The CP asymmetry in $b \rightarrow s\gamma$ is extensively studied theoretically both in the SM and beyond [110]. According to the SM, the CP asymmetry in $b \rightarrow s\gamma$ is smaller than 1%, but some non-SM models allow significantly larger CP asymmetry ($\sim 10\%$) without altering the inclusive branching fraction. The current world average is $A_{CP} = -0.012 \pm 0.028$, again dominated by BaBar and Belle [111]. In addition to the CP asymmetry, BaBar also measured the isospin asymmetry $\Delta_{0-} = 0.06 \pm 0.17$ in $b \rightarrow s\gamma$ by measuring the companion B with full reconstruction in the hadronic decay modes [112].

In addition, all three experiments have measured the inclusive photon energy spectrum for $b \rightarrow s\gamma$, and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy ($1.7 < E_\gamma < 2.8 \text{ GeV}$) [106]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element V_{ub} .

Additional information on FCNC processes can be obtained from $B \rightarrow X_s\ell^+\ell^-$ decays, which are mediated by electroweak penguin and W -box diagrams. Their branching fractions have been measured by Belle [113], BaBar [114], and CDF [115]. Average branching fractions over all charged and neutral modes have been determined from BaBar and Belle data for $B \rightarrow K\ell^+\ell^-$: $(0.45 \pm 0.04) \times 10^{-6}$ and for $B \rightarrow K^*(892)\ell^+\ell^-$: $(1.08 \pm 0.11) \times 10^{-6}$, consistent with the

Meson Particle Listings

b-flavored hadrons

SM expectation. Both experiments also measured the branching fractions for inclusive $B \rightarrow X_s \ell^+ \ell^-$ decays [116], with an average of $(3.66_{-0.77}^{+0.76}) \times 10^{-6}$ [117].

Finally the decays $B_{(s)}^0 \rightarrow e^+ e^-$ and $\mu^+ \mu^-$ are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to $(\tan \beta)^6$. CDF and D0 as well as the *B*-factory experiments have obtained results that exclude a portion of the region allowed by SUSY models. The most stringent limits in these modes are obtained by CDF. The limits in the $\mu^+ \mu^-$ mode are: $< 5.8 \times 10^{-8}$ and $< 1.8 \times 10^{-8}$, respectively, for B_s^0 and B^0 [118]. For the B_s^0 mode, the result is just one order of magnitude above SM predictions [119]. The limits for the $e^+ e^-$ modes are: $< 2.8 \times 10^{-7}$ and $< 8.3 \times 10^{-8}$, respectively, for B_s^0 and B^0 [120]. There are also limits for lepton flavor-violating channels $B_{(s)}^0 \rightarrow e^+ \mu^-$, which are around 10^{-7} [120].

Summary and Outlook: The study of *B* mesons continues to be one of the most productive fields in particle physics. With the two asymmetric *B*-factory experiments Belle and BaBar, we now have a combined data sample of well over 1 ab^{-1} . *CP* violation has been firmly established in many decays of *B* mesons. Evidence for direct *CP* violation has been observed. Many rare decays such as hadronic $b \rightarrow u$ transitions and $b \rightarrow s(d)$ penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the *B*-factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about 7 fb^{-1} , which is the equivalent of nearly 10^{12} *b*-hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on B_s^0 and *b*-flavored baryons, in which a first major step has been the determination of the B_s^0 oscillation frequency.

In addition, the LHC will soon produce huge samples of *b*-hadrons and consequently will enable us to test the CKM paradigm with unprecedented precision. There are also proposals for higher-luminosity *B* Factories at KEK and Frascati in order to increase the samples to $\sim 50 \text{ ab}^{-1}$, which will make it possible to explore the indirect evidence of new physics beyond the SM in the heavy-flavor particles (*b*, *c*, and τ), in a way that is complementary to the LHC.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and *CP*-violating phenomena.

A NOTE ON HFAG ACTIVITIES

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the b -flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ, LEP, and SLD.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has five subgroups providing averages for b -hadron lifetimes and B -oscillation parameters, CP -violation measurements, semileptonic parameters, rare branching fractions, and b -hadron decays to charm. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

<http://www.slac.stanford.edu/xorg/hfag> and also at
<http://belle.kek.jp/mirror/hfag> (KEK mirror site).

 B^\pm

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the B^\pm/B^0 ADMIXTURE and $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

 B^\pm MASS

The fit uses m_{B^+} , ($m_{B^0} - m_{B^+}$), and m_{B^0} to determine m_{B^+} , m_{B^0} , and the mass difference.

- ¹ Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decays.
² CSORNA 00 uses fully reconstructed $526 B^+ \rightarrow J/\psi(\ell^+) K^+$ events and invariant masses without beam constraint.
³ ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
⁴ Found using fully reconstructed decays with $J/\psi(1S)$. ALBRECHT 87D assume $m_{\Upsilon(4S)} = 10577$ MeV.

 B^\pm MEAN LIFE

See $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- ¹ Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
² Measurement performed using an inclusive reconstruction and B flavor identification technique.
³ Measured mean life using fully reconstructed decays.
⁴ Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
⁵ Data analyzed using $D/D^* \ell X$ event vertices.
⁶ Data analyzed using charge of secondary vertex.
⁷ ABREU 95Q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.
⁸ Data analyzed using vertex-charge technique to tag B charge.
⁹ Combined result of $D/D^* \ell X$ analysis and fully reconstructed B analysis.
¹⁰ Combined ABREU 95Q and ADAM 95 result.

 B^+ DECAY MODES

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\bar{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Semileptonic and leptonic modes		
Γ_1 $\ell^+ \nu_\ell$ anything	[a] (10.99 ± 0.28) %

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] An $CP(\pm 1)$ indicates the $CP=+1$ and $CP=-1$ eigenstates of the D^0 - \bar{D}^0 system.

[c] D denotes D^0 or \bar{D}^0 .

[d] $D_{CP^\pm}^{*0}$ decays into $D^0 \pi^0$ with the D^0 reconstructed in CP -even eigenstates $K^+ K^-$ and $\pi^+ \pi^-$.

[e] \bar{D}^{*+} represents an excited state with mass $2.2 < M < 2.8$ GeV/ c^2 .

[f] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[g] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.

[h] $(\bar{\Lambda}_c^- p)_s$ denotes a low-mass enhancement near 3.35 GeV/ c^2 .

 B^+ BRANCHING RATIOS

$\Gamma(\ell^+ \nu_e \text{ anything}) / \Gamma_{\text{total}}$ "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

11.15 \pm 0.26 \pm 0.41 ⁴ OKABE 05 BELL Repl. by URQUIJO 07

10.1 \pm 1.8 \pm 1.5 ATHANAS 94 CLE2 Sup. by ARTUSO 97

¹ URQUIJO 07 report a measurement of $(10.34 \pm 0.23 \pm 0.25)\%$ for the partial branching fraction of $B^+ \rightarrow e^+ \nu_e X_C$ decay with electron energy above 0.6 GeV. We converted the result to $B^+ \rightarrow e^+ \nu_e X$ branching fraction.

² The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

³ ARTUSO 97 uses partial reconstruction of $B \rightarrow D^* \ell \nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96b $(0.1049 \pm 0.0017 \pm 0.0043)$.

⁴ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements. $\ell = e$ or μ , not sum over e and μ modes.

0.070 ± 0.018 ± 0.014	9 ANTREASYAN	90B CBAL	$e^+e^- \rightarrow \Upsilon(4S)$

¹ Measured using the dependence of $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$ decay differential rate and the form factor description by CAPRINI 98.

² Simultaneous measurements of both $B^0 \rightarrow D^*(2010)^- \ell \nu$ and $B^+ \rightarrow \bar{D}^*(2007)^0 \ell \nu$.

³ ALBRECHT 92c reports $0.058 \pm 0.014 \pm 0.013$. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \rightarrow K^- \pi^+)$. Assumes equal production of $B^0\bar{B}^0$ and B^+B^- at the $\Upsilon(4S)$.

⁴ Uses a fully reconstructed B meson as a tag on the recoil side.

⁵ The results are based on the same analysis and data sample reported in ADAM 03.

⁶ BARISH 95 use $B(D^0 \rightarrow K^- \pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$ and $B(D^{*0} \rightarrow D^0 \pi^0) = (63.6 \pm 2.3 \pm 3.3)\%$.

⁷ Combining $\bar{D}^{*0} \ell^+ \nu_\ell$ and $\bar{D}^{*0} \ell^+ \nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+) / \Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb} , they measure $V_1, A_1,$ and A_2 , the three form factors for the $D^* \ell \nu_\ell$ decay, where results are slightly dependent on model assumptions.

⁸ Assumes equal production of $B^0\bar{B}^0$ and B^+B^- at the $\Upsilon(4S)$. Uncorrected for D and D^* branching ratio assumptions.

⁹ ANTREASYAN 90b is average over B and $\bar{D}^*(2010)$ charge states.

< 18	90	⁷ BUSKULIC	95 ALEP	$e^+ e^- \rightarrow Z$

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

² Requires one reconstructed semileptonic B decay $B^- \rightarrow D^0 \ell^- \bar{\nu}_\ell X$ in the recoil.

³ The analysis is based on a sample of events with one fully reconstructed tag B in a hadronic decay mode $B^- \rightarrow D^{(*)0} X^-$.

⁴ The energy-flow and b -tagging algorithms were used.

⁵ ACCIARRI 97F uses missing-energy technique and $f(b \rightarrow B^-) = (38.2 \pm 2.5)\%$.

⁶ ALBRECHT 95D uses full reconstruction of one B decay as tag.

⁷ BUSKULIC 95 uses same missing-energy technique as in $\bar{B} \rightarrow \tau^+ \nu_\tau X$, but analysis is restricted to endpoint region of missing-energy distribution.

$1.9 \pm 1.0 \pm 0.6$	7	9 ALBRECHT	88K	ARG $e^+e^- \rightarrow \Upsilon(4S)$

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
² ABULENCIA 06J reports $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{total}] / [B(B^0 \rightarrow D^- \pi^+)] = 1.97 \pm 0.10 \pm 0.21$ which we multiply by our best value $B(B^0 \rightarrow D^- \pi^+) = (2.68 \pm 0.13) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³ Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.

⁴ AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of B^0 and B^+ , which is not included here.

⁵ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses the Mark III branching fractions for the D .

⁶ BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

⁷ AUBERT,B 04P reports $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{total}] \times [B(D^0 \rightarrow K^- \pi^+)] = (1.846 \pm 0.032 \pm 0.097) \times 10^{-4}$ which we divide by our best value $B(D^0 \rightarrow K^- \pi^+) = (3.89 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁸ ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II absolute $B(D^0 \rightarrow K^- \pi^+)$ and the PDG 1992 $B(D^0 \rightarrow K^- \pi^+ \pi^0)/B(D^0 \rightarrow K^- \pi^+)$ and $B(D^0 \rightarrow K^- 2\pi^+ \pi^-)/B(D^0 \rightarrow K^- \pi^+)$.

⁹ ALBRECHT 88K assumes $B^0 \bar{B}^0 : B^+ B^-$ ratio is 45:55. Superseded by ALBRECHT 90J.

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.² AUBERT 08A1 reports $(0.70 \pm 0.10^{+0.12}_{-0.10}) \times 10^{-6}$ for $B(B^+ \rightarrow \chi_{c0}K^+) \times B(\chi_{c0} \rightarrow \pi^+\pi^-)$. We compute $B(B^+ \rightarrow \chi_{c0}K^+)$ using the PDG value $B(\chi_{c0} \rightarrow \pi\pi) = (8.4 \pm 0.4) \times 10^{-3}$ and 2/3 for the $\pi^+\pi^-$ fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.³ Measured in the $B^+ \rightarrow K^+K^-K^+$ decay.⁴ AUBERT,BE 06M reports $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{total}] \times [B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S))] = (6.1 \pm 2.6 \pm 1.1) \times 10^{-6}$ which we divide by our best value $B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S)) = (1.16 \pm 0.08) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. The significance of the observed signal is 2.4 σ .⁵ WICHT 08 reports $[\Gamma(B^+ \rightarrow \chi_{c0}(1P)K^+)/\Gamma_{total}] \times [B(\chi_{c0}(1P) \rightarrow \gamma\gamma)] < 0.11 \times 10^{-6}$ which we divide by our best value $B(\chi_{c0}(1P) \rightarrow \gamma\gamma) = 2.22 \times 10^{-4}$.⁶ Perform measurements of absolute branching fractions using a missing mass technique.⁷ AUBERT,B 05N reports $(0.66 \pm 0.22 \pm 0.08) \times 10^{-6}$ for $B(B^+ \rightarrow \chi_{c0}^0K^+) \times B(\chi_{c0}^0 \rightarrow \pi^+\pi^-)$. We compute $B(B^+ \rightarrow \chi_{c0}^0K^+)$ using the PDG value $B(\chi_{c0}^0 \rightarrow \pi^+\pi^-) = (7.1 \pm 0.6) \times 10^{-3}$ and 2/3 for the $\pi^+\pi^-$ fraction.⁸ The measurement performed using decay channels $\chi_{c0}^0 \rightarrow \pi^+\pi^-$ and $\chi_{c0}^0 \rightarrow K^+K^-$. The ratio of the branching ratios for these channels is found to be consistent with world average.⁹ AUBERT 04P reports $B(B^+ \rightarrow \chi_{c0}^0K^+) \times B(\chi_{c0}^0 \rightarrow \pi^+\pi^-) = (1.5 \pm 0.4 \pm 0.1) \times 10^{-6}$ and used PDG value of $B(\chi_{c0}^0 \rightarrow \pi\pi) = (7.4 \pm 0.8) \times 10^{-3}$ and Clebsh-Gordan coefficient to compute $B(B^\pm \rightarrow \chi_{c0}^0K^+)$.¹⁰ ABE 02b measures the ratio of $B(B^+ \rightarrow \chi_{c0}^0K^+)/B(B^+ \rightarrow J/\psi(1S)K^+) = 0.60 \pm 0.21 - 0.18 \pm 0.05 \pm 0.08$, where the third error is due to the uncertainty in the $B(\chi_{c0}^0 \rightarrow \pi^+\pi^-)$, and uses $B(B^+ \rightarrow J/\psi(1S)K^+) = (10.0 \pm 1.0) \times 10^{-4}$ to obtain the result.¹¹ EDWARDS 01 assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$. The correlated uncertainties (28.3%) from $B(J/\psi(1S) \rightarrow \gamma\eta_c)$ in those modes have been accounted for. $\Gamma(\chi_{c0}K^*(892^+))/\Gamma_{total}$ Γ_{212}/Γ

< 680	90	ALBRECHT	91B ARG	$e^+e^- \rightarrow \Upsilon(4S)$	

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
² AUBERT 08A1 reports $(1.85 \pm 0.41^{+0.61}_{-0.29}) \times 10^{-6}$ for $B(B^+ \rightarrow K_S^0(1430)^0 \pi^+) \times B(K_S^0(1430)^0 \rightarrow K^+ \pi^-)$. We compute $B(B^+ \rightarrow K_S^0(1430)^0 \pi^+)$ using the PDG value $B(K_S^0(1430)^0 \rightarrow K^+ \pi^-) = (49.9 \pm 1.2) \times 10^{-2}$ and 2/3 for the $K^+ \pi^-$ fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.
³ AUBERT,B 05N reports 7.7×10^{-6} at 90% CL for $B(B^+ \rightarrow K_S^0(1430)^0 \pi^+) \times B(K_S^0(1430)^0 \rightarrow K^+ \pi^-)$. We rescaled it using the PDG value $B(K_S^0(1430)^0 \rightarrow K^+ \pi^-) = 49.9\%$ and 2/3 for the $K^+ \pi^-$ fraction.
⁴ GARMASH 05 reports 2.3×10^{-6} at 90% CL for $B(B^+ \rightarrow K_S^0(1430)^0 \pi^+) \times B(K_S^0(1430)^0 \rightarrow K^+ \pi^-)$. We rescaled it using the PDG value $B(K_S^0(1430)^0 \rightarrow K^+ \pi^-) = 49.9\%$ and 2/3 for the $K^+ \pi^-$ mode.

<90	90	⁷ AVERY	89B	CLEO $e^+e^- \rightarrow \Upsilon(4S)$
<210	90	AVERY	87	CLEO $e^+e^- \rightarrow \Upsilon(4S)$

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

² Uses $B(B^+ \rightarrow J/\psi K^+) = (1.00 \pm 0.04) \times 10^{-3}$ and $B(J/\psi \rightarrow \mu^+ \mu^-) = 0.0588 \pm 0.0010$.

³ Uses a reference decay mode $B^+ \rightarrow \bar{D}^0 \pi^+$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ with $B(B^+ \rightarrow \bar{D}^0 \pi^+) \cdot B(\bar{D}^0 \rightarrow K^+ \pi^-) = (20.3 \pm 2.0) \times 10^{-5}$.

⁴ ABE 00C assumes $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$ and the B fractions $f_{B^0} = f_{B^+} = (39.7 \pm 1.8 \pm 2.2)\%$ and $f_{B_s} = (10.5 \pm 1.8 \pm 2.2)\%$.

⁵ ADAM 96D assumes $f_{B^0} = f_{B^-} = 0.39$ and $f_{B_s} = 0.12$.

⁶ Assumes a B^0 , B^- production fraction of 0.39 and a B_s production fraction of 0.12.

⁷ AVERY 89B reports $< 8 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0 \bar{B}^0$. We rescale to 50%.

- AALTONEN 09B reports $[\Gamma(B^+ \rightarrow K^+ \mu^+ \mu^-)/\Gamma_{\text{total}}] / [B(B^+ \rightarrow J/\psi(1S) K^+)] = (0.59 \pm 0.15 \pm 0.03) \times 10^{-3}$ which we multiply by our best value $B(B^+ \rightarrow J/\psi(1S) K^+) = (1.014 \pm 0.034) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- Assumes equal production of B^0 and B^+ at $\Upsilon(4S)$. The second error is a total of systematic uncertainties including model dependence.
- The result is for di-lepton masses above 0.5 GeV.
- AFFOLDER 99B measured relative to $B^+ \rightarrow J/\psi(1S) K^+$.
- ABE 96L measured relative to $B^+ \rightarrow J/\psi(1S) K^+$ using PDG 94 branching ratios.
- ALBRECHT 91E reports $< 2.2 \times 10^{-4}$ assuming the $\Upsilon(4S)$ decays 45% to $B^0 \bar{B}^0$. We rescale to 50%.
- WEIR 90B assumes B^+ production cross section from LUND.
- AVERY 89B reports $< 1.5 \times 10^{-4}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0 \bar{B}^0$. We rescale to 50%.
- AVERY 87 reports $< 3.2 \times 10^{-4}$ assuming the $\Upsilon(4S)$ decays 40% to $B^0 \bar{B}^0$. We rescale to 50%.

POLARIZATION IN B^+ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (\parallel) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , $\Gamma_{\parallel}/\Gamma$, and the relative phases ϕ_{\parallel} and ϕ_{\perp} . See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

-------------------------	-----------------------	----------	----------------------

¹ Uses Dalitz plot analysis of $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ and $\bar{D}^0 \rightarrow K_S^0 K^+ K^-$ decays coming from $B^\pm \rightarrow D^{(*)} K^{(*)\pm}$ modes.
² Uses a Dalitz plot analysis of the $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ decays; Combines the DK^+ , $D^* K^+$ and DK^{*+} modes.
³ Uses a Dalitz analysis of neutral D decays to $K_S^0 \pi^+ \pi^-$ in the processes $B^\pm \rightarrow D^{(*)} K^\pm$, $D^* \rightarrow D\pi^0$, $D\gamma$.

VALUE ($^\circ$)	DOCUMENT ID	TECN	COMMENT
62 ± 15 OUR AVERAGE			
$76 \pm 23 \pm 7.1$	¹ AUBERT 08AL	BABR	$e^+ e^- \rightarrow \Upsilon(4S)$
$53 \pm 15 \pm 18$	² POLUEKTOV 06	BELL	$e^+ e^- \rightarrow \Upsilon(4S)$
$70 \pm 31 \pm 18$	³ AUBERT,B 05Y	BABR	Repl. by AUBERT 08AL
$77 \pm 17 \pm 19$	⁴ POLUEKTOV 04	BELL	Repl. by POLUEKTOV 06

¹ Uses Dalitz plot analysis of $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ and $\bar{D}^0 \rightarrow K_S^0 K^+ K^-$ decays coming from $B^\pm \rightarrow D^{(*)} K^{(*)\pm}$ modes. The corresponding two standard deviation interval is $29^\circ < \gamma < 122^\circ$.

² Uses a Dalitz plot analysis of the $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ decays; Combines the $D K^+$, $D^* K^+$ and $D K^{*+}$ modes. The corresponding two standard deviations interval for gamma is $8^\circ < \gamma < 111^\circ$.

³ Uses a Dalitz plot analysis of neutral $D \rightarrow K_S^0 \pi^+ \pi^-$ decays coming from $B^\pm \rightarrow D K^\pm$ and $B^\pm \rightarrow D^* K^\pm$ followed by $D^* \rightarrow D \pi^0, D \gamma$. The corresponding two standard deviations interval for gamma is $12^\circ < \gamma < 137^\circ$. AUBERT,B 05Y also reports the amplitude ratios and the strong phases.

⁴ Uses a Dalitz plot analysis of the 3-body $D \rightarrow K_S^0 \pi^+ \pi^-$ decays coming from $B^\pm \rightarrow D K^\pm$ and $B^\pm \rightarrow D^* K^\pm$ followed by $D^* \rightarrow D \pi^0$; here we use D to denote that the neutral D meson produced in the decay is an admixture of D^0 and \bar{D}^0 . The corresponding two standard deviations interval for γ is $26^\circ < \gamma < 126^\circ$. POLUEKTOV 04 also reports the amplitude ratios and the strong phases.

See the $B^0-\bar{B}^0$ MIXING PARAMETERS section near the end of these B^0 Listings.

B^0 MEAN LIFE

See $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 Measured mean life using $B^0 \rightarrow J/\psi K^*0$ decays.
- 2 Measured mean life using $B^0 \rightarrow J/\psi K_S$ decays.
- 3 Measured using a simultaneous fit of the B^0 lifetime and $\bar{B}^0 B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \rightarrow D^{*-} \ell \nu$ decays.
- 4 Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
- 5 Measured using the time-dependent angular analysis of $B_d^0 \rightarrow J/\psi K^*0$ decays.
- 6 Measurement performed using an inclusive reconstruction and B flavor identification technique.
- 7 Measurement performed with decays $B^0 \rightarrow D^{*-} \pi^+$ and $B^0 \rightarrow D^{*-} \rho^+$ using a partial reconstruction technique.
- 8 Measured mean life using fully reconstructed decays.
- 9 Data analyzed using partially reconstructed $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}$ decays.
- 10 Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
- 11 Data analyzed using $D/D^* \ell X$ event vertices.
- 12 Data analyzed using charge of secondary vertex.

B^0

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the B^\pm/B^0 ADMIXTURE and $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

See the Note "Production and Decay of b -flavored Hadrons" at the beginning of the B^\pm Particle Listings and the Note on " $B^0-\bar{B}^0$ Mixing" near the end of the B^0 Particle Listings.

B^0 MASS

The fit uses m_{B^\pm} , ($m_{B^0} - m_{B^\pm}$), and m_{B^0} to determine m_{B^\pm} , m_{B^0} , and the mass difference.

- 1 Uses the B -momentum distributions in the e^+e^- rest frame.
- 2 Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+ \mu^-$ decays.
- 3 BEBEK 87 actually measure the difference between half of E_{cm} and the B^\pm or B^0 mass, so the $m_{B^0} - m_{B^\pm}$ is more accurate. Assume $m_{\Upsilon(4S)} = 10580$ MeV.

¹³Data analyzed using inclusive $D/D^* \ell X$.

¹⁴Measured mean life using partially reconstructed $D^{*-} \pi^+ X$ vertices.

¹⁵ABREU 95q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.

¹⁶Data analyzed using vertex-charge technique to tag B charge.

¹⁷AKERS 95T assumes $B(B^0 \rightarrow D_s^{(*)} D^0) = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.

¹⁸AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed $B^0 \rightarrow D^*(2010)^- \ell \nu$ and simultaneously measures the lifetime and oscillation frequency.

¹⁹Combined result of $D/D^* \ell X$ analysis, fully reconstructed B analysis, and partially reconstructed $D^{*-} \pi^+ X$ analysis.

²⁰Combined ABREU 95q and ADAM 95 result.

²¹WAGNER 90 tagged B^0 mesons by their decays into $D^{*-} e^+ \nu$ and $D^{*-} \mu^+ \nu$ where the D^{*-} is tagged by its decay into $\pi^- \bar{D}^0$.

²²AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \rightarrow D^{*+} X$ always.

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

τ_{B^+}/τ_{B^0} (direct measurements)

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

¹Data analyzed using $D/D^* \mu X$ vertices.

²Measurement performed using a combined fit of CP -violation, mixing and lifetimes.

³Measurement performed using an inclusive reconstruction and B flavor identification technique.

⁴Measured using fully reconstructed decays.

⁵Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.

⁶Data analyzed using charge of secondary vertex.

⁷ABREU 95q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.

⁸Data analyzed using vertex-charge technique to tag B charge.

⁹AKERS 95T assumes $B(B^0 \rightarrow D_s^{(*)} D^0) = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.

¹⁰Combined result of $D/D^* \ell X$ analysis and fully reconstructed B analysis.

τ_{B^+}/τ_{B^0} (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+ . We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

¹ARTUSO 97 uses partial reconstruction of $B \rightarrow D^* \ell \nu_\ell$ and independent of B^0 and B^+ production fraction.

²Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

³ATHANAS 94 uses events tagged by fully reconstructed B^- decays and partially or fully reconstructed B^0 decays.

⁴Assumes equal production of B^0 and B^+ .

⁵ALBRECHT 92G data analyzed using $B \rightarrow D_s \bar{D}, D_s \bar{D}^*, D_s^* \bar{D}, D_s^* \bar{D}^*$ events.

⁶BEAN 87B assume the fraction of $B^0 \bar{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

$\text{sgn}(\text{Re}(\lambda_{CP})) \Delta \Gamma_{B^0} / \Gamma_{B^0}$

Γ_{B^0} and $\Delta \Gamma_{B^0}$ are the decay rate average and difference between two B^0 CP eigenstates (light – heavy). The λ_{CP} characterizes B^0 and \bar{B}^0 decays to states of charmonium plus K_L^0 , see the review on “ CP Violation” in the reviews section.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

< 0.80	95	2,3 BEHRENS	00B CLE2	$e^+ e^- \rightarrow \Upsilon(4S)$
--------	----	-------------	----------	------------------------------------

¹Using the measured $\tau_{B^0} = 1.55 \pm 0.03$ ps.

²BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\bar{B}^0 \rightarrow D^{*+} \pi^-, \rho^-$ decays to determine the flavor of the B meson.

³Assumes $\Delta m_d = 0.478 \pm 0.018$ ps^{-1} and $\tau_{B^0} = 1.548 \pm 0.032$ ps.

B^0 DECAY MODES

\bar{B}^0 modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0 \bar{B}^0$ and 50% $B^+ B^-$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] \bar{D}^{**} represents an excited state with mass $2.2 < M < 2.8$ GeV/ c^2 .

[c] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[d] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

[e] B^0 and B_S^0 contributions not separated. Limit is on weighted average of the two decay rates.

[f] This decay refers to the coherent sum of resonant and nonresonant $J^P = 0^+ K\pi$ components with $1.60 < m_{K\pi} < 2.15$ GeV/ c^2 .

[g] The value is for the sum of the charge states or particle/antiparticle states indicated.

[h] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.

 B^0 BRANCHING RATIOS

For branching ratios in which the charge of the decaying B is not determined, see the B^\pm section.

 $\Gamma(\ell^+\nu_\ell\text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

10.32 ± 0.36 ± 0.35	4 OKABE	05 BELL	Repl. by URQUIJO 07
10.9 ± 0.7 ± 1.1	ATHANAS	94 CLE2	Sup. by ARTUSO 97

1 URQUIJO 07 report a measurement of $(9.80 \pm 0.29 \pm 0.21)\%$ for the partial branching fraction of $B \rightarrow e\nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B \rightarrow e\nu_e X$ branching fraction.

2 The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+\nu_e X) / B(B^0 \rightarrow e^+\nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

3 ARTUSO 97 uses partial reconstruction of $B \rightarrow D^*\ell\nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96B ($0.1049 \pm 0.0017 \pm 0.0043$).

4 The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+\nu_e X) / B(B^0 \rightarrow e^+\nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

- 1 Uses a fully reconstructed B meson as a tag on the recoil side.
- 2 Measured using fully reconstructed D^* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2 = 1.191 \pm 0.048 \pm 0.028$, $R_1(1) = 1.429 \pm 0.061 \pm 0.044$, and $R_2(1) = 0.827 \pm 0.038 \pm 0.022$.
- 3 Measured using fully reconstructed D^* sample.
- 4 Uses the combined fit of both $B^0 \rightarrow D^*(2010)^-\ell\nu$ and $B^+ \rightarrow \bar{D}^*(2007)^0\ell\nu$ samples.
- 5 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 6 ABREU 01H measured using about 5000 partial reconstructed D^* sample.
- 7 ABBIENDI 00Q assumes the fraction $B(b \rightarrow B^0) = (39.7^{+1.8}_{-2.2})\%$. This result is an average of two methods using exclusive and partial D^* reconstruction.
- 8 BUSKULIC 97 assumes fraction $(B^+) = \text{fraction}(B^0) = (37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and D^* and D branching fractions.
- 9 Combines with previous partial reconstructed D^* measurement.
- 10 The results are based on the same analysis and data sample reported in ADAM 03.
- 11 ACKERSTAFF 97G assumes fraction $(B^+) = \text{fraction}(B^0) = (37.8 \pm 2.2)\%$ and PDG 96 values for B lifetime and branching ratio of D^* and D decays.
- 12 ABREU 96P result is the average of two methods using exclusive and partial D^* reconstruction.
- 13 BARISH 95 use $B(D^0 \rightarrow K^-\pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$ and $B(D^{*+} \rightarrow D^0\pi^+) = (68.1 \pm 1.0 \pm 1.3)\%$.
- 14 BUSKULIC 95N assumes fraction $(B^+) = \text{fraction}(B^0) = 38.2 \pm 1.3 \pm 2.2\%$ and $\tau_{B^0} = 1.58 \pm 0.06$ ps. $\Gamma(D^{*-}\ell^+\nu_\ell)/\text{total} = [5.18 - 0.13(\text{fraction}(B^0) - 38.2) - 1.5(\tau_{B^0} - 1.58)]\%$.
- 15 ALBRECHT 94 assumes $B(D^{*+} \rightarrow D^0\pi^+) = 68.1 \pm 1.0 \pm 1.3\%$. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.
- 16 ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \rightarrow K^-\pi^+)$. We have taken their average e and μ value. They also obtain $\alpha = 2*\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}| = 0.036 - 0.045$ depending on model assumptions.
- 17 Combining $\bar{D}^{*0}\ell^+\nu_\ell$ and $\bar{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb} , they measure V, A_1 , and A_2 , the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.
- 18 ANTREASYAN 90B is average over B and $\bar{D}^*(2010)$ charge states.
- 19 The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45, or $\alpha = 0.7 \pm 0.9$.
- 20 ALBRECHT 89J is ALBRECHT 87J value rescaled using $B(D^*(2010)^- \rightarrow D^0\pi^-) = 0.57 \pm 0.04 \pm 0.04$. Superseded by ALBRECHT 93.
- 21 We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \rightarrow K^-\pi^+)$. The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.
- 22 ALBRECHT 87J assume $\mu-e$ universality, the $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 0.45$, the $B(D^0 \rightarrow K^-\pi^+) = (0.042 \pm 0.004 \pm 0.004)$, and the $B(D^*(2010)^- \rightarrow D^0\pi^-) = 0.49 \pm 0.08$. Superseded by ALBRECHT 89J.

¹ Uses a fully reconstructed B meson as a tag on the recoil side.

² LIVENTSEV 08 reports $(5.6 \pm 2.1 \pm 0.8) \times 10^{-3}$ from a measurement of $[\Gamma(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell) / \Gamma_{\text{total}}] / [B(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell)]$ assuming $B(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell) = (2.12 \pm 0.20) \times 10^{-2}$, which we rescale to our best value $B(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell) = (2.17 \pm 0.12) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³ Excludes D^{*+} contribution to D π modes.

⁴ LIVENTSEV 05 reports $[\Gamma(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell) / \Gamma_{\text{total}}] / [B(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell)] = 0.10 \pm 0.02 \pm 0.01$ which we multiply by our best value $B(\bar{D}^{*0} \pi^- \ell^+ \nu_\ell) = (5.68 \pm 0.19) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

$$\Gamma(D_1^-(2420)^- \ell^+ \nu_\ell \times B(D_1^- \rightarrow \bar{D}^{*0} \pi^-)) / \Gamma_{\text{total}} \quad \Gamma_{13} / \Gamma$$

<4.1	90	⁹ BEAN	93B CLE2	$e^+ e^- \rightarrow \Upsilon(4S)$

¹ The B^0 and B^+ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the $\Upsilon(4S)$.

² The signal events are tagged by a second B meson reconstructed in the semileptonic mode $B \rightarrow D^{(*)} \ell \nu_\ell$.

³ B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.

⁴ ATHAR 03 reports systematic errors $+0.47 \pm 0.41 \pm 0.01$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.

⁵ Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.

⁶ Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors $\pm 0.33 \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.

⁷ BEHRENS 00 reports $+0.35 \pm 0.50$, where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \rightarrow \rho^- \ell^+ \nu) = 2\Gamma(B^+ \rightarrow \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \rightarrow \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.

⁸ ALEXANDER 96T reports $+0.5 \pm 0.5$ where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \rightarrow \rho^- \ell^+ \nu) = 2\Gamma(B^+ \rightarrow \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \rightarrow \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.

⁹ BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0 \ell^+ \nu)$ and $\Gamma(\omega \ell^+ \nu)$ with this result, they obtain a limit $<(1.6-2.7) \times 10^{-4}$ at 90% CL for $B^+ \rightarrow (\omega \text{ or } \rho^0) \ell^+ \nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08-0.13$ at 90% CL is derived as well.

$$\Gamma(\pi^- \ell^+ \nu_\ell) / \Gamma_{\text{total}} \quad \Gamma_{17} / \Gamma$$

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

¹ Using isospin relation, B^+ and B^0 branching fractions are combined.

² Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

³ The B^0 and B^+ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the $\Upsilon(4S)$.

⁴ Also report the rate for $q^2 > 16 \text{ GeV}^2$ of $(0.41 \pm 0.08 \pm 0.04) \times 10^{-4}$ from which they obtain $|V_{ub}| = 3.6 \pm 0.4 \pm 0.2^{+0.6}_{-0.4}$ (last error is from theory).

⁵ The analysis uses events in which the signal B decays are reconstructed with an innovative loose neutrino reconstruction technique.

⁶ The signal events are tagged by a second B meson reconstructed in the semileptonic mode $B \rightarrow D^{(*)} \ell \nu_\ell$.

Meson Particle Listings

 B^0

⁷ The signals are tagged by a second B meson reconstructed in a semileptonic or hadronic decay. The B^0 and B^+ results are combined assuming the isospin symmetry.

⁸ B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.

⁹ ATHAR 03 reports systematic errors $0.11 \pm 0.01 \pm 0.07$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.

¹⁰ ALEXANDER 96T gives systematic errors $\pm 0.3 \pm 0.2$ where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: $\Gamma(B^0 \rightarrow \pi^- \ell^+ \nu) = 2 \times \Gamma(B^+ \rightarrow \pi^0 \ell^+ \nu)$.

- ¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
² No assumption about the intermediate mechanism is made in the analysis.
³ BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D . The product branching fraction into $D_S^*(2340)\pi$ followed by $D_S^*(2340) \rightarrow D^0\pi$ is < 0.0001 at 90% CL and into $D_S^*(2460)$ followed by $D_S^*(2460) \rightarrow D^0\pi$ is < 0.0004 at 90% CL.
⁴ BEBEK 87 assumes the $\Upsilon(4S)$ decays 43% to $B^0\bar{B}^0$. We rescale to 50%. $B(D^0 \rightarrow K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $B(D^0 \rightarrow K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.
⁵ Corrected by us using assumptions: $B(D^0 \rightarrow K^-\pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 50\%$. The product branching ratio is $B(B^0 \rightarrow \bar{D}^0\pi^+\pi^-)B(\bar{D}^0 \rightarrow K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

- ¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
² AUBERT, BE 06j reports $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] / [B(B^0 \rightarrow D^-\pi^+)] = 0.99 \pm 0.11 \pm 0.08$ which we multiply by our best value $B(B^0 \rightarrow D^-\pi^+) = (2.68 \pm 0.13) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
³ Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.
⁴ BRANDENBURG 98 assume equal production of B^+ and B^0 at $\Upsilon(4S)$ and use the D^* reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of $B(D^* \rightarrow D\pi)$.
⁵ ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \rightarrow D^0\pi^+)$ and absolute $B(D^0 \rightarrow K^-\pi^+)$ and the PDG 1992 $B(D^0 \rightarrow K^-\pi^+\pi^0)/B(D^0 \rightarrow K^-\pi^+)$ and $B(D^0 \rightarrow K^-2\pi^+\pi^-)/B(D^0 \rightarrow K^-\pi^+)$.
⁶ BORTOLETTO 92 reports $(4.0 \pm 1.0 \pm 0.7) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$ assuming $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .
⁷ ALBRECHT 90j reports $(2.8 \pm 0.9 \pm 0.6) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$ assuming $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .
⁸ BEBEK 87 reports $(2.8 \pm 1.5 \pm 1.0) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$ assuming $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90j.
⁹ Assumes $B(Z \rightarrow b\bar{b}) = 0.217$ and 38% B_d production fraction.
¹⁰ ALBRECHT 87c use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \rightarrow B^+B^-) = 55\%$ and $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 45\%$. Superseded by ALBRECHT 90j.
¹¹ ALBRECHT 86f uses pseudomass that is independent of D^0 and D^+ branching ratios.
¹² Assumes $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.60 \pm 0.08_{-0.15}^{+0.08}$. Assumes $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

¹ AUBERT 06N reports $(1.68 \pm 0.21 \pm 0.19) \times 10^{-2}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^{*+})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)]$ assuming $B(D_s^+ \rightarrow \phi\pi^+) = 0.0462 \pm 0.0062$, which we rescale to our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.² A partial reconstruction technique is used and the result is independent of the particle decay rate of D_s^+ meson. It also provides a model-independent determination of $B(D_s^+ \rightarrow \phi\pi^+) = (4.81 \pm 0.52 \pm 0.38)\%$.³ AUBERT 03i reports $0.0197 \pm 0.0015 \pm 0.0030$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^{*+})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)]$ assuming $B(D_s^+ \rightarrow \phi\pi^+) = 0.036$, which we rescale to our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.⁴ AHMED 00b reports $0.0182 \pm 0.0037 \pm 0.0025$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^{*+})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)]$ assuming $B(D_s^+ \rightarrow \phi\pi^+) = 0.036$, which we rescale to our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.⁵ ALBRECHT 92G reports $0.026 \pm 0.014 \pm 0.006$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^{*+})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)]$ assuming $B(D_s^+ \rightarrow \phi\pi^+) = 0.027$, which we rescale to our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ and $D^*(2010)^+$ branching ratios, e.g., $B(D^0 \rightarrow K^- \pi^+) = 3.71 \pm 0.25\%$, $B(D^+ \rightarrow K^- 2\pi^+) = 7.1 \pm 1.0\%$, and $B(D^*(2010)^+ \rightarrow D^0 \pi^+) = 55 \pm 4\%$.⁶ GIBAUT 96 reports $0.0203 \pm 0.0050 \pm 0.0036$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^- D_s^{*+})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)]$ assuming $B(D_s^+ \rightarrow \phi\pi^+) = 0.035$, which we rescale to our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

$$\frac{\Gamma(D^*(2010)^- D_s^+) + \Gamma(D^*(2010)^- D_s^{*+})}{\Gamma_{\text{total}}} \quad (\Gamma_{71} + \Gamma_{73})/\Gamma$$

- 1 AUBERT 07AV reports $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow p\bar{p})] = (2.82 \pm 0.30 \pm 0.36 \pm 0.28 \pm 0.35) \times 10^{-6}$ which we divide by our best value $B(J/\psi(1S) \rightarrow p\bar{p}) = (2.17 \pm 0.07) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 2 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 3 ABE 980 reports $[B(B^0 \rightarrow J/\psi(1S)K^*(892)^0)]/[B(B^+ \rightarrow J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \rightarrow J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 4 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 5 BORTOLETTO 92 reports $(1.1 \pm 0.5 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow$

$e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

6 ALBRECHT 90J reports $(1.1 \pm 0.5 \pm 0.2) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

7 BEBEK 87 reports $(3.5 \pm 1.6 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

8 ABE 96H assumes that $B(B^+ \rightarrow J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$.

9 The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_{\perp}/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \rightarrow \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

10 ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_{\parallel}/\Gamma = 0.03 \pm 0.16 \pm 0.15$ making the neutral decay a CP eigenstate when the K^*0 decays through $K_S^0 \pi^0$.

11 ALBAJAR 91E assumes B_D^0 production fraction of 36%.

12 ALBRECHT 87D assume $B^+B^-/B^0\bar{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

13 ALAM 86 assumes B^{\pm}/B^0 ratio is 60/40. The observation of the decay $B^+ \rightarrow J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- ¹ Uses B production ratio $f(\bar{B} \rightarrow B^+)/f(\bar{B} \rightarrow B_s^0) = 3.86 \pm 0.59$, and the number of $B^+ \rightarrow J/\psi K^+$ decays.
- ² Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- ³ Assumes production cross section $\sigma(B^+)/\sigma(B_s) = 3.71 \pm 0.41$ and $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (5.88 \pm 0.26) \times 10^{-5}$.
- ⁴ Assumes production cross-section $\sigma(B_s)/\sigma(B^+) = 0.100/0.391$ and the CDF measured value of $\sigma(B^+) = 3.6 \pm 0.6 \mu\text{b}$.
- ⁵ ABE 98 assumes production of $\sigma(B^0) = \sigma(B^+)$ and $\sigma(B_s)/\sigma(B^0) = 1/3$. They normalize to their measured $\sigma(B^0, p_{\mathcal{T}}(B) > 6, |y| < 1.0) = 2.39 \pm 0.32 \pm 0.44 \mu\text{b}$.
- ⁶ ACCIARRI 97B assume PDG 96 production fractions for B^+ , B^0 , B_s , and Λ_b .
- ⁷ ABE 96L assumes equal B^0 and B^+ production. They normalize to their measured $\sigma(B^+, p_{\mathcal{T}}(B) > 6 \text{ GeV}/c, |y| < 1) = 2.39 \pm 0.54 \mu\text{b}$.
- ⁸ B^0 and B_s^0 are not separated.

- ⁹ Obtained from unseparated B^0 and B_s^0 measurement by assuming a $B^0:B_s^0$ ratio 2:1.
- ¹⁰ AVERY 89B reports $< 5 \times 10^{-3}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0 \bar{B}^0$. We rescale to 50%.
- ¹¹ ALBRECHT 87D reports $< 5 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 45% to $B^0 \bar{B}^0$. We rescale to 50%.
- ¹² AVERY 87 reports $< 9 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 40% to $B^0 \bar{B}^0$. We rescale to 50%.

POLARIZATION IN B DECAYS

Revised April 2010 by A. V. Gritsan (Johns Hopkins University) and J. G. Smith (University of Colorado at Boulder).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the B decays and the CP -violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor B meson decays, while more details about the theory and experimental results in B decays can be found in a separate mini-review [1] in this *Review*.

Figure 1 illustrates angular observables in an example of the sequential process $ab \rightarrow X \rightarrow P_1 P_2 \rightarrow (p_{11} p_{12})(p_{21} p_{22})$ [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle X , such as B meson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment

of the particles in the decay chain. The analyzer of the B -daughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent (e.g., $\rho \rightarrow 2\pi$) [3], and for three-body decays as the normal to the decay plane (e.g., $\omega \rightarrow 3\pi$) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes $A_{\lambda_1 \lambda_2}$, corresponding to the X -daughter helicity states λ_i .

Figure 1: Definition of the production and helicity angles in the sequential process $ab \rightarrow X \rightarrow P_1 P_2 \rightarrow (p_{11} p_{12})(p_{21} p_{22})$. The three helicity angles include θ_1 and θ_2 , defined in the rest frame of the two daughters P_1 and P_2 , and Φ , defined in the X frame as the angle between the two decay planes. The two production angles θ^* and Ψ are defined in the X frame, where Ψ is the angle between the production plane and the average of the two decay planes.

In the case of a spin-zero B -meson decay, its daughter helicities are constrained to $\lambda_1 = \lambda_2 = \lambda$. Therefore we simplify amplitude notation as A_λ . Moreover, most B -decay polarization analyses are limited to the case when the spin of one of the B -meson daughters is 1. In that case, there are only three independent amplitudes corresponding to $\lambda = 0$ or ± 1 [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes $A_{\parallel, \perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$. The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner d functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the B -meson daughters and of their decay products, and can be found in the literature [6,7]. The differential decay rate would involve six real quantities α_i , including interference terms,

$$\frac{d\Gamma}{\Gamma d \cos \theta_1 d \cos \theta_2 d\Phi} = \sum_i \alpha_i f_i(\cos \theta_1, \cos \theta_2, \Phi), \quad (1)$$

Meson Particle Listings

 B^0

where each f_i ($\cos \theta_1$, $\cos \theta_2$, Φ) has unique angular dependence specific to particle quantum numbers, and the α_i parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\sum |A_\lambda|^2} = f_L, \quad (2)$$

$$\alpha_2 = \frac{|A_\parallel|^2 + |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L), \quad (3)$$

$$\alpha_3 = \frac{|A_\parallel|^2 - |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L - 2f_\perp), \quad (4)$$

$$\alpha_4 = \frac{\Im m(A_\perp A_\parallel^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp(1 - f_L - f_\perp)} \sin(\phi_\perp - \phi_\parallel), \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_\parallel A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_L(1 - f_L - f_\perp)} \cos(\phi_\parallel), \quad (6)$$

$$\alpha_6 = \frac{\Im m(A_\perp A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp f_L} \sin(\phi_\perp), \quad (7)$$

where the amplitudes have been expressed with the help of polarization parameters f_L , f_\perp , ϕ_\parallel , and ϕ_\perp defined in Table 1. Note that the terms proportional to $\Re e(A_\perp A_\parallel^*)$, $\Im m(A_\parallel A_0^*)$, and $\Re e(A_\perp A_0^*)$ are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a B -meson daughter, see Ref. 7.

Table 1: Rate, polarization, and CP -asymmetry parameters defined for the B -meson decays to mesons with non-zero spin. Numerical examples are shown for the $B^0 \rightarrow \varphi K^*(892)^0$ decay. The first six parameters are defined under the assumption of no CP violation in decay, while they are averaged between the \bar{B} and B parameters in general. The last six parameters involve differences between the \bar{B} and B meson decay parameters. The phase convention δ_0 is chosen with respect to a single A_{00} amplitude from a reference B decay mode, which is $B^0 \rightarrow \varphi K_0^*(1430)^0$ for numerical results.

parameter	definition	average
\mathcal{B}	$\Gamma/\Gamma_{\text{total}}$	$(9.8 \pm 0.6) \times 10^{-6}$
f_L	$ A_0 ^2/\sum A_\lambda ^2$	0.480 ± 0.030
f_\perp	$ A_\perp ^2/\sum A_\lambda ^2$	0.24 ± 0.05
$\phi_\parallel - \pi$	$\arg(A_\parallel/A_0) - \pi$	-0.74 ± 0.13
$\phi_\perp - \pi$	$\arg(A_\perp/A_0) - \pi$	-0.75 ± 0.13
$\delta_0 - \pi$	$\arg(A_{00}/A_0) - \pi$	-0.32 ± 0.17
A_{CP}	$(\bar{\Gamma} - \Gamma)/(\bar{\Gamma} + \Gamma)$	$+0.01 \pm 0.05$
A_{CP}^0	$(\bar{f}_L - f_L)/(\bar{f}_L + f_L)$	$+0.04 \pm 0.06$
A_{CP}^\perp	$(\bar{f}_\perp - f_\perp)/(\bar{f}_\perp + f_\perp)$	-0.11 ± 0.12
$\Delta\phi_\parallel$	$(\bar{\phi}_\parallel - \phi_\parallel)/2$	$+0.11 \pm 0.22$
$\Delta\phi_\perp$	$(\bar{\phi}_\perp - \phi_\perp - \pi)/2$	$+0.08 \pm 0.22$
$\Delta\delta_0$	$(\bar{\delta}_0 - \delta_0)/2$	$+0.27 \pm 0.16$

Overall, six real parameters describe three complex amplitudes A_0 , A_\parallel , and A_\perp . These could be chosen to be the four polarization parameters f_L , f_\perp , ϕ_\parallel , and ϕ_\perp , one overall size normalization, such as decay rate Γ , or branching fraction \mathcal{B} ,

and one overall phase δ_0 . The phase convention is arbitrary for an isolated B decay mode. However, for several B decays, the relative phase could produce meaningful and observable effects through interference with other B decays with the same final states, such as for $B \rightarrow VK_J^*$ with $J = 0, 1, 2, 3, 4, \dots$. The phase could be referenced to the single $B \rightarrow VK_0^*$ amplitude A_{00} in such a case, as shown in Table 1. Here V stands for any spin-one vector meson.

Moreover, CP violation can be tested in the angular distribution of the decay as the difference between the B and \bar{B} . Each of the six real parameters describing the three complex amplitudes would have a counterpart CP -asymmetry term, corresponding to three direct- CP asymmetries in three amplitudes, and three CP -violating phase differences, equivalent to the phase measurements from the mixing-induced CP asymmetries in the time evolution of B -decays [1]. In Table 1 and Ref. 8, these are chosen to be the direct- CP asymmetries in the overall decay rate \mathcal{A}_{CP} , in the f_L fraction \mathcal{A}_{CP}^0 , and in the f_\perp fraction \mathcal{A}_{CP}^\perp , and three weak phase differences:

$$\Delta\phi_\parallel = \frac{1}{2} \arg(\bar{A}_\parallel A_0 / A_\parallel \bar{A}_0), \quad (8)$$

$$\Delta\phi_\perp = \frac{1}{2} \arg(\bar{A}_\perp A_0 / A_\perp \bar{A}_0) - \frac{\pi}{2}, \quad (9)$$

$$\Delta\delta_0 = \frac{1}{2} \arg(\bar{A}_{00} A_0 / A_{00} \bar{A}_0). \quad (10)$$

The $\frac{\pi}{2}$ term in Eq. (9) reflects the fact that A_\perp and \bar{A}_\perp differ in phase by π if CP is conserved. The two parameters $\Delta\phi_\parallel$ and $\Delta\phi_\perp$ are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [9]. The CP -violating phase difference in the reference decay mode [8] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2} \arg(A_{00}/\bar{A}_{00}). \quad (11)$$

This can be measured only together with the mixing-induced phase difference for some of the neutral B -meson decays similar to other mixing-induced CP asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define δ_0 and $\Delta\delta_0$ parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta\phi_0 = \frac{1}{2} \arg(A_0/\bar{A}_0). \quad (12)$$

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the $\Delta\phi_0$ and B -mixing phases. Examples include measurements of $\beta = \phi_1$ with $B \rightarrow J/\psi K^*$ and $\alpha = \phi_2$ with $B \rightarrow \rho\rho$.

Most of the B decays that arise from tree-level $b \rightarrow c$ transitions have the amplitude hierarchy $|A_0| > |A_+| > |A_-|$ which is expected from analyses based on quark-helicity conservation [10]. The larger the mass of the vector-meson daughters, the weaker the inequality. The B meson decays to heavy vector particles with charm, such as $B \rightarrow J/\psi K^*$, $\psi(2S)K^*$, $\chi_{c1}K^*$,

$D^*\rho$, D^*K^* , D^*D^* , and $D^*D_s^*$, show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ($A_{\pm 1}$), in agreement with the factorization prediction. The detailed amplitude analysis of the $B \rightarrow J/\psi K^*$ decays has been performed by the BABAR [11], Belle [12], CDF [13], CLEO [14], and D0 [15] collaborations. Most analyses are performed under the assumption of the absence of direct CP violation. The parameter values are given in the particle listing of this *Review*. The difference between the strong phases ϕ_{\parallel} and ϕ_{\perp} deviates significantly from zero. The recent measurements [11,12] of CP -violating terms similar to those in $B \rightarrow \varphi K^*$ [8] shown in Table 1 are consistent with zero.

