement, to being a key vector for scientific innovation,^{4,53} BIPOC youth and students are desperately necessary to tackle the climate crisis. There are opportunities to listen and to include them in designing to build their own capacity, and the capacity of their communities, in ways that are forward looking. There is a pressing need for mentorship from people who share values with and believe in them and are grounded in strengths-based, not deficit-based, models, and a need for diverse pathways to scientific and policy leadership positions.

However, the geosciences remain persistently segregated due to issues with culture.^{21,37,48,51} In 2018, only 207 black students from a total pool of 7431 students graduated with undergraduate degrees in earth, atmospheric, and ocean sciences, and this number had barely doubled over the preceding decade.^{21,23,30,50} The institutions making significant impact are few.^{23,49,50,54} Given the culture of geoscience, trainees and more senior participants from marginalized groups continue to face hostility, isolation, and other barriers.^{55–59}

Such experiences impact retention and recruitment by causing continual damage to BIPOC people's mental and physical health.⁶⁰ Higher education needs to replace traditional models that demand that individuals persist in inhospitable or hostile environments, or leave, with redesigned environments and revised policies and practices that make spaces, partnerships, and institutions more welcoming and equitable, so all can thrive. Changes in practices and policies in the academy are also needed, including around admissions, hiring,⁶¹ tenure, and promotion, retention, paper reviews,⁶² funding,⁶³ awards,^{64,65}

social norms, and other aspects of traditional academia. Such changes will have a cascade of downstream effects, given the role of higher education in transmitting culture.

Geosciences education and research need to focus on redressing colonial relationships that are strongly expressed in science.^{66,67} Some models show that change is possible.^{37,54} MSIs have made headway in equity and access issues that impact undergraduate and graduate education. Howard University in partnership with NOAA produced 60% of all African American atmospheric sciences PhDs in the past decade with 98% in the workforce, whereas top 10 programs produced fewer than 10 in the past 25 years.^{23,36,50,54}

Other examples of effective geoscience programs include NOAA's José E. Serrano Education Partnership Program with MSIs,^{68,69} responsible for training graduates who have become 37% of the NOAA minority science hires from 2000 to 2005; the Center for Diverse Leadership in Science at UCLA,^{70–72} which takes a human-centered relational approach grounded in equity, and works to build power in marginalized people, groups, and communities, while taking an interdisciplinary, intergenerational, and ecological approach, and has supported >200 fellows including students, community practitioners, and faculty fellows, and is effective at diversifying the geosciences workforce; and the Significant Opportunities in Atmospheric Research and Science program at University Corporation for Atmospheric Research that through effective mentored research experiences is significantly broadening graduate school participation of historically underrepresented groups in the geosciences.^{67,73}

Major increases in investment for effective strategies have recently been proposed to broaden participation in STEM and advance systemic change.^{68,74} Such an approach could be targeted to develop equity-driven centers focused on basic and applied climate, environment, and sustainability research, education, and partnerships.

Another key area for higher education reform relates to the development of curricula on climate and environmental justice and ethics, and how they are related to the geosciences. Topics could include resource extraction, land dispossession, settler colonialism, structural racism, pollution, climate change, extreme weather events, and their inter-relationships. Within these materials, emphasizing traditional knowledge systems and sustainability in Western and Indigenous contexts will enable this country's next generation of students and leaders to have broader critical awareness.

Communicating climate risk: equitable, timely, and culturally responsive

The nation's weather, water, and climate services have the responsibility of providing equitable access to accurate and up-to-date information and resources for all, regardless of language or documentation status, with equitable rules and mechanisms for distributing resources. Greater federal investment is needed to assist communities with climate preparedness and resiliency planning, and to support agencies producing knowledge around equitable and culturally responsive provision of services.

Government agencies must provide accessible tools and products; to ensure community confidence in these resources, they must also support community expertise and ambassadorship in the design and deployment of climate services, and offer opportunities for community evaluation and feedback. It is critical that agency workforces listen to community leaders and build relationships between different and diverse communities.

