C.2 Electroweak Single-Top Quark Production: $D\emptyset$ [14] and CDF [15] have recently announced the discovery of electroweak production of single top quarks. The announcement is the culmination of a multi-year effort that required the use of many advanced analysis techniques to separate the signal from an overwhelming background. In s-channel single-top production, the top quark is accompanied by a bottom quark and the final state is therefore a W boson and two bottom jets. In t-channel production, the top is accompanied by both a bottom quark and a light quark jet, but the accompanying bottom quark is typically at large pseudorapidity and low transverse energy and hence escapes detection. The t-channel final state results also dominantly in W +2 jets, with just one of the jets coming from a bottom quark. Event selection therefore requires a high p_T electron or muon, two to four jets, one of which must be identified as originating from a bottom quark, and missing E_T . In addition, CDF uses events selected with large missing E_T and two or three energetic jets. The expected signal-to-background ratio in these samples is about 5%, and the challenge is to separate the signal not just from QCD-produced W +jets events, but also from $t\bar{t}$ events which end up in the signal region.

To overcome this challenge, both experiments have used a variety of multivariate techniques, including neural networks, boosted decision trees, multivariate likelihood functions and matrix elements. With the exception of the CDF missing E_T plus jets analysis, all the analyses use nearly the same datasets. Nevertheless, they are not completely correlated and the final results come from a combination of all analyses. Both experiments use a neural-network technique to combine the individual results into a final result. DØ reports a combined s- plus t-channel cross section of 3.94 ± 0.88 pb (for $m_t = 170$ GeV/ c^2), with a corresponding p -value of 2.5×10^{-7} (5.0σ), based on 2.3 fb $^{-1}$ of integrated luminosity [14]. CDF reports a combined cross section of $2.3_{-0.5}^{+0.6}$ pb for $m_t = 175$ GeV/ c^2 with a corresponding p -value of 3.1×10^{-7} (5.0σ), based on 3.2 fb $^{-1}$ of integrated luminosity [15]. A Bayesian analysis yields a combined single-top production cross section of $2.76_{-0.47}^{+0.58}$ pb [55].

The CKM matrix element V_{tb} is extracted from the measured cross sections using the ratio to the theoretical values, which assume $V_{tb} = 1.0$. The results are summarized in Table 2.

Table 2: Measurements of $|V_{tb}|$ from CDF and DØ single-top results.

$ V_{tb} $ or $ V_{tb}f_1^T $	Source	$\int \mathcal{L} dt$ (fb $^{-1}$)	Ref.
$ V_{tb}f_1^T = 1.07 \pm 0.12$	DØ Run II	2.3	[14]
$ V_{tb} > 0.78$	DØ Run II	2.3	[14]
$ V_{tb} = 0.91 \pm 0.13$	CDF Run II	3.2	[15]
$ V_{tb} = 0.88 \pm 0.07$	CDF + DØ Run II	3.2	[55]
$ V_{tb} > 0.77$	CDF + DØ Run II	3.2	[55]

Both experiments have done separate measurements of the s- and t-channel cross sections by reoptimizing the analysis for one or both of the channels separately. In a simultaneous measurement of s- and t-channel cross sections, CDF measures $2.0_{-0.6}^{+0.7}$ pb and 0.7 ± 0.5 pb, respectively, in 3.2 fb $^{-1}$ of data [56], while DØ measures 1.05 ± 0.81 pb and $3.14_{-0.80}^{+0.94}$ pb, respectively in 2.3 fb $^{-1}$ of integrated luminosity [57]. In a separate analysis, optimized for the s-channel alone, CDF measures $1.49_{-0.75}^{+0.92}$ pb in 3.2 fb $^{-1}$ of data [58].

In the SM single-top-quark production yields a nearly 100% polarization of the top-quark spin along the direction, in the top rest frame, of the down-type quark or charged lepton from the W boson decay. This corresponds to the fact that single top quarks produced at the V-A Wtb vertex are left-handed. Recently CDF has searched for a small right-handed (V+A) component in 3.2 fb $^{-1}$ of integrated luminosity [59]. To discriminate between the SM V-A and a V+A component, the sample is split into a $\cos\theta < 0$ piece and a $\cos\theta > 0$ piece, where θ is the angle between the lepton and the down-type quark in the top-quark rest frame. The single-top production cross section in the two samples is measured separately, using the multivariate likelihood technique. The result is consistent with no V+A component and a polarization of $-1_{-0}^{+0.5}$.

C.3 Top Quark Mass Measurements: The top mass has been measured in the lepton+jets, dilepton, and the all-jets channel by both CDF and DØ. At present, the most precise measurements come from the lepton+jets channel containing four or more jets, and large missing E_T . The samples for the mass measurement are selected using topological or b -tagging methods. In this channel, four basic techniques are employed to extract the top mass. In the first, the so-called “template method” (TM) [60], an over-constrained (2C) kinematic fit is performed to the hypothesis $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow \ell \bar{\nu}_\ell b q \bar{q}' \bar{b}$ for each event, assuming that the four jets of highest E_T originate from the four quarks in $t\bar{t}$ decay. There are 24 possible solutions, reflecting the allowed assignment of the final-state quarks to jets, and the two possible solutions for the longitudinal momentum, p_z , of the neutrino when the W -mass constraint is imposed on the leptonic W decay. The number of solutions is reduced to 12 when a jet is b -tagged and assigned as one of the b quarks, and to 4 when the event has two such b -tags. A χ^2 variable describes the agreement of the measurements with each possible solution under the $t\bar{t}$ hypothesis given jet-energy resolutions. The solution with the lowest χ^2 is defined as the best choice, resulting in one value for the reconstructed top quark mass per event. The distribution of reconstructed top-quark mass from the data events is then compared to templates modeled from a combination of signal and background distributions for a series of assumed top masses. The best fit value for the top quark mass and its uncertainty are obtained from a maximum-likelihood fit. In the second method, the “Matrix Element/Dynamic Likelihood Method” (ME/DLM), similar to that originally suggested by Kondo *et al.* [61] and Dalitz and Goldstein [62], a probability for each event is calculated as a function of the top mass, using an LO matrix element for the production and decay of $t\bar{t}$ pairs. All possible assignments of reconstructed jets to final-state quarks are used, each weighted by a probability determined from the matrix element. The correspondence between measured four-vectors and parton-level four-vectors is taken into account using probabilistic transfer functions. In a third method, the “Ideogram Method” [63,64], which combines some of the features of the above two techniques, each event is compared to the signal and background mass spectrum, weighted by the χ^2 probability of the kinematic fit for all 24 jet-quark combinations and an event probability. The latter is determined from the signal fraction in the sample and the event-by-event purity, as determined from a topological discriminant in Monte Carlo events. An additional variation on these techniques is the “Multivariate Likelihood” (ML) technique, where an integral over the matrix element is performed for each permutation, and then summed with weights determined by the b -tagging information on each jet. Backgrounds are handled in the ML technique by “deweighting” events according to a background probability calculated using variables based on the topology of the event.

Quark Particle Listings

t

With at least four jets in the final state, the dominant systematic uncertainty on the top quark mass is from the uncertainty on the jet-energy scale. CDF (TM, ME, ML) and DØ (ME) have reduced the jet-energy scale uncertainty by performing a simultaneous, *in situ*, fit to the $W \rightarrow jj$ hypothesis.

There are several techniques that rely solely on tracking, and thus avoid the jet-energy scale uncertainty. One method [65] exploits the fact that, in the rest frame of the top quark, the boost given to the bottom quark has a Lorentz factor $\gamma_b \approx 0.4 m_t/m_b$. The measurement of the transverse decay length L_{xy} of the b -hadrons from the top quark decay is therefore sensitive to the mass of the top quark. Another uses the correlation between the p_T spectrum of the leptons from the W -boson decay and m_t [67,66]. Finally, a recent measurement [68] uses the invariant mass of the lepton from the W -boson decay and the muon from a semileptonic decay of the associated B hadron to measure m_t .

mass from direct reconstruction without adding additional information. Assuming a value for m_t , the $t\bar{t}$ system can be reconstructed up to an eight-fold ambiguity from the choice of associating leptons and quarks to jets, and due to the two solutions for the p_z of each neutrino. Recently, an analytic solution to the problem has been proposed [69]. At the Tevatron, two basic techniques are employed: one based on templates, and one using matrix elements. The first class of techniques incorporates additional information to render the kinematic system solvable. In this class, there are two techniques that assign a weight as a function of top mass for each event based on solving for either the azimuth, ϕ , of each neutrino given an assumed pseudorapidity, η , ($\eta(\nu)$) [70,71], or for η of each neutrino given an assumed ϕ , ($\phi(\nu)$) [72]. An alternative approach, (MWT) [70], solves for η of each neutrino requiring the sum of the neutrino \vec{p}_T 's to equal the measured missing E_T vector. In another technique,

Table 3: Measurements of top quark mass from CDF and DØ. $\int \mathcal{L} dt$ is given in fb^{-1} . Only preliminary results (not yet submitted for publication as of April 2010) are shown; for published results see the Listings. Statistical uncertainties are listed first, followed by systematic uncertainties.

m_t (GeV/ c^2)	Source	$\int \mathcal{L} dt$	Ref.	Method

* PDG uses this TEVEWWG result as its best value. It is a combination of published Run I + II measurements, yielding a χ^2 of 5.8 for 10 deg. of freedom.

**The TEVEWWG world average is a combination of published Run I and preliminary or pub. Run-II meas., yielding a χ^2 of 6.3 for 10 deg. of freedom.

Additional determinations of the top mass come from the dilepton channel with two or more jets and large missing E_T , and from the all-jets channel. The dilepton channel, with two unmeasured neutrinos, is under-constrained by one measurement. It is not possible to extract a value for the top-quark

($p_z(t\bar{t})$) [72], the kinematic system is rendered solvable by the addition of the requirement that the p_z of the $t\bar{t}$ system, equal to the sum of the p_z of the t and \bar{t} , be zero within a Gaussian uncertainty of 180 GeV/ c . In a variation of the $p_z(t\bar{t})$ technique, the theoretical relation between the top mass and its production cross section is used as an additional constraint. In most of the

techniques in this class, a single mass per event is extracted and a top-mass value found using a Monte Carlo template fit to the single-event masses, in a manner similar to that employed in the lepton+jets TM technique. The $D\bar{O}$ ($\eta(\nu)$) analysis uses the shape of the weight distribution as a function of m_{top} in the template fit. The second class, ME/DLM, uses weights based on the LO matrix element for an assumed mass, given the measured four-vectors (and integrating over the unknowns) to form a joint likelihood as a function of the top mass for the ensemble of fitted events.

The P_T spectrum of the leptons in the dilepton channel has also been used to extract a top mass measurement [67]. The resulting statistical uncertainty of the measurement is large, but as with the L_{xy} technique, it is almost free of the systematic uncertainty due to the jet-energy scale.

In the most recent set of CDF results (see Table 3), a measurement has been done using the lepton+jets and dilepton channels simultaneously. In the lepton+jets channel, the TM is used together with an *in situ* $W \rightarrow jj$ fit. In the dilepton channel, $\eta(\nu)$ is used plus a fit to the scalar sum of transverse energies (H_T), which is sensitive to the top mass.

In the all-jets channel, there is no unknown neutrino momentum to deal with, but the S/B is the poorest. Both CDF and $D\bar{O}$ use events with 6 or more jets, of which at least one is b -tagged. In addition, both experiments have employed a neural network selection, based on an array of kinematic variables to improve the S/B. At $D\bar{O}$, a top-quark mass is reconstructed from the jet-quark combination that best fits the hadronic W -mass constraint and the equal-mass constraint for the two top quarks. At CDF, the top-quark mass for each event was reconstructed applying the same fitting technique used in the ℓ +jets mode. In the most recent analysis, the *in situ* jet-energy scale calibration from the $W \rightarrow jj$ fit is also used. At both CDF and $D\bar{O}$, the resulting mass distribution is compared to Monte Carlo templates for various top-quark masses and the background distribution, and a maximum likelihood technique is used to extract the final measured value of m_t and its uncertainty.

$D\bar{O}$ also measures the top-quark mass via comparison of the $t\bar{t}$ production cross section with the SM expectation [38]. This method has the advantage that it is very simple and sensitive to the top quark pole mass, which is a very well defined concept. The fully-inclusive cross-section calculation, used for comparison, contains current best theoretical knowledge with reduced scheme- or scale-dependence.

Recent results are shown in Table 3. See the Top Quark Listings for a complete set of published results. The systematic uncertainty (second uncertainty shown) is comparable to the statistical uncertainty, and is primarily due to uncertainties in the jet-energy scale and in the Monte Carlo modeling. In the Run-II analyses, CDF and $D\bar{O}$ have controlled the jet-energy scale uncertainty via *in situ* $W \rightarrow jj$ calibration using the same $t\bar{t}$ events, as mentioned above.

The Tevatron Electroweak Working Group (TEVEWWG), responsible for the combined CDF/ $D\bar{O}$ average top mass in Table 3, took account of correlations between systematic uncertainties in the different measurements in a sophisticated manner [83]. The Particle Data Group (PDG) uses their combination of published Run-I and Run-II top-mass measurements, $m_t = 172.0 \pm 1.6 \text{ GeV}/c^2$ (statistical and systematic uncertainties combined in quadrature), as the PDG best value. The latest TEVEWWG world average [83], also including published and some preliminary Run-II results, yields $m_t = 173.1 \pm 1.3 \text{ GeV}/c^2$ (statistical and systematic uncertainties combined in quadrature).

Given the experimental technique used to extract the top mass, these mass values should be taken as representing the top *pole mass* (see the review “Note on Quark Masses” in this *Review* for more information). The top pole mass, like any quark mass, is defined up to an intrinsic ambiguity of order $\Lambda_{QCD} \sim 200 \text{ MeV}$ [84]. Ultimately, the precision of the mass measurements will be limited by the theoretical understanding of the relation between the observables and the theoretical definition of the mass.

Recently, $D\bar{O}$ has tested CPT invariance in the top sector. They measured the mass difference between t and \bar{t} quarks in lepton+jets final states of $t\bar{t}$ events in 1 fb^{-1} . The measured mass difference of $3.8 \pm 3.7 \text{ GeV}$ is consistent with the equality of t and \bar{t} masses [85].

Current global fits performed within the SM or its minimal supersymmetric extension, in which the top-mass measurements play a crucial role, provide indications for a relatively light Higgs (see “ H^0 Indirect Mass Limits” in the Particle Listings of this *Review* for more information). Such fits, including Z -pole data [86] and direct measurements of the mass and width of the W -boson, yield $m_t = 179_{-9}^{+12} \text{ GeV}/c^2$ [87]. A fit including additional electroweak precision data (see the review “Electroweak Model and Constraints on New Physics” in this *Review*) yields $m_t = 174.7_{-7.8}^{+10.0} \text{ GeV}/c^2$ (OUR EVALUATION). Both indirect evaluations are in good agreement with the direct top-quark mass measurements.

C.4 Top Quark Electric Charge: The top quark is the only quark whose electric charge has not been measured through production at threshold in e^+e^- collisions. Since the CDF and $D\bar{O}$ analyses on top quark production do not associate the b , \bar{b} , and W^\pm uniquely to the top or antitop, decays such as $t \rightarrow W^+\bar{b}$, $\bar{t} \rightarrow W^-b$ are not excluded. A charge $4/3$ quark of this kind would be consistent with current electroweak precision data. The $Z \rightarrow \ell^+\ell^-$ and $Z \rightarrow b\bar{b}$ data, in particular the discrepancy between A_{LR} from SLC at SLAC and $A_{FB}^{0,b}$ of b -quarks and $A_{FB}^{0,\ell}$ of leptons from LEP at CERN, can be fitted with a top quark of mass $m_t = 270 \text{ GeV}/c^2$, provided that the right-handed b quark mixes with the isospin $+1/2$ component of an exotic doublet of charge $-1/3$ and $-4/3$ quarks, $(Q_1, Q_4)_R$ [29,88].

CDF and $D\bar{O}$ study the top quark charge in double-tagged lepton+jets events and (CDF) single-tagged dilepton events.

Quark Particle Listings

t

Assuming the top and antitop quarks have equal but opposite electric charge, then reconstructing the charge of the b -quark through jet charge discrimination techniques, the $|Q_{top}| = 4/3$ and $|Q_{top}| = 2/3$ scenarios can be differentiated. For the exotic model of Chang *et al.* [88] with a top-quark charge $|Q_{top}| = 4/3$, DØ yields a p -value, corresponding to the probability of consistency with the exotic model, of 7.8% [89]. CDF excludes the model at 87% C.L. [90]. While these two results are not directly comparable, they both indicate that the observed particle is indeed consistent with being a SM $|Q_{top}| = 2/3$ quark. More recently CDF has measured the top quark charge using the soft e or μ from semileptonic b -decays in $t\bar{t}$ events [91]. The soft lepton carries the flavor information of the bottom quark (with a dilution factor) and a kinematic fitter is used to associate the soft-lepton-tagged jet with either the W^+ or W^- from the top decay. The result excludes a charge $4/3$ top quark at the 95% C.L. and strongly favors the Standard Model charge $2/3$ top quark.

C.5 Top Branching Ratio: CDF and DØ report direct measurements of the $t \rightarrow Wb$ branching ratio [34,92–93]. Comparing the number of events with 0, 1 and 2 tagged b jets in the lepton+jets channel, and for CDF also in the dilepton channel, and using the known b -tagging efficiency, the ratio $R = B(t \rightarrow Wb) / \sum_{q=d,s,b} B(t \rightarrow Wq)$ can be extracted. DØ performs a simultaneous fit for the number of $t\bar{t}$ events and the ratio R . A deviation of R from unity would imply either non-SM top decay, a non-SM background to $t\bar{t}$ production, or a fourth generation of quarks. The results are summarized in Table 4.

Table 4: Measurements and 95% C.L. lower limits of $R = B(t \rightarrow Wb) / B(t \rightarrow Wq)$ from CDF and DØ. A complete set of published results can be found in the Listings.