In addition, the mixing-induced CP -violating asymmetry is measured in the $B^0 \rightarrow J/\psi K^{*0}$ decay [1,11,12] where angular analysis allows one to separate CP -eigenstate amplitudes. This allows one to resolve the sign ambiguity of the $\cos 2\beta$ ($\cos 2\phi_1$) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases ϕ_{\parallel} and ϕ_{\perp} , as discussed below. The BABAR experiment used a method based on the dependence on the $K\pi$ invariant mass of the interference between the S - and P -waves to resolve the discrete ambiguity in the determination of the strong phases ($\phi_{\parallel}, \phi_{\perp}$) in $B \rightarrow J/\psi K^*$ decays [11]. The result is in agreement with the amplitude hierarchy expectation [10]. The CDF [13,16] and D0 [15,17] experiments have studied the $B_s^0 \rightarrow J/\psi \varphi$ decay and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy $|A_0| \gg |A_+| \gg |A_-|$ was expected in B decays to light vector particles in both penguin transitions [18,19] and tree-level transitions [10]. There is confirmation by the BABAR and BELLE experiments of predominantly longitudinal polarization in the tree-level $b \rightarrow u$ transition, such as $B^0 \rightarrow \rho^+ \rho^-$ [20], $B^+ \rightarrow \rho^0 \rho^+$ [21], and $B^+ \rightarrow \omega \rho^+$ [22]; this is consistent with the analysis of the quark helicity conservation [10]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current B samples, and limits on the transverse amplitude fraction are obtained. Only limits have been set for $B^0 \rightarrow \omega \rho^0, \omega \omega$ [22]; there is some evidence for $B^0 \rightarrow \rho^0 \rho^0$ [23] decays. The small values for these branching fractions indicates that $b \rightarrow d$ penguin pollution is small in the charmless, strangeless vector-vector B decays.

The interest in the polarization and CP -asymmetry measurements in penguin transition, such as $b \rightarrow s$ decays $B \rightarrow \varphi K^*, \rho K^*, \omega K^*$, or $B_s^0 \rightarrow \varphi \varphi$, and $b \rightarrow d$ decay $B \rightarrow K^* \bar{K}^*$, is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for $B \rightarrow \varphi K^*$ have been measured by the BABAR and Belle experiments [8,24,25]. The fractions of longitudinal polarization $f_L = 0.50 \pm 0.05$ for the $B^+ \rightarrow \varphi K^{*+}$ decay, and $f_L = 0.48 \pm 0.03$ for the $B^0 \rightarrow \varphi K^{*0}$ decay, indicate significant departure from the naive expectation of predominant longitudinal polarization,

and suggest other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [27] or QCD rescattering [28], or from physics beyond the Standard Model [29]. The complete set of twelve amplitude parameters measured in the $B^0 \rightarrow \varphi K^{*0}$ decay are given in Table 1. Several other parameters could be constructed from the above twelve parameters, as suggested in Ref. 30.

The discrete ambiguity in the phase ($\phi_{\parallel}, \phi_{\perp}, \Delta\phi_{\parallel}, \Delta\phi_{\perp}$) measurements has been resolved by BABAR in favor of $|A_+| \gg |A_-|$ through interference between the S - and P -waves of $K\pi$. The search for vector-tensor and vector-axialvector $B \rightarrow \varphi K_J^{(*)}$ decays with $J = 1, 2, 3, 4$ revealed a large fraction of longitudinal polarization in the decay $B \rightarrow \varphi K_2^*(1430)$ with $f_L = 0.90_{-0.07}^{+0.06}$ [8,31], but large contribution of transverse amplitude in $B \rightarrow \varphi K_1(1270)$ with $f_L = 0.46_{-0.15}^{+0.13}$ [32].

Like $B \rightarrow \varphi K^*$, the decays $B \rightarrow \rho K^*$ and $B \rightarrow \omega K^*$ may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in $B^+ \rightarrow \rho^0 K^{*0}, B^+ \rightarrow \rho^+ K^{*0}$ [33] and in both vector-vector and vector-tensor final states of $B \rightarrow \omega K_J^*$ [22] reveal a large fraction of transverse polarization, indicating an anomaly similar to $B \rightarrow \varphi K^*$ except for different pattern in vector-tensor final states. At the same time, first measurement of the polarization in the $b \rightarrow d$ penguin decays $B \rightarrow K^* \bar{K}^*$ indicates a large fraction of longitudinal polarization [34]. There is also evidence for the $B_s^0 \rightarrow \varphi \varphi$ decay [35]. The polarization pattern in penguin-dominated B -meson decays is not fully understood [27,28,29].

The three-body smilpionic B -meson decays, such as $B \rightarrow V l_1 l_2$, share many features with the two-body $B \rightarrow VV$ decays. Their differential decay width can be parameterized with the two helicity angles defined in the V and $(l_1 l_2)$ frames and with the azimuthal angle, as defined in Fig. 1. However, since the $(l_1 l_2)$ pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass m_{ll} spectrum. The polarization measurements as a function of m_{ll} provide complementary information on physics beyond the Standard Model, as discussed for $B \rightarrow K^* l^+ l^-$ decay in Ref. 36, though the current data in this mode [37] are not yet sufficient for precise tests.

The examples of the angular distributions and observables in $B \rightarrow K^* l^+ l^-$ are discussed in Ref. 36. With the present statistics only two angular observables have been measured in this decay when integrated over certain ranges of the dilepton mass m_{ll} [37]. One parameter is the fraction of longitudinal polarization F_L , which is determined by the K^* angular distribution and is similar to f_L defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair A_{FB} , which is the asymmetry of the decay rate with positive and negative values of $\cos \theta_1$.

In summary, there has been considerable recent interest in the polarization measurements of B -meson decays because they reveal both weak- and strong-interaction dynamics [27–29,38]. New measurements will further elucidate the pattern of spin

Meson Particle Listings

 B^0

alignment measurements in rare B decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the B -decay amplitudes.

POLARIZATION IN B^0 DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (\parallel) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , Γ_{\perp}/Γ , and the relative phases ϕ_{\parallel} and ϕ_{\perp} . See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

$0.80 \pm 0.08 \pm 0.05$	⁴² 5 ALAM	94	CLE2	Sup. by JESSOP 97

¹ Measured the angular and lifetime parameters for the time-dependent angular untagged decays $B_d^0 \rightarrow J/\psi K^{*0}$ and $B_s^0 \rightarrow J/\psi \phi$.

² Obtained by combining the B^0 and B^+ modes.

³ AFFOLDER 00N measurements are based on 190 B^0 candidates obtained from a data sample of 89 pb^{-1} . The P -wave fraction is found to be $0.13^{+0.12}_{-0.09} \pm 0.06$.

⁴ JESSOP 97 is the average over a mixture of B^0 and B^+ decays. The P -wave fraction is found to be $0.16 \pm 0.08 \pm 0.04$.

⁵ Averaged over an admixture of B^0 and B^+ decays.

⁶ Averaged over an admixture of B^0 and B^+ decays and the P wave fraction is $(19 \pm 2 \pm 3)\%$.

⁷ Averaged over an admixture of B^0 and B^- decays and the P wave fraction is $(16.0 \pm 3.2 \pm 1.4) \times 10^{-2}$.

B^0 - \bar{B}^0 MIXING

Updated April 2010 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral B^0 - \bar{B}^0 meson systems, B_d^0 - \bar{B}_d^0 and B_s^0 - \bar{B}_s^0 (generically denoted B_q^0 - \bar{B}_q^0 , $q = s, d$), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{L,H}\rangle = p|B_q^0\rangle \pm q|\bar{B}_q^0\rangle, \quad (1)$$

have a mass difference $\Delta m_q = m_H - m_L > 0$, and a total decay width difference $\Delta\Gamma_q = \Gamma_L - \Gamma_H$. In the absence of CP violation in the mixing, $|q/p| = 1$, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta\Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B_q^0\rangle$ or $|\bar{B}_q^0\rangle$ state at $t = 0$ is given by

$$|B_q^0(t)\rangle = g_+(t)|B_q^0\rangle + \frac{q}{p}g_-(t)|\bar{B}_q^0\rangle, \quad (2)$$

$$|\bar{B}_q^0(t)\rangle = g_+(t)|\bar{B}_q^0\rangle + \frac{p}{q}g_-(t)|B_q^0\rangle, \quad (3)$$

which means that the flavor states remain unchanged (+) or oscillate into each other (-) with time-dependent probabilities proportional to

$$|g_{\pm}(t)|^2 = \frac{e^{-\Gamma_q t}}{2} \left[\cosh\left(\frac{\Delta\Gamma_q t}{2}\right) \pm \cos(\Delta m_q t) \right], \quad (4)$$

where $\Gamma_q = (\Gamma_H + \Gamma_L)/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2 dt / (\int |g_-(t)|^2 dt + \int |g_+(t)|^2 dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2 + 1)}, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}. \quad (5)$$

Figure 1: Dominant box diagrams for the $B_q^0 \rightarrow \bar{B}_q^0$ transitions ($q = d$ or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B_q^0 \rightarrow \bar{B}_q^0$ and $\bar{B}_q^0 \rightarrow B_q^0$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for K^0 - \bar{K}^0 mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2} S_0(m_t^2/m_W^2) (V_{tq}^* V_{tb})^2, \quad (6)$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta_B' m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb} \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2 \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right) \right], \quad (7)$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i ; m_{B_q} , f_{B_q} and B_{B_q} are the B_q^0 mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784 x_t^{0.76}$ [4], and V_{ij} are the elements of the CKM matrix [5]. The QCD corrections η_B and η_B' are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right), \quad (8)$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the K^0 - \bar{K}^0 system, the heavy state is expected to have a smaller decay width than that of the light state: $\Gamma_H < \Gamma_L$. Hence, $\Delta\Gamma = \Gamma_L - \Gamma_H$ is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left| \frac{\Gamma_{12}}{M_{12}} \right| \simeq \frac{3\pi}{2} \frac{m_b^2}{m_W^2} \frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \quad (9)$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left| \frac{q}{p} \right|^2 = 1 + \left| \frac{\Gamma_{12}}{M_{12}} \right| \sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left| \frac{\Gamma_{12}}{M_{12}} \right|^2\right). \quad (10)$$

Therefore, considering both Eqs. (8) and (9), the CP -violating parameter

$$1 - \left| \frac{q}{p} \right|^2 \simeq \text{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \quad (11)$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the B_d^0 - \bar{B}_d^0 system and $\lesssim \mathcal{O}(10^{-4})$ for the B_s^0 - \bar{B}_s^0 system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the B_d^0 - \bar{B}_d^0 and B_s^0 - \bar{B}_s^0 systems. Calculations [7] yield $\sim 5 \times 10^{-3}$ with a $\sim 20\%$ uncertainty. Given the current experimental knowledge on the mixing parameter x_q

$$\begin{cases} x_d = 0.774 \pm 0.008 & (B_d^0\text{-}\bar{B}_d^0 \text{ system}) \\ x_s = 26.2 \pm 0.5 & (B_s^0\text{-}\bar{B}_s^0 \text{ system}) \end{cases}, \quad (12)$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger ($\sim 10\%$). These width differences are caused by the existence of final states to which both the B_q^0 and \bar{B}_q^0 mesons can decay. Such decays

Meson Particle Listings

B^0

involve $b \rightarrow c\bar{c}q$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$.

A complete set of Standard Model predictions for all mixing parameters in both the $B_d^0\text{--}\bar{B}_d^0$ and $B_s^0\text{--}\bar{B}_s^0$ systems can be found in Ref. 7.

Experimental issues and methods for oscillation analyses

Time-integrated measurements of $B^0\text{--}\bar{B}^0$ mixing were published for the first time in 1987 by UA1 [8] and ARGUS [9], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\bar{b}$ pairs. Such analyses cannot easily separate the contributions from the different b -hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B_d^0 and charged B_u mesons are produced) is in principle best suited to measure χ_d .

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies Δm_d and Δm_s , from the proper time distributions of B_d^0 or B_s^0 candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the $B_s^0\text{--}\bar{B}_s^0$ system, where the large value of x_s implies maximal mixing, *i.e.*, $\chi_s \simeq 1/2$. In such analyses, the B_d^0 or B_s^0 mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \rightarrow \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron), the proper time $t = \frac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the B momentum p . At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \rightarrow \Upsilon(4S) \rightarrow B_d^0\bar{B}_d^0$ events with a boost $\beta\gamma$ ($= 0.425, 0.55$), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance \mathcal{S} of a B_d^0 or B_s^0 oscillation signal can be approximated as [10]

$$\mathcal{S} \approx \sqrt{N/2} f_{\text{sig}} (1 - 2\eta) e^{-(\Delta m \sigma_t)^2/2}, \quad (13)$$

where N is the number of selected and tagged candidates, f_{sig} is the fraction of signal in that sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity \mathcal{S} decreases very quickly as Δm increases; this dependence is controlled by σ_t , which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \frac{m_B}{\langle p \rangle} \sigma_L \oplus t \frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.05–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies,

and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f , degrade \mathcal{S} by a total factor $(1 - 2\eta) = (1 - 2\eta_i)(1 - 2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \rightarrow \ell^-$ decays; the largest contribution to η_f is then due to $\bar{b} \rightarrow \bar{c} \rightarrow \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B_d^0 or D_s^- from B_s^0), or that of a kaon hypothesized to come from a $b \rightarrow c \rightarrow s$ decay [11], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jet-charge [12] and charge-dipole [13,14] methods. At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag the initial charge of the \bar{b} quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the charge of a track from the primary vertex is correlated with the production state of the B if that track is a decay product of a B^{**} state or the first particle in the fragmentation chain [15,16]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \rightarrow \ell^-$ or of a kaon from $b \rightarrow c \rightarrow s$ can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \rightarrow b\bar{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [13]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [16,17], or even 22% at SLD [13] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency $Q = \epsilon D^2 = \epsilon(1 - 2\eta)^2$, where ϵ is the tagging efficiency, in the range 23 – 31%. The equivalent figure achieved by CDF during Tevatron Run I was $\sim 3.5\%$ [18], reflecting the fact that tagging is more difficult at hadron colliders. The current CDF and DØ analyses of Tevatron Run II data reach $\epsilon D^2 = (1.8 \pm 0.1)\%$ [19] and $(2.5 \pm 0.2)\%$ [20] for opposite-side tagging, while same-side kaon tagging (for B_s^0 oscillation analyses) is contributing an additional 3.7 – 4.8% at CDF [19], and pushes the combined performance to $(4.5 \pm 0.9)\%$ at DØ [21].

At B factories, the flavor of a B_d^0 meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P -wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the “initial state” tag of a B can be taken as the final-state tag of the other B . Effective tagging efficiencies Q of 30% are achieved by BaBar and Belle [22], using different techniques including $b \rightarrow \ell^-$ and $b \rightarrow c \rightarrow s$ tags. It is worth noting that, in this case, mixing of

the other B (*i.e.*, the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

In the absence of experimental observation of a decay-width difference, oscillation analyses typically neglect $\Delta\Gamma$ in Eq. (4), and describe the data with the physics functions $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm_d are usually extracted from the data using a maximum likelihood fit. To extract information useful for the interpretation of B_s^0 oscillation searches and for the combination of their results, a method [10] is followed in which a B_s^0 oscillation amplitude \mathcal{A} is measured as a function of a fixed test value of Δm_s , using a maximum likelihood fit based on the functions $\Gamma_s e^{-\Gamma_s t}(1 \pm \mathcal{A} \cos(\Delta m_s t))/2$. To a good approximation, the statistical uncertainty on \mathcal{A} is Gaussian and equal to $1/\mathcal{S}$ from Eq. (13). If Δm_s is equal to its true value, one expects $\mathcal{A} = 1$ within the total uncertainty $\sigma_{\mathcal{A}}$; in case a signal is seen, its observed (or expected) significance will be defined as $\mathcal{A}/\sigma_{\mathcal{A}}$ (or $1/\sigma_{\mathcal{A}}$). However, if Δm_s is (far) below its true value, a measurement consistent with $\mathcal{A} = 0$ is expected. A value of Δm_s can be excluded at 95% CL if $\mathcal{A} + 1.645 \sigma_{\mathcal{A}} \leq 1$ (since the integral of a normal distribution from $-\infty$ to 1.645 is equal to 0.95). Because of the proper time resolution, the quantity $\sigma_{\mathcal{A}}(\Delta m_s)$ is a steadily increasing function of Δm_s . We define the sensitivity for 95% CL exclusion of Δm_s values (or for a 3σ or 5σ observation of B_s^0 oscillations) as the value of Δm_s for which $1/\sigma_{\mathcal{A}} = 1.645$ (or $1/\sigma_{\mathcal{A}} = 3$ or 5).

B_d^0 mixing studies

Many B_d^0 - \bar{B}_d^0 oscillations analyses have been published [23] by the ALEPH [24], BaBar [25], Belle [26], CDF [15], DØ [20], DELPHI [14,27], L3 [28], and OPAL [29,30] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric B factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b -hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b -hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [14,15,20,24–30] and accounting for all identified correlations yields $\Delta m_d = 0.508 \pm 0.003(\text{stat}) \pm 0.003(\text{syst}) \text{ ps}^{-1}$ [31], a result dominated by the B factories.

On the other hand, ARGUS and CLEO have published time-integrated measurements [32–34], which average to $\chi_d =$

0.182 ± 0.015 . Following Ref. 34, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies published by DELPHI [14] and BaBar [35] provide stronger constraints, which can be combined to yield $\text{sign}(\text{Re}\lambda_{CP})\Delta\Gamma_d/\Gamma_d = 0.010 \pm 0.037$ [31].

Assuming $\Delta\Gamma_d = 0$ and no CP violation in mixing, and using the measured B_d^0 lifetime of $1.525 \pm 0.009 \text{ ps}$, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.507 \pm 0.005 \text{ ps}^{-1} \quad (14)$$

or, equivalently,

$$\chi_d = 0.1873 \pm 0.0024. \quad (15)$$

Evidence for CP violation in B_d^0 mixing has been searched for, both with flavor-specific and inclusive B_d^0 decays, in samples where the initial flavor state is tagged. In the case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\text{SL}}^d = \frac{N(\bar{B}_d^0(t) \rightarrow \ell^+ \nu_\ell X) - N(B_d^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)}{N(\bar{B}_d^0(t) \rightarrow \ell^+ \nu_\ell X) + N(B_d^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)} \simeq 1 - |q/p|_d^2 \quad (16)$$

has been measured, either in time-integrated analyses at CLEO [34,36], CDF [37,38] and DØ [39], or in time-dependent analyses at LEP [30,40,41], BaBar [35,42,43] and Belle [44]. In the inclusive case, also investigated at LEP [40,41,45], no final-state tag is used, and the asymmetry [46]

$$\begin{aligned} & \frac{N(B_d^0(t) \rightarrow \text{all}) - N(\bar{B}_d^0(t) \rightarrow \text{all})}{N(B_d^0(t) \rightarrow \text{all}) + N(\bar{B}_d^0(t) \rightarrow \text{all})} \\ & \simeq \mathcal{A}_{\text{SL}}^d \left[\frac{x_d}{2} \sin(\Delta m_d t) - \sin^2 \left(\frac{\Delta m_d t}{2} \right) \right] \end{aligned} \quad (17)$$

must be measured as a function of the proper time to extract information on CP violation. In all cases, asymmetries compatible with zero have been found, with a precision limited by the available statistics. A simple average of all published results for the B_d^0 meson [30,34–36,39,41,42,44,45] yields $\mathcal{A}_{\text{SL}}^d = -0.0049 \pm 0.0038$, under the assumption of no CP violation in B_s^0 mixing. Published results at B factories only [34–36,42,44], where no B_s^0 is produced, average to

$$\mathcal{A}_{\text{SL}}^d = -0.0005 \pm 0.0056, \text{ or } |q/p|_d = 1.0002 \pm 0.0028, \quad (18)$$

a result which does not yet constrain the Standard Model.

The Δm_d result of Eq. (14) provides an estimate of $2|M_{12}|$, and can be used, together with Eq. (6), to extract the magnitude of the CKM matrix element V_{td} within the Standard Model [47]. The main experimental uncertainties on the resulting estimate of $|V_{td}|$ come from m_t and Δm_d ; however, the extraction is at present completely dominated by the uncertainty on the hadronic matrix element $f_{B_d} \sqrt{B_{B_d}} = 244 \pm 26 \text{ MeV}$ obtained from lattice QCD calculations [48].

 B^0 B_s^0 mixing studies

Figure 2: Combined measurements of the B_s^0 oscillation amplitude as a function of Δm_s . Top: CDF result based on Run II data, published in 2006 [19]. Middle: Average of all preliminary $D\bar{O}$ results available at the end of 2007 [21]. Bottom: Average of all other results (mainly from LEP and SLD) published between 1997 and 2004. All measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated. Color version at end of book.

Interesting Tevatron Run II results based on 1 fb^{-1} of data became available in 2006: after $D\bar{O}$ [49] reported $17 < \Delta m_s < 21 \text{ ps}^{-1}$ (90% CL) and a most probable value of 19 ps^{-1} with an observed (expected) significance of 2.5σ (0.9σ), CDF published the first direct evidence of B_s^0 oscillations shortly followed by a $> 5\sigma$ observation (shown at the top of Fig. 2). The measured value of Δm_s is [19]

$$\Delta m_s = 17.77 \pm 0.10(\text{stat}) \pm 0.07(\text{syst}) \text{ ps}^{-1}, \quad (19)$$

based on samples of flavour-tagged hadronic and semileptonic B_s^0 decays, partially or fully reconstructed in flavour-specific final states. More recently, $D\bar{O}$ [21] obtained with 2.4 fb^{-1} an independent 2.9σ preliminary evidence for B_s^0 oscillations (middle of Fig. 2) at $\Delta m_s = 18.53 \pm 0.93(\text{stat}) \pm 0.30(\text{syst}) \text{ ps}^{-1}$ [50], consistent with the CDF measurement.

In the decade before the Tevatron Run II results became available, $B_s^0\text{-}\bar{B}_s^0$ oscillations had been the subject of many studies from ALEPH [51], CDF [52], DELPHI [14,17,53], OPAL [54] and SLD [13,55,56], which only lead to lower limits on Δm_s due to the limited statistics. For comparison with the Tevatron Run II measurements, the B_s^0 oscillation amplitude obtained [31] by combining all earlier published results [13,14,17,51–55] is also shown in Fig. 2 (bottom) as a function of Δm_s . The Δm_s values between 14.6 and 21.7 ps^{-1}

could not be excluded at 95% CL, because the data was compatible with a signal in this region. However, the largest deviation from $\mathcal{A} = 0$ in this range is a 1.9σ effect only, so no signal could be claimed.

The information on $|V_{ts}|$ obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the B_d^0 case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}} \xi^2 \left| \frac{V_{ts}}{V_{td}} \right|^2, \quad (20)$$

where $\xi = (f_{B_s} \sqrt{B_{B_s}})/(f_{B_d} \sqrt{B_{B_d}}) = 1.210_{-0.035}^{+0.047}$ is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [48]. Using the measurements of Eqs. (14) and (19), one can extract

$$\left| \frac{V_{td}}{V_{ts}} \right| = 0.2061 \pm 0.0012(\text{exp})_{-0.0060}^{+0.0080}(\text{lattice}), \quad (21)$$

in good agreement with (but much more precise than) the recent results obtained by the Belle [57] and BaBar [58] collaborations based on the observation of the $b \rightarrow d\gamma$ transition. The CKM matrix can be constrained using experimental results on observables such as Δm_d , Δm_s , $|V_{ub}/V_{cb}|$, ϵ_K , and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [47,59,60]. The constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is presently more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (20). We also note that the measured value of Δm_s is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on Δm_s is used, *e.g.*, $16.8 \pm 1.6 \text{ ps}^{-1}$ [59] or $17.6_{-1.8}^{+1.7} \text{ ps}^{-1}$ [60].

Information on $\Delta\Gamma_s$ can be obtained by studying the proper time distribution of untagged B_s^0 samples [61]. In the case of an inclusive B_s^0 selection [62], or a semileptonic (or flavour-specific) B_s^0 decay selection [17,63,64], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_{L,H} = \Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the lifetime of B_s^0 candidates decaying to CP eigenstates; measurements exist for $B_s^0 \rightarrow K^+K^-$ [65], $B_s^0 \rightarrow J/\psi\phi$ [66,67], and $B_s^0 \rightarrow D_s^{(*)+}D_s^{(*)-}$ [68], which are mostly CP -even states [69]. However, in the case of $B_s^0 \rightarrow J/\psi\phi$, this technique has now been replaced by more sensitive time-dependent angular analyses that allow the simultaneous extraction of $\Delta\Gamma_s/\Gamma_s$ and the CP -even and CP -odd amplitudes [70,71]. Applying the combination procedure of Ref. 31 (including the constraint from the

flavour-specific lifetime measurements) on the published results of Refs. [17,63,66,70,71] yields

$$\Delta\Gamma_s/\Gamma_s = +0.092_{-0.054}^{+0.051} \quad \text{and} \quad 1/\Gamma_s = 1.472_{-0.026}^{+0.024} \text{ ps}, \quad (22)$$

or equivalently

$$1/\Gamma_L = 1.408_{-0.030}^{+0.033} \text{ ps} \quad \text{and} \quad 1/\Gamma_H = 1.543_{-0.060}^{+0.058} \text{ ps}, \quad (23)$$

under the assumption of no CP violation in B_s^0 mixing.

Independent estimates of $\Delta\Gamma_s/\Gamma_s$, leading to the average $\Delta\Gamma_s/\Gamma_s = +0.092 \pm 0.032$ [31], have also been obtained directly from measurements of the $B_s^0 \rightarrow D_s^{(*)+} D_s^{(*)-}$ branching ratio [68,72], under the assumption that these decays account for all CP -even final states (however, no systematic uncertainty due to this assumption is included in the above average).

Recent untagged or tagged analyses [70,73,74,71] also consider CP violation in $B_s^0 \rightarrow J/\psi\phi$ decays, and start to constrain the phase difference $-2\beta_s$ between the B_s^0 mixing diagram and the $b \rightarrow c\bar{c}s$ tree decay diagram. In the Standard Model (SM), $\beta_s = \arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*))$ is expected to be approximately 0.02 [7,59,60]. A two-dimensional combination of the published results [70,73,71] yields $\beta_s \in [+0.14; +0.73] \cup [+0.82; +1.43]$ and $\Delta\Gamma_s \in [+0.036; +0.264] \cup [-0.264; -0.036] \text{ ps}^{-1}$ at 90% CL [31]. Another combination including preliminary results [74], treating all analyses on the same footing, and allowing the strong phases to vary freely in the fit, gives $\beta_s \in [+0.10; +1.42]$ at 95% CL [75]. The probability to obtain a result less consistent with the SM prediction if the SM is correct is estimated to be 2% (p-value).