Risk and crisis communication also necessitate connection and partnership with communities. For example, communities may speak different languages, or dialects of a language, which can impact the ability of community members to fully participate—including being reached with emergency alerts—unless paid translators are provided.⁴

Language accessibility cannot be sustained by communities alone: government agencies should fund and develop multilingual centers that not only produce effective translations for life-saving hazards, but also guarantee connections with community partners. Key documents representing community voices and leadership show that current efforts are not enough, such as was highlighted in recent recommendations on environmental and climate justice by the White House Environmental Justice Advisory Council.³²

Poor infrastructure and information availability are major impediments that lead to disproportionate impacts from environmental disasters in underserved communities. To ensure equitable services, harm reduction, mitigation, and adaptation need to be emphasized, with granular information at the level of neighborhoods, localities, communities, and tribal nations. Verification of critical services should be expanded to understand who is impacted, what the impacts are, what languages are relevant, how information is received, and who benefits from existing and new resources. Given fragmentation of existing services across different agencies, new interagency coordination is needed among services, with equity centered from the outset. Additional capacity is severely needed.

The United States Geological Survey (USGS) Climate Adaptation Science Centers (CASCs), a partnership-driven program wherein scientists collaborate with natural and cultural resource managers to combat climate change, and the NOAA Regional Integrated Sciences and Assessments (RISAs) programs, which supports applied and co-developed research partnerships with communities to combat climate change, are examples. USGS CASCs and NOAA RISAs emphasize transferring science and data to local communities, and additional regional and local weather services capacity such as these models are critical to effectively addressing inequities.

Collection and assessment of demographic data are needed to understand who becomes ill or dies because of extreme events, climate change, and pollution; what health and warning information they had; and whether they had access to harm mitigation resources (e.g., local cooling centers during extreme heat). When collecting demographic data, strategies in counting marginalized populations should be re-evaluated.^{6,75} Overall, a joint effort of physical, social, and health scientists is needed to study and understand disparate and inequitable climate change vulnerabilities and impacts.^{70,76} National and regional climate assessments should more thoroughly present the unequally distributed impacts on different demographics.

Alternative models of relationship: communities and the academic sector

Educational institutions should revisit what it means to be a geoscientist, what valued education and research look like, and the many roles geoscientists can have with communities and employers. Institutions have the opportunity to reframe and build a professional culture in

which working with local communities and a science career are synergistic, not exclusive as traditionally framed in STEM, and can provide deep long-term investments to build and sustain community integration. Departments and universities should support training and practice in applied opportunities, including community-based work.

One example can be found in Science Shops, crafted in response to concerns raised by the popular education and participatory action research movements in the global south, which coordinates community-engaged research that centers the needs of community-based organizations that brings in university-based scientists and students.^{71,77} In American universities, it has demonstrated both its ability to channel community voice into research agendas and potential for catalyzing institutional culture change.⁷⁸ Programs such as American Geophysical Union's Thriving Earth Exchange train volunteer scientists to work in authentic ways in support of community environmental projects.⁷⁹

Highlighting a breadth of career options and role models, and fostering multiple career pathways, would help future scientists and science fields as a whole. Institutions need to understand the sacrifices most programs ask of students for their training (e.g., separation from home communities, support structures, and relationship to place), which can cause harm to people from structurally excluded groups, particularly Indigenous students. Much can be learned from nontraditional models utilized by academic experts, including extension programs, such as used in the department of environmental science at the University of Arizona by Prof. Karletta Chief,⁸⁰ and other frameworks such as that developed by Prof. Bryan Brayboy at Arizona State University centered on empowering, engaging, and enhancing communities.^{81–83}

Finally, funding opportunities should require that research is framed using an equity lens, with explicitly developed action plans to allow for self-determined rather than exploitative community engagement.⁵⁸ For community-based work, research planning should include discussions of listening and engagement sessions with partners, and review processes should include information on protocols and consents, in the model of institutional review board protocols and similar structures in many tribal organizations. Social vulnerabilities need to be explicitly incorporated in resilience research, policy, and planning.⁷⁰

CONCLUSION

The necessary work of moving from good intentions to sustained action lies ahead. Although past efforts have often been piecemeal, incremental, and not maintainable over time, the intersections of climate change with inequality demand that equity, as well as justice and inclusion, be centered across the board. All status-quo processes, systems, and procedures must be examined and challenged. Institutional leaders must adopt an equity-centered mindset to facilitate the implementation of effective, inclusive, and sustainable solutions that will save lives. The necessary changes are reflected in recent calls to change policy to achieve systemic reform, to share power and information, and to ensure equitable access to networks and resources.

Leaders with positional authority and resources must manifest responsibility through action in the four areas already described: (1) recognizing, integrating, and prioritizing community expertise; (2) building a stronger and more equitable workforce; (3) communicating about climate risk in equitable, relevant, timely, and culturally responsive ways; and (4) developing new models of relationship between communities and the academic sector. Collectively, these actions will help to ensure there is equity in the nation's weather, climate, and water services, for current and future generations.