R	Source	$\int \mathcal{L} dt$ (pb $^{-1}$)	Ref.
$R = 0.97^{+0.09}_{-0.08}$	DØ Run II	900	[34]
$R > 0.79$	DØ Run II	900	[34]

C.6 W -Boson Helicity: Studies of decay angular distributions provide a direct check of the V - A nature of the Wtb coupling and information on the relative coupling of longitudinal and transverse W bosons to the top quark. In the SM, the fraction of decays to longitudinally polarized W bosons is expected to be [94] $\mathcal{F}_0^{\text{SM}} \approx x / (1 + x)$, $x = m_t^2 / 2M_W^2$ ($\mathcal{F}_0^{\text{SM}} \sim 70\%$ for $m_t = 175$ GeV/ c^2). Fractions of left-handed, right-handed, and longitudinal W bosons are denoted as \mathcal{F}_- , \mathcal{F}_+ , and \mathcal{F}_0 respectively. In the SM, \mathcal{F}_- is expected to be $\approx 30\%$ and $\mathcal{F}_+ \approx 0\%$. CDF and DØ use various techniques to measure the helicity of the W boson in top quark decays, in both the lepton+jets events and dilepton channels. The first method uses a kinematic fit, similar to that used in the lepton+jets mass analyses, but with the top quark mass constrained to 175 GeV/ c^2 ,

to improve the reconstruction of final-state observables, and render the under-constrained dilepton channel solvable. The distribution of the helicity angle ($\cos\theta^*$) between the lepton and the b quark in the W rest frame provides the most direct measure of the W helicity. The second method (p_T^ℓ) uses the different lepton p_T spectra from longitudinally or transversely polarized W -decays to determine the relative contributions. A third method uses the invariant mass of the lepton and the b -quark in top decays ($M_{b\ell}^2$) as an observable, which is directly related to $\cos\theta^*$. Finally, the Matrix Element method (ME) has also been used, in which a likelihood is formed from a product of event probabilities calculated from the ME for a given set of measured kinematic variables and assumed W -helicity fractions. The results of recent CDF and DØ analyses are summarized in Table 5. The datasets are now large enough to allow for a simultaneous fit of \mathcal{F}_0 and \mathcal{F}_+ , which we denote by ‘2-param’ in the table. Results with either \mathcal{F}_0 or \mathcal{F}_+ fixed at its SM value are denoted ‘1-param’. For the simultaneous fits the correlation coefficient between the two values is about -0.8 for both experiments. A complete set of published results can be found in the Listings. All results are in agreement with the SM expectation.

Table 5: Measurement and 95% C.L. upper limits of the W helicity in top quark decays. Published results are given in the Listings. Results listed are preliminary and not yet submitted for publication, as of April 2010.

W Helicity	Source	$\int \mathcal{L} dt$ (fb $^{-1}$)	Ref.	Method

C.7 $t\bar{t}$ Spin Correlations & Top Width: The t and \bar{t} are expected to be unpolarized, but to be correlated in their spins. Since top quarks decay before hadronizing, their spins at production are transmitted to their decay-daughter particles. Spin correlation is studied by analyzing the joint decay angular distribution of one t daughter and one \bar{t} daughter. The sensitivity to top spin is greatest when the daughters are down-type fermions (charged leptons or d -type quarks), in which case, the joint distribution is [97–99]

$$\frac{1}{\sigma} \frac{d^2\sigma}{d(\cos\theta_+)d(\cos\theta_-)} = \frac{1 + \kappa \cdot \cos\theta_+ \cdot \cos\theta_-}{4}, \quad (2)$$

where θ_+ and θ_- are the angles of the daughters in the top rest frames with respect to a particular spin quantization axis. The maximum value for κ , 0.782 at NLO at the Tevatron [100], is

found in the off-diagonal basis [97]. An alternative basis is the beam direction, which yields $\kappa = 0.777$ at the Tevatron.

DØ has measured κ in the dilepton sample using the neutrino weighting technique to reconstruct the t and \bar{t} rest frames, in which the angles θ_+ and θ_- are measured. Using an integrated luminosity of 4.2 fb^{-1} they measure $\kappa = -0.17^{+0.64}_{-0.53}$ [101]. Using 2.8 fb^{-1} of integrated luminosity, CDF measures κ in the dilepton sample using a full-reconstruction method similar to the $p_z(t\bar{t})$ technique used in the mass measurement in dileptons, but with the inclusion of $p_T(t\bar{t})$ and $M_{(t\bar{t})}$ probability distribution functions. The result is a 68% confidence interval of $-0.455 < \kappa < 0.865$ corresponding to a central value of $\kappa = 0.320^{+0.545}_{-0.775}$ [102]. Recently CDF has measured κ in lepton plus jets events using an integrated luminosity of 4.3 fb^{-1} . A χ^2 adapted from the TM mass measurement is used to assign observed objects to the W^+b and W^-b from t and \bar{t} , while constraining the top mass at $172.5 \text{ GeV}/c^2$, allowing reconstruction of the respective rest frames. With this technique a value of $\kappa = 0.60 \pm 0.52$ is measured [103].

Because production through gluon fusion produces predominantly like-helicity $t\bar{t}$ pairs, whereas production through $q\bar{q}$ annihilation produces predominantly opposite-helicity pairs [99], the putative spin correlations can be used to extract the fraction of $t\bar{t}$ pairs produced through each of these mechanisms. In 2 fb^{-1} of integrated luminosity, CDF has used the azimuthal correlation of the charged leptons in the dilepton decay channel to measure the fraction of $t\bar{t}$ production from gluon fusion, F_{gg} , and find $F_{gg} = 0.53^{+0.36}_{-0.38}$ [104], to be compared with the expectation of approximately 0.15 in the SM.

Related to the measurement of top-spin correlations, which requires a top lifetime less than the hadronization timescale, is the measurement of the top width. The top width is expected to be of order $1 \text{ GeV}/c^2$ (Eq. 1). The sensitivity of current experiments does not approach this level in direct measurements. CDF has made the first direct measurement of the top width using the mass fitting template method in lepton+jets events, fixing the top mass at $175 \text{ GeV}/c^2$ and varying the top width in constructing the Monte Carlo templates. The top width is found to be less than $7.5 \text{ GeV}/c^2$ at the 95% C.L. [105].

DØ extracts the total width of the top quark from the partial decay width $\Gamma(t \rightarrow Wb)$ and the branching fraction $B(t \rightarrow Wb)$. $\Gamma(t \rightarrow Wb)$ is obtained from the measured t -channel cross section for single top quark production in 2.3 fb^{-1} , and $B(t \rightarrow Wb)$ is extracted from a measurement of the ratio $R = B(t \rightarrow Wb)/B(t \rightarrow Wq)$ in $t\bar{t}$ events in lepton+jets channels with 0, 1 and 2 b-tags in 1 fb^{-1} of integrated luminosity. Assuming $B(t \rightarrow Wq) = 1$, where q includes any kinematically accessible quark, the result is: $\Gamma_t = 2.1 \pm 0.6 \text{ GeV}$ which translates to a top quark lifetime of $\tau_t = (3 \pm 1) \times 10^{-25} \text{ s}$. The use of the partial width measurement alone yields the limits $\Gamma_t > 1.2 \text{ GeV}$ and $\tau_t < 5 \times 10^{-25} \text{ s}$, at 95% C.L. [106].

C.8 Non-SM $t\bar{t}$ Production: Motivated by the large mass of the top quark, several models suggest that the top quark

plays a role in the dynamics of electroweak symmetry breaking. One example is topcolor [26], where a large top quark mass can be generated through the formation of a dynamic $t\bar{t}$ condensate, X , which is formed by a new strong gauge force coupling preferentially to the third generation. Another example is topcolor-assisted technicolor [27], predicting a heavy Z' boson that couples preferentially to the third generation of quarks with cross sections expected to be visible at the Tevatron. CDF and DØ have searched for $t\bar{t}$ production via intermediate, narrow-width, heavy-vector bosons X in the lepton+jets channels. The possible $t\bar{t}$ production via an intermediate resonance X is sought for as a peak in the spectrum of the invariant $t\bar{t}$ mass. CDF and DØ exclude narrow-width heavy-vector bosons X in the top-assisted technicolor model [107], with mass $M_X < 480 \text{ GeV}/c^2$ and $M_X < 560 \text{ GeV}/c^2$, respectively, in Run I [30,31], and $M_X < 805 \text{ GeV}/c^2$ and $M_X < 820 \text{ GeV}/c^2$ in Run II [52,53]. With 955 pb^{-1} of Run-II data, CDF has produced a less model-dependent limit for a narrow-width Z' , ruling out at the 95% C.L. a contribution greater than 0.64 pb for a Z' heavier than $700 \text{ GeV}/c^2$ decaying to $t\bar{t}$ [108]. Using a measurement of the forward-backward asymmetry in $t\bar{t}$ production, DØ extracts a 95% C.L. limit on the fraction of $t\bar{t}$ pairs produced by a Z' resonance as a function of the Z' mass [23]. A recent CDF analysis has placed limits on the coupling strength of a massive gluon to $t\bar{t}$ [54]. In 0.9 fb^{-1} and 3.1 fb^{-1} , DØ has set limits on scalar top-quark pair production, with subsequent decays to top quarks in the lepton+jets and the dilepton channel, respectively [50,109].

The existence of flavor-changing neutral-currents (FCNC) couplings can enhance the rate of single-top quark production, and both experiments have used upper limits on the observed rate to place limits on these couplings. In 230 pb^{-1} of Run-II data, DØ uses their single-top analysis to place limits on anomalous production via the FCNC coupling of a gluon to the top quark and a charm ($t c g$) or up quark ($t u g$) [110]. The observed limits are at 95% C.L.: $\kappa_{gtc}/\Lambda < 0.15 \text{ TeV}^{-1}$ and $\kappa_{gtu}/\Lambda < 0.037 \text{ TeV}^{-1}$. CDF has searched for FCNC in the s -channel Wtb production vertex. In 2.2 fb^{-1} of integrated luminosity, CDF sets limits on the couplings of $\kappa_{gtc}/\Lambda < 0.105 \text{ TeV}^{-1}$ and $\kappa_{gtu}/\Lambda < 0.025 \text{ TeV}^{-1}$ [111].

C.9 Non-SM Top Decays: Both CDF and DØ have searched for non-SM top decays [112–116], particularly those expected in supersymmetric models, such as $t \rightarrow H^+b$, followed by $H^+ \rightarrow \tau^+\bar{\nu}$ or $c\bar{s}$. The $t \rightarrow H^+b$ branching ratio has a minimum at $\tan\beta = \sqrt{m_t/m_b} \simeq 6$, and is large in the region of either $\tan\beta \ll 6$ or $\tan\beta \gg 6$. In the former range, $H^+ \rightarrow c\bar{s}$ is dominant, while $H^+ \rightarrow \tau^+\bar{\nu}$ dominates in the latter range. These studies are based either on direct searches for these final states, or on top “disappearance.” In the standard lepton+jets or dilepton cross-section analyses, any charged-Higgs decays are not detected as efficiently as $t \rightarrow W^\pm b$, primarily because the selection criteria are optimized for the standard decays, and because of the absence of energetic isolated leptons in Higgs

Quark Particle Listings

t

decays. A significant $t \rightarrow H^+b$ contribution would give rise to measured $t\bar{t}$ cross sections that would be lower than the prediction from the SM (assuming that non-SM contributions to $t\bar{t}$ production are negligible), and the measured cross-section ratio $\sigma_{t\bar{t}}^{\ell^+\ell^-j\ell^+s}/\sigma_{t\bar{t}}^{\ell\ell}$ would differ from unity.

In Run II, CDF has searched for charged-Higgs production in dilepton, lepton+jets, and lepton+hadronic tau final states, considering possible H^+ decays to $c\bar{s}$, $\tau\bar{\nu}$, t^*b , or W^+h^0 , in addition to the SM decay $t \rightarrow W^+b$ [114,115]. Depending on the top and Higgs-decay branching ratios, which are scanned in a particular 2-Higgs doublet benchmark model, the number of expected events in these decay channels can show an excess or deficit when compared to SM expectations. A model-independent interpretation yields a limit of $B(t \rightarrow H^\pm b) < 0.91$ at 95% C.L. for $m_{H^\pm} \approx 100$ GeV, and $B(t \rightarrow H^\pm b) < 0.4$ in the tauonic model with $B(H^\pm \rightarrow \tau\nu) = 100\%$. In a more recent search, the dijet invariant mass in lepton+jets events has been used to search for a charged Higgs decaying to $c\bar{s}$ with mass above the W boson mass. The absence of a signal leads to a 95% C.L. limit of $B(t \rightarrow H^\pm b) < 0.1$ to 0.3 for masses between 60 and 150 GeV/ c^2 [115]. In 1 fb^{-1} of integrated luminosity, the DØ collaboration has used the $t\bar{t}$ dilepton and lepton+jets events, including τ lepton channels, to search for evidence of charged-Higgs decays into τ leptons via the ratio of events with τ leptons to those with e and μ [38], global fits [117] and topological searches [118]. They exclude regions of $B(t \rightarrow H^\pm b)$ as a function of Higgs mass, ranging from $B(t \rightarrow H^\pm b) > 0.12$ at low mass to $B(t \rightarrow H^\pm b) > 0.2$ at high mass. In a companion analysis they look for evidence of leptophobic charged Higgs production in top decays in which the Higgs decays purely hadronically, leading to a suppression of the measured $t\bar{t}$ rate in all leptonic channels. They exclude $B(t \rightarrow H^\pm b) > 0.2$ for charged-Higgs masses between 80 and 155 GeV/ c^2 .

More details, and the results of these studies for the exclusion in the $m_{H^\pm}, \tan\beta$ plane, can be found in the review “Search for Higgs bosons” and in the “ H^+ Mass Limits” section of the Higgs Particle Listings of the current edition.

In the SM, the top-quark lifetime is expected to be about 0.5×10^{-24} s ($c\tau_t \approx 1.5 \times 10^{-10}$ μm), while additional quark generations, non-standard top-quark decays, or other extensions of the SM could yield long-lived top quarks in the data. CDF has studied the top-quark lifetime by measuring the distance between the initial $p\bar{p}$ scattering and the leptonic W^\pm decay vertex in lepton+jets events [119]. The measured lifetime is consistent with zero, and an upper limit $c\tau_t < 52.5$ μm is found at 95% C.L. DØ extracts the lifetime to be $\tau_t = (3 \pm 1) \times 10^{-25}$ s from the t -channel cross section for single top quark production and the measurement of the ratio $R = B(t \rightarrow Wb)/B(t \rightarrow Wq)$ [106].

Using up to 2.7 fb^{-1} of data, DØ has measured the Wtb coupling form factors by combining information from the W boson helicity in top quark decays in $t\bar{t}$ events and single-top

quark production, allowing to place limits on the left-handed and right-handed vector and tensor couplings [120,121].

DØ excludes the production of W' bosons with masses below 731 GeV for a W' boson with standard-model-like couplings, below 739 GeV for a W' boson with right-handed couplings that is allowed to decay to both leptons and quarks, and below 768 GeV for a W' boson with right-handed couplings that is only allowed to decay to quarks [122]. CDF has recently released W' limits also using the single-top analysis [123]. In 1.9 fb^{-1} of Run-II data, a W' with Standard-Model couplings is searched for in the $t\bar{t}$ decay mode. Masses below 800 GeV are excluded, assuming that any right-handed neutrino is lighter than the W' , and below 825 GeV if the right-handed neutrino is heavier than the W' .

CDF reported a search for flavor-changing neutral-current (FCNC) decays of the top quark $t \rightarrow q\gamma$ and $t \rightarrow qZ$ in the Run-I data [124], and recently with enhanced sensitivity in Run II [125]. The SM predicts such small rates that any observation would be a sign of new physics. CDF assumes that one top decays via FCNC, while the other decays via Wb . The Run-I analysis included a $t \rightarrow q\gamma$ search in which two signatures are examined, depending on whether the W decays leptonically or hadronically. For leptonic W decay, the signature is $\gamma\ell$ and missing E_T and two or more jets, while for hadronic W decay, it is $\gamma + \geq 4$ jets. In either case, one of the jets must have a secondary vertex b tag. One event is observed ($\mu\gamma$) with an expected background of less than half an event, giving an upper limit on the top branching ratio of $B(t \rightarrow q\gamma) < 3.2\%$ at 95% C.L. In the search for $t \rightarrow qZ$, CDF considers $Z \rightarrow \mu\mu$ or ee and $W \rightarrow qq'$, giving a $Z +$ four jets signature. A Run-II dataset of 1.9 fb^{-1} is found consistent with background expectations and a 95% C.L. on the $t \rightarrow qZ$ branching fraction of $< 3.7\%$ (for $M_{\text{top}}=175$ GeV/ c^2) is set. By comparison to the number expected from the theoretical production cross section, CDF has used the observed number of double b -tagged lepton+jets candidate events to place limits on a variety of decay modes, ranging from $B(t \rightarrow Zc) < 13\%$ to $B(t \rightarrow \text{invisible}) < 9\%$ [126].

Constraints on FCNC couplings of the top quark can also be obtained from searches for anomalous single-top production in e^+e^- collisions, via the process $e^+e^- \rightarrow \gamma, Z^* \rightarrow t\bar{q}$ and its charge-conjugate ($q = u, c$), or in $e^\pm p$ collisions, via the process $e^\pm u \rightarrow e^\pm t$. For a leptonic W decay, the topology is at least a high- p_T lepton, a high- p_T jet and missing E_T , while for a hadronic W -decay, the topology is three high- p_T jets. Limits on the cross section for this reaction have been obtained by the LEP collaborations [127] in e^+e^- collisions, and by H1 [128] and ZEUS [129] in $e^\pm p$ collisions. When interpreted in terms of branching ratios in top decay [130,131], the LEP limits lead to typical 95% C.L. upper bounds of $B(t \rightarrow qZ) < 0.137$. Assuming no coupling to the Z boson, the 95% C.L. limits on the anomalous FCNC coupling $\kappa_\gamma < 0.17$ and < 0.27 by ZEUS and H1, respectively, are stronger than the CDF limit of $\kappa_\gamma < 0.42$, and improve over LEP sensitivity in that domain. The H1 limit is slightly weaker than the ZEUS limit due to

an observed excess of five-candidate events over an expected background of 3.2 ± 0.4 . If this excess is attributed to FCNC top-quark production, this leads to a total cross section of $\sigma(ep \rightarrow e + t + X, \sqrt{s} = 319 \text{ GeV}) < 0.25 \text{ pb}$ [128,132].

Appendix. Expected Sensitivity at the LHC:

The top pair-production cross section at the LHC at $\sqrt{s} = 14 \text{ TeV}$ is predicted at NLO to be about 800 pb [133]. In the first years, the LHC will operate at $\sqrt{s} = 7 \text{ TeV}$, yielding an expected cross section of about 170 pb [134]. At $\sqrt{s} = 14 \text{ TeV}$ there will be 8 million $t\bar{t}$ pairs produced per year at a luminosity of $10^{33} \text{ cm}^{-2} \text{ s}^{-1}$. Such large event samples will permit precision measurements of the top-quark parameters. The statistical uncertainties on m_t will become negligible, and will allow to monitor the systematic uncertainties at a level at least comparable to the current Tevatron uncertainty on m_{top} [135–137].