On the other hand CP violation in B_s^0 mixing has been investigated through the asymmetry between positive and negative same-sign muon pairs from semi-leptonic decays of $b\bar{b}$ pairs [37–39], and directly through the charge asymmetry of $B_s^0 \rightarrow D_s\mu\nu X$ decays [76,77]. Combining all published results [37,39,76] with the knowledge of CP violation in B_d^0 mixing from Eq. (18) leads to

$$\mathcal{A}_{\text{SL}}^s = -0.0036 \pm 0.0094, \quad \text{or} \quad |q/p|_s = 1.0018 \pm 0.0047. \quad (24)$$

A large New Physics phase could possibly contribute to both CP violation in $B_s^0 \rightarrow J/\psi\phi$, and to the mixing phase difference of Eq. (8) on which $\mathcal{A}_{\text{SL}}^s$ depends. Combined fits [78,79] based on β_s and $\mathcal{A}_{\text{SL}}^s$ measurements already yield interesting constraints on this New Physics phase.

Average b -hadron mixing probability and b -hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions f_u , f_d , f_s , and f_{baryon} , defined as the fractions of B_u , B_d^0 , B_s^0 and b -baryon in an unbiased sample of weakly decaying b hadrons produced in high-energy collisions. Indeed, time-integrated mixing analyses performed with lepton pairs from $b\bar{b}$ events at high energy measure the quantity

$$\bar{\chi} = f'_d \chi_d + f'_s \chi_s, \quad (25)$$

where f'_d and f'_s are the fractions of B_d^0 and B_s^0 hadrons in a sample of semileptonic b -hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q\tau_b)$ ($q = s, d$), where τ_b is the average b -hadron lifetime. Hence $\bar{\chi}$ measurements, together with the χ_d average of Eq. (15) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s = 0.49927 \pm 0.00003$ from Eqs. (5), (19) and (22)), provide constraints on the fractions f_d and f_s .

The LEP experiments have measured $f_s \times \text{BR}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell X)$ [80], $\text{BR}(b \rightarrow \Lambda_b^0) \times \text{BR}(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell X)$ [81], and $\text{BR}(b \rightarrow \Xi_b^-) \times \text{BR}(\Xi_b^- \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X)$ [82] from partially reconstructed final states including a lepton, f_{baryon} from protons identified in b events [83], and the production rate of charged b hadrons [84]. The b -hadron fractions measured at CDF using double semileptonic $K^*\mu\mu$ and $\phi\mu\mu$ final states [85] and lepton-charm final states [86] are at slight discrepancy with the ones measured at LEP. Furthermore the averages of the $\bar{\chi}$ values measured at LEP, 0.1259 ± 0.0042 [87], and at Tevatron, 0.147 ± 0.011 [39,88], show a 1.8σ deviation with respect to each other. This is a hint that the fractions at the Tevatron might be different from the ones in Z decays, and calls for separate averages of the LEP and Tevatron results. A combination of all the available information under the constraints $f_u = f_d$ and $f_u + f_d + f_s + f_{\text{baryon}} = 1$, including the recent strange b -baryon measurements at the Tevatron [89], yields the three set of averages shown in Table 1 [31]. The third set, obtained using both LEP and Tevatron results, has larger errors than the first set, obtained using LEP results only, because scale factors have been applied as advocated by the PDG for the treatment of marginally consistent data.

Table 1: $\bar{\chi}$ and b -hadron fractions (see text).

	in Z decays	at Tevatron	combined
$\bar{\chi}$	0.1259 ± 0.0042	0.147 ± 0.011	0.1284 ± 0.0069
$f_u = f_d$	0.402 ± 0.009	0.332 ± 0.030	0.400 ± 0.012
f_s	0.105 ± 0.009	0.122 ± 0.014	0.115 ± 0.013
f_{baryon}	0.090 ± 0.015	0.214 ± 0.068	0.085 ± 0.021

Summary and prospects

B^0 - \bar{B}^0 mixing has been and still is a field of intense study. While fairly little experimental progress was achieved in the B_d^0 sector during the past few years, impressive new B_s^0 results became available from Run II of the Tevatron. B_s^0 oscillations are established and the mass difference in the B_s^0 - \bar{B}_s^0 system is measured very accurately, with a central value compatible with the Standard Model (SM) expectation and a relative precision (0.7%) matching that in the B_d^0 - \bar{B}_d^0 system (0.9%). However, the extraction of $|V_{td}/V_{ts}|$ from these measurements in the SM framework is limited by the hadronic uncertainty, which will be an important challenge to reduce in the future. New time-dependent angular analyses of $B_s^0 \rightarrow J/\psi\phi$ decays and measurements of time-integrated B_s^0 asymmetries at CDF

Meson Particle Listings

 B^0

and $D\bar{O}$ are improving our knowledge of the other B_s^0 mixing parameters: while CP violation in $B_s^0-\bar{B}_s^0$ mixing is consistent with zero, with an uncertainty still large compared to the SM prediction, the relative decay width difference $\Delta\Gamma_s/\Gamma_s$ is now determined to an absolute precision of $\sim 5\%$, smaller than the central value of the SM prediction. The data prefer $\Gamma_L > \Gamma_H$ as predicted in the SM.

Improved B_s^0 results are still to come, with very promising short-term prospects, both for $\Delta\Gamma_s$ and CP -violating phases induced by mixing such as β_s and $\arg(-M_{12}/\Gamma_{12})$. Although first interesting experimental constraints have been published, very little is known yet about these phases, which are predicted to be very small in the SM. A full search for New Physics effects in these observables will require statistics beyond that of the Tevatron. These will eventually become available at CERN's Large Hadron Collider, which started physics operation in 2010 and where LHCb expects to be able to measure β_s down to the SM value after many years of operations [90].

B mixing may still reveal a surprize, but much effort is needed for this, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavour-physics observables will be possible within the SM, leading to very tight limits (or otherwise new interesting knowledge!) on New Physics.

 $B^0\text{-}\bar{B}^0$ MIXING PARAMETERS

For a discussion of $B^0\text{-}\bar{B}^0$ mixing see the note on " $B^0\text{-}\bar{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated $B^0\text{-}\bar{B}^0$ mixing probability that a produced $B^0(\bar{B}^0)$ decays as a $\bar{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$\chi_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L}) \tau_{B^0},$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B^0_H} + \Gamma_{B^0_L})}$.

 χ_d

This $B^0\text{-}\bar{B}^0$ mixing parameter is the probability (integrated over time) that a produced B^0 (or \bar{B}^0) decays as a \bar{B}^0 (or B^0), e.g. for inclusive lepton decays

$$\chi_d = \frac{\Gamma(B^0 \rightarrow \ell^- X \text{ (via } \bar{B}^0)) / \Gamma(B^0 \rightarrow \ell^\pm X)}{\Gamma(\bar{B}^0 \rightarrow \ell^+ X \text{ (via } B^0)) / \Gamma(\bar{B}^0 \rightarrow \ell^\pm X)}$$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ . Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\bar{B}^0)$ or $B_s^0(\bar{B}_s^0)$. They are listed in the $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\text{-}\bar{B}^0$ fraction and about the ratio of the B^\pm and B^0 semileptonic branching ratios (usually that it equals one).

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements, includes χ_d calculated from Δm_{B^0} and τ_{B^0} .

¹ BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\bar{B}^0 \rightarrow D^{*+} \pi^-, \rho^-$ decays to determine the flavor of the B meson.

² ALBRECHT 94 reports $r=0.194 \pm 0.062 \pm 0.054$. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

³ BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016 \pm 0.033 \pm 0.028$.

⁴ ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+,-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14) (f_{+,-}/f_0)$.

⁵ Uses $D^{*+} K^\pm$ correlations.

⁶ Uses $(D^{*+} \ell^-) K^\pm$ correlations.

⁷ These experiments see a combination of B_s and B_d mesons.

⁸ ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures $r=0.21 \pm 0.08$. We convert to χ for comparison. Superseded by ALBRECHT 92L.

⁹ BEAN 87B measured $r < 0.24$; we converted to χ .

¹⁰ Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If B^0/B^\pm ratio < 0.58 , no limit exists. The limit was corrected in BEAN 87B from $r < 0.30$ to $r < 0.37$. We converted this limit to χ .

 $\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

Δm_{B^0} is a measure of 2π times the $B^0\text{-}\bar{B}^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

- Uses opposite-side flavor-tagging with $B \rightarrow D^{(*)} \mu \nu_\mu X$ events.
- Measured using a simultaneous fit of the B^0 lifetime and $\overline{B}^0 B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \rightarrow D^{*-} \ell \nu$ decays.
- Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
- Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.
- HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$ and CPT violation parameters in B^0 - \overline{B}^0 mixing.
- ZHENG 03 data analyzed using partially reconstructed $\overline{B}^0 \rightarrow D^{*-} \pi^+$ decay and a flavor tag based on the charge of the lepton from the accompanying B decay.
- Uses a tagged sample of fully-reconstructed neutral B decays at $\Upsilon(4S)$.
- Measured based on the time evolution of dilepton events in $\Upsilon(4S)$ decays.
- Data analyzed using partially reconstructed $\overline{B}^0 \rightarrow D^{*+} \ell^- \overline{\nu}$ decay and a combination of flavor tags from the rest of the event.
- Uses di-muon events.
- Uses jet-charge and lepton-flavor tagging.
- Uses $\ell^- D^{*+} - \ell$ events.
- Uses π - B in the same side.
- Uses ℓ - ℓ .
- Uses ℓ - Q_{hem} .
- Uses ℓ - ℓ with impact parameters.
- Uses $D^{*+} - Q_{\text{hem}}$.
- Uses $\pi_s^\pm \ell - Q_{\text{hem}}$.
- Uses $D^{*+} - \ell / Q_{\text{hem}}$.
- Uses $D^{*+} \ell - Q_{\text{hem}}$.
- Uses $D^{*+} - \ell$.
- AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed $B^0 \rightarrow D^*(2010)^- \ell \nu$ and simultaneously measures the lifetime and oscillation frequency.
- AUBERT 02N result based on the same analysis and data sample reported in AUBERT 02i.
- Uses a tagged sample of B^0 decays reconstructed in the mode $B^0 \rightarrow D^* \ell \nu$.
- Uses a tagged sample of fully-reconstructed hadronic B^0 decays at $\Upsilon(4S)$.
- ACCIARRI 98D combines results from ℓ - ℓ , ℓ - Q_{hem} , and ℓ - ℓ with impact parameters.
- ABREU 97N combines results from $D^{*+} - Q_{\text{hem}}$, ℓ - Q_{hem} , $\pi_s^\pm \ell - Q_{\text{hem}}$, and ℓ - ℓ .
- ACKERSTAFF 97V combines results from ℓ - ℓ , ℓ - Q_{hem} , $D^{*+} - \ell$, and $D^{*+} - Q_{\text{hem}}$.
- BUSKULIC 97D combines results from $D^{*+} - \ell / Q_{\text{hem}}$, ℓ - Q_{hem} , and ℓ - ℓ .
- ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.
- ALEXANDER 96V combines results from $D^{*+} - \ell$ and $D^{*+} \ell - Q_{\text{hem}}$.
- AKERS 95J combines results from charge measurement, $D^{*+} \ell - Q_{\text{hem}}$ and ℓ - ℓ .

$\chi_d = \Delta m_{B^0} / \Gamma_{B^0}$

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes χ_d measured at $\Upsilon(4S)$.

••• We do not use the following data for averages, fits, limits, etc. •••

¹ Assuming $\Delta\Gamma = 0$, the result becomes $Im(z) = -0.0037 \pm 0.0046$.
² Measured using inclusive dilepton events from B^0 decay.
³ Corresponds to 90% confidence range [-0.028, 0.104].

CP VIOLATION PARAMETERS

$Re(\epsilon_{B^0}) / (1 + |\epsilon_{B^0}|^2)$

CP impurity in B_d^0 system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{CP} , the time-dependent asymmetry of inclusive B^0 and \overline{B}^0 decays.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no CP violation in B_s mixing.

The first "OUR EVALUATION", also provided by the HFAG, uses the measurements from B -factories only.

¹ Uses fully reconstructed B⁰ → D(*)[±]π[∓] and D[±]ρ[∓] decays and some theoretical assumptions.
² Combines the results from fully reconstructed and partially reconstructed D(*)π events by taking weighted averages. Assumes that systematic errors from physics parameters and fit biases in the two measurements are 100% correlated.
³ Uses partially reconstructed B⁰ → D^{∓±}π[∓] decays and some theoretical assumptions.
⁴ Uses fully reconstructed B⁰ → D(*)[±]π[∓] decays and some theoretical assumptions, such as the SU(3) symmetry relation.
⁵ Combining this measurement with the results from AUBERT 04V for fully reconstructed B⁰ → D(*)[±]π[∓] and some theoretical assumptions, such as the SU(3) symmetry relation.

2β + γ

VALUE (°)	DOCUMENT ID	TECN	COMMENT
83 ± 53 ± 20	¹ AUBERT	08AC BABR	e ⁺ e ⁻ → γ(4S)

¹ Used a time-dependent Dalitz-plot analysis of B⁰ → D[∓]K⁰π[±] assuming the ratio of the b → u and b → c decay amplitudes to be 0.3.

γ(B⁰ → D⁰K^{*0})

VALUE (°)	DOCUMENT ID	TECN	COMMENT
162 ± 56	¹ AUBERT	09R BABR	e ⁺ e ⁻ → γ(4S)

¹ Uses Dalitz plot analysis of D⁰ → K_S⁰π⁺π⁻ decays coming from B⁰ → D⁰K^{*0} modes. The corresponding 95% CL interval is 77° < γ < 247°. A 180 degree ambiguity is implied.

α

For angle α(φ₂) of the CKM unitarity triangle, see the review on "CP violation" in the reviews section.

¹ Obtained using the time dependent analysis of B⁰ → a₁(1260)[±]π[∓] and branching fraction measurements of B → a₁(1260)K and B → K₁π.
² Based on the favored B → ρρ isospin method.
³ Obtained using isospin relation and selecting a solution closest to the CKM best fit average; the 90% CL allowed interval is 59° < φ₂ (≡ α) < 115°.
⁴ The angle α_{eff} is obtained using the measured CP parameters of B⁰ → a₁(1260)[±]π[∓] and choosing one of the four solutions that is compatible with the result of SM-based fits.
⁵ Obtained using isospin relation and selecting a solution closest to the CKM best fit average; 90% CL allowed interval is 79° < α < 123°.
⁶ Obtained from the measured CP parameters of the longitudinal polarization by selecting the solution closest to the CKM best fit central value of α = 95° – 98°.

B^\pm/B^0 ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons that the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the treatment of multiple D 's in the final state must be defined. One possibility would be to count the number of events with one-or-more D 's and divide by the total number of B 's. Another possibility would be to count the total number of D 's and divide by the total number of B 's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Event though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

\bar{B} modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Semileptonic and leptonic modes		
Γ_1	$B \rightarrow e^+ \nu_e$ anything	[a] (10.74 \pm 0.16) %
Γ_2	$B \rightarrow \bar{\nu} e^+ \nu_e$ anything	< 5.9 $\times 10^{-4}$ CL=90%
Γ_3	$B \rightarrow \mu^+ \nu_\mu$ anything	[a] (10.74 \pm 0.16) %

[a] These values are model dependent.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d] D^{**} stands for the sum of the $D(1^1P_1)$, $D(1^3P_0)$, $D(1^3P_1)$, $D(1^3P_2)$, $D(2^1S_0)$, and $D(2^1S_1)$ resonances.

[e] The value is for the sum of the charge states or particle/antiparticle states indicated.

[f] $D^*(\bar{D}^*)$ stands for the sum of $D^* \bar{D}^*$, $D^* \bar{D}$, $D \bar{D}^*$, and $D \bar{D}$.[g] $X(3945)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.

[h] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

 B^\pm/B^0 ADMIXTURE BRANCHING RATIOS $\Gamma(e^+ \nu_e \text{ anything})/\Gamma_{\text{total}}$

These branching fraction values are model dependent.

 Γ_1/Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

¹ URQUIJO 07 report a measurement of $(10.07 \pm 0.18 \pm 0.21)\%$ for the partial branching fraction of $B \rightarrow e \nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B \rightarrow e \nu_e X$ branching fraction.

² The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

³ Uses charge and angular correlations in $\Upsilon(4S)$ events with a high-momentum lepton and an additional electron.

⁴ ALBRECHT 93H analysis performed using tagged semileptonic decays of the B . This technique is almost model independent for the lepton branching ratio.

⁵ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

⁶ The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

⁷ Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

⁸ Uses the high-momentum lepton tag method. They also report $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$.

⁹ Uses the high-momentum lepton tag method. ABE 02Y also reports $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$. The second error is due to uncertainties of theoretical inputs.

¹⁰ BARISH 96B analysis performed using tagged semileptonic decays of the B . This technique is almost model independent for the lepton branching ratio.

¹¹ YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6-10.5% depending on assumptions about the relative production of different B meson species.

¹² ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89b.

¹³ Using data above $p(e) = 2.4$ GeV, WACHS 89 determine $\sigma(B \rightarrow e \nu \mu) / \sigma(B \rightarrow e \nu \text{charm}) < 0.065$ at 90% CL.

¹⁴ Ratio $\sigma(B \rightarrow e \nu \mu) / \sigma(B \rightarrow e \nu \text{charm}) < 0.055$ at CL = 90%.

2.24 ± 0.27 ± 0.47	^{7,8} AUBERT 04i	BABR	Repl. by AUBERT,B 05x

- ¹ Obtained from the partial rate $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$ for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.
² Determined from the partial rate $\Delta B = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$ measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV², and calculated acceptance 0.174 in that region. The V_{ub} is measured as $(4.41 \pm 0.30 ^{+0.65}/_{-0.47}) \times 10^{-3}$.
³ Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The V_{ub} is found to be $(5.08 \pm 0.47 ^{+0.49}/_{-0.48}) \times 10^{-3}$.
⁴ BORNHEIM 02 uses the observed yield of leptons from semileptonic B decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on $B \rightarrow X_s\gamma$. The V_{ub} is found to be $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$.
⁵ Uses a multivariate analysis method and requires lepton momentum in the B rest frame, $p_T^{B^*} > 1.0$ GeV/c.
⁶ Measures several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass $M_X < 1.55$ GeV/c², and is $\Delta B = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$. The corresponding $|V_{ub}|$ from the BLNP method is $(4.27 \pm 0.16 \pm 0.13 \pm 0.30) \times 10^{-3}$, where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.
⁷ Used BaBar measurement of Semileptonic branching fraction $B(B \rightarrow X\ell\nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$ to convert the ratio of rates to branching fraction.
⁸ The third error includes the systematics and theoretical errors summed in quadrature.

 $\Gamma(X_u\ell^+\nu_\ell)/\Gamma(\ell^+\nu_\ell\text{anything})$ Γ_{23}/Γ_4

ℓ denotes e or μ , not the sum. These experiments measure this ratio in very limited momentum intervals.

<4.0	90	CHEN 84	CLEO	Direct e at $\Upsilon(4S)$
<5.5	90	KLOPFEN...	83B	CUSB Direct e at $\Upsilon(4S)$

- ¹ The third error includes the systematics and theoretical errors summed in quadrature.
² ALBRECHT 94C find $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow \text{all}) = 0.99 \pm 0.02 \pm 0.04$.
³ BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \rightarrow u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008 , respectively.
⁴ ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \rightarrow u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.
⁵ ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$ –2.6 GeV signaling the presence of the $b \rightarrow u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.
⁶ FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$ –2.6 GeV signaling the presence of the $b \rightarrow u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \rightarrow c\nu) = 10.2 \pm 0.2 \pm 0.7\%$.
⁷ The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

 0.27 ± 0.06 ± 0.08 6 CSORNA 85 CLEO Repl. by BORTOLETTO 87

1 GIBBONS 97b reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$ using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

2 ALBRECHT 96D reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.196 \pm 0.019$ using CLEO measured $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.681 \pm 0.01 \pm 0.013$, $B(D^0 \rightarrow K^- \pi^+) = 0.0401 \pm 0.0014$, $B(D^0 \rightarrow K^- \pi^+ \pi^+) = 0.081 \pm 0.005$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

3 BORTOLETTO 92 reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.25 \pm 0.03 \pm 0.04$ using MARK II $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.57 \pm 0.06$ and $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.008$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

4 ALBRECHT 91H reports $0.348 \pm 0.060 \pm 0.035$ from a measurement of $[\Gamma(B \rightarrow D^*(2010)^\pm \text{ anything})/\Gamma_{\text{total}}] \times [B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm)]$ assuming $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.55 \pm 0.04$, which we rescale to our best value $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \rightarrow K^- \pi^+) = 0.0371 \pm 0.0025$.

5 BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \rightarrow K^- \pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.60 \pm 0.08$. The product branching ratio for $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.13 \pm 0.02 \pm 0.012$. Superseded by BORTOLETTO 92.

6 $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.006$ and $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.6 \pm 0.08$. The product branching fraction is $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (68 \pm 15 \pm 9) \times 10^{-4}$.

 B^\pm/B^0 ADMIXTURE

- ¹ AUBERT 03F also reports the momentum distribution and helicity of $J/\psi \rightarrow \ell^+ \ell^-$ in the $T(4S)$ center-of-mass frame.
- ² MASCHMANN 90 reports $(1.12 \pm 0.33 \pm 0.25) \times 10^{-2}$ from a measurement of $[\Gamma(B \rightarrow J/\psi(1S) \text{ anything})/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+ e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ³ ALBRECHT 87D reports $(1.07 \pm 0.16 \pm 0.22) \times 10^{-2}$ from a measurement of $[\Gamma(B \rightarrow J/\psi(1S) \text{ anything})/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+ e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. ALBRECHT 87D find the branching ratio for J/ψ not from $\psi(2S)$ to be 0.0081 ± 0.0023 .
- ⁴ ALAM 86 reports $(1.09 \pm 0.16 \pm 0.21) \times 10^{-2}$ from a measurement of $[\Gamma(B \rightarrow J/\psi(1S) \text{ anything})/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow \mu^+ \mu^-)]$ assuming $B(J/\psi(1S) \rightarrow \mu^+ \mu^-) = 0.074 \pm 0.012$, which we rescale to our best value $B(J/\psi(1S) \rightarrow \mu^+ \mu^-) = (5.93 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ⁵ BALEST 95B reports $(1.12 \pm 0.04 \pm 0.06) \times 10^{-2}$ from a measurement of $[\Gamma(B \rightarrow J/\psi(1S) \text{ anything})/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow e^+ e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+ e^-) = 0.0599 \pm 0.0025$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+ e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. They measure $J/\psi(1S) \rightarrow e^+ e^-$ and $\mu^+ \mu^-$ and use PDG 1994 values for the branching fractions. The rescaling is the same for either mode so we use $e^+ e^-$.
- ⁶ Statistical and systematic errors were added in quadrature. ALBRECHT 85H also report a CL = 90% limit of 0.007 for $B \rightarrow J/\psi(1S) + X$ where $m_X < 1$ GeV.
- ⁷ Dimuon and dielectron events used.

$2.32 \pm 0.57 \pm 0.35$ ALAM 95 CLE2 Repl. by CHEN 01c

¹ Measured using sums of seven exclusive final states $B \rightarrow X_{d(s)}\gamma$ where $X_{d(s)}$ is a

nonstrange (strange) charmless hadronic system in mass range 0.6–1.8 GeV/ c^2 .

² The measurement reported is $(3.45 \pm 0.15 \pm 0.40) \times 10^{-4}$ for $E_\gamma > 1.7$ GeV.

³ We correct it to $E_\gamma > 1.6$ GeV using the method of hep-ph/0507253 (average of three theoretical models).

⁴ Uses a fully reconstructed B meson as a tag on the recoil side. The measurement reported is $(3.66 \pm 0.85 \pm 0.60) \times 10^{-4}$ for $E_\gamma > 1.9$ GeV.

⁵ The measurement reported is $(3.67 \pm 0.29 \pm 0.45) \times 10^{-4}$ for $E_\gamma > 1.9$ GeV.

⁶ The measurement reported is $(3.27 \pm 0.18 \pm 0.55) \times 10^{-4}$ for $E_\gamma > 1.9$ GeV.

⁷ ABE 01f reports their systematic errors $(\pm 0.42 \pm 0.50) \times 10^{-4}$, where the second error is due to the theoretical uncertainty. We combine them in quadrature.

⁸ The measurement reported is $(3.21 \pm 0.43 \pm 0.32) \times 10^{-4}$ for $E_\gamma > 2.0$ GeV.

⁹ The measurement reported is $(3.55 \pm 0.32 \pm 0.32) \times 10^{-4}$ for $E_\gamma > 1.8$ GeV.

< 0.068 90	¹ COAN 98 CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
< 0.08 2	² ALBRECHT 95d ARG $e^+e^- \rightarrow \Upsilon(4S)$

• • • We do not use the following data for averages, fits, limits, etc. • • •

¹ COAN 98 uses D - ℓ correlation.

² ALBRECHT 95d use full reconstruction of one B decay as tag. Two candidate events for charmless B decay can be interpreted as either $b \rightarrow s\text{gluon}$ or $b \rightarrow u$ transition. If interpreted as $b \rightarrow s\text{gluon}$ they find a branching ratio of ~ 0.026 or the upper limit quoted above. Result is highly model dependent.

4.2 ± 0.9 OUR AVERAGE	
$3.9 \pm 0.8 \pm 0.9$	¹ AUBERT,B 04f BABR $e^+e^- \rightarrow \Upsilon(4S)$
$4.6 \pm 1.1 \pm 0.6$	² BONVICINI 03 CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
$6.2 \pm 1.6 \pm 1.3$	³ BROWDER 98 CLE2 $e^+e^- \rightarrow \Upsilon(4S)$

¹ The reported branching ratio is for high momentum η between 2.0 and 2.7 GeV in the $\Upsilon(4S)$ center-of-mass frame. X_s represents a recoil system consisting of a kaon and zero to four pions.

² BONVICINI 03 observed a signal of 61.2 ± 13.9 events in $B \rightarrow \eta' X_{nc}$ production for high momentum η' between 2.0 and 2.7 GeV/ c in the $\Upsilon(4S)$ center-of-mass frame. The X_{nc} denotes "charmless" hadronic states recoiling against η' . The second error combines systematic and background subtraction uncertainties in quadrature.

³ BROWDER 98 observed a signal of 39.0 ± 11.6 events in high momentum $B \rightarrow \eta' X_s$ production between 2.0 and 2.7 GeV/ c . The branching fraction is based on the interpretation of $b \rightarrow sg$, where the last error includes additional uncertainties due to the color-suppressed $b \rightarrow$ backgrounds.

$0.068 \pm 0.005 \pm 0.003$		¹ ALBRECHT 92o	ARG	$e^+e^- \rightarrow \Upsilon(4S)$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.076 ± 0.014		² ALBRECHT 89k	ARG	$e^+e^- \rightarrow \Upsilon(4S)$

¹ ALBRECHT 92o result is from simultaneous analysis of p and Λ yields, $p\bar{p}$ and $\Lambda\bar{\Lambda}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89k.

² ALBRECHT 89k obtain this result by adding their measurements ($5.5 \pm 1.6\%$ for direct protons and $4.2 \pm 0.5 \pm 0.6\%$ for inclusive Λ production). They then assume ($5.5 \pm 1.6\%$ for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain $(7.6 \pm 1.4)\%$.

$\Gamma(p\bar{p} \text{ anything})/\Gamma_{\text{total}}$				Γ_{110}/Γ

 B^\pm/B^0 ADMIXTURELEPTON FORWARD-BACKWARD ASYMMETRY
IN $B \rightarrow K^{(*)} \ell^+ \ell^-$ DECAY

The forward-backward angular asymmetry of the lepton pair in $B \rightarrow K^{(*)} \ell^+ \ell^-$ decay is defined as

$$A_{FB}(s) = \frac{N(\cos\theta > 0) - N(\cos\theta < 0)}{N(\cos\theta > 0) + N(\cos\theta < 0)},$$

where $s = q^2/m_B^2$, and θ is the angle of the lepton with respect to the flight direction of the B meson, measured in the dilepton rest frame. In addition, the fraction of longitudinal polarization F_L of the K^* and F_S , the relative contribution from scalar and pseudoscalar penguin amplitudes in $B \rightarrow K^* \ell^+ \ell^-$, can be measured from the angular distribution of its decay products.

 $A_{FB}(B \rightarrow K^* \ell^+ \ell^-) (q^2 > 0.1 \text{ GeV}^2/c^2)$

⁶ ABE,K 95B uses an inclusive topological technique.
⁷ ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
⁸ ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.
⁹ BUSKULIC 93O analyzed using dipole method.
¹⁰ Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
¹¹ From proper time distribution of $b \rightarrow J/\psi(1S)$ anything.
¹² ABE 93J analyzed using $J/\psi(1S) \rightarrow \mu\mu$ vertices.
¹³ ABREU 93D data analyzed using $D/D^* \ell$ anything event vertices.
¹⁴ ABREU 93G data analyzed using charged and neutral vertices.
¹⁵ ACTON 93C analysed using $D/D^* \ell$ anything event vertices.
¹⁶ ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
¹⁷ ACTON 92 is combined result of muon and electron impact parameter analyses.
¹⁸ BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.
¹⁹ BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b -flavored hadrons are in the same ratio.
²⁰ Using $Z \rightarrow e^+ X$ or $\mu^+ X$, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
²¹ Using $Z \rightarrow J/\psi(1S) X$, $J/\psi(1S) \rightarrow \ell^+ \ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
²² Using $Z \rightarrow e X$ or μX , DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
²³ HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
²⁴ LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
²⁵ We have combined an overall scale error of 15% in quadrature with the systematic error of ± 0.7 to obtain ± 2.1 systematic error.
²⁶ Statistical and systematic errors were combined by BROM 87.

³⁰ Data analyzed using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

 \bar{b} PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $S\bar{p}\bar{S}$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a \bar{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
------	--------------------------------	-----------------------------------

PRODUCTION FRACTIONS

The production fractions for weakly decaying b -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note " B^0 - \bar{B}^0 Mixing" in the B^0 Particle Listings. The production fractions in b -hadronic Z decay or $p\bar{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$\begin{aligned} B(\bar{b} \rightarrow B^+) &= B(\bar{b} \rightarrow B^0) \\ B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) &= 100\%. \end{aligned}$$

The correlation coefficients between production fractions are also reported:

$$\begin{aligned} \text{cor}(B_s^0, b\text{-baryon}) &= -0.041 \\ \text{cor}(B_s^0, B^\pm=B^0) &= -0.483 \\ \text{cor}(b\text{-baryon}, B^\pm=B^0) &= -0.855. \end{aligned}$$

The notation for production fractions varies in the literature ($f_d, d_{B^0}, f(b \rightarrow \bar{B}^0), \text{Br}(b \rightarrow \bar{B}^0)$). We use our own branching fraction notation here, $B(\bar{b} \rightarrow B^0)$.

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

³⁹ Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

⁴⁰ The experimental systematic and model uncertainties are combined in quadrature.

⁴¹ ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

⁴² ACCIARRI 00 result obtained from a combined fit of $R_b = \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons})$ and $B(b \rightarrow \ell\nu X)$, using double-tagging method.

⁴³ ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

⁴⁴ Assumes Standard Model value for R_B .

⁴⁵ ABREU 95D give systematic errors ± 0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.

⁴⁶ BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p_T and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T , but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ± 0.0026 and is included in the systematic error.

⁴⁷ ABREU 93c event count includes $e e$ events. Combining $e e$, $\mu\mu$, and $e\mu$ events, they obtain $0.100 \pm 0.007 \pm 0.007$.

⁴⁸ AKERS 93B analysis performed using single and dilepton events.

⁴⁹ ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

⁵⁰ ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

⁵¹ Assumes Standard Model value for R_B .

⁵² ABREU 93c event count includes $e e$ events. Combining $e e$, $\mu\mu$, and $e\mu$ events, they obtain $0.100 \pm 0.007 \pm 0.007$.

⁵³ ADEVA 91c measure the average $B(b \rightarrow eX)$ branching ratio using single and double tagged b enhanced Z events. Combining e and μ results, they obtain $0.113 \pm 0.010 \pm 0.006$. Constraining the initial number of b quarks by the Standard Model prediction ($378 \pm 3 \text{ MeV}$) for the decay of the Z into $b\bar{b}$, the electron result gives $0.112 \pm 0.004 \pm 0.008$. They obtain $0.119 \pm 0.003 \pm 0.006$ when e and μ results are combined. Used to measure the $b\bar{b}$ width itself, this electron result gives $370 \pm 12 \pm 24 \text{ MeV}$ and combined with the muon result gives $385 \pm 7 \pm 22 \text{ MeV}$.

⁵⁴ ABE 93E experiment also measures forward-backward asymmetries and fragmentation functions for b and c .

⁵⁵ AKERS 93B analysis performed using single and dilepton events.

⁵⁶ ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

⁵⁷ ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

⁵⁸ Assumes Standard Model value for R_B .

⁵⁹ ABREU 93c event count includes $\mu\mu$ events. Combining $e e$, $\mu\mu$, and $e\mu$ events, they obtain $0.100 \pm 0.007 \pm 0.007$.

⁶⁰ ADEVA 91c measure the average $B(b \rightarrow eX)$ branching ratio using single and double tagged b enhanced Z events. Combining e and μ results, they obtain $0.113 \pm 0.010 \pm 0.006$. Constraining the initial number of b quarks by the Standard Model prediction ($378 \pm 3 \text{ MeV}$) for the decay of the Z into $b\bar{b}$, the muon result gives $0.123 \pm 0.003 \pm 0.006$. They obtain $0.119 \pm 0.003 \pm 0.006$ when e and μ results are combined. Used to measure the $b\bar{b}$ width itself, this muon result gives $394 \pm 9 \pm 22 \text{ MeV}$ and combined with the electron result gives $385 \pm 7 \pm 22 \text{ MeV}$.

⁶¹ AKERS 93B analysis performed using single and dilepton events.

80 Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

81 The experimental systematic and model uncertainties are combined in quadrature.

82 ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

83 ABREU 95D give systematic errors ± 0.0033 (model) and 0.0032 (R_C). We combine these in quadrature. This result is from the same global fit as their $\Gamma(\overline{b} \rightarrow \ell^+ \nu_\ell X)$ data.

84 BUSKULIC 94G uses e and μ events. This value is from the same global fit as their $\Gamma(\overline{b} \rightarrow \ell^+ \nu_\ell \text{ anything})/\Gamma_{\text{total}}$ data.

85 AKERS 93B analysis performed using single and dilepton events.

χ_b AT HIGH ENERGY

For a discussion of $B\text{-}\bar{B}$ mixing, see the note on " $B^0\text{-}\bar{B}^0$ Mixing" in the B^0 Particle Listings.

χ_b is the average $B\text{-}\bar{B}$ mixing parameter at high-energy $\chi_b = f'_d \chi_d + f'_s \chi_s$ where f'_d and f'_s are the fractions of B^0 and B_s^0 hadrons in an unbiased sample of semileptonic b -hadron decays.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

130 Uses the dimuon charge asymmetry. Averaged over the mix of b -flavored hadrons.

131 Measurement performed using events containing a dimuon or an e/μ pair.

132 The average B mixing parameter is determined simultaneously with b and c forward-backward asymmetries in the fit.

133 The experimental systematic and model uncertainties are combined in quadrature.

134 ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A_{FB}^b in $Z \rightarrow b\bar{b}$ events containing prompt leptons.

135 This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.

136 BUSKULIC 94G data analyzed using $ee, e\mu,$ and $\mu\mu$ events.

137 BUSKULIC 92B uses a jet charge technique combined with electrons and muons.

138 ABE 91G measurement of χ is done with $e\mu$ and ee events.

139 ALBAJAR 91D measurement of χ is done with dimuons.

140 Uses di-muon events.

141 ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \rightarrow Z \rightarrow b\bar{b}$ and $c\bar{c}$.

142 UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.

143 ABREU 94F uses the average electric charge sum of the jets recoiling against a b -quark jet tagged by a high p_T muon. The result is for $\bar{\chi} = f_d \chi_d + 0.9 f_s \chi_s$.

144 This ABREU 94J result combines $\ell\ell, \Lambda\ell,$ and jet-charge ℓ (ABREU 94F) analyses. It is for $\bar{\chi} = f_d \chi_d + 0.96 f_s \chi_s$.

145 ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.

146 ABREU 93C data analyzed using $ee, e\mu,$ and $\mu\mu$ events.

147 AKERS 93B analysis performed using dilepton events.

148 ACTON 92C uses electrons and muons. Superseded by AKERS 93B.

149 ADEVA 92C uses electrons and muons.

150 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.

151 ADEVA 90P measurement uses $ee, \mu\mu,$ and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.

152 These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.

153 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.

154 ALBAJAR 87C measured $\chi = (\bar{B}^0 \rightarrow B^0 \rightarrow \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.

155 Limit is average probability for hadron containing B quark to produce a positive lepton.

Meson Particle Listings

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE, V_{cb} and V_{ub} CKM Matrix Elements**B-HADRON PRODUCTION FRACTIONS IN HADRONIC Z DECAY**

The production fractions of b -hadrons in hadronic Z decays have been calculated using the best values of mean lives, mixing parameters and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.403 \pm 0.009$$

$$f(\bar{b} \rightarrow B_s^0) = 0.104 \pm 0.009$$

$$f(b \rightarrow b\text{-baryon}) = 0.091 \pm 0.015$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = +0.017$$

$$\text{cor}(B_s^0, B^+ = B^0) = -0.522$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.862$$

as obtained using a time-integrated mixing parameter $\bar{\kappa} = 0.1259 \pm 0.0042$ given by a fit to heavy quark quantities with asymmetries removed (see the note "The Z boson").

B-HADRON PRODUCTION FRACTIONS IN $p\bar{p}$ COLLISIONS AT Tevatron

The production fractions for b -hadrons in $p\bar{p}$ collisions at the Tevatron have been calculated from the best values of mean lifetimes, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.333 \pm 0.030$$

$$f(\bar{b} \rightarrow B_s^0) = 0.121 \pm 0.015$$

$$f(b \rightarrow b\text{-baryon}) = 0.214 \pm 0.068$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.603$$

$$\text{cor}(B_s^0, B^+ = B^0) = +0.439$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.981$$

as obtained with the Tevatron average of time-integrated mixing parameter $\bar{\kappa} = 0.147 \pm 0.011$.

 V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF V_{cb} AND V_{ub}

Updated March 2010 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

INTRODUCTION

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$, making its determination a high priority of the heavy flavor physics program.

The semileptonic transitions $b \rightarrow c\ell\bar{\nu}_\ell$ and $b \rightarrow u\ell\bar{\nu}_\ell$ provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. The experimental and theoretical techniques underlying these two avenues are independent, providing a crucial cross-check on our understanding. Recent measurements and calculations are reflected in the values quoted in this article, which is an update on the previous review [1].

The theory underlying the determination of $|V_{qb}|$ is mature, in particular for $|V_{cb}|$. The theoretical approaches all use the fact that the mass m_b of the b quark is large compared to the scale Λ_{QCD} that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of Λ/m_b , where $\Lambda \sim 500 - 700$ MeV is a hadronic scale of the order of Λ_{QCD} , using effective-field-theory methods to separate non-perturbative from perturbative contributions. The expansion in Λ/m_b and α_s works well enough to enable a precision determination of $|V_{cb}|$ and $|V_{ub}|$ in semileptonic decays.

The large data samples available at the B factories have opened up new possibilities experimentally. Analyses where one B meson from an $\Upsilon(4S)$ decay is fully reconstructed allow a recoiling semileptonic B decay to be studied with higher purity than was previously possible. Improved knowledge of $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays allows partial rates for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ transitions to be measured in regions previously considered inaccessible, increasing the acceptance for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ transitions and reducing theoretical uncertainties.

Experimental measurements of the exclusive $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ decay are quite precise. Further improvement in the theoretical calculation of the form factor normalization is needed to fully exploit these measurements.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [2].

DETERMINATION OF $|V_{cb}|$

Summary: The determination of $|V_{cb}|$ from $\overline{B} \rightarrow D^* \ell \overline{\nu}_\ell$ decays is currently at a relative precision of about 3%. The main limitation is the knowledge of the form factor near the maximum momentum transfer to the leptons. For the $\overline{B} \rightarrow D \ell \overline{\nu}_\ell$ channel experimental measurements have recently been substantially improved, allowing this channel to provide a meaningful cross-check on $\overline{B} \rightarrow D^* \ell \overline{\nu}_\ell$.

Determinations of $|V_{cb}|$ from inclusive decays are currently below 2% relative uncertainty. The limitations arise mainly from our ignorance of higher order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are currently only marginally consistent with each other:

$$|V_{cb}| = (41.5 \pm 0.7) \times 10^{-3} \text{ (inclusive)} \quad (1)$$

$$|V_{cb}| = (38.7 \pm 1.1) \times 10^{-3} \text{ (exclusive)}. \quad (2)$$

An average of the above gives $|V_{cb}| = (40.6 \pm 0.6) \times 10^{-3}$, with $P(\chi^2) = 0.03$. Scaling the error by $\sqrt{\chi^2/\text{ndf}} = 2.2$ we quote

$$|V_{cb}| = (40.6 \pm 1.3) \times 10^{-3}. \quad (3)$$

$|V_{cb}|$ from exclusive decays

Exclusive determinations of $|V_{cb}|$ are based on a study of semileptonic B decays into the ground state charmed mesons D and D^* . The main uncertainties in this approach stem from

our ignorance of the form factors describing the $B \rightarrow D$ and $B \rightarrow D^*$ transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [3], which depends on the product of the four-velocities v and v' of the initial and final-state hadrons.

The extraction of $|V_{cb}|$ is based on the distribution of the variable $w \equiv v \cdot v'$, which corresponds to the energy of the final state $D^{(*)}$ meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [3,4] predicts the normalization of the rate at $w = 1$, the point of maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation of the measured spectrum to $w = 1$. This extrapolation relies on a parametrization of the form factor, as explained below.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point $w = 1$, since the phase space vanishes there. The corrections to the HQS prediction due to finite quark masses are given in terms of the symmetry-breaking parameter

$$\frac{1}{\mu} = \frac{1}{m_c} - \frac{1}{m_b},$$

which is essentially $1/m_c$ for realistic quark masses. HQS ensures that those matrix elements that correspond to the currents that generate the HQS are normalized at $w = 1$; as a result, some of the form factors either vanish or are normalized at $w = 1$. Due to Luke's Theorem [5] (which is an application of the Ademollo-Gatto theorem [6] to heavy quarks), the leading correction to those form factors normalized due to HQS is quadratic in $1/\mu$, while for the form factors that vanish in the infinite mass limit the corrections are in general linear in $1/m_c$ and $1/m_b$. Thus we have, using the definitions as in Eq. (2.84) of Ref. [7]

$$\begin{aligned} h_i(1) &= 1 + \mathcal{O}(1/\mu^2) & \text{for } i = +, V, A_1, A_3, \\ h_i(1) &= \mathcal{O}(1/m_c, 1/m_b) & \text{for } i = -, A_2. \end{aligned} \quad (4)$$

In addition to these corrections, there are perturbatively calculable radiative corrections from QCD and QED, which will be discussed in the relevant sections. Both - radiative corrections as well as $1/m$ corrections - are considered in the framework of Heavy Quark Effective Theory (HQET) [8], which provides for a systematic expansion.

$\overline{B} \rightarrow D^* \ell \overline{\nu}_\ell$

The decay rate for $\overline{B} \rightarrow D^* \ell \overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \rightarrow D^* \ell \overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 m_{D^*}^3 (w^2 - 1)^{1/2} P(w) (\mathcal{F}(w))^2 \quad (5)$$

where $P(w)$ is a phase space factor with $P(1) = 12(m_B - m_{D^*})^2$ and $\mathcal{F}(w)$ is dominated by the axial vector form factor h_{A_1} as $w \rightarrow 1$. In the infinite-mass limit, the HQS normalization gives $\mathcal{F}(1) = 1$.

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

The form factor $\mathcal{F}(w)$ must be parametrized to perform an extrapolation to the zero-recoil point. A frequently used one-parameter form motivated by analyticity and unitarity is [9,10]

$$\mathcal{F}(w) = \eta_{\text{QED}}\eta_{\text{A}} \left[1 + \delta_{1/m^2} + \dots \right] \\ \left[1 - 8\rho_{A_1}^2 z + (53\rho_{A_1}^2 - 15)z^2 - (231\rho_{A_1}^2 - 91)z^3 \right] \quad (6)$$

with $z = (\sqrt{w+1} - \sqrt{2})/(\sqrt{w+1} + \sqrt{2})$ originating from a conformal transformation. The parameter $\rho_{A_1}^2$ is the slope of the form factor at $w = 1$. The η_{QED} and η_{A} factors are the QED [11] and QCD [12] short-distance radiative corrections

$$\eta_{\text{QED}} = 1.007, \quad \eta_{\text{A}} = 0.960 \pm 0.007 \quad (7)$$

and δ_{1/m^2} comes from non-perturbative $1/m^2$ corrections.

Recently, lattice simulations which include effects from finite quark masses have been used to calculate the deviation of $\mathcal{F}(1)$ from unity. The value quoted from these calculations, multiplied by η_{QED} , is

$$\mathcal{F}(1) = 0.927 \pm 0.024 \quad (8)$$

where the errors quoted in Ref. [14] have been added in quadrature. The leading uncertainties are due to lattice statistical and dis

Figure 1: Measurements of $|V_{cb}|\mathcal{F}(1)$ vs. $\rho_{A_1}^2$ are shown as $\Delta\chi^2 = 1$ ellipses. Color version at end of book.

Non-lattice estimates based on sum rules for the the form factor tend to yield lower values for $\mathcal{F}(1)$ [15,16]. Omitting the contributions from excited states, the sum rules indicate that $\mathcal{F}(1) < 0.9$; including the excited states will further reduce the form factor.

Many experiments [17–25] have measured the differential rate as a function of w . Fig. 1 shows corresponding values of $|V_{cb}|\mathcal{F}(1)$ and $\rho_{A_1}^2$ (as defined in Ref. [10]) . These measurements have been updated using more precise values [23] for the form factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$. The

leading sources of uncertainty on $|V_{cb}|\mathcal{F}(1)$ are due to detection efficiencies and $D^{(*)}$ decay branching fractions, while for ρ^2 the uncertainties in R_1 and R_2 still dominate. Recent BABAR measurements, one using $\overline{B}^0 \rightarrow D^{*0}\ell\overline{\nu}_\ell$ decays [24] and the other using a global fit to $\overline{B} \rightarrow D\ell\overline{\nu}_\ell X$ decays [25] are completely insensitive to uncertainties related to the reconstruction of the charged pion from $D^* \rightarrow D\pi$ decays; both measurements agree with the average given below. Related measurements [26,27] of $\Gamma(\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell)$ using samples at the $\Upsilon(4S)$ in which the opposite B is fully reconstructed have also been made. These use the measured missing mass squared to isolate signal decays and have very little sensitivity to the form factor slope.

The confidence level of the average based on the measurements in Fig. 1 is $\sim 0.004\%$. In light of the poor consistency we choose to rescale the errors by $\sqrt{\chi^2/\text{ndf}} = 1.65$ to find $|V_{cb}|\mathcal{F}(1) = (35.75 \pm 0.70) \times 10^{-3}$. Along with the value given above for $\mathcal{F}(1)$ this yields

$$|V_{cb}| = (38.5 \pm 0.8_{\text{exp}} \pm 1.0_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell). \quad (9)$$

The values of $\mathcal{F}(1)$ obtained from QCD sum rules result in larger values for $|V_{cb}|$.

$\overline{B} \rightarrow D\ell\overline{\nu}_\ell$

The differential rate for $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \rightarrow D\ell\overline{\nu}_\ell) = \\ \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\mathcal{G}(w))^2. \quad (10)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (11)$$

where h_+ is normalized due to HQS and h_- vanishes in the heavy mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D} \frac{1}{m_c}\right) \quad (12)$$

and the corrections to the HQET predictions are parametrically larger than was the case for $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$.

In order to get a more precise prediction for the form factor $\mathcal{G}(1)$ the heavy quark limit can be supplemented by additional assumptions. It has been argued in Ref. [28] that in a limit in which the kinetic energy μ_π^2 is equal to the chromomagnetic moment μ_G^2 (these quantities are discussed below in more detail) one may obtain the value

$$\mathcal{G}(1) = 1.04 \pm 0.01_{\text{power}} \pm 0.01_{\text{pert}} \quad (13)$$

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$ is irrelevant. These unquenched calculations quote a (preliminary) value [29]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016 \quad (14)$$

which has an error comparable to the one quoted for $\mathcal{F}(1)$, although some uncertainties have not been taken into account.

Figure 2: Measurements of $|V_{cb}|\mathcal{G}(1)$ vs. ρ^2 are shown as $\Delta\chi^2 = 1$ ellipses. Color version at end of book.

The measurements of $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ have improved substantially in the last year. The two new measurements [25,30] are consistent with previous measurements [17,31,32] but significantly more precise, as shown in Fig. 2. The average of these inputs gives $|V_{cb}|\mathcal{G}(1) = (42.3 \pm 0.7 \pm 1.3) \times 10^{-3}$. Using the value given in Eq. (14) for $\mathcal{G}(1)$, accounting for the QED correction and conservatively adding the theory uncertainties linearly results in

$$|V_{cb}| = (39.1 \pm 1.4 \pm 1.3) \times 10^{-3} \quad (\bar{B} \rightarrow D\ell\bar{\nu}_\ell) \quad (15)$$

where the first uncertainty is from experiment and the second from theory.

Using the non-lattice estimate from Eq. (13) one finds $|V_{cb}| = (40.4 \pm 1.4 \pm 0.8) \times 10^{-3}$.

Measuring the differential rate at $w = 1$ is more difficult in $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ decays than in $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$ decays, since the rate is smaller and the background from mis-reconstructed $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$ decays is significant; this is reflected in the larger experimental uncertainty. The B factories can address these limitations by studying decays recoiling against fully reconstructed B mesons or doing a global fit to $\bar{B} \rightarrow X_c\ell\bar{\nu}_\ell$ decays. Theoretical input on the shape of the w spectrum in $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ is valuable, as precise measurements of the total rate are easier; a recent measurement [26] of $\mathcal{B}(\bar{B} \rightarrow D\ell\bar{\nu}_\ell)$ has an uncertainty of $\sim 5\%$.

The determinations from $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$ and $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ decays are consistent, and their uncertainties are largely uncorrelated. Averaging the two results gives

$$|V_{cb}| = (38.7 \pm 1.1) \times 10^{-3} \quad (\text{exclusive}). \quad (16)$$

Prospects for Lattice determinations of the $B \rightarrow D^{(*)}$ form factors

Lattice determinations of the $B \rightarrow D^{(*)}$ form factors have improved significantly over the last few years. The key for the

improvements [13,33] is a set of double-ratios, constructed so that all uncertainties scale with the deviation of the form factor from unity. In combination with the possibility to perform unquenched calculations, i.e. calculations with realistic sea quarks, these double ratios yield quite precise predictions for form factors.

The remaining uncertainties are due to the chiral extrapolation from the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and to discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings. The total uncertainty in the lattice values of $\mathcal{F}(1)$ and $\mathcal{G}(1)$ obtained from this method will be 2-3%. However, in the light of the current $> 2\sigma$ tension between inclusive and exclusive $|V_{cb}|$ a revision of the systematic uncertainties becomes important.

In addition to the lattice calculations of form factor normalizations, first results for the w dependence of the form factors are available [34]. While these first results are still in the quenched approximation, one can expect further calculations of form factor shapes in the near future.

Decays to Excited D Meson States

Above the ground state D and D^* mesons lie four positive-parity states with one unit of orbital angular momentum, generically denoted as D^{**} . In the heavy mass limit they form two spin symmetry doublets with $j_\ell = 1/2$ and $j_\ell = 3/2$, where j_ℓ is the total angular momentum of the light degrees of freedom. The doublet with $j_\ell = 3/2$ is expected to be narrow while the states with $j_\ell = 1/2$ should be broad, consistent with experimental measurements. Furthermore, one expects that in the heavy mass limit $\Gamma(B \rightarrow D^{**}(j_\ell = 3/2)\ell\bar{\nu}) \gg \Gamma(B \rightarrow D^{**}(j_\ell = 1/2)\ell\bar{\nu})$ [35,36,37]. Recent measurements indicate that this expectation may be violated, although the experimental situation is not clear. BELLE [27] and BABAR [38] report different results for the broad states and the experiments do not have the sensitivity to identify the spin-parity of these states. If a violation is confirmed, it may indicate substantial mixing between the two spin symmetry doublets, which can occur due to terms of order $1/m_c$. However, the impact on the exclusive $|V_{cb}|$ determination is expected to be small, since the zero-recoil point is protected against corrections of order $1/m_c$ by Luke's theorem.

$|V_{cb}|$ from inclusive decays

At present the most precise determinations of $|V_{cb}|$ come from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE), a systematic

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

expansion in inverse powers of the b -quark mass [39,40]. The validity of the OPE is proven in the deep Euclidean region for the momenta (which is satisfied, *e.g.*, in deep inelastic scattering), but its application to heavy quark decays requires a continuation to time-like momenta $p_B^2 = M_B^2$, where possible contributions which are exponentially damped in the Euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of parton-hadron duality, hereafter referred to simply as duality, and possible oscillatory contributions would be an indication of duality violation.