Precision measurements of the top pair-production cross section are expected to be limited by the estimated 3–10% accuracy on the luminosity determination [135,136], but far more accurate measurements would be available from the ratio of the $t\bar{t}$ production to inclusive W or Z production.

Single-top production will also be of keen interest at the LHC, where a $|V_{tb}|$ measurement at the 5% level per experiment is projected with 10 fb^{-1} [135,136].

Tests of the $V - A$ nature of the tWb vertex through a measurement of the W helicity will be extended from the Tevatron to the LHC. Current estimates are that the longitudinal fraction can be measured with a precision of about 5% [136] with 10 fb^{-1} of data.

Top-antitop spin correlations should be relatively easy to observe and measure at the LHC, where the preferred dilepton mode will have large event samples, despite the small branching fraction. At the LHC, where $t\bar{t}$ is dominantly produced through gluon fusion, the correlation is such that the top quarks are mainly either both left- or both right-handed. The CMS collaboration [136] estimates that the relative asymmetry (defined as the difference in the fraction of like-handed and the fraction of oppositely-handed $t\bar{t}$ pairs) can be measured to about 17% accuracy with 10 fb^{-1} of data.

In addition to these SM measurements, the large-event samples will allow sensitive searches for new physics. The search for heavy resonances that decay to $t\bar{t}$, already begun at the Tevatron, will acquire enhanced reach both in mass and $\sigma \cdot B$. The ATLAS collaboration [135] has studied the reach for a 5σ discovery of a narrow resonance decaying to $t\bar{t}$. With 30 fb^{-1} , it is estimated that a resonance can be discovered at $4 \text{ TeV}/c^2$ for $\sigma \cdot B = 10 \text{ fb}$, and at $1 \text{ TeV}/c^2$ for $\sigma \cdot B = 1000 \text{ fb}$. FCNC decays, $t \rightarrow Zq, \gamma q, gq$, can take place in the SM, or in the MSSM, but at rates too small to be observed even at the LHC. As such, searches for these decay modes can provide sensitive tests of other extensions of the SM [135,136]. Updated sensitivity studies at $\sqrt{s} = 10 \text{ TeV}$ by the ATLAS Collaboration are available at [138]. Recently, the CERN management decided

to start proton-proton collisions in late 2009 at $\sqrt{s} = 7 \text{ TeV}$. The production rates and the estimated sensitivities change accordingly.

t-Quark Mass in $p\bar{p}$ Collisions

OUR EVALUATION of $172.0 \pm 0.9 \pm 1.3$ GeV (TEVEWWG 10) is an average of top mass measurements from Tevatron Run-I (1992–1996) and Run-II (2001–present) that were published at the time of preparing this Review. This average was provided by the Tevatron Electroweak Working Group (TEVEWWG). It takes correlated uncertainties properly into account and has a χ^2 of 5.8 for 10 degrees of freedom.

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

¹ Based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.

² Based on 943 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09k selected 6 jet events with one or more vertex b -tags and used the tree-level matrix element to construct template models of signal and background.

³ Based on 2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Matrix Element method. Optimal selection criteria for candidate events with two high p_T leptons, high \cancel{E}_T , and two or more jets with and without b -tag are obtained by neural network with neuroevolution technique to minimize the statistical error of m_t .

⁴ Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Events with two identified leptons, and those with one lepton plus one isolated track and a b -tag were used to constrain m_t . The result is a combination of the ν WWT (ν Weighting Technique) result of $176.2 \pm 4.8 \pm 2.1 \text{ GeV}$ and the MWT (Matrix-element Weighting Technique) result of $173.2 \pm 4.9 \pm 2.0 \text{ GeV}$.

⁵ Result is based on 1 fb^{-1} of data at 1.96 TeV . The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.

⁶ Based on 695 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The transverse decay length of the b hadron is used to determine m_t , and the result is free from the JES (jet energy scale) uncertainty.

⁷ Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98F. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.

⁸ Based on $125 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.

⁹ Based on $\sim 106 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.

¹⁰ Based on $109 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.

¹¹ See AFFOLDER 01 for details of systematic error re-evaluation.

¹² Based on the first observation of all hadronic decays of $t\bar{t}$ pairs. Single b -quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.

¹³ Based on 2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The top mass is obtained from the measurement of the invariant mass of the lepton (e or μ) from W decays and the soft μ in b -jet. The result is insensitive to jet energy scaling.

¹⁴ Based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain m_t and JES. Lepton + jets data only give $m_t = 171.8 \pm 2.2 \text{ GeV}$, and dilepton data only give $m_t = 171.2 \pm 5.3 \pm 5.1 \text{ GeV}$.

¹⁵ Based on 2.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Mass m_t is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.

¹⁶ Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Uses $\ell + \text{jets}, \ell\ell$ and $\ell\tau + \text{jets}$. Compares the measured $t\bar{t}$ cross section to an approx. NNLO theoretical prediction - see their Table IV.

¹⁷ Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Uses $\ell\ell$ and $\ell\tau + \text{jets}$. Compares the measured $t\bar{t}$ cross section to a partial NNLO theoretical prediction.

¹⁸ Reports measurement of $170.7 \pm 4.2 \pm 2.6 \pm 2.4 \text{ GeV}$ based on 1.2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The last error is due to the theoretical uncertainty on $\sigma_{t\bar{t}}$. Without the cross-section constraint a top mass of $169.7 \pm 5.2 \pm 4.9 \pm 3.1 \text{ GeV}$ is obtained.

¹⁹ Template method.

²⁰ Based on 310 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

²¹ Ideogram method.

²² Based on 311 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Events with 4 or more jets with $E_T > 15 \text{ GeV}$, significant missing E_T , and secondary vertex b -tag are used in the fit. About 44% of the signal acceptance is from $\tau\nu + 4$ jets. Events with identified e or μ are vetoed to provide a statistically independent measurement.

²³ Based on 1.02 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

²⁴ Based on 955 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. m_t and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of 1.5 GeV .

²⁵ Matrix element method.

²⁶ Based on 425 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is a combination of statistics and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give JES = $0.989 \pm 0.029(\text{stat})$.

²⁷ Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Combined result of MWT (Matrix-element Weighting Technique) and ν WWT (ν Weighting Technique) analyses is $178.1 \pm 6.7 \pm 4.8 \text{ GeV}$.

²⁸ Based on 1.0 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.

²⁹ Based on $\sim 400 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the b -tagging information. The result without b -tagging is $169.2 \pm 5.0 \pm 1.5 \pm 7.4 \pm 1.4 \text{ GeV}$. Superseded by ABAZOV 08AH.

³⁰ Based on 318 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

³¹ Dynamical likelihood method.

³² Based on 340 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

³³ Based on 360 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

³⁴ Based on $110.2 \pm 5.8 \text{ pb}^{-1}$ at $\sqrt{s} = 1.8 \text{ TeV}$.

³⁵ Based on the all hadronic decays of $t\bar{t}$ pairs. Single b -quark tagging via the decay chain $b \rightarrow c \rightarrow \mu$ was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.

³⁶ Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.

³⁷ Obtained by combining the D0 result m_t (GeV) = $168.4 \pm 12.3 \pm 3.6$ from 6 di-lepton events (see also ABBOTT 98D) and m_t (GeV) = $173.3 \pm 5.6 \pm 5.5$ from lepton+jet events (ABBOTT 98F).

³⁸ Obtained by combining the CDF results of m_t (GeV) = $167.4 \pm 10.3 \pm 4.8$ from 8 dilepton events, m_t (GeV) = $175.9 \pm 4.8 \pm 5.3$ from lepton+jet events (ABE 98E), and m_t (GeV) = $186.0 \pm 10.0 \pm 5.7$ from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.

³⁹ See ABAZOV 04c.

⁴⁰ The updated systematic error is listed. See AFFOLDER 01, appendix C.

⁴¹ Obtained by combining the D0 results of m_t (GeV) = $168.4 \pm 12.3 \pm 3.6$ from 6 dilepton events and m_t (GeV) = $173.3 \pm 5.6 \pm 5.5$ from 77 lepton+jet events.

⁴² Obtained by combining the D0 results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.

$2(m_t - m_{\bar{t}}) / (m_t + m_{\bar{t}})$

Test of CPT conservation.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 Result is based on 0.9 fb⁻¹ of data. The 95% CL lower bound $R > 0.79$ gives $|V_{tb}| > 0.89$ (95% CL).
- 2 ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of $t\bar{t}$ candidate events with ~ 162 pb⁻¹ of data at $\sqrt{s} = 1.96$ TeV. The first error is statistical and the second systematic. It gives $R > 0.61$, or $|V_{tb}| > 0.78$ at 95% CL.
- 3 ABAZOV 06K result is from the analysis of $t\bar{t} \rightarrow \ell\nu + \geq 3$ jets with 230 pb⁻¹ of data at $\sqrt{s} = 1.96$ TeV. It gives $R > 0.61$ and $|V_{tb}| > 0.78$ at 95% CL. Superseded by ABAZOV 08M.
- 4 AFFOLDER 01C measures the top-quark decay width ratio $R = \Gamma(Wb)/\Gamma(Wq)$, where q is a d , s , or b quark, by using the number of events with multiple b tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives $R > 0.61$ (0.56) at 90% (95%) CL. By assuming three generation unitarity, $|V_{tb}| = 0.97 \pm 0.16$ or $|V_{tb}| > 0.78$ (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb⁻¹ of data at $\sqrt{s} = 1.8$ TeV.

- 1 AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb⁻¹. The upper bound of the cross section gives the bound on the FCNC coupling $\kappa_{t u \gamma} / \Lambda < 1.03$ TeV⁻¹, which corresponds to the result for $m_t = 175$ GeV.
- 2 CHEKANOV 03 looked for single top production via FCNC in the reaction $e^\pm p \rightarrow e^\pm (t \text{ or } \bar{t}) X$ in 130.1 pb⁻¹ of data at $\sqrt{s} = 300\text{--}318$ GeV. No evidence for top production and its decay into bW was found. The result is obtained for $m_t = 175$ GeV when $B(\gamma c) = B(Zq) = 0$, where q is a u or c quark. Bounds on the effective t - u - γ and t - u - Z couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.
- 3 ABDALLAH 04c looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 541 pb⁻¹ of data at $\sqrt{s} = 189\text{--}208$ GeV. No deviation from the SM is found, which leads to the bound on $B(t \rightarrow \gamma q)$, where q is a u or c quark, for $m_t = 175$ GeV when $B(t \rightarrow Zq) = 0$ is assumed. The conversion to the listed bound is from private communication, O. Yushmanov, April 2005. The bounds on the effective t - q - γ and t - q - Z couplings are given in their Fig. 7 and Table 4, for $m_t = 170\text{--}180$ GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.
- 4 AKTAS 04 looked for single top production via FCNC in e^\pm collisions at HERA with 118.3 pb⁻¹, and found 5 events in the e or μ channels. By assuming that they are due to statistical fluctuation, the upper bound on the $t u \gamma$ coupling $\kappa_{t u \gamma} < 0.27$ (95% CL) is obtained. The conversion to the partial width limit, when $B(\gamma c) = B(Zu) = B(Zc) = 0$, is from private communication, E. Perez, May 2005.
- 5 ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 634 pb⁻¹ of data at $\sqrt{s} = 189\text{--}209$ GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(\gamma q)$, where q is a u or c quark. The bound assumes $B(Zq) = 0$ and is for $m_t = 175$ GeV; bounds for $m_t = 170$ GeV and 180 GeV and $B(Zq) \neq 0$ are given in Fig. 5 and Table 7.
- 6 ABE 98G looked for $t\bar{t}$ events where one t decays into $q\gamma$ while the other decays into bW . The quoted bound is for $\Gamma(\gamma q)/\Gamma(Wb)$.

 $\Gamma(Zq(q=u,c))/\Gamma_{\text{total}}$ Γ_6/Γ

Test for $\Delta T = 1$ weak neutral current. Allowed by higher-order electroweak interaction.

- 1 Result is based on 1.9 fb⁻¹ of data at 1.96 TeV. $t\bar{t} \rightarrow WbZq$ or $ZqZq$ processes have been looked for in $Z + \geq 4$ jet events with and without b -tag. No signal leads to the bound $B(t \rightarrow Zq) < 0.037$ (0.041) for $m_t = 175$ (170) GeV.
- 2 ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 541 pb⁻¹ of data at $\sqrt{s} = 189\text{--}208$ GeV. No deviation from the SM is found, which leads to the bound on $B(t \rightarrow Zq)$, where q is a u or c quark, for $m_t = 175$ GeV when $B(t \rightarrow \gamma q) = 0$ is assumed. The conversion to the listed bound is from private communication, O. Yushmanov, April 2005. The bounds on the effective t - q - γ and t - q - Z couplings are given in their Fig. 7 and Table 4, for $m_t = 170\text{--}180$ GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.
- 3 ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 634 pb⁻¹ of data at $\sqrt{s} = 189\text{--}209$ GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(Zq)$, where q is a u or c quark. The bound assumes $B(\gamma q) = 0$ and is for $m_t = 175$ GeV; bounds for $m_t = 170$ GeV and 180 GeV and $B(\gamma q) \neq 0$ are given in Fig. 5 and Table 7. Table 6 gives constraints on t - c - e - e four-fermi contact interactions.
- 4 HEISTER 02Q looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 214 pb⁻¹ of data at $\sqrt{s} = 204\text{--}209$ GeV. No deviation from the SM is found, which leads to a bound on the branching fraction $B(Zq)$, where q is a u or c quark. The bound assumes $B(\gamma q) = 0$ and is for $m_t = 174$ GeV. Bounds on the effective t - $(c \text{ or } u)$ - γ and t - $(c \text{ or } u)$ - Z couplings are given in their Fig. 2.
- 5 ABBIENZI 01T looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 600 pb⁻¹ of data at $\sqrt{s} = 189\text{--}209$ GeV. No deviation from the SM is found, which leads to bounds on the branching fractions $B(Zq)$ and $B(\gamma q)$, where q is a u or c quark. The result is obtained for $m_t = 174$ GeV. The upper bound becomes 9.7% (20.6%) for $m_t = 169$ (179) GeV. Bounds on the effective t - $(c \text{ or } u)$ - γ and t - $(c \text{ or } u)$ - Z couplings are given in their Fig. 4.
- 6 Based on $p\bar{p}$ data of 1.52 fb⁻¹. AALTONEN 09AL compared $t\bar{t} \rightarrow WbWb \rightarrow \ell\nu b j j b$ and $t\bar{t} \rightarrow ZcWb \rightarrow \ell\ell c j j b$ decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical $t\bar{t}$ production cross section. The results for different Z polarizations and those without the cross section assumption are given in their Table XII.
- 7 BARATE 00S looked for single top production via FCNC in the reaction $e^+e^- \rightarrow \bar{c}c$ or $\bar{u}u$ in 411 pb⁻¹ of data at c.m. energies between 189 and 202 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction. The bound assumes $B(\gamma q) = 0$. Bounds on the effective t - $(c \text{ or } u)$ - γ and t - $(c \text{ or } u)$ - Z couplings are given in their Fig. 4.
- 8 ABE 98G looked for $t\bar{t}$ events where one t decays into three jets and the other decays into qZ with $Z \rightarrow \ell\ell$. The quoted bound is for $\Gamma(Zq)/\Gamma(Wb)$.

t-quark EW Couplings

W helicity fractions in top decays. F_0 is the fraction of longitudinal and F_\perp the fraction of right-handed W bosons. F_{V+A} is the fraction of $V+A$ current in top decays. The effective Lagrangian (cited by ABAZOV 08A) has terms f_L^R and f_R^R for $V-A$ and $V+A$ couplings, f_L^L and f_R^L for tensor couplings with b_R and b_L respectively.

 t

¹ Results are based on 1.9 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV. F_0 result is obtained assuming $F_{\pm} = 0$, while F_{\pm} result is obtained for $F_0 = 0.70$, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_{\pm} = -0.03 \pm 0.06 \pm 0.03$.

² Based on 1 fb^{-1} of data at $p\bar{p}$ collisions $\sqrt{s} = 1.96 \text{ TeV}$. Combined result of the W helicity measurement in $t\bar{t}$ events (ABAZOV 08b) and the search for anomalous tbW couplings in the single top production (ABAZOV 08a). Constraints when t_1^L and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

³ Result is based on 0.9 fb^{-1} of data at 1.96 TeV. Single top quark production events are used to measure the Lorentz structure of the tbW coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $t_1^L = V_{tb}^*$.

⁴ Based on 1 fb^{-1} at $\sqrt{s} = 1.96 \text{ TeV}$.

⁵ Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$, using the ℓ + jets and dilepton decay channels. The result assumes $F_0 = 0.70$, and it gives $F_{\pm} < 0.23$ at 95% CL.

⁶ Based on 700 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

⁷ Based on 318 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

⁸ Based on 200 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. $t \rightarrow Wb \rightarrow \ell\nu b$ ($\ell = e$ or μ). The errors are stat + syst.

⁹ ABAZOV 05g studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized W under the constraint of no right-handed current, $F_{\pm} = 0$. Based on 125 pb^{-1} of data at $\sqrt{s} = 1.8 \text{ TeV}$.

¹⁰ ABAZOV 05L studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ events, where one of the W 's from t or \bar{t} decays into e or μ and the other decays hadronically. The fraction of the "+" helicity W boson is obtained by assuming $F_0 = 0.7$, which is the generic prediction for any linear combination of V and A currents. Based on $230 \pm 15 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.96 \text{ TeV}$.

¹¹ ACOSTA 05d measures the $m_{\ell}^2 + b$ distribution in $t\bar{t}$ production events where one or both W 's decay leptonically to $\ell = e$ or μ , and finds a bound on the V+A coupling of the tbW vertex. By assuming the SM value of the longitudinal W fraction $F_0 = \text{B}(t \rightarrow W_0 b) = 0.70$, the bound on F_{\pm} is obtained. If the results are combined with those of AFFOLDER 00b, the bounds become $F_{V+A} < 0.61$ (95% CL) and $F_{\pm} < 0.18$ (95% CL), respectively. Based on $109 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$ (run I).