Duality-violating effects are hard to quantify. In practice, they would appear as unnaturally large coefficients of higher order terms in the $1/m$ expansion [41]. The description of ~ 60 measurements in terms of ~ 6 free parameters in global fits to $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ decays provides a non-trivial testing ground for the HQE predictions. Present fits include terms up to order $1/m_b^3$, the coefficients of which have sizes as expected a priori by theory and are in quantitative agreement with extractions from other observables. The consistency of the data with these OPE fits will be discussed later; no indication is found that terms of order $1/m_b^4$ or higher are large, and there is no evidence for duality violations in the data. Thus duality or, likewise, the validity of the OPE, is assumed in the analysis, and no further uncertainty is assigned to potential duality violations.

The OPE result for the total rate can be written schematically (the details of the expression can be found, *e.g.*, in Ref. [42]) as

$$\begin{aligned} \Gamma = & |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu) (1 + A_{ew}) A^{\text{pert}}(r, \mu) \times \\ & \left[z_0(r) + z_2(r) \left(\frac{\mu_\pi^2}{m_b^2}, \frac{\mu_G^2}{m_b^2} \right) + z_3(r) \left(\frac{\rho_D^3}{m_b^3}, \frac{\rho_{LS}^3}{m_b^3} \right) \right. \\ & \left. + z_4(r) \left(\frac{s_i}{m_b^4} \right) + \dots \right] \end{aligned} \quad (17)$$

where A_{ew} denotes the electroweak and $A^{\text{pert}}(r, \mu)$ the QCD radiative corrections, r is the ratio m_c/m_b and the z_i are known phase-space functions.

This expression is known up to order $1/m_b^4$, where the terms of order $1/m_b^3$ and $1/m_b^4$ have been computed only at tree level [43,44,45]. The leading term is the parton model, which is known completely to order α_s , and the terms of order $\alpha_s^2 \beta_0$ (where β_0 is the first coefficient of the QCD β function, $\beta_0 = (33 - 2n_f)/3$) have been included by the usual BLM procedure [42,46]. Furthermore, the corrections of order $\alpha_s \mu_\pi^2/m_b^2$ have been computed [47].

Starting at order $1/m_b^3$ contributions with an infrared sensitivity to the charm mass m_c appear [45,48,49]. At order $1/m_b^3$ this ‘‘intrinsic charm’’ contribution is a $\log(m_c)$ in the coefficient of the Darwin term ρ_D . At higher orders, terms such as $1/m_b^3 \times 1/m_c^2$ and $\alpha_s(m_c) 1/m_b^3 \times 1/m_c$ appear, which are comparable in size to the contributions of order $1/m_b^4$

The HQE parameters are given in terms of forward matrix elements by

$$\begin{aligned} \bar{\Lambda} &= M_B - m_b \\ \mu_\pi^2 &= -\langle B | \bar{b} (iD_\perp)^2 b | B \rangle \\ \mu_G^2 &= \langle B | \bar{b} (iD_\perp^\mu) (iD_\perp^\nu) \sigma_{\mu\nu} b | B \rangle \\ \rho_D^3 &= \langle B | \bar{b} (iD_{\perp\mu}) (ivD) (iD_\perp^\nu) b | B \rangle \\ \rho_{LS}^3 &= \langle B | \bar{b} (iD_\perp^\mu) (ivD) (iD_\perp^\nu) \sigma_{\mu\nu} b | B \rangle \end{aligned} \quad (18)$$

while the five hadronic parameters s_i of the order $1/m_b^4$ can be found in Ref. [44]; these have not yet been included in the fits. The non-perturbative matrix elements depend on the renormalization scale μ , on the chosen renormalization scheme and on the quark mass m_b . The rates and the spectra depend strongly on m_b (or equivalently on $\bar{\Lambda}$), which makes the discussion of renormalization issues mandatory.

Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of $|V_{cb}|$ in such a scheme impossible. The solution to this problem is to choose an appropriate ‘‘short-distance’’ mass definition. Frequently used mass definitions are the kinetic scheme [15], or the 1S scheme [50]. Both of these schemes have been applied to semi-leptonic $b \rightarrow c$ transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the b quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the Υ system. The physical mass of the $\Upsilon(1S)$ contains non-perturbative contributions, which have been estimated in Ref. [52]. These non-perturbative contributions are small; nevertheless, the best determination of the b quark mass in the 1S scheme is obtained from sum rules for $e^+e^- \rightarrow b\bar{b}$ [51].

Alternatively one may use a short-distance mass definition such as the $\overline{\text{MS}}$ mass $m_b^{\overline{\text{MS}}}(m_b)$. However, it has been argued that the scale m_b is unnaturally high for B decays, while for smaller scales $\mu \sim 1 \text{ GeV}$ $m_b^{\overline{\text{MS}}}(\mu)$ is under poor control. For this reason the so-called ‘‘kinetic mass’’ $m_b^{\text{kin}}(\mu)$, has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy quark sum rules [15].

The HQE parameters also depend on the renormalization scale and scheme. The matrix elements given in Eq. (18) are defined with the full QCD fields and states, which is the definition frequently used in the kinetic scheme. Sometimes slightly different parameters λ_1 and λ_2 are used, which are defined in the infinite mass limit. The relation between these parameters is

$$\begin{aligned} \bar{\Lambda}_{\text{HQET}} &= \lim_{m_b \rightarrow \infty} \bar{\Lambda}, \quad -\lambda_1 = \lim_{m_b \rightarrow \infty} \mu_\pi^2 \\ \lambda_2 &= \lim_{m_b \rightarrow \infty} \mu_G^2, \quad \rho_1 = \lim_{m_b \rightarrow \infty} \rho_D^3 \\ \rho_2 &= \lim_{m_b \rightarrow \infty} \rho_{LS}^3 \end{aligned}$$

Defining the kinetic energy and the chromomagnetic moment in the infinite-mass limit (as, *e.g.*, in the 1S scheme) requires that

$1/m_b$ corrections to the matrix elements defined in Eq. (18) be taken into account once one goes beyond order $1/m_b^2$. As a result, additional quantities $\mathcal{T}_1 \cdots \mathcal{T}_4$ appear at order $1/m_b^3$. However, these quantities are correlated such that the total number of non-perturbative parameters to order $1/m_b^3$ is the same as in the scheme where m_b is kept finite in the matrix elements which define the non-perturbative parameters. A detailed discussion of these issues can be found in Ref. [53].

In order to define the HQE parameters properly one must adopt a renormalization scheme, as was done for the heavy quark mass. Since all these parameters can again be determined by heavy quark sum rules, one may adopt a scheme similar to the kinetic scheme for the quark mass. The HQE parameters in the kinetic scheme depend on powers of the renormalization scale μ , and the above relations are valid in the limit $\mu \rightarrow 0$, leaving only logarithms of μ .

Some of these parameters also appear in the relation for the heavy hadron masses. The quantity $\bar{\Lambda}$ is determined once a definition is specified for the quark mass. The parameter μ_G^2 can be extracted from the mass splitting in the lowest spin-symmetry doublet of heavy mesons

$$\mu_G^2(\mu) = \frac{3}{4} C_G(\mu, m_b) (M_{B^*}^2 - M_B^2) \quad (19)$$

where $C_G(\mu, m_b)$ is a perturbatively-computable coefficient which depends on the scheme. In the kinetic scheme we have

$$\mu_G^2(1\text{GeV}) = 0.35_{-0.02}^{+0.03} \text{GeV}^2. \quad (20)$$

Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ decays [54–61] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum (0th-3rd) and of the squared hadronic mass spectrum (0th-2nd) have statistical uncertainties that are roughly equal to their systematic uncertainties. They can be improved with more data and significant effort. The moments measured by each experiment have strong correlations; the full statistical and systematic correlation matrices are required to allow these to be used in a global fit. Measurements of photon energy moments (0th-2nd) in $B \rightarrow X_s \gamma$ decays [62–66] as a function of the minimum accepted photon energy are still primarily statistics limited.

Global fits to the full set of moments [63,67–70] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of m_b and m_c very accurately but leave the orthogonal combination poorly determined [71]; the addition of radiative moments allows m_b to be extracted with greater precision. The most recent global fit in the kinetic scheme gives [69]

$$|V_{cb}| = (41.54 \pm 0.44 \pm 0.58) \times 10^{-3} \quad (21)$$

$$m_b^{\text{kin}} = 4.620 \pm 0.035 \text{ GeV} \quad (22)$$

$$\mu_\pi^2(\text{kin}) = 0.424 \pm 0.042 \text{ GeV} \quad (23)$$

where the first error includes experimental and theoretical uncertainties and the second error on $|V_{cb}|$ is from the estimated accuracy of the HQE for the total semileptonic rate.

A fit to the same moments in the 1S scheme gives [70]

$$|V_{cb}| = (41.87 \pm 0.25 \pm 0.08) \times 10^{-3} \quad (24)$$

$$m_b^{1\text{S}} = 4.685 \pm 0.029 \text{ GeV} \quad (25)$$

$$\lambda_1(1\text{S}) = -0.373 \pm 0.052 \text{ GeV}^2 \quad (26)$$

where the last error on $|V_{cb}|$ is due to the uncertainties in the B meson lifetimes.

Theoretical uncertainties are estimated and included in performing the fits. The χ^2/dof is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated, or correlations incompletely accounted for. In any case, the low χ^2 shows no evidence for duality violations at a significant level. Similar values for the parameters are obtained when only experimental uncertainties are used in the fits. If the photon energy spectrum moments from $\bar{B} \rightarrow X_s \gamma$ are excluded from the fit input in the kinetic scheme, the results for $|V_{cb}|$ and μ_π^2 change by only small amounts, while m_b^{kin} increases to $4.68 \pm 0.05 \text{ GeV}$.

The mass in the $\overline{\text{MS}}$ scheme corresponding to Eq. (22) is $m_b^{\overline{\text{MS}}} = 4.25 \pm 0.05 \text{ GeV}$. This can be compared with a recent value obtained using relativistic sum rules [72], $m_b^{\overline{\text{MS}}} = 4.163 \pm 0.016 \text{ GeV}$. The uncertainties on m_b are further discussed in the section on the determination of $|V_{ub}|$.

The precision of these results can be further improved. Some of the measurements, in particular of the $\bar{B} \rightarrow X_s \gamma$ photon energy spectrum, can be improved by using the full B-factory data sets. Improvements can be made in the theory by calculating higher order perturbative corrections [73] and, more importantly, by calculating perturbative corrections to the matrix elements defining the HQE parameters. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

Determination of $|V_{ub}|$

Summary: The determination of $|V_{ub}|$ is the focus of significant experimental and theoretical work. The determinations based on inclusive semileptonic decays using different calculational ansätze are consistent. The largest parametric uncertainty comes from the error on m_b . Significant progress has been made in determinations of $|V_{ub}|$ from $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ decays by using combined fits to theory and experimental data as a function of q^2 . Further improvements in the form factor normalization are needed to improve the precision.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.27 \pm 0.38) \times 10^{-3} \quad (\text{inclusive}), \quad (27)$$

$$|V_{ub}| = (3.38 \pm 0.36) \times 10^{-3} \quad (\text{exclusive}). \quad (28)$$

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. The inclusive and

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

exclusive values are weighted by their relative errors and the uncertainties are treated as normally distributed. The resulting average has $P(\chi^2) = 0.10$. We choose to scale the error on the average by $\sqrt{\chi^2/1} = 1.62$ to find

$$|V_{ub}| = (3.89 \pm 0.44) \times 10^{-3} \quad (29)$$

Since the dominant uncertainties come from theory, the uncertainty on the average cannot be assumed to be normally distributed.

$|V_{ub}|$ from inclusive decays

The theoretical description of inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays is based on the Heavy Quark Expansion, as for $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays, and leads to a predicted total decay rate with uncertainties below 5% [74,75]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ transitions. Calculating the partial decay rate in regions of phase space where $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays are suppressed is more challenging, as the HQE convergence in these regions is spoiled, requiring the introduction of a non-perturbative distribution function, the ‘‘shape function’’ (SF) [76,77], whose form is unknown. The shape function becomes important when the light-cone momentum component $P_+ \equiv E_X - |P_X|$ is not large compared to Λ_{QCD} . This additional difficulty can be addressed in two complementary ways. The leading shape function can either be measured in the radiative decay $\overline{B} \rightarrow X_s \gamma$, or be modeled with constraints on the 0th-2nd moments, and the results applied to the calculation of the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial decay rate [78–80]; in such an approach the largest challenges are for the theory. Alternatively, measurements of $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial decay rates can be extended further into the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ -allowed region, enabling a simplified theoretical (pure HQE) treatment [81] but requiring precise experimental knowledge of the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background.

The shape function is a universal property of B mesons at leading order. It has been recognized for over a decade [76,77] that the leading SF can be measured in $\overline{B} \rightarrow X_s \gamma$ decays. However, sub-leading shape functions [82–87] arise at each order in $1/m_b$, and differ in semileptonic and radiative B decays. The form of the SFs cannot be calculated from first principles. Prescriptions that relate directly the partial rates for $\overline{B} \rightarrow X_s \gamma$ and $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays and thereby avoid any parameterization of the leading SF are available [88–91]; uncertainties due to sub-leading SF remain in these approaches. Existing measurements have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments. At leading order the first and second moments are equal to $\overline{\Lambda} = M_B - m_b$ and μ_π^2 , respectively. The relations between SF moments and the non-perturbative parameters of the HQE are known to second order in α_s [92]. As a result, measurements of HQE parameters from global fits to $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_s \gamma$ moments can be used to constrain the SF moments, as well as provide accurate values of m_b and other parameters for use in determining $|V_{ub}|$. The

possibility of measuring these HQE parameters directly from moments in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays has been explored [93], but the experimental precision achievable there is not competitive with other approaches.

A recent development is to use appropriate basis functions to approximate the shape function, thereby also including the known short-distance contributions as well as the renormalization properties of the SF [94], allowing finally a global fit of all inclusive B meson decay data.

The calculations that are used for the fits performed by HFAG are documented in Refs. [78] (BLNP), [95] (GGOU), [96] (DGE) and [81] (BLL).

The calculations start from the triple differential rate using the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (30)$$

for which the differential rate becomes

$$\frac{d^3\Gamma}{dP_+ dP_- dP_l} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2} (M_B - P_+) \left\{ (P_- - P_l)(M_B - P_- + P_l - P_+) \mathcal{F}_1 + (M_B - P_-)(P_- - P_+) \mathcal{F}_2 + (P_- - P_l)(P_l - P_+) \mathcal{F}_3 \right\}. \quad (31)$$

The ‘‘structure functions’’ \mathcal{F}_i can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion.

The BLNP [78] calculation uses these factorization theorems to write the \mathcal{F}_i in terms of perturbatively calculable hard coefficients H and jet functions J , which are convolved with the (soft) light-cone distribution functions S , the shape functions of the B meson.

The leading order term in the $1/m_b$ expansion of the \mathcal{F}_i contains a single non-perturbative function and is calculated to subleading order in α_s , while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions which have been calculated only at tree level in the α_s expansion.

To extract the non-perturbative input one can study the photon energy spectrum in $B \rightarrow X_s \gamma$ [80]. This spectrum is known at a similar accuracy as the P_+ spectrum in $B \rightarrow X_u \ell \overline{\nu}_\ell$. Going to subleading order in the $1/m_b$ expansion requires the modeling of subleading SFs, a large variety of which were studied in Ref. [78].

A recent calculation (GGOU) [95] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite m_b and depend on the light-cone component k_+ of the b quark momentum and on the momentum transfer q^2 to the leptons. These functions include sub-leading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (31). Their k_+ moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. [78].

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the SF. It has been noted that the relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [78,80], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can also attempt to calculate the SF by using additional assumptions. One possible approach (DGE) is the so-called “dressed gluon exponentiation” [96], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large β_0 limit, where β_0 has been defined following Eq. (17). Alternatively, one may assume an analytic behaviour for the strong coupling in the infrared to perform an extrapolation of perturbation theory [97].

While attempts to quantify the SF are important, the impact of uncertainties in the SF is significantly reduced in some recent measurements that cover a larger portion of the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ phase space. Several measurements using a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass M_X as suggested in Ref. [98] have been made. Measurements of the electron spectrum in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays have been made down to momenta of 1.9 GeV or even lower, where SF uncertainties are not dominant. Of course, determining $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial rates in charm-dominated regions can bring in a strong dependence on the modeling of the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ spectrum, which is problematic [99]. The measurements quoted below have used a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on $|V_{ub}|$.

Weak Annihilation [100,101,95] (WA) can in principle contribute significantly in the restricted region (at high q^2) accepted by measurements of $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays. An estimate [81] based on leptonic D_s decays [101,49] leads to a $\sim 3\%$ uncertainty on the total $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ rate from the $\Upsilon(4S)$. The differential spectrum from WA decays is not known, but they are expected to contribute predominantly at high q^2 , and may be a significant source of uncertainty for $|V_{ub}|$ measurements that only accept a small fraction, f_u , of the full $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ phase space. Model-dependent limits on WA were determined in Ref. [102], where the CLEO data were fitted to combinations of WA models and a spectator $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ component and background. More direct experimental constraints [103] on WA have recently been made by comparing the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decay rates of charged and neutral B mesons. However, these constraints are not sensitive to the isoscalar contribution to WA. The sensitivity of $|V_{ub}|$ determinations to WA can also be reduced by removing the region at high q^2 in those measurements where q^2 is determined.

Measurements

We summarize the measurements used in the determination of $|V_{ub}|$ below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [104–107] will not be further considered in this review.

Inclusive electron momentum measurements [108–110] reconstruct a single charged electron to determine a partial decay rate for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ near the kinematic endpoint. This results in a high $\mathcal{O}(50\%)$ selection efficiency and only modest sensitivity to the modeling of detector response. The decay rate can be cleanly extracted for $E_e > 2.3$ GeV, but this is deep in the SF region, where theoretical uncertainties are large. Measurements down to 2.0 or 1.9 GeV exist, but have low ($< 1/10$) signal-to-background (S/B) ratio, making the control of the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background a crucial point. In these analyses the inclusive electron momentum spectrum from $B\overline{B}$ events is determined by subtracting the $e^+e^- \rightarrow q\overline{q}$ continuum background using data samples collected just below $B\overline{B}$ threshold. The continuum-subtracted spectrum is fitted to a combination of a model $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ spectrum and several components ($D\ell\overline{\nu}_\ell$, $D^*\ell\overline{\nu}_\ell$, ...) of the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background. The resulting $|V_{ub}|$ values for various E_e cuts are given in Table 1. The leading uncertainty at the lower lepton momentum cuts comes from the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background. Prospects for reducing further the lepton momentum cut are improving in light of better knowledge of the semileptonic decays to higher mass $X_c \ell \overline{\nu}$ states [26,27]. The determination of $|V_{ub}|$ from these measurements is discussed below.

An untagged “neutrino reconstruction” measurement [111] from BABAR uses a combination [112] of a high energy electron with a measurement of the missing momentum vector. This allows a much higher S/B ~ 0.7 at the same E_e cut and a $\mathcal{O}(5\%)$ selection efficiency, but at the cost of a smaller accepted phase space for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum. A control sample of $\Upsilon(4S) \rightarrow B\overline{B}$ decays where one B is reconstructed as $\overline{B} \rightarrow D^0(X)e\overline{\nu}$ with $D^0 \rightarrow K^-\pi^+$ is used to reduce uncertainties from detector and background modeling. The corresponding values for $|V_{ub}|$ are given in Table 1.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [113–116]. The experiments can fully reconstruct a “tag” B candidate in about 0.5% (0.3%) of B^+B^- ($B^0\overline{B}^0$) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B and the remaining particles are assigned to the X_u system. The full set of kinematic properties (E_ℓ , M_X , q^2 , etc.) are available for studying the semileptonically decaying B , making possible selections that accept up to 70% of the full $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

additional missing particles, undetected or mis-measured particles from $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decay (e.g., K_L^0 and additional neutrinos) remain an important source of uncertainty.

BABAR [113] and BELLE [114,115] have measured partial rates with cuts on M_X , M_X and q^2 , and P_+ based on large samples of $B\overline{B}$ events. Correlations amongst these related partial rates are taken into account in the average given in Table 1. In each case the experimental systematics have significant contributions from the modeling of $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons.

Recoil-based analyses [115,116] of something approaching the full $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ rate are noteworthy for the smallness of their theoretical uncertainties, since they are in the region where the OPE is well behaved. The new Belle measurement [115] is quite precise; the leading experimental error comes from uncertainty in the modeling of $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays.

Determination of $|V_{ub}|$

The determination of $|V_{ub}|$ from the measured partial rates requires input from theory. The BLNP, GGOU and DGE calculations described previously are used to determine $|V_{ub}|$ from all measured partial $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ rates; the values are given in Table 1. The m_b input values used [118] are $m_b^{SF} = 4.650_{-0.037}^{+0.043}$ GeV for BLNP, $m_b^{\text{kin}} = 4.620 \pm 0.035$ GeV for GGOU, and $m_b^{MS} = 4.248 \pm 0.051$ GeV for DGE. These values come from the OPE fit to $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_s \gamma$ moments described above. An additional contribution for WA has been added to the DGE error budget.

As an illustration of the relative sizes of the uncertainties entering $|V_{ub}|$ we give the error breakdown for the BLNP average: statistical—2.6%; experimental—1.9%; $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ modeling—0.9%; $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ modeling—1.7%; HQE parameters—3.5%; shape function parameterization—0.4%; subleading SFs—0.7%; scale matching—3.5%; Weak Annihilation—1.2%. The uncertainty on m_b dominates the uncertainty on $|V_{ub}|$ from HQE parameters.

The correlations amongst the three BABAR recoil-based measurements are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments.

The theoretical calculations produce very similar results for $|V_{ub}|$; the rms difference between the calculated partial rates for each measurement, averaged over the set of measurements, is 2.1%. The $|V_{ub}|$ values do not show a marked trend versus f_u , the kinematic acceptance for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays. The P-values of the averages are all good, suggesting that the ratios of calculated partial widths in the different phase space regions are in reasonable agreement with ratios of measured widths.

A recent calculation [120] at NNLO accuracy of the leading term in the partial rate shows a surprisingly large change from the NLO calculation used in the BLNP method; these

Table 1: $|V_{ub}|$ (in units of 10^{-5}) from inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing f_u (0.19 to 0.90).

[115]	$436 \pm 26 \pm 22$	$441 \pm 26 \pm 13$	$446 \pm 26 \pm 16$
	$420 \pm 16 \pm 23$	$427 \pm 16 \pm 18$	$433 \pm 15 \pm 17$

updated calculations are not yet reflected in the values shown in Table 1. Their impact is to increase $|V_{ub}|$ by about 8%. This suggests that the uncertainties assigned to renormalization scale matching have been underestimated. While similar calculations are not yet available for the other approaches, the impact of NNLO terms may be underestimated there as well.

All calculations yield compatible $|V_{ub}|$ values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.27 \pm 0.15_{\text{exp}} \pm 0.19_{\text{th}} \pm 0.30_{\text{NNLO}}) \times 10^{-3} \quad (\text{inclusive}) \quad (32)$$

where the last uncertainty (7%) has been added to account for the large shift seen at NNLO. Note that while the average $|V_{ub}|$ quoted here is not shifted, the findings in Ref. [120] imply the NNLO corrections will raise $|V_{ub}|$.

As was the case with $|V_{cb}|$, it is hard to assign an uncertainty to $|V_{ub}|$ for possible duality violations. However, theoretical arguments suggest that duality should hold even better in $b \rightarrow u \ell \overline{\nu}_\ell$ than in $b \rightarrow c \ell \overline{\nu}_\ell$ [41]. On the other hand, unless duality violations are much larger in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays than in $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays, the precision of the $|V_{ub}|$ determination is not yet at the level where duality violations are likely to be significant.

Hadronization uncertainties also impact the $|V_{ub}|$ determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (e.g. $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$); this must be added “by hand” to the simulated $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables averaged over the sample. The resulting uncertainties have been estimated to be ~ 1 -2% on $|V_{ub}|$.

A separate class of analyses follows the strategy discussed in Refs. [88–91], where integrals of differential distributions in

$\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays are compared with corresponding integrals in $\overline{B} \rightarrow X_s \gamma$ decays to extract $|V_{ub}|$, thereby eliminating the need to model the leading shape function. A study [121] using the measured BABAR electron spectrum in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays provides $|V_{ub}|$ determinations using all available “SF-free” calculations; the resulting $|V_{ub}|$ values have total uncertainties of $\sim 12\%$ and are fully compatible with the average quoted above.

The BLL [98] calculation can be used for measurements with cuts on M_X and q^2 . Using the same HQE parameter input as above yields a $|V_{ub}|$ value of $(4.87 \pm 0.24 \pm 0.38) \times 10^{-3}$, which is about 15% higher than the values given in Table 1 for these measurements.

HQE parameters and shape function input

The global fits to $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_s \gamma$ moments discussed earlier provide input values for the heavy quark parameters needed in calculating $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial rates. These HQE parameters are also used to constrain the first and second moments of the shape function. The determinations of m_b using $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ moments are on solid theoretical ground and are performed using order α_S^2 calculations. Concern has been expressed about the theoretical control of $\mathcal{O}(1/m_b)$ corrections to the $\overline{B} \rightarrow X_s \gamma$ moments. On the other hand, the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ moments alone constrain only a linear combination of m_b and m_c with precision. Another way of determining precise values for m_b is to use determinations from relativistic sum rules [122,72] or Lattice QCD determinations [123], or to combine input on m_c from these sources with the global fit to $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ moments. Further work in this area is needed to critically assess the uncertainties quoted in the various methods. A convergence of the m_b values from these different techniques would enhance our confidence in the m_b used to extract $|V_{ub}|$ from inclusive decays. The uncertainty on m_b will continue to be a leading contribution to the uncertainty in $|V_{ub}|$.

For use in calculating inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decay rates, the m_b values determined in the global fit need to be translated into the renormalization scheme used in the calculation. These translations are done at fixed-order in α_S and bring in an additional source of uncertainty. Recently, the BLNP calculation has been updated to include the full $\mathcal{O}(\alpha_S^2)$ contributions [120]. Still the dependence on the b quark mass remains a large parametric uncertainty in the $|V_{ub}|$ determination.