¹² AFFOLDER 00b studied the angular distribution of leptonic decays of W bosons in $t \rightarrow Wb$ events. The ratio F_0 is the fraction of the helicity zero (longitudinal) W bosons in the decaying top quark rest frame. $\text{B}(t \rightarrow W_{\pm} b)$ is the fraction of positive helicity (right-handed) positive charge W bosons in the top quark decays. It is obtained by assuming the Standard Model value of F_0 .

 t -quark FCNC couplings κ^{utg}/Λ and κ^{ctg}/Λ

¹ Based on 3.2 fb^{-1} of data. Events with isolated ℓ + \cancel{E}_T + jets with at least one b -tag are analyzed and s - and t -channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for s -channel process, and neural-network based analysis of events with \cancel{E}_T that has sensitivity for $W \rightarrow \tau\nu$ decays. The result is for $m_t = 175 \text{ GeV}$, and the mean value decreases by 0.02 pb/GeV for smaller m_t . The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 0.91 \pm 0.11$ (stat+syst) ± 0.07 (theory), or $|V_{tb}| > 0.71$ at 95% CL.

² Based on 2.3 fb^{-1} of data. Events with isolated ℓ + \cancel{E}_T + ≥ 2 jets with 1 or 2 b -tags are analyzed and s - and t -channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 1.07 \pm 0.12$, or $|V_{tb}| > 0.78$ at 95% CL. The analysis assumes $m_t = 170 \text{ GeV}$.

³ Result is based on 2.3 fb^{-1} of data. Events with isolated ℓ + \cancel{E}_T + 2, 3, 4 jets with one or two b -tags are selected. The analysis assumes $m_t = 170 \text{ GeV}$.

⁴ Result is based on 2.2 fb^{-1} of data. Events with isolated ℓ + \cancel{E}_T + 2, 3 jets with at least one b -tag are selected, and s - and t -channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as $|V_{tb}| = 0.88^{+0.13}_{-0.12}$ (stat + syst) ± 0.07 (theory), and $|V_{tb}| > 0.66$ (95% CL) under the $|V_{tb}| < 1$ constraint.

⁵ Result is based on 0.9 fb^{-1} of data. Events with isolated ℓ + \cancel{E}_T + 2, 3, 4 jets with one or two b -vertex-tag are selected, and contributions from W + jets, $t\bar{t}$, s - and t -channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element $|V_{tb}| = 1.31^{+0.25}_{-0.21}$, or $|V_{tb}| > 0.68$ (95% CL) under the $|V_{tb}| < 1$ constraint.

⁶ Result is based on 0.9 fb^{-1} of data. This result constrains V_{tb} to $0.68 < |V_{tb}| \leq 1$ at 95% CL.

⁷ ABAZOV 05P bounds single top-quark production from either the s -channel W -exchange process, $q'\bar{q} \rightarrow t\bar{b}$, or the t -channel W -exchange process, $q'g \rightarrow qt\bar{b}$, based on $\sim 230 \text{ pb}^{-1}$ of data.

⁸ ACOSTA 05N bounds single top-quark production from the t -channel W -exchange process ($q'g \rightarrow qt\bar{b}$), the s -channel W -exchange process ($q'\bar{q} \rightarrow t\bar{b}$), and from the combined cross section of t - and s -channel. Based on $\sim 162 \text{ pb}^{-1}$ of data.

Single t -Quark Production Cross Section in $e\bar{p}$ Collisions

VALUE (pb)	CL%	DOCUMENT ID	TECN	COMMENT
<0.25	95	¹ AARON 09A H1	$e^{\pm}p \rightarrow e^{\pm}tX$	
<0.55	95	² AKTAS 04 H1	$e^{\pm}p \rightarrow e^{\pm}tX$	
<0.225	95	³ CHEKANOV 03 ZEUS	$e^{\pm}p \rightarrow e^{\pm}tX$	

¹ AARON 09A looked for single top production via FCNC in $e^{\pm}p$ collisions at HERA with 474 pb^{-1} of data at $\sqrt{s} = 301$ - 319 GeV . The result supersedes that of AKTAS 04.

² AKTAS 04 looked for single top production via FCNC in e^{\pm} collisions at HERA with 118.3 pb^{-1} , and found 5 events in the e or μ channels while 1.31 ± 0.22 events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of $\sigma(e\bar{p} \rightarrow e\bar{t}X) = 0.29^{+0.15}_{-0.14} \text{ pb}$ at $\sqrt{s} = 319 \text{ GeV}$ gives the quoted upper bound if the observed events are due to statistical fluctuation.

³ CHEKANOV 03 looked in 130.1 pb^{-1} of data at $\sqrt{s} = 301$ and 318 GeV . The limit is for $\sqrt{s} = 318 \text{ GeV}$ and assumes $m_t = 175 \text{ GeV}$.

 $t\bar{t}$ production cross section in $p\bar{p}$ collisions at $\sqrt{s} = 1.8 \text{ TeV}$

Only the final combined $t\bar{t}$ production cross sections obtained from Tevatron Run I by the CDF and D0 experiments are quoted below.

¹ Based on 1.1 fb⁻¹ of data. The last error is from luminosity. The result is for $B(W \rightarrow \ell\nu) = 10.8\%$ and $m_t = 175$ GeV; the mean value is 9.8 for $m_t = 172.5$ GeV and 10.1 for $m_t = 170$ GeV. AALTONEN 09AD used high p_T e or μ with an isolated track to select $t\bar{t}$ decays into dileptons including $\ell = \tau$. The result is based on the candidate event samples with and without vertex b -tag.

² Based on 2 fb⁻¹ of data. The last error is from luminosity. The result is for $m_t = 175$ GeV; the mean value is 3% higher for $m_t = 170$ GeV and 4% lower for $m_t = 180$ GeV.

³ Result is based on 1 fb⁻¹ of data. The result is for $m_t = 170$ GeV, and the mean value decreases with increasing m_t ; see their Fig. 2. The result is obtained after combining $\ell +$ jets, $\ell\ell$, and $\ell\tau$ final states, and the ratios of the extracted cross sections are $R^{\ell\ell}/\ell j = 0.86^{+0.19}_{-0.17}$ and $R^{\ell\tau}/\ell\ell - \ell j = 0.97^{+0.32}_{-0.29}$, consistent with the SM expectation of $R = 1$. This leads to the upper bound of $B(t \rightarrow bH^+)$ as a function of m_{H^+} . Results are shown in their Fig. 1 for $B(H^+ \rightarrow \tau\nu) = 1$ and $B(H^+ \rightarrow c\bar{s}) = 1$ cases. Comparison of the m_t dependence of the extracted cross section and a partial NNLO prediction gives $m_t = 169.1^{+5.9}_{-5.2}$ GeV.

⁴ Result is based on 1 fb⁻¹ of data. The last error is from luminosity. The result is for $m_t = 170$ GeV, and the mean value changes by $-0.07 [m_t(\text{GeV}) - 170]$ pb near the reference m_t value. Comparison of the m_t dependence of the extracted cross section and a partial NNLO QCD prediction gives $m_t = 171.5^{+9.9}_{-8.8}$ GeV. The $\ell\tau$ channel alone gives $7.6^{+4.9+3.5+1.4}_{-4.3-3.4-0.9}$ pb and the $\ell\ell$ channel gives $7.5^{+1.2+0.7+0.7}_{-1.1-0.6-0.5}$ pb.

⁵ Result is based on 0.9 fb⁻¹ of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for $m_t = 175$ GeV, and the mean value changes by $-0.09 \text{ pb} [m_t(\text{GeV}) - 175]$.

⁶ Result is based on 0.9 fb⁻¹ of data. The cross section is obtained from the $\ell + \geq 3$ jet event rates with 1 or 2 b -tag, and also from the kinematical likelihood analysis of the $\ell + 3, 4$ jet events. The result is for $m_t = 172.6$ GeV, and its m_t dependence shown in Fig. 3 leads to the constraint $m_t = 170 \pm 7$ GeV when compared to the SM prediction.

⁷ Result is based on 360 pb⁻¹ of data. Events with high p_T oppositely charged dileptons $\ell^+ \ell^-$ ($\ell = e, \mu$) are used to obtain cross sections for $t\bar{t}$, W^+W^- , and $Z \rightarrow \tau^+\tau^-$ production processes simultaneously. The other cross sections are given in Table IV.

⁸ Based on 1.02 fb⁻¹ of data. Result is for $m_t = 175$ GeV. The last error is for luminosity. Secondary vertex b -tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.

⁹ Based on 425 pb⁻¹ of data. Result is for $m_t = 175$ GeV. For $m_t = 170.9$ GeV, $7.8 \pm 1.8(\text{stat} + \text{syst})$ pb is obtained.

¹⁰ Based on 405 ± 25 pb⁻¹ of data. Result is for $m_t = 175$ GeV. The last error is for luminosity. Secondary vertex b -tag and neural network are used to separate the signal events from the background.

¹¹ Based on 425 pb⁻¹ of data. Assumes $m_t = 175$ GeV. The last error is for luminosity.

¹² Based on ~ 425 pb⁻¹. Assuming $m_t = 175$ GeV. The first error is combined statistical and systematic, the second one is luminosity.

¹³ Based on ~ 318 pb⁻¹. Assuming $m_t = 178$ GeV. The cross section changes by ± 0.08 pb for each ± 1 GeV change in the assumed m_t . Result is for at least one b -tag. For at least two b -tagged jets, $t\bar{t}$ signal of significance greater than 5σ is found, and the cross section is $10.1^{+1.6+2.0}_{-1.4-1.3}$ pb for $m_t = 178$ GeV.

¹⁴ Based on ~ 311 pb⁻¹. Assuming $m_t = 178$ GeV. The first error is statistical and the second systematic. For $m_t = 175$ GeV, the result is $6.0 \pm 1.2^{+0.9}_{-0.7}$. This is the first CDF measurement without lepton identification, and hence it has sensitivity to the $W \rightarrow \tau\nu$ mode.

¹⁵ ABULENCIA,A 06E measures the $t\bar{t}$ production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one b -jet. $S/B = 1/5$ has been achieved. Based on 311 pb⁻¹. Assuming $m_t = 178$ GeV. The first error is statistical, the second is systematic, and the third one is luminosity.

¹⁶ Based on ~ 318 pb⁻¹. Assuming $m_t = 178$ GeV. Result is for at least one b -tag. For at least two b -tagged jets, the cross section is $11.1^{+2.3+2.5}_{-1.9-1.9}$ pb.

¹⁷ ABAZOV 05Q measures the top-quark pair production cross section with ~ 230 pb⁻¹ of data, based on the analysis of W plus n -jet events where W decays into e or μ

plus neutrino, and at least one of the jets is b -jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes $m_t = 175$ GeV; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.06$ pb in the mass range 160 to 190 GeV.

¹⁸ ABAZOV 05R measures the top-quark pair production cross section with 224–243 pb⁻¹ of data, based on the analysis of events with two charged leptons in the final state. The first error is statistical, the second one is systematic, and the last one gives the luminosity uncertainty. The result assumes $m_t = 175$ GeV; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.08$ pb in the mass range 160 to 190 GeV.

¹⁹ Based on 230 pb⁻¹. Assuming $m_t = 175$ GeV. The last error accounts for the luminosity uncertainty.

²⁰ Based on 194 pb⁻¹. Assuming $m_t = 175$ GeV.

²¹ Based on 194 ± 11 pb⁻¹. Assuming $m_t = 175$ GeV.

²² Based on 162 ± 10 pb⁻¹. Assuming $m_t = 175$ GeV.

²³ ACOSTA 05V measures the top-quark pair production cross section with ~ 162 pb⁻¹ data, based on the analysis of W plus n -jet events where W decays into e or μ plus neutrino, and at least one of the jets is b -jet like. Assumes $m_t = 175$ GeV. The first error is statistical and the latter is systematic, which include the luminosity uncertainty.

²⁴ ACOSTA 04I measures the top-quark pair production cross section with 197 ± 12 pb⁻¹ data, based on the analysis of events with two charged leptons in the final state. Assumes $m_t = 175$ GeV. The first error is statistical, the second one is systematic, and the last one gives the luminosity uncertainty.

$gg \rightarrow t\bar{t}$ fraction in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
0.07 ± 0.14 ± 0.07		¹ AALTONEN	08AG CDF	low p_T number of tracks
• • •		• • • We do not use the following data for averages, fits, limits, etc. • • •		
< 0.33	68	² AALTONEN	09F CDF	$t\bar{t}$ correlations

¹ Result is based on 0.96 fb⁻¹ of data. The contribution of the subprocesses $gg \rightarrow t\bar{t}$ and $q\bar{q} \rightarrow t\bar{t}$ is distinguished by using the difference between quark and gluon initiated jets in the number of small p_T ($0.3 \text{ GeV} < p_T < 3 \text{ GeV}$) charged particles in the central region ($|\eta| < 1.1$).

² Based on 955 pb⁻¹. AALTONEN 09F used differences in the $t\bar{t}$ production angular distribution and polarization correlation to discriminate between $gg \rightarrow t\bar{t}$ and $q\bar{q} \rightarrow t\bar{t}$ subprocesses. The combination with the result of AALTONEN 08AG gives $0.07^{+0.15}_{-0.07}$.

A_{FB} of $t\bar{t}$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV

VALUE (%)	DOCUMENT ID	TECN	COMMENT
• • •	• • • We do not use the following data for averages, fits, limits, etc. • • •		
17 ± 8	¹ AALTONEN	08AB CDF	$p\bar{p}$ frame
24 ± 14	¹ AALTONEN	08AB CDF	$t\bar{t}$ frame
12 ± 8 ± 1	² ABAZOV	08L D0	$\ell + \cancel{E}_T + \geq 4$ jets

¹ Result is based on 1.9 fb⁻¹ of data. The FB asymmetry in the $t\bar{t}$ events has been measured in the $\ell +$ jets mode, where the lepton charge is used as the flavor tag. The asymmetry in the $p\bar{p}$ frame is defined in terms of $\cos(\theta)$ of hadronically decaying t -quark momentum, whereas that in the $t\bar{t}$ frame is defined in terms of the t and \bar{t} rapidity difference. The results are consistent ($\leq 2\sigma$) with the SM predictions.

² Result is based on 0.9 fb⁻¹ of data. The asymmetry in the number of $t\bar{t}$ events with $y_t > y_{\bar{t}}$ and those with $y_t < y_{\bar{t}}$ has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the $Z' \rightarrow t\bar{t}$ contribution for the SM Z -like couplings is given in Fig. 2 for $350 \text{ GeV} < m_{Z'} < 1 \text{ TeV}$.

t -Quark Electric Charge

VALUE	DOCUMENT ID	TECN	COMMENT
• • •	• • • We do not use the following data for averages, fits, limits, etc. • • •		
	¹ ABAZOV	07c D0	fraction of $ q = 4e/3$ pair

¹ ABAZOV 07c reports an upper limit $\rho < 0.80$ (90% CL) on the fraction ρ of exotic quark pairs $Q\bar{Q}$ with electric charge $|q| = 4e/3$ in $t\bar{t}$ candidate events with high p_T lepton, missing E_T and ≥ 4 jets. The result is obtained by measuring the fraction of events in which the quark pair decays into $W^- + b$ and $W^+ + \bar{b}$, where b and \bar{b} jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb⁻¹ of data at $\sqrt{s} = 1.96$ TeV.

> 72	95	11	ABE	90B	CDF	CC: $e + \mu$
> 54	95	12	AKESSON	90	UA2	CC: $e + \text{jets} + \text{missing } E_T$
> 43	95	13	ALBAJAR	90B	UA1	CC: $\mu + \text{jets}$
> 34	95	14	ALBAJAR	88	UA1	CC: e or $\mu + \text{jets}$

¹ Result is based on 1.1 fb^{-1} of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for $2 < c\tau < 7000 \text{ mm}$; see Fig. 3. 95% CL excluded region of b' lifetime and mass is shown in Fig. 4.

² Result is based on 1.06 fb^{-1} of data. No excess from the SM Z +jet events is found when Z decays into ee or $\mu\mu$. The $m_{b'}$ bound is found by comparing the resulting upper bound on $\sigma(b'\bar{b}') [1 - (1 - B(b' \rightarrow bZ))^2]$ and the LO estimate of the b' pair production cross section shown in Fig. 38 of the article.

³ HUANG 08 reexamined the b' mass lower bound of 268 GeV obtained in AALTONEN 07C that assumes $B(b' \rightarrow bZ) = 1$, which does not hold for $m_{b'} > 255 \text{ GeV}$. The lower mass bound is given in the plane of $\sin^2(\theta_{tb'})$ and $m_{b'}$.

⁴ ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb^{-1} of $\sqrt{s}=1.8 \text{ TeV } p\bar{p}$ collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge $(2/3)e$ quark (t') is 220 GeV. The t' bound is higher than the b' bound because t' is more likely to produce charged hadrons than b' . The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

⁵ ABACHI 95F bound on the top-quark also applies to b' and t' quarks that decay predominantly into W . See FROGGATT 97.

⁶ AFFOLDER 00 looked for b' that decays in to $b+Z$. The signal searched for is $bbZZ$ events where one Z decays into e^+e^- or $\mu^+\mu^-$ and the other Z decays hadronically. The bound assumes $B(b' \rightarrow bZ) = 100\%$. Between 100 GeV and 199 GeV, the 95%CL upper bound on $\sigma(b' \rightarrow \bar{b}') \times B^2(b' \rightarrow bZ)$ is also given (see their Fig. 2).

⁷ ABE 98N looked for $Z \rightarrow e^+e^-$ decays with displaced vertices. Quoted limit assumes $B(b' \rightarrow bZ)=1$ and $c\tau_{b'}=1 \text{ cm}$. The limit is lower than $m_{Z^+} + m_b$ ($\sim 96 \text{ GeV}$) if $c\tau > 22 \text{ cm}$ or $c\tau < 0.009 \text{ cm}$. See their Fig. 4.

⁸ ABACHI 97D searched for b' that decays mainly via FCNC. They obtained 95%CL upper bounds on $B(b'\bar{b}' \rightarrow \gamma + 3 \text{ jets})$ and $B(b'\bar{b}' \rightarrow 2\gamma + 2 \text{ jets})$, which can be interpreted as the lower mass bound $m_{b'} > m_{Z^+} + m_b$.

⁹ MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes $B(b' \rightarrow b\ell^+\ell^-)=1\%$. For an exotic quark decaying only via virtual Z [$B(b\ell^+\ell^-) = 3\%$], the limit is 85 GeV.

¹⁰ ABE 92 dilepton analysis limit of $>85 \text{ GeV}$ at $\text{CL}=95\%$ also applies to b' quarks, as discussed in ABE 90B.

¹¹ ABE 90B exclude the region 28–72 GeV.

¹² AKESSON 90 searched for events having an electron with $p_T > 12 \text{ GeV}$, missing momentum $> 15 \text{ GeV}$, and a jet with $E_T > 10 \text{ GeV}$, $|\eta| < 2.2$, and excluded $m_{b'}$ between 30 and 69 GeV.

¹³ For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

¹⁴ ALBAJAR 88 study events at $E_{\text{cm}} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\bar{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

MASS LIMITS for b' (4th Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b' .

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

>21		32	ALTHOFF	84c	TASS	R , event shape
>19		33	ALTHOFF	84i	TASS	Aplanarity

- ¹⁵DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \rightarrow bg$ for $B(b' \rightarrow bg) > 65\%$ $b' \rightarrow b\gamma$ for $B(b' \rightarrow b\gamma) > 5\%$ are excluded. Charged Higgs decay were not discussed.
- ¹⁶ABDALLAH 07 searched for b' pair production at $E_{cm}=196-209$ GeV, with 420 pb⁻¹. No signal leads to the 95% CL upper limits on $B(b' \rightarrow bZ)$ and $B(b' \rightarrow cW)$ for $m_{b'} = 96$ to 103 GeV.
- ¹⁷ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium- Z mixing parameter $\delta m^2 < (10-30)$ GeV² (95%CL) for the mass 88-94.5 GeV. Using Richardson potential, a $1S$ ($b'\bar{b}'$) state is excluded for the mass range 87.7-94.7 GeV. This range depends on the potential choice.
- ¹⁸ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.
- ¹⁹Superseded by ABREU 91F.
- ²⁰AKRAWY 90B search was restricted to data near the Z peak at $E_{cm} = 91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between $(m_{H^+} + 1.5$ GeV) and 45.5 GeV.
- ²¹AKRAWY 90J search for isolated photons in hadronic Z decay and derive $B(Z \rightarrow b'\bar{b}')B(b' \rightarrow \gamma X)/B(Z \rightarrow \text{hadrons}) < 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \rightarrow \gamma X) > 10\%$.
- ²²ABE 89E search at $E_{cm} = 56-57$ GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.
- ²³ABE 89G search was at $E_{cm} = 55-60.8$ GeV at TRISTAN.
- ²⁴If the photonic decay mode is large ($B(b' \rightarrow b\gamma) > 25\%$), the ABRAMS 89c limit is 45.4 GeV. The limit for Higgs decay ($b' \rightarrow cH^-, H^- \rightarrow \bar{c}s$) is 45.2 GeV.
- ²⁵ADACHI 89c search was at $E_{cm} = 56.5-60.8$ GeV at TRISTAN using multi-hadron events accompanying muons.
- ²⁶ADACHI 89c also gives limits for any mixture of CC and bg decays.
- ²⁷ENO 89 search at $E_{cm} = 50-60.8$ at TRISTAN.
- ²⁸ENO 89 considers arbitrary mixture of the charged current, bg , and $b\gamma$ decays.
- ²⁹IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4$ GeV.
- ³⁰SAGAWA 88 set limit $\sigma(\text{top}) < 6.1$ pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{cm} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.
- ³¹ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of $1/3$ charge quarks is excluded up to $E_{cm} = 45.4$ GeV.
- ³²ALTHOFF 84c narrow state search sets limit $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4$ keV CL = 95% and heavy charge $1/3$ quark pair production $m > 21$ GeV, CL = 95%.
- ³³ALTHOFF 84i exclude heavy quark pair production for $7 < m < 19$ GeV ($1/3$ charge) using aplanarity distributions (CL = 95%).

 t' (4th Generation) Quark, Searches forMASS LIMITS for t' (4th Generation) Quark or Hadron in $p\bar{p}$ Collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>256	95	1,2 AALTONEN	08H CDF	$p\bar{p}$ at 1.96 GeV

¹ Searches for pair production of a new heavy top-like quark t' decaying to a W boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed t' mass in the lepton + jets events.

² HUANG 08 reexamined the t' mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes $B(b' \rightarrow qZ) = 1$ for $q = u, c$ which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{bt'})$ is so tiny that the decay occurs outside of the vertex detector.

Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{bt'})$ and $m_{b'}$.

Free Quark Searches

FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to “unglue” quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1-4.

¹ ABE 92J flux limits decrease as the mass increases from 50 to 500 GeV.
² HE 91 limits are for charges of the form $N \pm 1/3$ from 23/3 to 38/3.
³ Hadronic or leptonic quarks.
⁴ Cross section cm^2/GeV^2 .
⁵ 3×10^{-5} <lifetime < 1×10^{-3} s.
⁶ Includes BOTT 72 results.
⁷ Assumes isotropic cm production.
⁸ Cross section inferred from flux.

⁹ Cross section in cm^2/sr equivalent quanta.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

- (a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
- (b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
- (c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
- (d) is quarks per collision.
- (e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.
- (f) is quark flux per charged particle.
- (g) is the flux per ν -event.
- (h) is quark yield per π^- yield.
- (i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.

- ¹⁰ HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as $\pm 1/3$ (in units of e) for charge $6 \leq Z \leq 10$.
- ¹¹ BUSKULIC 93c limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.
- ¹² CECCHINI 93 limit at 90%CL for $23/3 \leq Z \leq 40/3$, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3 \leq Z \leq 20/3$ and 1.2×10^{-4} for $20/3 \leq Z \leq 23/3$.
- ¹³ GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge 5e/3, and 4 with 7e/3.
- ¹⁴ Hadronic quark.
- ¹⁵ Leptonic quark.
- ¹⁶ HE 91 limits are for charges of the form $N \pm 1/3$ from 23/3 to 38/3, and correspond to cross-section limits of $380\mu b$ (Pb) and $320\mu b$ (Cu).
- ¹⁷ The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of e/3.
- ¹⁸ The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of e/3.
- ¹⁹ Flux limits and mass range depend on charge.
- ²⁰ Bound to nuclei.
- ²¹ Quark lifetimes $> 1 \times 10^{-8}$ s.
- ²² One candidate $m < 0.17$ GeV.

Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm².

²³ AMBROSIO 00C limit is below 11×10^{-15} for $0.25 < q/e < 0.5$, and is changing rapidly near $q/e=2/3$, where it is 2×10^{-14} .

²⁴ Distribution in celestial sphere was described as anisotropic.

²⁵ With telescope axis at zenith angle 40° to the south.

²⁶ Leptonic quarks.

²⁷ Lifetime $> 10^{-8}$ s; charge $\pm 0.70, 0.68, 0.42$; and mass $> 4.4, 4.8$, and 20 GeV, respectively.

²⁸ Time delayed air shower search.

²⁹ Prompt air shower search.

³⁰ Also $e/4$ and $e/6$ charges.

³¹ No events in subsequent experiments.

³² 95% CL limit for fractional charge particles with $0.18e \leq |Q_{residual}| \leq 0.82e$ in total of 70.1 mg of silicone oil.

³³ 95% CL limit for particles with fractional charge $|Q_{residual}| > 0.16e$ in total of 17.4 mg of silicone oil.

³⁴ Also set limits for $Q = \pm e/6$.

³⁵ Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.

³⁶ Limit inferred by JONES 77b.

 π^\pm

$$I^G(J^P) = 1^-(0^-)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

π^\pm MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in π^- -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with π -mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of > 0.005 MeV have been omitted from this Listing.

¹ LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

² JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m_{\nu_\mu}^2$.

³ ASSAMAGAN 96 measures the μ^+ momentum p_μ in $\pi^+ \rightarrow \mu^+ \nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{\nu_\mu} = 0$, this gives the π^+ mass above; if $m_{\nu_\mu} > 0$, m_{π^+} given above is a lower limit.

Combined instead with m_μ and (assuming *CPT*) the π^- mass of JECKELMANN 94, p_μ gives an upper limit on m_{ν_μ} (see the ν_μ).

⁴ JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m_{\nu_\mu}^2$. It is accordingly not used in our fits.

⁵ The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

⁶ JECKELMANN 86b gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible π^\pm masses.

⁷ These values are scaled with a new wavelength-energy conversion factor $\lambda E = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

⁸ This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

$$m_{\pi^+} - m_{\mu^+}$$

Measurements with an error > 0.05 MeV have been omitted from this Listing.

π^+ DECAY MODES

π^- modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1 $\mu^+ \nu_\mu$	[a] (99.98770 ± 0.00004) %	
Γ_2 $\mu^+ \nu_\mu \gamma$	[b] (2.00 ± 0.25) × 10^{-4}	
Γ_3 $e^+ \nu_e$	[a] (1.230 ± 0.004) × 10^{-4}	
Γ_4 $e^+ \nu_e \gamma$	[b] (7.39 ± 0.05) × 10^{-7}	
Γ_5 $e^+ \nu_e \pi^0$	(1.036 ± 0.006) × 10^{-8}	
Γ_6 $e^+ \nu_e e^+ e^-$	(3.2 ± 0.5) × 10^{-9}	
Γ_7 $e^+ \nu_e \nu \bar{\nu}$	< 5	× 10^{-6} 90%

Lepton Family number (LF) or Lepton number (L) violating modes

Γ_8 $\mu^+ \bar{\nu}_e$	L	[c] < 1.5	× 10^{-3} 90%
Γ_9 $\mu^+ \nu_e$	LF	[c] < 8.0	× 10^{-3} 90%
Γ_{10} $\mu^- e^+ e^+ \nu$	LF	< 1.6	× 10^{-6} 90%

[a] Measurements of $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+ \nu_e \gamma)$ and $\Gamma(\mu^+ \nu_\mu \gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy γ 's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

π^+ BRANCHING RATIOS

¹⁸ POCANIC 04 normalizes to $e^+\nu_e$ decays, using the PDG 2004 value $B(\pi^+ \rightarrow e^+\nu_e) = (1.230 \pm 0.004) \times 10^{-4}$. We add their statistical (0.004×10^{-8}) , systematic (0.004×10^{-8}) and systematic error due to the uncertainty of $B(\pi^+ \rightarrow e^+\nu_e)$ (0.003×10^{-8}) in quadrature.					
¹⁹ This result can be used to calculate V_{ud} from pion beta decay: $V_{ud}^{PIBETA} = 0.9728 \pm 0.0030$.					
²⁰ MCFARLANE 85 combines a measured rate $(0.394 \pm 0.015)/s$ with 1982 PDG mean life.					
²¹ DEPOMMIER 68 says the result of DEPOMMIER 63 is at least 10% too large because of a systematic error in the π^0 detection efficiency, and that this may be true of all the previous measurements (also V. Soergel, private communication, 1972).

FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated August 2009 by W. Bertl (Paul Scherrer Inst.)

The radiative decays, $\pi^\pm \rightarrow l^\pm \nu \gamma$ and $K^\pm \rightarrow l^\pm \nu \gamma$, with l standing for an e or a μ , and γ for a real or virtual photon (e^+e^- pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part SD_i of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors F_i , with $i = V, A$ (vector, axial vector), in the standard description [1,2]. Exotic, non-standard contributions like $i = T, S$ (tensor, scalar) have also been considered, and we shall discuss them below. Apart from the SD terms, the decay amplitude depends also on Inner Bremsstrahlung IB from the weak decay $\pi^\pm(K^\pm) \rightarrow l^\pm \nu$ accompanied by the photon radiated from the external charged particles. Naturally, experiments try to optimize their kinematics so as to minimize the "trivial" IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^\mu \ell^\nu F_V^P \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau \quad (1)$$

$$M(SD_A) = \frac{-ieG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^\mu \ell^\nu \{F_A^P [(qk - k^2)g_{\mu\nu} - q_\mu k_\nu] + R^P k^2 g_{\mu\nu}\}, \quad (2)$$

which contains an additional axial form factor R^P which only can be accessed if the photon remains virtual. $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^μ is the polarization vector of the photon (or the effective vertex, $\epsilon^\mu = (e/k^2)\bar{u}(p_-)\gamma^\mu v(p_+)$, of the e^+e^- pair); $\ell^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_l)$ is the lepton-neutrino current; q and k are the meson

and photon four-momenta ($k = p_+ + p_-$ for virtual photons); and P stands for π or K .

The pion vector form factor, F_V^π , is related via CVC (Conserved Vector Current) to the $\pi^0 \rightarrow \gamma\gamma$ decay width by $|F_V^\pi| = (1/\alpha)\sqrt{2\Gamma_{\pi^0 \rightarrow \gamma\gamma}/\pi m_{\pi^0}}$ [3]. The resulting value, $F_V^\pi(0) = 0.0259(9)$, has been confirmed by calculations based on chiral perturbation theory (χPT) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained an F_V that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter a in $F_V^\pi(s) = F_V^\pi(0)(1 + a \cdot s)$, where $s = (1 - 2E_\gamma/m_\pi)$, and E_γ is the gamma energy in the pion rest frame: $a = 0.095 \pm 0.058$. A functional dependence on s is expected for all form factors. It becomes non-negligible in the case of $F_V^\pi(s)$ when a wide range of photon momenta is recorded; proper treatment in the analysis of K decays is mandatory.

The form factor, R^P , can be related to the electromagnetic radius, r_P , of the meson [2]: $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$ using PCAC (Partial Conserved Axial vector Current; f_P is the meson decay constant). In lowest order χPT , the ratio F_A/F_V is related to the pion electric polarizability $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times F_A/F_V$ [6]. The calculation of the other form factors, F_A^π, F_V^K , and F_A^K , is model-dependent [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\begin{aligned} \frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dx dy} &= \frac{d^2(\Gamma_{\text{IB}} + \Gamma_{\text{SD}} + \Gamma_{\text{INT}})}{dx dy} \\ &= \frac{\alpha}{2\pi} \Gamma_{P \rightarrow \ell\nu} \frac{1}{(1-r)^2} \left\{ \text{IB}(x, y) \right. \\ &+ \frac{1}{r} \left(\frac{m_P}{2f_P} \right)^2 \left[(F_V + F_A)^2 \text{SD}^+(x, y) + (F_V - F_A)^2 \text{SD}^-(x, y) \right] \\ &\left. + \frac{m_P}{f_P} \left[(F_V + F_A) \text{S}_{\text{INT}}^+(x, y) + (F_V - F_A) \text{S}_{\text{INT}}^-(x, y) \right] \right\}. \quad (3) \end{aligned}$$

Here

$$\begin{aligned} \text{IB}(x, y) &= \left[\frac{1-y+r}{x^2(x+y-1-r)} \right] \\ &\left[x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r} \right] \\ \text{SD}^+(x, y) &= (x+y-1-r) \left[(x+y-1)(1-x) - r \right] \\ \text{SD}^-(x, y) &= (1-y+r) \left[(1-x)(1-y) + r \right] \\ \text{S}_{\text{INT}}^+(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[(1-x)(1-x-y) + r \right] \\ \text{S}_{\text{INT}}^-(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[x^2 - (1-x)(1-x-y) - r \right] \end{aligned} \quad (4)$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$. Recently, formulas (3) and (4) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The ‘‘helicity’’ factor r is responsible for the enhancement of the SD over the IB amplitude in the decays $\pi^\pm \rightarrow e^\pm \nu \gamma$, while $\pi^\pm \rightarrow \mu^\pm \nu \gamma$ is dominated by IB. Interference terms are important for the decay $K^\pm \rightarrow \mu^\pm \nu \gamma$ [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of F_V and F_A . Radiative corrections to the decay $\pi^+ \rightarrow e^+ \nu \gamma$ have to be taken into account in the analysis of the precision experiments. They make up to 4% corrections in the total decay rate [9]. In $\pi^\pm \rightarrow e^\pm \nu e^+ e^-$ and $K^\pm \rightarrow \ell^\pm \nu e^+ e^-$ decays, all three form factors, F_V^P, F_A^P , and R^P , can be determined [10,11].

We give the experimental π^\pm form factors F_V^π, F_A^π , and R^π in the Listings below. In the K^\pm Listings, we give the extracted sum $F_A^K + F_V^K$ and difference $F_A^K - F_V^K$, as well as F_V^K, F_A^K and R^K .

Several searches for the exotic form factors F_T^K, F_T^K (tensor), and F_S^K (scalar) have been pursued in the past, some of them claiming non-zero results [12,13]. In particular, F_T^K has been brought into focus by experimental as well as theoretical work. It was shown that a tensor contribution could destructively interfere with the inner bremsstrahlung amplitude, leading to a substantial reduction of the branching ratio as compared with standard V–A calculations [14]. In addition, a tensor contribution as large as $F_T = -(5.6 \pm 1.7) \times 10^{-3}$ could not be completely ruled out by constraints from other measurements [15]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts F_T to the range $-5.2 \times 10^{-4} < F_T < 4.0 \times 10^{-4}$ at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region. The structure-dependent form factors have direct relations to (renormalized) coupling constants of chiral perturbation theories. Therefore, they are of interest beyond the scope of radiative decays. On the other hand, the interest in searching for new physics manifesting in exotic form factors F_T or F_S has weakened over the last years mainly for two reasons: (i) on the experimental side, the lack of results confirming the non-zero findings; (ii) on the theoretical side, numerical uncertainties are still too large to allow a clear distinction of exotic and standard contributions at the currently required level. Likely this will change in the future, but meanwhile other processes such as $\pi^+ \rightarrow e^+ \nu$ seem to be better suited to search for new physics at the precision frontier, because of the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

8.4 ± 0.5 ± 0.5	1182	3 WILLIAMS 88	CBAL	$e^+ e^- \rightarrow e^+ e^- \pi^0$

1 BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor F_V and the π^0 lifetime.

2 BROWMAN 74 gives a π^0 width $\Gamma = 8.02 \pm 0.42$ eV. The mean life is \hbar/Γ .

3 WILLIAMS 88 gives $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$ eV. We give here $\tau = \hbar/\Gamma(\text{total})$.

WEIGHTED AVERAGE
8.4 ± 0.5 (Error scaled by 2.6)

[a] Astrophysical and cosmological arguments give limits of order 10⁻¹³; see the Particle Listings below.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 4.6$ for 4 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{array}{cc} x_2 & \begin{array}{c} -100 \\ 0 \end{array} \\ x_4 & \begin{array}{cc} 0 & -1 \\ x_1 & x_2 \end{array} \end{array}$$

The astrophysical and cosmological limits are many orders of magnitude lower, but we use the best laboratory limit for the Summary Tables.