Status and outlook

At present, as indicated by the average given above, the uncertainty on $|V_{ub}|$ from inclusive decays is at the 9% level. A large portion of this error has been added by the authors to reflect the larger-than-expected changes seen in the BLNP calculation when including NNLO terms. Determining the impact of NNLO terms in the other partial rate calculations should be pursued with high priority. The uncertainty on m_b taken here is ~ 40 MeV, contributing an uncertainty of $\sim 4\%$ on $|V_{ub}|$. Complimentary determinations of m_b with robust error estimates can be a valuable addition to the use of B decay moments. Further progress can also be expected on some of

the other leading sources of uncertainty. The Weak Annihilation contribution is now being addressed with data; further improvement can be expected with the full B factory dataset. The uncertainties on $|V_{ub}|$ quoted in the calculations are at the few percent level, and it has been suggested that these may be underestimated. Improving our confidence in, and eventually reducing, these theory uncertainties will require improvements in the calculations. For the approaches making use of the shape function this amounts to improvements in relating the spectra from $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_s \gamma$ decays by calculating radiative corrections and the effects of subleading SFs, while approaches less sensitive to SFs require calculations of higher-order radiative corrections. Experimental uncertainties will be reduced through higher statistics, a better understanding of $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays and the incorporation of improved measurements on D decays. Better measurement of exclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decay modes will also help reduce experimental uncertainties. The two approaches stated earlier, namely determining the shape function from the $\overline{B} \rightarrow X_s \gamma$ photon spectrum and applying it to $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays and pushing the measurements into regions where shape function and duality uncertainties become negligible, are complementary and should both be pursued.

$|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$, as it is the most promising mode for both experiment and theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [124–129].

$\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ form factor calculations The relevant form factors for the decay $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ are usually defined as

$$\langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = \tag{33}$$

$$f_+(q^2) \left[p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu$$

in terms of which the rate becomes (in the limit $m_\ell \rightarrow 0$)

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2 \tag{34}$$

where p_π is the momentum of pion in the B meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD and light-cone sum rules. The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer q^2 to the leptons, due to large discretization errors, while light-cone sum rules

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

provide information near $q^2 = 0$. Interpolations between these two regions may be constrained by unitarity and analyticity.

Unquenched simulations, for which quark loop effects in the QCD vacuum are fully incorporated, have become quite common, and the first results based on these simulations for the $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ form factors have been obtained recently by the Fermilab/MILC collaboration [130] and the HPQCD collaboration [131].

The two calculations differ in the way the b quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy quark method; they agree within the quoted errors.

In order to obtain the partially-integrated differential rate, the BK parameterization [132]

$$f_+(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \bar{q}^2)(1 - \alpha_B \bar{q}^2)}, \quad (35)$$

$$f_0(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \bar{q}^2/\beta_B)}, \quad (36)$$

with $\bar{q}^2 \equiv q^2/m_{B^*}^2$ has been used frequently to extrapolate to small values of q^2 . It includes the leading pole contribution from B^* , and higher poles are modeled by a single pole. The heavy quark scaling is satisfied if the parameters c_B , α_B and β_B scale appropriately. However, the BK parameterization should be used with some caution, since it is not consistent with SCET [133]. More recently, analyticity and unitarity bounds have been employed to constrain the form factors. Making use of the heavy quark limit, stringent constraints on the shape of the form factor can be derived [134], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in this variable. The use of lattice data in combination with a data point at small q^2 from SCET or sum rules provides a stringent constraint on the shape of the form factor [135]. The most recent form factor parametrization is given in Ref. [136] and has been applied to the extraction of $|V_{ub}|$ from $B \rightarrow \pi \ell \bar{\nu}_\ell$ using lattice data in Ref. [130].

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the $\sim 10\%$ level on $|V_{ub}|$ and need to be reduced. Reduction of errors to the $5 \sim 6\%$ level for $|V_{ub}|$ may be feasible within the next few years, although that could involve carrying out a two-loop (or fully non-perturbative) matching between lattice and continuum QCD heavy-to-light current operators, and/or going to smaller lattice spacing.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), where the heavy mass limit has been discussed from the point of view of SCET in Ref. [137]. The sum-rule approach provides an approximation for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 < \sim 14 \text{ GeV}^2$. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B , which usually is obtained by replacing f_B by its two-point QCD (SVZ) sum rule [138] in terms of perturbative and condensate

contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/f_B$. The LCSR for $f_B f_+$ is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b -quark mass. The resulting expressions actually comprise a triple expansion: in the twist t of the operators near the light-cone, in α_s , and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

There are multiple sources of uncertainties in the LCQCD calculation, which are discussed in Refs. [139,140]. The total uncertainty adds up to about 15%, resulting in the LCQCD prediction

$$f_+(0) = 0.26 \pm 0.04 \quad (37)$$

which is consistent with the values quoted in Refs. [139] and [140]. It is interesting to note that the results from the LQCD and LCSR are consistent with each other when the BK parameterization is used to relate them. This increases confidence in the theoretical predictions for the rate of $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$.

LC-sum rules are valid in the kinematic region of small q^2 and thus can be used to obtain an estimate of the q^2 dependence in a region $q^2 \leq 14 \text{ GeV}^2$ [139]. This is complementary to the lattice results at large values of q^2 , and the results from LCQCD smoothly extrapolate the lattice data to small values of q^2 .

An alternative determination of $|V_{ub}|$ has been proposed by several authors [141,142]. It is based on a model-independent relation between rare decays such as $\bar{B} \rightarrow K^* \ell^+ \ell^-$ and $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$, which can be obtained at large momentum transfer q to the leptons. This method is based on the HQET relations between the matrix elements of the $B \rightarrow K^*$ and the $B \rightarrow \rho$ transitions and a systematic, OPE-based expansion in powers of m_c^2/q^2 and Λ_{QCD}/q . The theoretical uncertainty is claimed to be of the order of 5% for $|V_{ub}|$; however, it requires a precise measurement of the exclusive rare decay $\bar{B} \rightarrow K^* \ell^+ \ell^-$, which is a task for future ultra-high-rate experiments.

$\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements

The $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels (S/B ≤ 1) and make slightly more restrictive kinematic cuts, but have adequate statistics to measure the q^2 dependence of the form factor.

Table 2: Total and partial branching fractions for $\overline{B}^0 \rightarrow \pi^+ \ell^- \overline{\nu}_\ell$. The uncertainties are from statistics and systematics. Measurements of $\mathcal{B}(B^- \rightarrow \pi^0 \ell^- \overline{\nu}_\ell)$ have been multiplied by a factor $2\tau_{B^0}/\tau_{B^-}$ to obtain the values below.

	$\mathcal{B} \times 10^4$	$\mathcal{B}(q^2 > 16) \times 10^4$

BABAR had π^0 [147]	$1.54 \pm 0.41 \pm 0.30$	$0.49 \pm 0.23 \pm 0.12$
Average	$1.36 \pm 0.05 \pm 0.05$	$0.37 \pm 0.03 \pm 0.02$

CLEO has analyzed $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow \rho \ell \overline{\nu}_\ell$ using an untagged analysis [128]. Similar analyses have been done by BABAR [129,143]. The leading systematic uncertainties in the untagged $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ analyses are associated with modeling the missing momentum reconstruction, with backgrounds from $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays, and with varying the form factor for the $\overline{B} \rightarrow \rho \ell \overline{\nu}_\ell$ decay. The values obtained for the full and partial branching fractions are listed in Table 2 above the horizontal line.

BABAR has measured the differential $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ rate versus q^2 with good accuracy [143]. A fit using the BK parameterization [132] gives $\alpha = 0.52 \pm 0.05 \pm 0.03$ with $P(\chi^2) = 65\%$. The q^2 spectrum, shown in Fig. 3, is compatible with the shapes expected from both LCSR and LQCD calculations, but is incompatible ($P(\chi^2) = 0.06\%$) with the ISGW2 [148] model.

BELLE [144] and BABAR [146] have performed analyses based on reconstructing a B in the $\overline{D}^{(*)} \ell^+ \nu_\ell$ decay mode and looking for a $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ or $\overline{B} \rightarrow \rho \ell \overline{\nu}_\ell$ decay amongst the remaining particles in the event. The fact that the B and \overline{B} are back-to-back in the $\Upsilon(4S)$ frame is used to construct a discriminating variable and obtain a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. [149]. BABAR [146] and BELLE [145] have also used their samples of B mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2. The average of the tagged analyses provides an accuracy on the $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ branching fraction comparable to that obtained with untagged analyses.

The outlook for further improvements in these measurements with larger B-factory data samples is good. The tagged measurements in particular will improve; the current estimates of systematic uncertainties in these measurements have

Figure 3: The differential branching fraction versus q^2 from BABAR [143] with several theoretical predictions overlaid.

a significant statistical component, so the total experimental uncertainty should fall as $1/\sqrt{N}$.

$|V_{ub}|$ can be obtained from the average $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ branching fraction and the measured q^2 spectrum. Fits to the measured q^2 spectrum from Ref. [143] using a theoretically motivated parameterization (e.g. from Ref. [9]) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum.

Recent determinations [130,150] of $|V_{ub}|$ from $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ decays have used simultaneous fits to the experimental partial rate and lattice points versus q^2 , using the form factor parameterization of Ref. [9]. We quote here the value from Ref. [130],

$$|V_{ub}| = (3.38 \pm 0.36) \times 10^{-3} \quad (\text{exclusive}). \quad (38)$$

The contributions to the uncertainty from experimental, lattice statistical and lattice systematic errors are all comparable, and each can be further improved.

Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, with fits to moments of $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $B \rightarrow X_s \gamma$ decays providing precise values for $|V_{cb}|$ and m_b . However, the tension between the inclusive and exclusive $|V_{cb}|$ values highlights the need for further work.

Measurements of inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays have improved, and additional theoretical treatments and improved knowledge of m_b have strengthened our determination of $|V_{ub}|$. Further progress in these areas is possible, but will require higher order radiative corrections from the theory and, in the case of $|V_{ub}|$, improved experimental knowledge of the

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

$\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ background, and independent confirmations of the input used for m_b . While there has been impressive progress in the past few years, the quest to achieve a precision of 5% on $|V_{ub}|$ from inclusive decays remains elusive.

Progress in both $b \rightarrow u$ and $b \rightarrow c$ exclusive channels depends crucially on progress in lattice calculations. Here the prospects are good (see, *e.g.*, Ref. [151]), since unquenched lattice simulations are now possible, although the ultimate attainable precision is hard to estimate.

The measurements of $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ have improved significantly, including the first reasonably precise determination of the q^2 dependence. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is clearly vital.

The difference between the values for $|V_{ub}|$ obtained from inclusive and exclusive decays has persisted for many years, despite significant improvements in both theory and experiment for both methods. How to reconcile these results remains an intriguing puzzle.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with good precision allows a test of CKM unitarity in the most direct way, by comparing the length of the $|V_{ub}|$ side of the unitarity triangle with the measurement of $\sin(2\beta)$. This comparison of a “tree” process ($b \rightarrow u$) with a “loop-induced” process ($B^0 - \bar{B}^0$ mixing) provides sensitivity to possible contributions from new physics. While the effort required to further improve our knowledge of these CKM matrix elements is large, it is well motivated.

The authors would like to acknowledge helpful discussions with M. Artuso, I. I. Bigi, A. Hoang, C. Schwanda and E. Barberio.

 V_{cb} MEASUREMENTS

For the discussion of V_{cb} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{cb}|$ can be determined by studying the rate of the semileptonic decay $B \rightarrow D^{(*)} \ell \nu$ as a function of the recoil kinematics of $D^{(*)}$ mesons. Taking advantage of theoretical constraints on the normalization and a linear ω dependence of the form factors ($F(\omega)$, $G(\omega)$) provided by Heavy Quark Effective Theory (HQET), the $|V_{cb}| \times F(\omega)$ and ρ^2 (a^2) can be simultaneously extracted from data, where ω is the scalar product of the two-meson four velocities, $F(1)$ is the form factor at zero recoil ($\omega=1$) and ρ^2 is the slope, sometimes denoted as a^2 . Using the theoretical input of $F(1)$, a value of $|V_{cb}|$ can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

 $|V_{cb}| \times F(1)$ (from $B^0 \rightarrow D^{*-} \ell^+ \nu$)

¹ Obtained from a global fit to $B \rightarrow D^{(*)} \ell \nu$ events, with reconstructed $D^0 \ell$ and $D^+ \ell$ final states and $\rho^2 = 1.22 \pm 0.02 \pm 0.07$.

² Measured using the dependence of $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$ decay differential rate and the form factor description by CAPRINI 98 with $\rho^2 = 1.16 \pm 0.06 \pm 0.08$.

³ Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.32 \pm 0.15 \pm 0.33$.

⁴ Average of the $B^0 \rightarrow D^*(2010)^- \ell^+ \nu$ and $B^+ \rightarrow \bar{D}^*(2007)^+ \ell^+ \nu$ modes with $\rho^2 = 1.61 \pm 0.09 \pm 0.21$ and $f_{+-} = 0.521 \pm 0.012$.

⁵ Measured using exclusive $B^0 \rightarrow D^*(892)^- e^+ \nu$ decays with $\rho^2 = 1.35 \pm 0.17 \pm 0.19$ and a correlation of 0.91.

⁶ ABREU 01H measured using about 5000 partial reconstructed D^* sample with a $\rho^2 = 1.34 \pm 0.14 \pm 0.24$
-0.22.

⁷ ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples with a $\rho^2 = 1.21 \pm 0.12 \pm 0.20$. The statistical and systematic correlations between $|V_{cb}| \times F(1)$ and ρ^2 are 0.90 and 0.54 respectively.

⁸ BUSKULIC 97: measured using exclusively reconstructed $D^{*\pm}$ with a $a^2 = 0.31 \pm 0.17 \pm 0.08$. The statistical correlation is 0.92.

⁹ Measured using fully reconstructed D^* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2 = 1.191 \pm 0.048 \pm 0.028$, $R_1(1) = 1.429 \pm 0.061 \pm 0.044$, and $R_2(1) = 0.827 \pm 0.038 \pm 0.022$.

¹⁰ Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.29 \pm 0.03 \pm 0.27$.

¹¹ Combines with previous partial reconstructed D^* measurement with a $\rho^2 = 1.39 \pm 0.10 \pm 0.33$.

¹² BRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.

¹³ ABREU 96P: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples.

¹⁴ BARISH 95: measured using both exclusive reconstructed $B^0 \rightarrow D^{*-} \ell^+ \nu$ and $B^+ \rightarrow D^{*0} \ell^+ \nu$ samples. They report their experiment's uncertainties $\pm 0.0019 \pm 0.0018 \pm 0.0008$, where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.

- 15 Obtained from a fit to the combined $B \rightarrow \bar{D} \ell^+ \nu \ell$ sample in which a hadronic decay of the second B meson is fully reconstructed and $\rho^2 = 1.20 \pm 0.09 \pm 0.04$.
- 16 Obtained from a global fit to $B \rightarrow D^{(*)} \ell \nu \ell$ events, with reconstructed $D^0 \ell$ and $D^+ \ell$ final states and $\rho^2 = 1.20 \pm 0.04 \pm 0.07$.
- 17 Using the missing energy and momentum to extract kinematic information about the undetected neutrino in the $B^0 \rightarrow D^- \ell^+ \nu$ decay.
- 18 BARTELT 99: measured using both exclusive reconstructed $B^0 \rightarrow D^- \ell^+ \nu$ and $B^+ \rightarrow D^0 \ell^+ \nu$ samples.
- 19 BUSKULIC 97: measured using exclusively reconstructed D^+ with a $a^2 = -0.05 \pm 0.53 \pm 0.38$. The statistical correlation is 0.99.
- 20 ATHANAS 97: measured using both exclusive reconstructed $B^0 \rightarrow D^- \ell^+ \nu$ and $B^+ \rightarrow D^0 \ell^+ \nu$ samples with a $\rho^2 = 0.59 \pm 0.22 \pm 0.12^{+0.59}_{-0.0012}$. They report their experiment's uncertainties $\pm 0.0044 \pm 0.0048^{+0.0053}_{-0.0012}$, where the first error is statistical, the second is systematic, and the third is the uncertainty due to the form factor model variations. We combine the last two in quadrature.

V_{ub} MEASUREMENTS

For the discussion of V_{ub} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{ub}|$ can be determined by studying the rate of the charmless semileptonic decay $b \rightarrow u \ell \nu$. The relevant branching ratio measurements based on exclusive and inclusive decays can be found in the B Listings, and are not repeated here.

Meson Particle Listings

 $B_J^*(5732)$, $B_1(5721)^0$, $B_2^*(5747)^0$

¹AFFOLDER 01F uses the reconstructed B meson through semileptonic decay channels. The fraction of light B mesons that are produced at $L=1$ B^{**} states is measured to be $0.28 \pm 0.06 \pm 0.03$.

²BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\pi^\pm$ system. In the framework of heavy quark symmetry (HQS), they also measured the mass of B_2^* to be 5739_{-11}^{+8+6} MeV/ c^2 and the relative production rate of $B(b \rightarrow B_2^* \rightarrow B^*(*)\pi)/B(b \rightarrow B_{u,d}) = (31 \pm 9_{-5}^{+6})\%$.

³Using $m_{B\pi} - m_B = 424 \pm 4 \pm 10$ MeV.

⁴ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^*(*)\pi^\pm$ system. In the framework of HQET, they measured the mass of B_1^* and B_2^* to be $5670 \pm 10 \pm 13$ MeV and $5768 \pm 5 \pm 6$ with the $B(b \rightarrow B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$. They also reported the evidence for the existence of an excited B -meson state or mixture of states in the region 5.9–6.0 GeV.

80 to 130	68	LEE-FRANZINI 90	CSB2	$e^+e^- \rightarrow \Upsilon(5S)$

- ⁴ The reported result is $m_{B_s^0} - m_{B^0} = 86.38 \pm 0.90 \pm 0.06$ MeV. We convert it to the mass difference with respect to the average of ($m_{B^\pm} + m_{B^0}$)/2.

$m_{B_s^0} - m_{B_s^L}$

See the $B_s^0 - \bar{B}_s^0$ MIXING section near the end of these B_s^0 Listings.

B_s^0 MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

The First "OUR EVALUATION" is an average of $1 / [0.5 (\Gamma_{B_s^0} + \Gamma_{B_s^H})]$.
The Second "OUR EVALUATION" is the average of $B_s \rightarrow D_s X^L$ data listed below.

⁴⁴ Measured using the time-dependent angular analysis of $B_s^0 \rightarrow J/\psi\phi$ decays.			

B_s^0 DECAY MODES

These branching fractions all scale with $B(\bar{b} \rightarrow B_s^0)$, the LEP B_s^0 production fraction. The first four were evaluated using $B(\bar{b} \rightarrow B_s^0) = (10.7 \pm 1.2)\%$ and the rest assume $B(\bar{b} \rightarrow B_s^0) = 12\%$.

The branching fraction $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ is not a pure measurement since the measured product branching fraction $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ was used to determine $B(\bar{b} \rightarrow B_s^0)$, as described in the note on “ B^0 - \bar{B}^0 Mixing”

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction (Γ_i/Γ)	Confidence level

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.93 ± 0.25 OUR AVERAGE				
0.91 ± 0.18 ± 0.41	45	DRUTSKOY 07 BELL		$e^+ e^- \rightarrow T(4S)$
0.81 ± 0.24 ± 0.22	90	46 BUSKULIC 96E ALEP		$e^+ e^- \rightarrow Z$
1.56 ± 0.58 ± 0.44	147	47 ACTON 92N OPAL		$e^+ e^- \rightarrow Z$
⁴⁵ The extraction of this result takes into account the correlation between the measurements of $B(T(5S) \rightarrow D_s X)$ and $B(T(5S) \rightarrow D^0 X)$.				
⁴⁶ BUSKULIC 96E separate $c\bar{c}$ and $b\bar{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\bar{b} \rightarrow W^+ \rightarrow D_s^+$ events, and obtain $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \text{ anything}) = 0.088 \pm 0.020 \pm 0.020$ assuming $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to other D_s channels. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.				
⁴⁷ ACTON 92N assume that excess of 147 ± 48 D_s^0 events over that expected from $B^0, B^+,$ and $c\bar{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $B(\bar{b} \rightarrow B_s^0) B(B_s^0 \rightarrow D_s^- \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.				

$\Gamma(D_s^- \ell^+ \nu_\ell \text{ anything})/\Gamma_{\text{total}}$

Γ_2/Γ

The values and averages in this section serve only to show what values result if one assumes our $B(\bar{b} \rightarrow B_s^0)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(\bar{b} \rightarrow B_s^0)$ as described in the note on “Production and Decay of b-Flavored Hadrons.”

0.13 ± 0.04 ± 0.04	27	51 BUSKULIC 92E ALEP		$e^+ e^- \rightarrow Z$
⁴⁸ BUSKULIC 95o use $D_s \ell$ correlations. The measured product branching ratio is $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = (0.82 \pm 0.09 \pm 0.13 / 0.14) \%$ assuming $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $T(4S)$ experiments this can be used to extract $B(\bar{b} \rightarrow B_s^0) = (11.0 \pm 1.2 \pm 2.5 / 2.6) \%$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.				
⁴⁹ ABREU 92M measured muons only and obtained product branching ratio $B(Z \rightarrow b\bar{b}) \times B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \mu^+ \nu_\mu \text{ anything}) \times B(D_s^- \rightarrow \phi\pi) = (18 \pm 8) \times 10^{-5}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$. We use $B(Z \rightarrow b\bar{b}) = 2B(Z \rightarrow b\bar{b}) = 2 \times (0.2212 \pm 0.0019)$.				
⁵⁰ ACTON 92N is measured using $D_s \rightarrow \phi\pi^+$ and $K^*(892)^0 K^+$ events. The product branching fraction measured is measured to be $B(\bar{b} \rightarrow B_s^0) B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.				
⁵¹ BUSKULIC 92E is measured using $D_s \rightarrow \phi\pi^+$ and $K^*(892)^0 K^+$ events. They use $2.7 \pm 0.7\%$ for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be $B(\bar{b} \rightarrow B_s^0) B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = 0.020 \pm 0.0055 \pm 0.005 / 0.006$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$. Superseded by BUSKULIC 95o.

 $B_s^0\text{-}\bar{B}_s^0$ MIXING

For a discussion of $B_s^0\text{-}\bar{B}_s^0$ mixing see the note on " $B^0\text{-}\bar{B}^0$ Mixing" in the B^0 Particle Listings above.

x_s is a measure of the time-integrated $B_s^0\text{-}\bar{B}_s^0$ mixing probability that produced $B_s^0(\bar{B}_s^0)$ decays as a $\bar{B}_s^0(B_s^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$x_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_s^0 H} - m_{B_s^0 L}) \tau_{B_s^0}$$

where H, L stand for heavy and light states of two B_s^0 CP eigenstates and

$$\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_s^0 H} + \Gamma_{B_s^0 L})}$$

 $\Delta m_{B_s^0} = m_{B_s^0 H} - m_{B_s^0 L}$

$\Delta m_{B_s^0}$ is a measure of 2π times the $B_s^0\text{-}\bar{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

115 Significance of oscillation signal is 5.4σ . Also reports $|V_{td} / V_{ts}| = 0.2060 \pm 0.0007 \pm 0.0081 - 0.0060$.

116 A likelihood scan over the oscillation frequency, Δm_s , gives a most probable value of 19 ps^{-1} and a range of $17 < \Delta m_s < 21 \text{ (ps}^{-1})$ at 90% C.L. assuming Gaussian uncertainties. Also excludes $\Delta m_s < 14.8 \text{ ps}^{-1}$ at 95% C.L.

117 Significance of oscillation signal is 0.2%. Also reported the value $|V_{td} / V_{ts}| = 0.208 \pm 0.001 \pm 0.008 - 0.208 - 0.002 - 0.006$.

118 Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.

119 Updates of D_s -lepton analysis.

120 Combined results from all Delphi analyses.

121 Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

122 ABE 03 uses the novel "charge dipole" technique to reconstruct separate secondary and tertiary vertices originating from the $B \rightarrow D$ decay chain. The analysis excludes $\Delta m_s < 4.9 \text{ ps}^{-1}$ and $7.9 < \Delta m_s < 10.3 \text{ ps}^{-1}$.

123 Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with D_s exclusively reconstructed; (3) inclusive semileptonic decays.

124 ABE 02v uses exclusively reconstructed D_s^- mesons and excludes $\Delta m_s < 1.4 \text{ ps}^{-1}$ and $2.4 < \Delta m_s < 5.3 \text{ ps}^{-1}$ at 95% CL.

125 Uses fully or partially reconstructed $D_s \ell$ vertices and a mixing tag as a flavor tagging.

126 Replaced by ABDALLAH 04A. Uses $D_s^- \ell^+$ and $\phi \ell^+$ vertices, and a multi-variable discriminant as a flavor tagging.

127 Uses inclusive D_s vertices and fully reconstructed B_s decays and a multi-variable discriminant as a flavor tagging.

128 Uses $\ell\text{-}Q_{\text{hem}}$ and $\ell\text{-}\ell$.

129 ABE 99D assumes $\tau_{B^0} = 1.55 \pm 0.05 \text{ ps}$ and $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$.

130 ABE 99J uses $\phi\text{-}\ell$ correlation.

131 BARATE 99J uses combination of an inclusive lepton and D_s^- -based analyses.

132 BARATE 98C combines results from $D_s h\text{-}\ell/Q_{\text{hem}}$, $D_s h\text{-}K$ in the same side, $D_s \ell\text{-}\ell/Q_{\text{hem}}$ and $D_s \ell\text{-}K$ in the same side.

133 Uses $\ell\text{-}Q_{\text{hem}}$.

134 Uses $\ell\text{-}\ell$.

135 ADAM 97 combines results from $D_s \ell\text{-}Q_{\text{hem}}$, $\ell\text{-}Q_{\text{hem}}$, and $\ell\text{-}\ell$.

136 BUSKULIC 96M uses D_s lepton correlations and lepton, kaon, and jet charge tags.

137 BUSKULIC 95J uses $\ell\text{-}Q_{\text{hem}}$. They find $\Delta m_s > 5.6$ [> 6.1] for $f_s = 10\%$ [12%]. We interpolate to our central value $f_s = 10.5\%$.

 $x_s = \Delta m_{B_s^0} / \Gamma_{B_s^0}$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on $\Delta m_{B_s^0}$ and "OUR EVALUATION" of the B_s^0 mean lifetime.

-0.9 ± 2.6 OUR EVALUATION			
6.1 ± 4.8 ± 0.9	138 ABAZOV	07A D0	$\rho\bar{p}$ at 1.96 TeV

138 The first direct measurement of the time integrated flavor untagged charge asymmetry in semileptonic B_S^0 decays is reported as $2\text{KA}_{SL}^{\pm}(\text{untagged}) = A_{SL}^{\pm} = (2.45 \pm 1.93 \pm 0.35) \times 10^{-2}$.

CP Violation phase β_S

$-2\beta_S$ is the weak phase difference between B_S^0 mixing amplitude and the $B_S^0 \rightarrow J/\psi\phi$ decay amplitude. The Standard Model value of β_S is $\arg(-\frac{V_{ts}V_{tb}^*}{V_{cs}V_{cb}^*})$.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/scaling procedure takes into account correlation between the measurements.