¹²This limit applies to all possible $\nu\nu'$ states as well as to other massless, weakly interacting states.¹³LAM 91 considers the production of right-handed neutrinos produced from the cosmic thermal background at the temperature of about the pion mass through the reaction $\gamma\gamma \rightarrow \pi^0 \rightarrow \nu\bar{\nu}$.¹⁴NATALE 91 considers the excess energy-loss rate from SN1987A if the process $\gamma\gamma \rightarrow \pi^0 \rightarrow \nu\bar{\nu}$ occurs, permitted if the neutrinos have a right-handed component. As pointed out in LAM 91 (and confirmed by Natale), there is a factor 4 error in the NATALE 91 published result (0.8×10^{-7}).¹⁵HOFFMAN 88 analyzes data from a 400-GeV BEBC beam-dump experiment.¹⁶HOFFMAN 88 analyzes data from a 400-GeV BEBC beam-dump experiment.¹⁷HOFFMAN 88 analyzes data from a 400-GeV BEBC beam-dump experiment.¹⁸These experiments give $B(3\gamma/2\gamma) < 5.0 \times 10^{-6}$.¹⁹HOFFMAN 88 analyzes data from a 400-GeV BEBC beam-dump experiment.²⁰HOFFMAN 88 analyzes data from a 400-GeV BEBC beam-dump experiment.

 π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \rightarrow e^+ e^- \gamma$ contains a form factor $F(x)$ at the $\pi^0 \gamma \gamma$ vertex, where $x = [m_{e^+ e^-}^2/m_{\pi^0}^2]$. The parameter a in the linear expansion $F(x) = 1 + ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

¹⁹BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of a is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

²⁰TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

²¹The FISCHER 78 error is statistical only. The result without radiation corrections is $+0.05 \pm 0.03$.

 η

$$I^G(J^{PC}) = 0^+(0^-+)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

 η MASS

The new measurements from CLEO-c and KLOE seem to resolve the obvious inconsistency of the previously available high-precision η mass measurements by NA48 (LAI 02) and GEM (ABDEL-BARY 05) in favor of the higher η mass from NA48. Therefore we now use only the results from LAI 02, MILLER 07, and AMBROSINO 07B for our η mass average.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to a decay rate and 19 branching ratios uses 48 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 56.0$ for 40 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 η DECAY RATES

$\Gamma(2\gamma)$ Γ_2

See the table immediately above giving the fitted decay rates. Following the advice of NEFKENS 02, we have removed the Primakoff-effect measurement from the average. See also the "Note on the Decay Width $\Gamma(\eta \rightarrow \gamma\gamma)$," in our 1994 edition, Phys. Rev. D50, 1 August 1994, Part I, p. 1451, for a discussion of the various measurements.

• • • We do not use the following data for averages, fits, limits, etc. • • •

0.476±0.062		² RODRIGUES	08 CNTR	Reanalysis
0.64 ± 0.14 ± 0.13		AIHARA	86 TPC	$e^+e^- \rightarrow e^+e^-\eta$
0.56 ± 0.16	56	WEINSTEIN	83 CBAL	$e^+e^- \rightarrow e^+e^-\eta$
0.324±0.046		BROWMAN	74B CNTR	Primakoff effect
1.00 ± 0.22		³ BEMPORAD	67 CNTR	Primakoff effect

² RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the η photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \rightarrow 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.

³ BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

0.12 ± 0.06	24	THALER 72	ASPK

24 The authors don't believe this indicates D -wave because the dependence of β on the γ energy is inconsistent with the theoretical prediction. A $\cos^2\theta$ dependence can also come from P - and F -wave interference.

 η CP -NONCONSERVING DECAY PARAMETER $\pi^+ \pi^- e^+ e^-$ DECAY-PLANE ASYMMETRY PARAMETER A_ϕ

In the η rest frame, the total momentum of the $e^+ e^-$ pair is equal and opposite to that of the $\pi^+ \pi^-$ pair. Let \hat{z} be the unit vector along the momentum of the $e^+ e^-$ pair; let \hat{n}_{ee} and $\hat{n}_{\pi\pi}$ be the unit vectors normal to the $e^+ e^-$ and $\pi^+ \pi^-$ planes; and let ϕ be the angle between the two normals. Then

$$\sin\phi \cos\phi = [(\hat{n}_{ee} \times \hat{n}_{\pi\pi}) \cdot \hat{z}] (\hat{n}_{ee} \cdot \hat{n}_{\pi\pi}),$$

and

$$A_\phi \equiv \frac{N_{\sin\phi \cos\phi > 0} - N_{\sin\phi \cos\phi < 0}}{N_{\sin\phi \cos\phi > 0} + N_{\sin\phi \cos\phi < 0}}.$$

NOTE ON SCALAR MESONS

Revised April 2010 by C. Amsler (University of Zurich), T. Gutsche (University of Tübingen), S. Spanier (University of Tennessee) and N.A. Törnqvist (University of Helsinki).

I. Introduction: The scalar mesons are especially important to understand because they have the same quantum numbers as the vacuum ($J^{PC} = 0^{++}$). Therefore they can condense into the vacuum and break a symmetry such as a global chiral $U(N_f) \times U(N_f)$. The details of how this symmetry breaking is implemented in Nature is one of the most profound problems in particle physics.

In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar

resonances are difficult to resolve because of their large decay widths which cause a strong overlap between resonances and background, and also because several decay channels open up within a short mass interval. In addition, the $K\bar{K}$ and $\eta\eta$ thresholds produce sharp cusps in the energy dependence of the resonant amplitude. Furthermore, one expects non- $q\bar{q}$ scalar objects, like glueballs and multiquark states in the mass range below 1800 MeV. For some recent reviews see Ref. [1–4].

Scalars are produced, for example, in πN scattering on polarized/unpolarized targets, $p\bar{p}$ annihilation, central hadronic production, J/Ψ , B^- , D^- and K -meson decays, $\gamma\gamma$ formation, and ϕ radiative decays. Experiments are accompanied by the development of theoretical models for the reaction amplitudes, which are based on common fundamental principles of two-body unitarity, analyticity, Lorentz invariance, and chiral- and flavor-symmetry using different techniques (K -matrix formalism, N/D -method, Dalitz Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories such as the linear sigma model, *etc.*). Dynamics near the lowest two-body thresholds in some analyses is described by crossed channel (t , u) meson exchange or with an effective range parameterization instead of or in addition to resonant features in the s -channel, only. Furthermore, elastic S -wave scattering amplitudes involving soft pions have zeros close to threshold [5–6], which may be shifted or removed in associated production processes.

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude (T -matrix or S -matrix) at an unphysical sheet of the complex energy plane: $(E - i\Gamma/2)$. It is important to note that only in the case of narrow well-separated resonances, far away from the opening of decay channels, does the naive Breit-Wigner parameterization (or K -matrix pole parameterization) agree with this pole position.

In this note, we discuss all light scalars organized in the listings under the entries ($I = 1/2$) $K_0^*(800)$ (or κ), $K_0^*(1430)$, ($I = 1$) $a_0(980)$, $a_0(1450)$, and ($I = 0$) $f_0(600)$ (or σ), $f_0(980)$, $f_0(1370)$, and $f_0(1500)$. This list is minimal and does not necessarily exhaust the list of actual resonances. The ($I = 2$) $\pi\pi$ and ($I = 3/2$) $K\pi$ phase shifts do not exhibit any resonant behavior. See also our notes in previous issues for further comments on *e.g.*, scattering lengths and older papers.

II. The $I = 1/2$ States: The $K_0^*(1430)$ [7] is perhaps the least controversial of the light scalar mesons. The $K\pi$ S -wave scattering has two possible isospin channels, $I = 1/2$ and $I = 3/2$. The $I = 3/2$ wave is elastic and repulsive up to 1.7 GeV [8] and contains no known resonances. The $I = 1/2$ $K\pi$ phase shift, measured from about 100 MeV above threshold in Kp production, rises smoothly, passes 90° at 1350 MeV, and continues to rise to about 170° at 1600 MeV. The first important inelastic threshold is $K\eta'(958)$. In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the $K\pi$ threshold using effective range type formulas [7,9], or chiral perturbation predictions [10–12].

In analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence [13] finds a larger width of 500 MeV.

The presence and properties of the light $K^*(800)$ or “ κ ” meson in the 700-900 MeV region are difficult to establish since it appears to have a very large width ($\Gamma \approx 500$ MeV) and resides close to the $K\pi$ threshold. Hadronic D -meson decays provide additional data points in the vicinity of the $K\pi$ threshold - experimental results from E791 *e.g.* Ref. [14,15], FOCUS [13,16], CLEO [17], and BaBar [18] are discussed in the *Review of Charm Dalitz Plot Analyses*. Precision information from semileptonic D decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [19] (re-analyzed by [20]) finds a κ like structure in J/ψ decays to $\bar{K}^{*0}(892)K^+\pi^-$ where κ recoils against the $K^*(892)$. Also clean with respect to final state interaction is the decay $\tau^- \rightarrow K_S^0\pi^-\nu_\tau$ studied by Belle [21], with $K^*(800)$ parameters fixed to Ref. [19].

Some authors find a κ pole in their phenomenological analysis (see *e.g.* [11,17,22–34]), while others do not (see *e.g.* [12,18,35–37]). The pole position for the κ was found in a theoretical analysis [38] in the $K\pi \rightarrow K\pi$ amplitude on the second sheet. This analysis involves the Mandelstam representation, which includes unitarity, analyticity and crossing symmetry.

III. The $I = 1$ States: Two isovector states are known, the established $a_0(980)$ and the $a_0(1450)$. Independent of any model, the $K\bar{K}$ component in the $a_0(980)$ wave function must be large: it lies just below the opening of the $K\bar{K}$ channel to which it strongly couples. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled channel model with energy-dependent widths and mass shift contributions is necessary. All listed $a_0(980)$ measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the $p\bar{p}$ -annihilation data [9] using an unitary K -matrix description finds a width as determined from the T -matrix pole of 92 ± 8 MeV, while the observed width of the peak in the $\pi\eta$ mass spectrum is about 45 MeV.

The relative coupling $K\bar{K}/\pi\eta$ is determined indirectly from $f_1(1285)$ [39–41] or $\eta(1410)$ decays [42–44], from the line shape observed in the $\pi\eta$ decay mode [45–48], or from the coupled-channel analysis of $\pi\pi\eta$ and $K\bar{K}\pi$ final states of $p\bar{p}$ annihilation at rest [9].

The $a_0(1450)$ is seen in $p\bar{p}$ annihilation experiments with stopped and higher momenta \bar{p} , with a mass of about 1450 MeV or close to the $a_2(1320)$ meson which is typically a dominant feature. A contribution from $a_0(1450)$ is also found in the analysis of the $D^\pm \rightarrow K^+K^-\pi^\pm$ decay [49]. The broad structure at about 1300 MeV observed in $\pi N \rightarrow K\bar{K}N$ reactions [50] needs further confirmation in its existence and isospin assignment.

Meson Particle Listings

$f_0(600)$

IV. The $I = 0$ States: The $I = 0 J^{PC} = 0^{++}$ sector is the most complex one, both experimentally and theoretically. The data have been obtained from $\pi\pi$, $K\bar{K}$, $\eta\eta$, 4π , and $\eta\eta'(958)$ systems produced in S -wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from $\pi\pi$ threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries σ or $f_0(600)$, $f_0(980)$, $f_0(1370)$, and $f_0(1500)$.

For discussions of the $\pi\pi$ S wave below the $K\bar{K}$ threshold and on the long history of the $\sigma(600)$, which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the conference proceedings [51].

Information on the $\pi\pi$ S -wave phase shift $\delta_J^0 = \delta_0^0$ was already extracted 35 years ago from the πN scattering [52,53], and near threshold from the K_{e4} -decay [54]. The reported $\pi\pi \rightarrow K\bar{K}$ cross sections [55–58] have large uncertainties. The πN data have been analyzed in combination with high-statistics data (see entries labeled as RVUE for re-analyses of the data). The $2\pi^0$ invariant mass spectra of the $p\bar{p}$ annihilation at rest [59,60] and the central collision [61] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for πN data [52,62], which allows for the existence of the broad σ . An enhancement is observed in the $\pi^+\pi^-$ invariant mass near threshold in the decays $D^+ \rightarrow \pi^+\pi^-\pi^+$ [63–65] and $J/\psi \rightarrow \omega\pi^+\pi^-$ [66,67], and in $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$ with very limited phase space [68,69].

The precise σ pole is difficult to establish because of its large width, and because it can certainly not be modelled by a naive Breit-Wigner resonance. It is distorted by background as required by chiral symmetry, and from crossed channel exchanges, the $f_0(1370)$, and other dynamical features. However, most of the analyzes under $f_0(600)$ listed in our previous issues agree on a pole position near $(500 - i250)$ MeV. In particular, analyses of $\pi\pi$ data that include unitarity, $\pi\pi$ threshold behavior and the chiral symmetry constraints from Adler zeroes and scattering lengths need the σ .

A precise pole position with an uncertainty of less than 20 MeV (see our table for T -matrix pole) is derived by Ref. [70]. An important ingredient is the use of Roy-Steiner equations derived from crossing symmetry, analyticity and unitarity. With these constraints [70] find that their position of the σ pole depends, almost exclusively, only on the value of the isosinglet S -wave phase shift at 800 MeV and the S -wave scattering lengths a_0^0 and a_0^2 . Using analyticity and unitarity only to describe data from $K_{2\pi}$ and K_{e4} decays [71] find comparable pole position and scattering length a_0^0 . A similar determination in a fit by [72] to K_{e4} decay data and to higher energy $\pi\pi$ phase shifts also results in a σ pole position consistent with the result of [70].

According to Ref. [73,74] the data for $\sigma \rightarrow \gamma\gamma$ are consistent with what is expected for a two step process of $\gamma\gamma \rightarrow \pi^+\pi^-$ via pion exchange in the t - and u -channel, followed by a final state interaction $\pi^+\pi^- \rightarrow \pi^0\pi^0$. The same conclusion is drawn

in Ref. [75] where the bulk part of the $\sigma \rightarrow \gamma\gamma$ decay width is dominated by rescattering. Therefore it may be difficult to learn anything new about the nature of the σ from its $\gamma\gamma$ coupling. There are theoretical indications (e.g. [76–79]) that the σ pole behaves differently from a $q\bar{q}$ -state.

The $f_0(980)$ overlaps strongly with the σ and background represented by a very slowly varying phase extending to higher masses and/or the $f_0(1370)$. This can lead to a dip in the $\pi\pi$ spectrum at the $K\bar{K}$ threshold. It changes from a dip into a peak structure in the $\pi^0\pi^0$ invariant mass spectrum of the reaction $\pi^-p \rightarrow \pi^0\pi^0n$ [80], with increasing four-momentum transfer to the $\pi^0\pi^0$ system, which means increasing the a_1 -exchange contribution in the amplitude, while the π -exchange decreases. The σ , and the $f_0(980)$, are also observed in data for radiative decays ($\phi \rightarrow f_0\gamma$) from SND [81,82], CMD2 [83], and KLOE [84,85]. Analyses of $\gamma\gamma \rightarrow \pi\pi$ data [86–88] underline the importance of the $K\bar{K}$ coupling of $f_0(980)$, while the resulting two-photon width of the $f_0(980)$ cannot be determined precisely [89]. A reliable interpretation of the $f_0(980)$ based on these observations is not possible at present.

The f_0 's above 1 GeV. A meson resonance that is very well studied experimentally, is the $f_0(1500)$ seen by the Crystal Barrel experiment in five decay modes: $\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta\eta'(958)$, and 4π [9,59,60]. Due to its interference with the $f_0(1370)$ (and $f_0(1710)$), the peak attributed to $f_0(1500)$ can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrive at slightly different resonance masses for $f_0(1500)$. Analyses of central-production data of the likewise five decay modes Ref. [90,91] agree on the description of the S -wave with the one above. The $p\bar{p}$, $p\bar{n}/n\bar{p}$ measurements [92–94,60] show a single enhancement at 1400 MeV in the invariant 4π mass spectra, which is resolved into $f_0(1370)$ and $f_0(1500)$ [95,96]. The data on 4π from central production [97] require both resonances, too, but disagree on the relative content of $\rho\rho$ and $\sigma\sigma$ in 4π . All investigations agree that the 4π decay mode represents about half of the $f_0(1500)$ decay width and is dominant for $f_0(1370)$.

The determination of the $\pi\pi$ coupling of $f_0(1370)$ is aggravated by the strong overlap with the broad $f_0(600)$ and $f_0(1500)$. Since it does not show up prominently in the 2π spectra, its mass and width are difficult to determine. Multi-channel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow $f_0(1500)$, but arrive at a somewhat smaller width for $f_0(1370)$.

Both Belle and BaBar have observed scalars in B and D meson decays. They observe broad or narrow structures between 1 and 1.6 GeV in K^+K^- and $\pi^+\pi^-$ decays [98–102] (see also [103]). It could be a result of interference of several resonances in this mass range, but lack of statistics prevents an unambiguous identification of this effect.

V. Interpretation of the scalars below 1 GeV: In the literature, many suggestions are discussed, such as conventional $q\bar{q}$ mesons, $qq\bar{q}\bar{q}$ or meson-meson bound states mixed with a

scalar glueball. In reality, they can be superpositions of these components, and one depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The $f_0(980)$ and $a_0(980)$ are often interpreted as multi-quark states [104–108] or $K\bar{K}$ bound states [109]. The insight into their internal structure using two-photon widths [82,110–115] is not conclusive. The $f_0(980)$ appears as a peak structure in $J/\psi \rightarrow \phi\pi^+\pi^-$ and in D_s decays without $f_0(600)$ background. Based on that observation it is suggested that $f_0(980)$ has a large $s\bar{s}$ component, which according to Ref. [116] is surrounded by a virtual $K\bar{K}$ cloud (see also [117]). Data on radiative decays ($\phi \rightarrow f_0\gamma$ and $\phi \rightarrow a_0\gamma$) from SND, CMD2, and KLOE (see above) favor a 4-quark picture of the $f_0(980)$ and $a_0(980)$. The underlying model for this conclusion [118,119] however may be oversimplified. But it remains quite possible that the states $f_0(980)$ and $a_0(980)$, together with the $f_0(600)$ and the $K_0^*(800)$, form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see e.g. Ref. [120]). Different QCD sum rule studies [121–125] do not agree on a tetraquark configuration for the same particle group.

Attempts have been made to start directly from chiral Lagrangians [24,119,126–130] which predict the existence of the σ meson near 500 MeV. Hence, e.g., in the chiral linear sigma model with 3 flavors, the σ , $a_0(980)$, $f_0(980)$, and κ (or $K_0^*(1430)$) would form a nonet (not necessarily $q\bar{q}$), while the lightest pseudoscalars would be their chiral partners.

In such models inspired by the linear sigma model the light $\sigma(600)$ is often referred to as the "Higgs boson of strong interactions", since the σ plays a role similar to the Higgs particle in electro-weak symmetry breaking. It is important for chiral symmetry breaking which generates most of the proton and η' mass, and what is referred to as the constituent quark mass.

In the approach of Ref. [24] the above resonances are generated starting from chiral perturbation theory predictions near the first open channel, and then by extending the predictions to the resonance regions using unitarity.

In the unitarized quark model with coupled $q\bar{q}$ and meson-meson channels, the light scalars can be understood as additional manifestations of bare $q\bar{q}$ confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong 3P_0 coupling to S -wave two-meson decay channels [131–135]. Thus, the light scalar nonet comprising the $f_0(600)$, $f_0(980)$, $K_0^*(800)$, and $a_0(980)$, as well as the regular nonet consisting of the $f_0(1370)$, $f_0(1500)$ (or $f_0(1700)$), $K_0^*(1430)$, and $a_0(1450)$, respectively, are two manifestations of the same bare input states (see also Ref. [136]).

Other models with different groupings of the observed resonances exist and may e.g. be found in earlier versions of this review and papers listed as other related papers below.

VI. Interpretation of the f_0 's above 1 GeV:

The $f_0(1370)$ and $f_0(1500)$ decay mostly into pions (2π and 4π) while the $f_0(1710)$ decays mainly into $K\bar{K}$ final states. The $K\bar{K}$ decay branching ratio of the $f_0(1500)$ is small [90,137].

If one uses the naive quark model it is natural to assume that the $f_0(1370)$, $a_0(1450)$, and the $K_0^*(1430)$ are in the same SU(3) flavor nonet, being the $(u\bar{u} + d\bar{d})$, $u\bar{d}$ and $u\bar{s}$ states, respectively, while the $f_0(1710)$ is the $s\bar{s}$ state. Indeed, the production of $f_0(1710)$ (and $f_2'(1525)$) is observed in $p\bar{p}$ annihilation [138] but the rate is suppressed compared to $f_0(1500)$ (respectively $f_2(1270)$), as would be expected from the OZI rule for $s\bar{s}$ states. The $f_0(1500)$ would also qualify as $(u\bar{u} + d\bar{d})$ state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in $\gamma\gamma$ collisions leading to $K_S^0 K_S^0$ [139] a spin 0 signal is observed at the $f_0(1710)$ mass (together with a dominant spin 2 component), while the $f_0(1500)$ is not observed in $\gamma\gamma \rightarrow K\bar{K}$ nor $\pi^+\pi^-$ [140]. In $\gamma\gamma$ collisions leading to $\pi^0\pi^0$ Ref. [141] reports the observation of a scalar around 1470 MeV albeit with large uncertainties on the mass and $\gamma\gamma$ couplings. This state could be the $f_0(1370)$ or the $f_0(1500)$. The upper limit from $\pi^+\pi^-$ [140] excludes a large $n\bar{n}$ content for the $f_0(1500)$ and hence points to a mainly $s\bar{s}$ state [142]. This appears to contradict the small $K\bar{K}$ decay branching ratio of the $f_0(1500)$ and makes a $q\bar{q}$ assignment difficult for this state. Hence the $f_0(1500)$ could be mainly glue due the absence of a 2γ -coupling, while the $f_0(1710)$ coupling to 2γ would be compatible with an $s\bar{s}$ state. However, the 2γ -couplings are sensitive to glue mixing with $q\bar{q}$ [143].

Note that an isovector scalar, possibly the $a_0(1450)$ (albeit at a lower mass of 1317 MeV) is observed in $\gamma\gamma$ collisions leading to $\eta\pi^0$ [144]. The state interferes destructively with the non-resonant background, but its $\gamma\gamma$ coupling is comparable to that of the $a_2(1320)$, in accord with simple predictions (see e.g. Ref. [142]).

The narrow width of $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions [145–147] also favor $f_0(1500)$ to be non- $q\bar{q}$. In the mixing scheme of Ref. [143], which uses central production data from WA102 and the recent hadronic J/ψ decay data from BES [148,149], glue is shared between $f_0(1370)$, $f_0(1500)$ and $f_0(1710)$. The $f_0(1370)$ is mainly $n\bar{n}$, the $f_0(1500)$ mainly glue and the $f_0(1710)$ dominantly $s\bar{s}$. This agrees with previous analyses [150,151].

However, alternative schemes have been proposed (e.g. in Ref. [152,153]; for a review see e.g. Ref. [1]) . In particular, for a scalar glueball, the two-gluon coupling to $n\bar{n}$ appears to be suppressed by chiral symmetry [154] and therefore the $K\bar{K}$ decay could be enhanced. This mechanism would imply that the $f_0(1710)$ can possibly be interpreted as an unmixed glueball [155]. In Ref. [156] the large K^+K^- scalar signal reported by Belle in B decays into $KK\bar{K}$ [157], compatible with the $f_0(1500)$, is explained as due to constructive interference with a broad glueball background. However, the Belle data

Meson Particle Listings

 $f_0(600)$

are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for B decays into both $K^\pm K^\pm K^\mp$ [101] and $K^+ K^- \pi^0$ [158].

Whether the $f_0(1500)$ is observed in 'gluon rich' radiative J/ψ decays is debatable [159] because of the limited amount of data - more data for this and the $\gamma\gamma$ mode are needed.

- From the K_{e4} data of BATLEY 08A and $\pi N \rightarrow \pi\pi N$ data of HYAMS 73.
- From the K_{e4} data of BATLEY 08A and $\pi N \rightarrow \pi\pi N$ data of PROTOPOESCU 73, GRAYER 74, and ESTABROOKS 74.
- From a mean of three different $f_0(600)$ parametrizations. Uses 40k events.
- From an isobar model using 2.6k events.
- Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.
- From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPOESCU 73 data.
- Reanalysis of the data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
- From a mean of six different analyses and $f_0(600)$ parameterizations.
- Using data on $\psi(2S) \rightarrow J/\psi\pi\pi$ from BAI 00E and on $\Upsilon(nS) \rightarrow \Upsilon(mS)\pi\pi$ from BUTLER 94B and ALEXANDER 98.
- Reanalysis of data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.
- From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01B, and PISLAK 01.
- A similar analysis (KOMADA 01) finds $(580^{+79}_{-30}) - i(190^{+107}_{-49})$ MeV.
- Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82B using the uniformizing variable.
- Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
- Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
- Demonstrates explicitly that $f_0(600)$ and $f_0(1370)$ are two different poles.
- Coupled channel analysis of $\bar{p}p \rightarrow 3\pi^0, \pi^0\eta\eta$ and $\pi^0\pi^0\eta$ on sheet II.
- Coupled channel analysis of $\bar{p}p \rightarrow 3\pi^0, \pi^0\eta\eta$ and $\pi^0\pi^0\eta$ on sheet III.
- Analysis of data from FALVARD 88.
- Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
- Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
- Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.
- Coupled-channel analysis using data from PROTOPOESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEEN 79, BISWAS 81.
- Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
- Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPOESCU 73, and WALKER 67.

 $\rho(770)$

$$I^G(J^{PC}) = 1^+(1^-)$$

THE $\rho(770)$

Updated May 2010 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits for hadroproduced ρ mesons, the line shape does not correspond to a relativistic Breit-Wigner function with a P -wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final state systems [2].

The same model dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift δ_1^1 , or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the η and η' reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole [3,4].

The cleanest determination of the $\rho(770)$ mass and width comes from e^+e^- annihilation and τ -lepton decays. Barate *et al.* [5] shows that the charged $\rho(770)$ parameters measured in τ -lepton decays are consistent with those of the neutral one determined from e^+e^- data [6]. This conclusion is qualitatively supported by the high-statistics study of Anderson *et al.* [7]. However, model-independent comparison of the two-pion mass spectrum in τ decays, and the $e^+e^- \rightarrow \pi^+\pi^-$ cross section, gives indications of discrepancies between the overall normalization: τ data are about 3% higher than e^+e^- data [7,8]. A detailed analysis using such two-pion mass spectra from τ decays measured by OPAL [9], CLEO [7], and ALEPH [10], as well as recent pion form factor measurements in e^+e^- annihilation by CMD-2 [11,12], show that the discrepancy can be as high as 10% above the ρ meson [13,14]. This discrepancy remains after recent measurements of the two-pion cross section in e^+e^- annihilation at KLOE [15,16] and SND [17,18]. The effect is not accounted for by isospin breaking [19-21], but the accuracy of its calculation may be overestimated [22,23]. Ghozzi [24] suggests that this effect can be explained if the charged ρ mass were higher than that of the neutral one by a few MeV. Existing theoretical models of the possible mass difference predict either a much smaller value [25], or a heavier neutral ρ meson [26]. Experimental accuracy is not yet sufficient for unambiguous conclusions. The size of the effect is also sensitive to the possible width difference [27,28]. The discrepancy between e^+e^- and τ becomes smaller after a new measurement of the pion form factor using radiative return at BaBar [29], a high-statistics study of τ decays into two pions at Belle [30] and reanalysis of isospin breaking effects [31]. Benayoun *et al.* [32,33] performs a detailed analysis of the whole set of the ρ , ω , and ϕ decays, consistently taking into account mixing effects in the hidden local symmetry model, and claims

Meson Particle Listings

 $\rho(770)$

that in this approach τ decays to two pions can be naturally accounted for.

WEIGHTED AVERAGE
769.0 ± 0.9 (Error scaled by 1.4)

- 1 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.
- 2 Supersedes ACHASOV 05A.
- 3 A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.
- 4 Using the GOUNARIS 68 parametrization with the complex phase of the $\rho-\omega$ interference.
- 5 Update of AKHMETSHIN 02.
- 6 Assuming $m_{\rho^+} = m_{\rho^-}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-}$.
- 7 From the GOUNARIS 68 parametrization of the pion form factor.
- 8 Assuming $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$.
- 9 Without limitations on masses and widths.
- 10 Assuming $m_{\rho^0} = m_{\rho^\pm}$, $g_{\rho^0\pi\pi} = g_{\rho^\pm\pi\pi}$.
- 11 Using the data of BARKOV 85 in the hidden local symmetry model.
- 12 From the fit to $e^+e^- \rightarrow \pi^+\pi^-\pi^0$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.
- 13 A fit of BARKOV 85 data assuming the direct $\omega\pi\pi$ coupling.
- 14 Applying the S-matrix formalism to the BARKOV 85 data.
- 15 Includes BARKOV 85 data. Model-dependent width definition.
- 16 $|F_\pi(0)|^2$ fixed to 1.
- 17 From the GOUNARIS 68 parametrization of the pion form factor.
- 18 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- 19 $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.
- 20 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- 21 Using the data of BARATE 97M and the effective chiral Lagrangian.
- 22 From a fit of the model-independent parametrization of the pion form factor to the data of BARATE 97M.
- 23 Assuming the equality of ρ^+ and ρ^- masses and widths.
- 24 Mass errors enlarged by us to Γ/\sqrt{N} ; see the note with the $K^*(892)$ mass.
- 25 Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- 26 From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- 27 From the parametrization according to SOEDING 66.
- 28 From the parametrization according to ROSS 66.
- 29 HEYN 81 includes all spacelike and timelike F_π values until 1978.
- 30 From pole extrapolation.
- 31 From phase shift analysis of GRAYER 74 data.
- 32 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDHABER 64, ABOLINS 63.
- 33 Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPOPOESCU 73 data.
- 34 Using relativistic Breit-Wigner and taking into account $\rho-\omega$ interference.
- 35 Systematic errors not evaluated.
- 36 Systematic effects not studied.
- 37 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

$\rho(770)$ RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1 + q_r^2 R^2) / (1 + q^2 R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

Γ_{10}	$\pi^0\pi^0\gamma$	(4.5 ± 0.8)	$\times 10^{-5}$
Γ_{11}	$\mu^+\mu^-$	$[a]$ (4.55 ± 0.28)	$\times 10^{-5}$
Γ_{12}	e^+e^-	$[a]$ (4.72 ± 0.05)	$\times 10^{-5}$
Γ_{13}	$\pi^+\pi^-\pi^0$	$(1.01^{+0.54}_{-0.36} \pm 0.34)$	$\times 10^{-4}$
Γ_{14}	$\pi^+\pi^-\pi^+\pi^-$	(1.8 ± 0.9)	$\times 10^{-5}$
Γ_{15}	$\pi^+\pi^-\pi^0\pi^0$	(1.6 ± 0.8)	$\times 10^{-5}$
Γ_{16}	$\pi^0e^+e^-$	< 1.2	$\times 10^{-5}$
Γ_{17}	ηe^+e^-		$\times 10^{-5}$

[a] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+\mu^-) = \Gamma(\rho^0 \rightarrow e^+e^-) \times 0.99785$.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 7 branching ratios uses 21 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 6.0$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

⁹⁷ Possibly large ρ - ω interference leads us to increase the minus error.

⁹⁸ Result contains 11 ± 11% correction using SU(3) for central value. The error on the correction takes account of possible ρ - ω interference and the upper limit agrees with the upper limit of $\omega \rightarrow \mu^+\mu^-$ from this experiment.

⁹⁹ HYAMS 67's mass resolution is 20 MeV. The ω region was excluded.

¹⁰⁰ The ρ' contribution is not taken into account.

¹⁰¹ ACHASOV 07B reports $[\Gamma(\rho(770) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\rho(770) \rightarrow e^+e^-)] = (1.32 \pm 0.14 \pm 0.08) \times 10^{-8}$ which we divide by our best value $B(\rho(770) \rightarrow e^+e^-) = (4.72 \pm 0.05) \times 10^{-5}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00D and ACHASOV 06A.

¹⁰² Solution corresponding to constructive ω - ρ interference.

¹⁰³ Using $B(\rho \rightarrow e^+e^-) = (4.67 \pm 0.09) \times 10^{-5}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

¹⁰⁴ Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.

¹⁰⁵ The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).

¹⁰⁶ Using $B(\rho \rightarrow e^+e^-) = (4.75 \pm 0.10) \times 10^{-5}$ from AKHMETSHIN 02 and $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.

1 Update of AKHMETSHIN 00c.

2 From the combined fit of ANTONELLI 92, ACHASOV 01E, ACHASOV 02E, and ACHASOV 03D data on the $\pi^+\pi^-\pi^0$ and ANTONELLI 92 on the $\omega\pi^+\pi^-$ final states. Supersedes ACHASOV 99E and ACHASOV 02E.3 From the $\eta \rightarrow \gamma\gamma$ decay.4 From the $\eta \rightarrow 3\pi^0$ decay.

5 Observed by threshold-crossing technique. Mass resolution = 4.8 MeV FWHM.

6 Systematic uncertainties underestimated.

7 From best-resolution sample of COYNE 71.

8 From ω - ρ interference in the $\pi^+\pi^-$ mass spectrum assuming ω width 12.6 MeV.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 51.8$ for 42 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

PARAMETER Λ IN $\omega \rightarrow \pi^0\mu^+\mu^-$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass M is given by the expression:

$$|F|^2 = (1 - M^2/\Lambda^2)^{-2},$$

where for the parameter Λ vector dominance predicts $\Lambda = M_\rho \approx 0.770$ GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for $\eta \rightarrow \mu^+\mu^-\gamma$ decay ARNALDI 09 and DZHELYADIN 80 obtain the value of Λ consistent with vector dominance.

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 13 branching ratios uses 39 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 29.6$ for 31 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ On sheet II in a 2-pole solution. The other pole is found on sheet III at (850–100j) MeV

² Using a relativistic Breit-Wigner function and taking into account the finite D_S mass.

³ Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio g_{f₀}² K K / g_{f₀}² π π = 0.

⁴ In the kaon-loop fit.

⁵ In the no-structure fit.

⁶ Systematic errors not estimated.

⁷ FLATTE 76 parameterization. g_{f₀} π π = 329 ± 96 MeV/c² assuming g_{f₀} K K / g_{f₀} π π = 2.

⁸ Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio g_{f₀}² K K / g_{f₀}² π π = 4.21 ± 0.25 ± 0.21 from ABLKIM 05.

⁹ In the kaon-loop fit following formalism of ACHASOV 89.

¹⁰ In the no-structure fit assuming a direct coupling of φ to f₀γ.

¹¹ FLATTE 76 parameterization. Supersedes GARMASH 05.

¹² FLATTE 76 parameterization. g_{f₀}² K K / g_{f₀}² π π = 4.21 ± 0.25 ± 0.21.

¹³ K-matrix pole from combined analysis of π⁻p → π⁰π⁰n, π⁻p → K⁺K⁻n, π⁺π⁻ → π⁺π⁻, p̄p → π⁰π⁰π⁰, π⁰ηη, π⁰π⁰η, π⁺π⁻π⁰, K⁺K⁻π⁰, K_S⁰K_S⁰π⁰, K⁺K_S⁰π⁻ at rest, p̄n → π⁻π⁻π⁺, K_S⁰K⁻π⁰, K_S⁰K_S⁰π⁻ at rest.

¹⁴ From the negative interference with the f₀(600) meson of AITALA 01B using the ACHASOV 89 parameterization for the f₀(980), a Breit-Wigner for the f₀(600), and ACHASOV 01F for the ρπ contribution.

¹⁵ Coupled-channel Breit-Wigner, couplings g_π = 0.09 ± 0.01 ± 0.01, g_K = 0.02 ± 0.04 ± 0.03.

¹⁶ Supersedes ACHASOV 98i. Using the model of ACHASOV 89.

¹⁷ Supersedes ACHASOV 98i.

¹⁸ In the "narrow resonance" approximation.

¹⁹ Assuming Γ(f₀) = 40 MeV.

²⁰ From a narrow pole fit taking into account f₀(980) and f₀(1200) intermediate mechanisms.

²¹ From the combined fit of the photon spectra in the reactions e⁺e⁻ → π⁺π⁻γ, π⁰π⁰γ.

²² Supersedes BARBERIS 99 and BARBERIS 99B

²³ T-matrix pole.

²⁴ From invariant mass fit.

²⁵ On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93i) MeV.

²⁶ On sheet II in a 2 pole solution. The other pole is found on sheet III at (963–29i) MeV.

²⁷ Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.

²⁸ At high |t|.

²⁹ At low |t|.

³⁰ On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55i) MeV and on sheet IV at (938–35i) MeV.

³¹ Combined fit of ALDE 95B, ANISOVICH 94, AMSLER 94D.

³² On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103i) MeV.

³³ From sheet II pole position.

³⁴ On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.

³⁵ On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.

³⁶ From coupled channel analysis.

³⁷ Coupled channel analysis with finite width corrections.