------------------	----------------	--------	----------------------

139 Reports $0.32 < 2\beta_S < 2.82$ at 68% C.L. and confidence regions in the two-dimensional space of $2\beta_S$ and $\Delta\Gamma$ from the first measurement of $B_S^0 \rightarrow J/\psi\phi$ decays using flavor tagging. The probability of a deviation from SM prediction as large as the level of observed data is 15%.

140 Measured using fully reconstructed $B_S \rightarrow J/\psi\phi$ decays.

141 Reports $\phi_S = -2\beta_S$ and obtains 90% CL interval $-0.03 < \beta_S < 0.60$.

142 The first direct measurement of the CP-violating mixing phase is reported from the time-dependent analysis of flavor untagged $B_S^0 \rightarrow J/\psi\phi$ decays.

143 Reports ϕ_S which equals to $-2\beta_S$.

144 Combines D0 collaboration measurements of time-dependent angular distributions in $B_S^0 \rightarrow J/\psi\phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

< 1.2	$\times 10^{-4}$	90	9 BARATE 97H	ALEP $e^+e^- \rightarrow Z$

- 6 ABE 98M result is derived from the measurement of $[\sigma(B_c) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell)] / [\sigma(B^+) \times B(B^+ \rightarrow J/\psi(1S)K^+)] = 0.132^{+0.041}_{-0.037}(\text{stat}) \pm 0.031(\text{sys}) \pm 0.032(\text{lifetime})$ by using PDG 98 values of $B(b \rightarrow B^+)$ and $B(B^+ \rightarrow J/\psi(1S)K^+)$.
- 7 ACKERSTAFF 98o reports $B(Z \rightarrow B_c X)/B(Z \rightarrow qq) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell) < 6.95 \times 10^{-5}$ at 90%CL. We rescale to our PDG 98 values of $B(Z \rightarrow b\bar{b})$.
- 8 ABREU 97E value listed is for an assumed $\tau_{B_c} = 0.4$ ps and improves to 1.6×10^{-4} for $\tau_{B_c} = 1.4$ ps.
- 9 BARATE 97H reports $B(Z \rightarrow B_c X)/B(Z \rightarrow qq) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell) < 5.2 \times 10^{-5}$ at 90%CL. We rescale to our PDG 96 values of $B(Z \rightarrow b\bar{b})$. A $B_c^+ \rightarrow J/\psi(1S)\mu^+\nu_\mu$ candidate event is found, compared to all the known background sources 2×10^{-3} , which gives $m_{B_c} = 5.96^{+0.25}_{-0.19}$ GeV and $\tau_{B_c} = 1.77 \pm 0.17$ ps.

Meson Particle Listings

Charmonium, $\eta_c(1S)$

c \bar{c} MESONS

The current state of knowledge of the charmonium system and transitions, as interpreted by the charmonium model. Uncertain states and transitions are indicated by dashed lines. The notation γ^* refers to decay processes involving intermediate virtual photons, including decays to e^+e^- and $\mu^+\mu^-$.

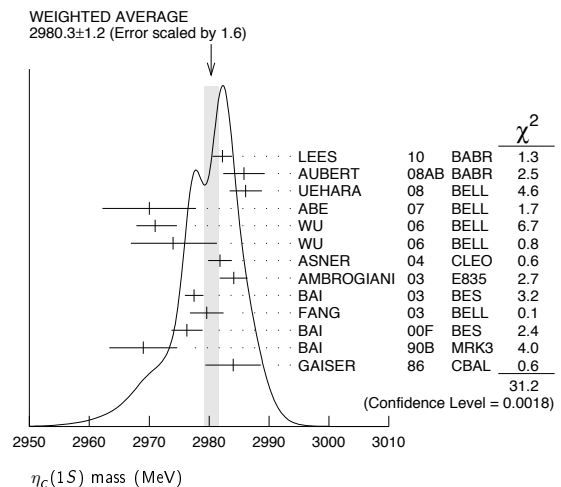

$\eta_c(1S)$

$I^G(J^{PC}) = 0^+(0^{-+})$

- ¹ Taking into account interference with the non-resonant $J^P = 0^-$ amplitude.
- ² From a fit of the J/ψ recoil mass spectrum. Supersedes ABE,K 02 and ABE 04c.
- ³ Using mass of $\psi(2S) = 3686.00$ MeV.
- ⁴ From a simultaneous fit of five decay modes of the η_c .
- ⁵ MITCHELL 09 observes a significant asymmetry in the lineshapes of $\psi(2S) \rightarrow \gamma\eta_c$ and $J/\psi \rightarrow \gamma\eta_c$ transitions. If ignored, this asymmetry could lead to significant bias whenever the mass and width are measured in $\psi(2S)$ or J/ψ radiative decays.
- ⁶ Using an η_c width of 13.2 MeV.
- ⁷ Weighted average of the $\psi(2S)$ and $J/\psi(1S)$ samples.
- ⁸ From the fit of the kaon momentum spectrum. Systematic errors not evaluated.
- ⁹ Superseded by LEES 10.
- ¹⁰ Average of several decay modes.
- ¹¹ Superseded by ASNEN 04.
- ¹² $\eta_c \rightarrow \phi\phi$.
- ¹³ Mass adjusted by us to correspond to $J/\psi(1S)$ mass = 3097 MeV.

32 From the corrected and unfolded mass spectrum.
 33 Calculated by us from the value reported in ASNER 04 that assumes $B(\eta_c \rightarrow K \bar{K} \pi) = 5.5 \pm 1.7\%$.
 34 We have multiplied $K^\pm K_S^0 \pi^\mp$ measurement by 3 to obtain $K \bar{K} \pi$.
 35 Calculated by us from the value reported in ABDALLAH 03J, which uses $B(\eta_c \rightarrow K_S^0 K^\pm \pi^\mp) = (1.5 \pm 0.4)\%$.
 36 Superseded by ASNER 04.
 37 Calculated by us from the value reported in ABDALLAH 03J, which uses $B(\eta_c \rightarrow \pi^+ \pi^- K^+ K^-) = (2.0 \pm 0.7)\%$.
 38 Calculated by us from the value reported in ABDALLAH 03J, which uses $B(\eta_c \rightarrow 2(K^+ K^-)) = (2.1 \pm 1.2)\%$.
 39 Includes all topological modes except $\eta_c \rightarrow \phi\phi$.
 40 Not independent from the $\Gamma_{\gamma\gamma}$ reported by the same experiment.

< 0.012	90	HIMEL	80B MRK2	$\psi(2S) \rightarrow \eta_c \gamma$

41 The quoted branching ratios use $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.

42 ABLIKIM 06A reports $[\Gamma(\eta_c(1S) \rightarrow K^*0\bar{K}^*0\pi^+\pi^-)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.91 \pm 0.64 \pm 0.48) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

43 Using $B(B^+ \rightarrow \eta_c K^+) = (1.25 \pm 0.12 \pm 0.10) \times 10^{-3}$ from FANG 03 and $B(\eta_c \rightarrow K\bar{K}\pi) = (5.5 \pm 1.7) \times 10^{-2}$.

44 ABLIKIM 06A reports $[\Gamma(\eta_c(1S) \rightarrow \phi 2(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] < 0.603 \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 1.7 \times 10^{-2}$.

45 We are assuming $B(a_0(980) \rightarrow \eta\pi) > 0.5$.

46 ABLIKIM 04M reports $[\Gamma(\eta_c(1S) \rightarrow f_2(1270)f_2(1270))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.3 \pm 0.3 \pm 0.3) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

47 Determined from the ratio of $B(B^\pm \rightarrow K^\pm \eta_c) B(\eta_c \rightarrow K\bar{K}\pi) = (7.4 \pm 0.5 \pm 0.7) \times 10^{-5}$ reported in AUBERT,B 04B and $B(B^\pm \rightarrow K^\pm \eta_c) = (8.7 \pm 1.5) \times 10^{-3}$ reported in AUBERT 06E.

48 Average from $K^+ K^- \pi^0$ and $K^\pm K_S^0 \pi^\mp$ decay channels.

49 Estimated using $B(\psi(2S) \rightarrow \gamma\eta_c(1S)) = 0.0028 \pm 0.0006$.

50 ABLIKIM 06A reports $[\Gamma(\eta_c(1S) \rightarrow K^+ K^- 2(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (1.21 \pm 0.32 \pm 0.24) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

51 Normalized to the sum of $B(\eta_c \rightarrow K^\pm K_S^0 \pi^\mp)$, $B(\eta_c \rightarrow \phi\phi)$, $B(\eta_c \rightarrow K^+ K^- \pi^+ \pi^-)$, and $B(\eta_c \rightarrow 2\pi^+ 2\pi^-)$.

52 ABLIKIM 06A reports $[\Gamma(\eta_c(1S) \rightarrow 3(\pi^+\pi^-))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (2.59 \pm 0.32 \pm 0.47) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

53 WU 06 reports $[\Gamma(\eta_c(1S) \rightarrow \rho\bar{\rho})/\Gamma_{total}] \times [B(B^+ \rightarrow \eta_c K^+)] = (1.42 \pm 0.11 \pm 0.16) \times 10^{-6}$ which we divide by our best value $B(B^+ \rightarrow \eta_c K^+) = (9.1 \pm 1.3) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

54 WU 06 reports $[\Gamma(\eta_c(1S) \rightarrow \Lambda\bar{\Lambda})/\Gamma_{total}] \times [B(B^+ \rightarrow \eta_c K^+)] = (0.95 \pm 0.25 \pm 0.08) \times 10^{-6}$ which we divide by our best value $B(B^+ \rightarrow \eta_c K^+) = (9.1 \pm 1.3) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

55 Not independent from other $\eta_c \rightarrow \Lambda\bar{\Lambda}, p\bar{p}$ branching ratios reported by WU 06.

$\eta_c(1S), J/\psi(1S)$

⁵⁶ADAMS 08 reports $[\Gamma(\eta_c(1S) \rightarrow \gamma\gamma)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow \gamma\eta_c(1S))] = (2.4_{-0.8}^{+1.1} \pm 0.3) \times 10^{-6}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁵⁷WICHT 08 reports $[\Gamma(\eta_c(1S) \rightarrow \gamma\gamma)/\Gamma_{\text{total}}] \times [B(B^+ \rightarrow \eta_c K^+)] = (2.2_{-0.7}^{+0.9} \pm 0.4) \times 10^{-7}$ which we divide by our best value $B(B^+ \rightarrow \eta_c K^+) = (9.1 \pm 1.3) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁵⁸Not independent from the values of the total and two-photon width quoted by the same experiment.

⁵⁹The quoted branching ratios use $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing averages.

⁶⁰Using $B(J/\psi(1S) \rightarrow \gamma\eta_c(1S)) = 0.0127 \pm 0.0036$.

¹Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).

²Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the $\psi(2S)$ mass from AULCHENKO 03.

³Superseded by ARTAMONOV 00.

⁴From a simultaneous fit to e^+e^- , $\mu^+\mu^-$ and hadronic channels assuming $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-)$.

1.3 ± 0.3	153	JEAN-MARIE	76	MRK1 e^+e^-	

⁴²From the ratio of $\Gamma(e^+e^-)B(\pi^+\pi^-\pi^0)$ and $\Gamma(e^+e^-)B(\mu^+\mu^-)$ (AUBERT 04).
⁴³Not independent of their $B(\pi^+\pi^-\pi^0)$.
⁴⁴From $J/\psi \rightarrow \pi^+\pi^-\pi^0$ events directly.
⁴⁵Obtained comparing the rates for $\pi^+\pi^-\pi^0$ and $\mu^+\mu^-$, using J/ψ events produced via $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$ and with $B(J/\psi \rightarrow \mu^+\mu^-) = 5.88 \pm 0.10\%$.

BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Updated May 2010 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Genova).

Since 2002, the treatment of the branching ratios of the $\psi(2S)$ and $\chi_{c0,1,2}$ has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles [1,2] as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles, $\psi(2S)$, χ_{c0} , χ_{c1} , and χ_{c2} , and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the $\chi_{c0,1,2}$ are measured independently of the $\psi(2S)$ radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 24 combinations of partial widths, 7 branching ratios, and 75 combinations of branching ratios. Of the latter 52 involve decays of more than one particle.

The overall fit uses 213 measurements to determine 47 parameters and has a χ^2 of 301.4 for 166 degrees of freedom.

The relatively high χ^2 of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No rescaling of errors has been applied.

Branching Ratios of ψ 's and χ 's, $\chi_{c0}(1P)$

In the listing we provide the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the corresponding parameter x_i .

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 24 combinations of partial widths obtained from integrated cross section, and 82 branching ratios uses 213 measurements to determine 47 parameters. The overall fit has a $\chi^2 = 301.4$ for 166 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 24 combinations of partial widths obtained from integrated cross section, and 82 branching ratios uses 213 measurements to determine 47 parameters. The overall fit has a $\chi^2 = 301.4$ for 166 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

⁸From a simultaneous fit to $e^+ e^-$, $\mu^+ \mu^-$, and hadronic channel, assuming $\Gamma_e = \Gamma_\mu = \Gamma_\gamma/0.38847$.

⁹From a simultaneous fit to $e^+ e^-$, $\mu^+ \mu^-$, and hadronic channels assuming $\Gamma(e^+ e^-) = \Gamma(\mu^+ \mu^-)$.

$\psi(2S) \Gamma(i)\Gamma(e^+ e^-)/\Gamma(\text{total})$

This combination of a partial width with the partial width into $e^+ e^-$ and with the total width is obtained from the integrated cross section into channel(i) in the $e^+ e^-$ annihilation. We list only data that have not been used to determine the partial width $\Gamma(i)$ or the branching ratio $\Gamma(i)/\text{total}$.

¹¹AUBERT 05D reports $[\Gamma(\psi(2S) \rightarrow J/\psi(1S)\pi^+\pi^-) \times \Gamma(\psi(2S) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow \mu^+\mu^-)] = 0.0450 \pm 0.0018 \pm 0.0022$ keV which we divide by our best value $B(J/\psi(1S) \rightarrow \mu^+\mu^-) = (5.93 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

¹²The value of $\Gamma(e^+e^-)$ quoted in BAI 98E is derived using $B(\psi(2S) \rightarrow J/\psi(1S)\pi^+\pi^-) = (32.4 \pm 2.6) \times 10^{-2}$ and $B(J/\psi(1S) \rightarrow \ell^+\ell^-) = 0.1203 \pm 0.0038$. Recalculated by us using $B(J/\psi(1S) \rightarrow \ell^+\ell^-) = 0.1181 \pm 0.0020$.

¹³AUBERT 07AU reports $[\Gamma(\psi(2S) \rightarrow J/\psi(1S)\pi^+\pi^-) \times \Gamma(\psi(2S) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \rightarrow \pi^+\pi^-\pi^0)] = 0.0186 \pm 0.0012 \pm 0.0011$ keV which we divide by our best value $B(J/\psi(1S) \rightarrow \pi^+\pi^-\pi^0) = (2.07 \pm 0.12) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

WEIGHTED AVERAGE
0.82±0.04 (Error scaled by 1.6)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

48 From a fit to the J/ψ recoil mass spectra.
 49 The value for $B(\psi(2S) \rightarrow J/\psi(1S)\eta)$ reported in HIMEL 80 is derived using $B(\psi(2S) \rightarrow J/\psi(1S)\pi^+\pi^-) = (33 \pm 3)\%$ and $B(J/\psi(1S) \rightarrow \ell^+ \ell^-) = 0.138 \pm 0.018$. Calculated by us using $B(J/\psi(1S) \rightarrow \ell^+ \ell^-) = (0.1181 \pm 0.0020)$.

Meson Particle Listings

$\psi(3770)$

¹ Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = 0^\circ$.

$m_{\psi(3770)} - m_{\psi(2S)}$

OUR FIT includes measurements of $m_{\psi(2S)}$, $m_{\psi(3770)}$, and $m_{\psi(3770)} - m_{\psi(2S)}$.

⁴ Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = 0^\circ$.

$\psi(3770)$ DECAY MODES

In addition to the dominant decay mode to $D\bar{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 3 branching ratios uses 21 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 17.9$ for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

• • • We do not use the following data for averages, fits, limits, etc. • • •

⁵ Reanalysis of data presented in BAI 02c. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = 0^\circ$.

⁶ BESSON 06 (as corrected in BESSON 10) measure $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = 6.36 \pm 0.08 \pm \frac{0.41}{-0.30}$ nb at $\sqrt{s} = 3773 \pm 1$ MeV, and obtain $\Gamma_{e^+e^-}$ from the Born-level cross section calculated using $\psi(3770)$ mass and width from our 2004 edition, PDG 04.

⁷ See also $\Gamma(e^+e^-) / \Gamma_{\text{total}}$ below.

- ⁸ Neglecting interference.
- ⁹ Obtained by comparing a measurement of the total cross section (corrected in BESSON 10) with that of $D\bar{D}$ reported by CLEO in DOBBS 07.
- ¹⁰ Using $\sigma_{obs} = 7.07 \pm 0.58$ nb and neglecting interference.
- ¹¹ Not independent of ABLIKIM 08b.
- ¹² From a measurement of $\sigma(e^+e^- \rightarrow D\bar{D})$ at $\sqrt{s} = 3773$ MeV, using the $\psi(3770)$ resonance parameters measured by ABLIKIM 06L.
- ¹³ See ADLER 88c for older measurements of this quantity.
- ¹⁴ Uses $B(\psi(2S) \rightarrow \gamma\chi_{c0}) = 9.33 \pm 0.14 \pm 0.61\%$ from ATHAR 04, $\psi(2S)$ mass and width from PDG 04, and $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$ keV from ADAM 06.
- ¹⁵ Using $\Gamma_{ee}(\psi(2S)) = (2.54 \pm 0.03 \pm 0.11)$ keV from ADAM 06 and taking $\sigma(e^+e^- \rightarrow D\bar{D})$ from HE 05 for $\sigma(e^+e^- \rightarrow \psi(3770))$.
- ¹⁶ Averages the two measurements from COAN 06A and BRIERE 06.
- ¹⁷ Uses $B(\psi(2S) \rightarrow \gamma\chi_{c1}) = 9.07 \pm 0.11 \pm 0.54\%$ from ATHAR 04, $\psi(2S)$ mass and width from PDG 04, and $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$ keV from ADAM 06.
- ¹⁸ Using $B(\psi(3770) \rightarrow J/\psi\pi^+\pi^-) = (1.89 \pm 0.20 \pm 0.20) \times 10^{-3}$ from ADAM 06.
- ¹⁹ Not independent of other results in BRIERE 06.
- ²⁰ Uses $B(\psi(2S) \rightarrow \gamma\chi_{c2}) = 9.22 \pm 0.11 \pm 0.46\%$ from ATHAR 04, $\psi(2S)$ mass and width from PDG 04, and $\Gamma_{ee}(\psi(2S)) = 2.54 \pm 0.03 \pm 0.11$ keV from ADAM 06.
- ²¹ Using $\sigma(e^+e^- \rightarrow \psi(3770) \rightarrow \text{hadrons}) = (6.38 \pm 0.08^{+0.41}_{-0.30})$ nb from BESSON 06 and $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6895 \pm 0.0014$.
- ²² Using $B(K_S^0 \rightarrow \pi^+\pi^-) = 0.6860 \pm 0.0027$.
- ²³ Using $\sigma_{tot}(e^+e^- \rightarrow \psi(3770)) = 7.9 \pm 0.6$ nb at the resonance.
- ²⁴ Assuming that interference effects between resonance and continuum can be neglected.
- ²⁵ Using $\sigma_{obs}(e^+e^- \rightarrow \psi(3770)) = 7.15 \pm 0.38$ nb.
- ²⁶ Using $\sigma_{obs} = 7.15 \pm 0.27 \pm 0.27$ nb and neglecting interference.
- ²⁷ Comparing $\sigma(e^+e^- \rightarrow \phi\eta)$ at $\sqrt{s} = 3.773$ GeV and $\sqrt{s} = 3.671$ GeV, and using $\sigma(\psi(3770) \rightarrow D\bar{D}) = 6.39 \pm 0.20$ nb.

$X(3872)$

$I^G(J^{PC}) = 0^?(?^{?+})$

Seen by CHOI 03 in $B \rightarrow K\pi^+\pi^- J/\psi(1S)$ decays as a narrow peak in the invariant mass distribution of the $\pi^+\pi^- J/\psi(1S)$ final state, but not seen in the $\gamma\chi_{c1}$ final state of these decays. Possibly absent in the invariant mass spectrum of the final state $\pi^+\pi^- J/\psi(1S)$ in e^+e^- collisions. Interpretation as a 1^{--} charmonium state not favored. Isovector hypothesis excluded by AUBERT 05B. A helicity amplitude analysis of the $X(3872) \rightarrow J/\psi\pi^+\pi^-$ decay gives two possible J^{PC} assignments: 1^{++} and 2^{--} + (ABULENCIA 07E).

See our note "New charmonium-like states" in the 2008 edition of this Review (PDG 08) and the extensive chapter on Spectroscopy in N. Brambilla *et al.* (Quarkonium Working Group), to be published in the Eur. Phys. J. in 2010.

$b\bar{b}$ MESONS

THE BOTTOMONIUM SYSTEM

The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b , triplet states Υ and χ_{bJ} . In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2, L = 1, S = 0, J = 1, PC = +-.$ If found, D -wave states would be called $\eta_b(nD)$ and $\Upsilon_J(nD)$, with $J = 1, 2, 3$ and $n = 1, 2, 3, 4, \dots$. For the χ_b states, the spins of only the $\chi_{b2}(1P)$ and $\chi_{b1}(1P)$ have been experimentally established. The spins of the other χ_b are given as the preferred values, based on the quarkonium models. The figure also shows the observed hadronic and radiative transitions.

WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\bar{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell} / B_{\ell\ell} , \tag{1}$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction ($\ell = e, \mu, \text{ or } \tau$). One then assumes $e\text{-}\mu\text{-}\tau$ universality and uses

$$\begin{aligned} \Gamma_{\ell\ell} &= \Gamma_{ee} \\ B_{\ell\ell} &= \text{average of } B_{ee}, B_{\mu\mu}, \text{ and } B_{\tau\tau} . \end{aligned} \tag{2}$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\text{had}}/\Gamma$, where Γ_{had} is the hadronic partial width and

$$\Gamma_{\text{had}} + 3\Gamma_{ee} = \Gamma . \tag{3}$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\begin{aligned} &\int_{\text{resonance}} \sigma(e^+e^- \rightarrow \Upsilon \rightarrow \text{hadrons})dE \\ &= \frac{6\pi^2 \Gamma_{ee}\Gamma_{\text{had}}}{M^2 \Gamma} C_r = \frac{6\pi^2 \Gamma_{ee}^{(0)}\Gamma_{\text{had}}}{M^2 \Gamma} C_r^{(0)} , \end{aligned} \tag{4}$$

where M is the Υ mass, and C_r and $C_r^{(0)}$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \rightarrow e^+e^-$. The lowest order QED value $\Gamma_{ee}^{(0)}$, relevant for comparison with potential-model calculations, is defined by the

Meson Particle Listings

Bottomonium, $\eta_b(1S)$, $\Upsilon(1S)$

lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee} .

The Listings give experimental results on B_{ee} , $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{had}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KU-RAEV 85. The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{had}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{had}}{\Gamma(1-3B_{\ell\ell})}. \quad (5)$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

 $\eta_b(1S)$

$$I^G(J^{PC}) = 0^+(0^{-+})$$

OMITTED FROM SUMMARY TABLE

Quantum numbers shown are quark-model predictions. Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$.

3.4 ±0.4 ±0.4	GILES	83 CLEO	$e^+e^- \rightarrow \tau^+\tau^-$	

⁸ BESSON 07 reports $[\Gamma(\Upsilon(1S) \rightarrow \tau^+\tau^-)/\Gamma(\text{total})] / [B(\Upsilon(1S) \rightarrow \mu^+\mu^-)] = 1.02 \pm 0.02 \pm 0.05$ which we multiply by our best value $B(\Upsilon(1S) \rightarrow \mu^+\mu^-) = (2.48 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
⁹ Using $B(\Upsilon(1S) \rightarrow ee) = B(\Upsilon(1S) \rightarrow \mu\mu) = 0.0256$; not used for width evaluations.

$\chi_{b0}(1P)$

$$J^{G(J^{PC})} = 0^+(0^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b1}(1P)$

$J^G(J^{PC}) = 0^+(1^{++})$
 J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 1$ from SKWARNICKI 87.

$$J^G(J^{PC}) = 0^+(2^+ +)$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 2$ from SKWARNICKI 87.

$\chi_{b0}(2P)$

$$I^G(J^{PC}) = 0^+(0^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

 $\chi_{b1}(2P)$

$$J^{G(JPC)} = 0^+(1^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

 $\chi_{b2}(2P)$

$$J^G(JPC) = 0^+(2^{++})$$

J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

 $\Upsilon(4S)$ WEIGHTED AVERAGE
0.272±0.029 (Error scaled by 1.5) $\Upsilon(4S)$ BRANCHING RATIOS $B\bar{B}$ DECAYS

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the B^+/B^0 lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xoig/hfag/>. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

19 SOKOLOV 09 reports $[\Gamma(\Upsilon(4S) \rightarrow \Upsilon(1S)\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(\Upsilon(1S) \rightarrow \mu^+\mu^-)] = (0.211 \pm 0.030 \pm 0.014) \times 10^{-5}$ which we divide by our best value $B(\Upsilon(1S) \rightarrow \mu^+\mu^-) = (2.48 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

20 Using $B(\Upsilon(1S) \rightarrow e^+e^-) = (2.38 \pm 0.11)\%$ and $B(\Upsilon(1S) \rightarrow \mu^+\mu^-) = (2.48 \pm 0.05)\%$.

21 SOKOLOV 07 reports $[\Gamma(\Upsilon(4S) \rightarrow \Upsilon(1S)\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(\Upsilon(1S) \rightarrow \mu^+\mu^-)] = (4.42 \pm 0.81 \pm 0.56) \times 10^{-6}$ which we divide by our best value $B(\Upsilon(1S) \rightarrow \mu^+\mu^-) = (2.48 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

22 According to the authors, systematic errors were underestimated.

23 Superseded by AUBERT 08BP. AUBERT 06R reports $[\Gamma(\Upsilon(4S) \rightarrow \Upsilon(1S)\pi^+\pi^-)/\Gamma_{\text{total}}] \times [B(\Upsilon(1S) \rightarrow \mu^+\mu^-)] = (2.23 \pm 0.25 \pm 0.27) \times 10^{-6}$ which we divide by our best value $B(\Upsilon(1S) \rightarrow \mu^+\mu^-) = (2.48 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