³⁸ Included in AGUILAR-BENITEZ 78 fit.

f₀(980) WIDTH

Width determination very model dependent. Peak width in ππ is about 50 MeV, but decay width can be much larger.

70 Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 0$.

71 Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.

72 Supersedes MORGAN 90.

73 OEST 90 quote systematic errors $+0.08$
 -0.18 . We use ± 0.18 . Observed 60 events.

74 From analysis allowing arbitrary background unconstrained by unitarity.

75 Data included in MORGAN 90, BOGLIONE 99 analyses.

76 From amplitude analysis of BOYER 90 and MARSISKE 90, data corresponds to resonance parameters $m = 989$ MeV, $\Gamma = 61$ MeV.

 $\Gamma(e^+e^-)$

77 Recalculated by us using $\Gamma(K^+K^-) / \Gamma(\pi^+\pi^-) = 0.69 \pm 0.32$ from AUBERT 06o and isospin relations.

78 Using data from ABLIKIM 04g.

79 From a combined K-matrix analysis of Crystal Barrel ($0. p\bar{p} \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta$), GAMS ($\pi p \rightarrow \pi^0\pi^0 n, \eta\eta n, \eta\eta' n$), and BNL ($\pi p \rightarrow K\bar{K} n$) data.

80 Measure $\pi\pi$ elasticity assuming two resonances coupled to the $\pi\pi$ and $K\bar{K}$ channels only.

¹⁹Update of AKHMETSHIN 99d

²⁰Recalculated by us from the cross section in the peak.

²¹From a combined fit of $\sigma(e^+e^- \rightarrow \eta\gamma)$ with $\eta \rightarrow 3\pi^0$ and $\eta \rightarrow \pi^+\pi^-\pi^0$, and fixing $B(\eta \rightarrow 3\pi^0) / B(\eta \rightarrow \pi^+\pi^-\pi^0) = 1.44 \pm 0.04$. Recalculated by us from the cross section at the peak. Supersedes ACHASOV 00d and ACHASOV 06a.

²²From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

²³From the $\eta \rightarrow 3\pi^0$ decay and using $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.

²⁴The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).

²⁵From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow 2\gamma) = (39.21 \pm 0.34) \times 10^{-2}$.

²⁶Recalculated by the authors from the cross section in the peak.

²⁷From the $\eta \rightarrow \pi^+\pi^-\pi^0$ decay and using $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.1 \pm 0.5) \times 10^{-2}$.

²⁸From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\pi^0 \rightarrow 2\gamma) = (98.798 \pm 0.032) \times 10^{-2}$.

²⁹Recalculated by the authors from the cross section at the peak.

³⁰AMBROSINO 08g reports $[\Gamma(\phi(1020) \rightarrow \omega\pi^0)/\Gamma_{total} \times \Gamma(\phi(1020) \rightarrow e^+e^-)/\Gamma_{total}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)] = (1.22 \pm 0.13 \pm 0.08) \times 10^{-8}$ which we divide by our best value $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³¹Calculated by the authors from the cross section at the peak.

32 Using $B(\phi \rightarrow e^+ e^-) = (2.93 \pm 0.14) \times 10^{-4}$.

33 Theoretical analysis of BRAMON 00 taking into account phase-space difference, electromagnetic radiative corrections, as well as isospin breaking, predicts 0.62. FLOREZ-BAEZ 08 predicts 0.63 considering also structure-dependent radiative corrections. FISCHBACH 02 calculates additional corrections caused by the close threshold and predicts 0.68. See also BENAYOUN 01 and DUBYNSKIY 07.

34 Using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$.35 Using $\Gamma(\phi) = 4.1$ MeV. If interference between the $\rho \pi \pi$ and $3\pi \pi$ modes is neglected, the fraction of the $\rho \pi \pi$ is more than 80% at the 90% confidence level.36 From a fit without limitations on charged and neutral ρ masses and widths.37 Adding the direct and $\omega \pi$ contributions and considering the interference between the $\rho \pi \pi$ and $\pi^+ \pi^- \pi^0$.38 Neglecting the interference between the $\rho \pi \pi$ and $\pi^+ \pi^- \pi^0$.39 Using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.2 \pm 0.4) \times 10^{-2}$.40 From $\pi^+ \pi^- \pi^0$ decay mode of η .41 From 2γ decay mode of η .42 From $3\pi^0$ decay mode of η .43 ACHASOV 07B reports $[\Gamma(\phi(1020) \rightarrow \eta \gamma)/\Gamma_{\text{total}}] \times [B(\phi(1020) \rightarrow e^+ e^-)] = (4.050 \pm 0.067 \pm 0.118) \times 10^{-6}$ which we divide by our best value $B(\phi(1020) \rightarrow e^+ e^-) = (2.954 \pm 0.030) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00D and ACHASOV 06A.44 Using $B(\phi \rightarrow e^+ e^-) = (2.98 \pm 0.04) \times 10^{-4}$ and $B(\eta \rightarrow \gamma \gamma) = 39.43 \pm 0.26\%$.45 Not independent of the corresponding $\Gamma(e^+ e^-) \times \Gamma(\eta \gamma)/\Gamma_{\text{total}}^2$.46 Using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.47 The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).48 From the $\eta \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$.49 From $\pi^+ \pi^- \pi^0$ decay mode of η and using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

50 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.

51 Using $B(\phi \rightarrow e^+ e^-) = (2.98 \pm 0.04) \times 10^{-4}$.52 Not independent of the corresponding $\Gamma(e^+ e^-) \times \Gamma(\pi^0 \gamma)/\Gamma_{\text{total}}^2$.53 From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+ e^-) = (2.99 \pm 0.08) \times 10^{-4}$.54 From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of $K^+ K^-$, $K_S^0 K_S^0$, $\pi^+ \pi^- \pi^0$, and $\eta \gamma$ decays modes and using ACHASOV 00B for the $\eta \gamma$ decay mode.55 Using total width 4.2 MeV. They detect 3π mode and observe significant interference with ω tail. This is accounted for in the result quoted above.

56 Neglecting interference between resonance and continuum.

Meson Particle Listings

 $\phi(1020)$

- 57 Using $B(\phi \rightarrow e^+e^-) = (2.91 \pm 0.07) \times 10^{-4}$.
- 58 Recalculated by us using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 59 Using $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.32)\%$, $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06)\%$, and $B(\phi \rightarrow e^+e^-) = (3.00 \pm 0.06) \times 10^{-4}$.
- 60 The average of the branching ratios separately obtained from the $\eta \rightarrow \gamma\gamma$, $3\pi^0$, $\pi^+\pi^-\pi^0$ decays.
- 61 From $\eta \rightarrow \gamma\gamma$ decays and using $B(\eta \rightarrow \gamma\gamma) = (39.33 \pm 0.25) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 62 From $\eta \rightarrow 3\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 63 From $\eta \rightarrow \pi^+\pi^-\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\pi^0 \rightarrow e^+e^-\gamma) = (1.198 \pm 0.032) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.0 \pm 0.4) \times 10^{-2}$, $B(\phi \rightarrow \pi^+\pi^-\pi^0) = (15.5 \pm 0.6) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 64 Using the 1996 and 1998 data.
- 65 $(2.3 \pm 0.3)\%$ correction for other decay modes of the $\omega(782)$ applied.
- 66 Not independent of the corresponding $\Gamma(\omega\pi^0) \times \Gamma(e^+e^-) / \Gamma^2(\text{total})$.
- 67 Using the 1996 data.
- 68 Using the 1998 data.
- 69 Supersedes AKHMETSHIN 97c.
- 70 For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible. Supersedes AKHMETSHIN 97c.
- 71 For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible.
- 72 Obtained by the authors taking into account the $\pi^+\pi^-$ decay mode. Includes a component due to $\pi\pi$ production via the $f_0(600)$ meson. Supersedes ALOISIO 02d.
- 73 From the combined fit of the photon spectra in the reactions $e^+e^- \rightarrow \pi^+\pi^-\gamma$, $\pi^0\pi^0\gamma$.
- 74 From the negative interference with the $f_0(600)$ meson of AITALA 01B using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(600)$, and ACHASOV 01F for the $\rho\pi$ contribution. Superseded by AMBROSINO 07.
- 75 Assuming that the $\pi^0\pi^0\gamma$ final state is completely determined by the $f_0\gamma$ mechanism, neglecting the decay $B(\phi \rightarrow K\bar{K}\gamma)$ and using $B(f_0 \rightarrow \pi^+\pi^-) = 2B(f_0 \rightarrow \pi^0\pi^0)$.
- 76 Using the value $B(\phi \rightarrow \eta\gamma) = (1.338 \pm 0.053) \times 10^{-2}$.
- 77 For $E_\gamma > 20$ MeV. Supersedes AKHMETSHIN 97c.
- 78 Neglecting other intermediate mechanisms ($\rho\pi, \sigma\gamma$).
- 79 A narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
- 80 For destructive interference with the Bremsstrahlung process
- 81 For constructive interference with the Bremsstrahlung process
- 82 Supersedes ALOISIO 02d.
- 83 Supersedes ACHASOV 98i. Excluding $\omega\pi^0$.
- 84 Using various branching ratios from the 2000 Edition of this Review (PDG 00).
- 85 Using $B(\pi^0 \rightarrow \gamma\gamma) = 0.98798 \pm 0.00032$, $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$, and $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$.
- 86 Combined results of $\eta \rightarrow \gamma\gamma$ and $\eta \rightarrow \pi^+\pi^-\pi^0$ decay modes measurements.
- 87 From the decay mode $\eta \rightarrow \gamma\gamma$.
- 88 From the decay mode $\eta \rightarrow \pi^+\pi^-\pi^0$.
- 89 Supersedes ACHASOV 98b.
- 90 Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \gamma\gamma) = (39.31 \pm 0.20)\%$.
- 91 Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (22.73 \pm 0.28)\%$.
- 92 Using $M_{\pi^0}(980) = 984.8$ MeV and assuming $a_0(980)\gamma$ dominance.
- 93 Assuming $a_0(980)\gamma$ dominance in the $\eta\pi^0\gamma$ final state.
- 94 Using data of ACHASOV 00f.
- 95 Using results of ALOISIO 02d and assuming that $f_0(980)$ decays into $\pi\pi$ only and $a_0(980)$ into $\eta\pi$ only.
- 96 AMBROSINO 07a reports $[\Gamma(\phi(1020) \rightarrow \eta'(958)\gamma) / \Gamma_{\text{total}}] / [B(\phi(1020) \rightarrow \eta\gamma)] = (4.77 \pm 0.09 \pm 0.19) \times 10^{-3}$ which we multiply by our best value $B(\phi(1020) \rightarrow \eta\gamma) = (1.309 \pm 0.024) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 97 Averaging AULCHENKO 03b with AULCHENKO 99.
- 98 Using $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033)\%$.
- 99 Using the value $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06) \times 10^{-2}$.
- 100 Using $B(\phi \rightarrow K_S^0 K_S^0) = (33.8 \pm 0.6)\%$.
- 101 Averaging AKHMETSHIN 00b with AKHMETSHIN 00f.
- 102 Using the value $B(\eta' \rightarrow \eta\pi^+\pi^-) = (43.7 \pm 1.5) \times 10^{-2}$ and $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.31) \times 10^{-2}$.
- 103 Using various branching ratios of $K_S^0, K_L^0, \eta, \eta'$ from the 2000 edition (The European Physical Journal **C15** 1 (2000)) of this Review.
- 104 From the decay mode $\eta' \rightarrow \eta\pi^+\pi^-, \eta \rightarrow \gamma\gamma$.
- 105 Superseded by AKHMETSHIN 00b.
- 106 For $E_\gamma > 20$ MeV.

1 The $\rho^\pm \pi^\mp$ state can be also due to the $\pi(1300)$.

2 Using the Breit-Wigner parameterization; strong correlation between mass and width.

3 Using the data of BARATE 98R.

4 From a fit to the 3π mass spectrum including the $K\bar{K}^*(892)$ threshold.

5 Uses the model of KUHN 90.

6 Uses the model of ISGUR 89.

7 Includes the effect of a possible a_1' state.

8 Uses the model of FEINDT 90.

9 Supersedes AKERS 95P.

10 Average and spread of values using 2 variants of the model of BOWLER 75.

11 Reanalysis of RUCKSTUHL 86.

12 Reanalysis of SCHMIDKE 86.

13 Reanalysis of ALBRECHT 86B.

14 From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.

15 From a combined reanalysis of ALBRECHT 86B and DAUM 81B.

16 Uses the model of BOWLER 75.

17 Produced in K^- backward scattering.

 <0.008 90 51 BARBERIS 01 450 $pp \rightarrow p_f 3\pi^0 p_s$
 41 From a fit to the Dalitz plot.
 42 Assuming for $\rho(1450)$ mass and width of 1370 and 386 MeV respectively.
 43 Assuming for σ mass and width of 860 and 880 MeV respectively.
 44 Assuming for $f_0(1370)$ mass and width of 1186 and 350 MeV respectively.
 45 Assuming for $f_2(1270)$ mass and width of 1275 and 185 MeV respectively.
 46 Using structure functions from KUHN 92 and DECKER 93a and B($\tau^- \rightarrow K^-\pi^-K^+\nu_\tau$) = (0.155 ± 0.006 ± 0.009)% from BRIERE 03.
 47 From a comparison to ALAM 94 assuming purely resonant production of the K^*K^0 system.
 48 From a fit to the 3π mass spectrum including the $K\bar{K}^*(892)$ threshold.
 49 Assuming $a_1(1260)$ dominance and taking B($\tau \rightarrow a_1(1260)\nu_\tau$) from BUSKULIC 96.
 50 Uses multichannel Aitchison-Bowler model (BOWLER 75). Uses data from GAVILLET 77, DAUM 80, and DANKOWYCH 81.
 51 Inconsistent with observations of $\sigma\pi$, $f_0(1370)\pi$, and $f_2(1270)\pi$ decay modes.

WEIGHTED AVERAGE
184.2±4.0-2.4 (Error scaled by 1.5)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

$f_2(1270)$ width (MeV)

$f_2(1270)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1 $\pi\pi$	(84.8 $^{+2.4}_{-1.2}$) %	S=1.2
Γ_2 $\pi^+ \pi^- 2\pi^0$	(7.1 $^{+1.4}_{-2.7}$) %	S=1.3
Γ_3 $K\bar{K}$	(4.6 ± 0.4) %	S=2.8
Γ_4 $2\pi^+ 2\pi^-$	(2.8 ± 0.4) %	S=1.2

Γ_7 $\gamma\gamma$	(1.64 ± 0.19) × 10 ⁻⁵	S=1.9
Γ_8 $\eta\pi\pi$	< 8 × 10 ⁻³	CL=95%
Γ_9 $K^0 K^- \pi^+ + c.c.$	< 3.4 × 10 ⁻³	CL=95%
Γ_{10} $e^+ e^-$	< 6 × 10 ⁻¹⁰	CL=90%

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 44 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 81.8$ for 37 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- 21 From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
 22 From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.
 23 A preferred solution in the amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
 24 With a narrow scalar state around 1220 MeV.
 25 Using a unitarized model with a 300–500 keV wide scalar at 1100 MeV.
 26 Using the unitarized model of LYTH 85.
 27 Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1370)$: $\Gamma(f_2) + 1/4 \Gamma(f_0) = 3.6 \pm 0.3$ KeV.
 28 Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes 2.66 ± 0.21 in the calculation of LANDRO 86.
 29 Using the MENNESSIER 83 model.
 30 Superseded by BOYER 90.
 31 If helicity = 2 assumption is not made.
 32 Using mass, width and $B(f_2(1270) \rightarrow 2\pi)$ from PDG 78.

36 Coupled channel analysis of $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, and $K^\pm K_S^0 \pi^\mp$.

37 Re-evaluated by CHABAUD 83.

38 Includes PAWLICKI 77 data.

39 Takes into account the $f_2(1270)-f_2'(1525)$ interference.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 24.7$ for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 9.3$ for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$(1365^{+20}_{-55}) - i(134 \pm 35)$	ANISOVICH 94	CBAR			$\bar{p}p \rightarrow 3\pi^0, \pi^0\eta\eta$
$(1340 \pm 40) - i(127^{+30}_{-20})$	¹⁰ BUGG 94	RVUE			$\bar{p}p \rightarrow 3\pi^0, \eta\eta\pi^0, \eta\pi^0\pi^0$
$(1430 \pm 5) - i(73 \pm 13)$	¹¹ KAMINSKI 94	RVUE			$\pi\pi \rightarrow \pi\pi, K\bar{K}$
$1420 - i220$	¹² AU 87	RVUE			$\pi\pi \rightarrow \pi\pi, K\bar{K}$

1 Another pole is found at $(1510 \pm 130) - i(800^{+100}_{-150})$ MeV.
2 Coupled channel analysis of $\pi^+\pi^-\pi^0, K^+K^-\pi^0$, and $K^\pm K_S^0\pi^\mp$.
3 Average between $\pi^+\pi^-\pi^0$ and $2(\pi^+\pi^-)$.
4 T-matrix pole on sheet ---.
5 Supersedes ANISOVICH 94.
6 Coupled-channel analysis of $\bar{p}p \rightarrow 3\pi^0, \pi^0\eta\eta$, and $\pi^0\pi^0\eta$ on sheet IV. Demonstrates explicitly that $f_0(600)$ and $f_0(1370)$ are two different poles.
7 Analysis of data from FALVAR 88.
8 The pole is on Sheet III. Demonstrates explicitly that $f_0(600)$ and $f_0(1370)$ are two different poles.
9 Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
10 Reanalysis of ANISOVICH 94 data.
11 T-matrix pole on sheet III.
12 Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.

$\eta(1405)$

$\eta(1405)$

$$J^{PC} = 0^{+}(0^{-+})$$

THE $\eta(1405)$, $\eta(1475)$, $f_1(1420)$, AND $f_1(1510)$

Revised February 2010 by C. Amsler (Zürich) and A. Masoni (INFN Cagliari).

The first observation of the $\eta(1440)$ was made in $p\bar{p}$ annihilation at rest into $\eta(1440)\pi^+\pi^-$, $\eta(1440) \rightarrow K\bar{K}\pi$ [1]. This state was reported to decay through $a_0(980)\pi$ and $K^*(892)\bar{K}$ with roughly equal contributions. The $\eta(1440)$ was also observed in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [2–4] and $\gamma\rho$ [5]. There is now evidence for the existence of two pseudoscalars in this mass region, the $\eta(1405)$ and $\eta(1475)$. The former decays mainly through $a_0(980)\pi$ (or direct $K\bar{K}\pi$) and the latter mainly to $K^*(892)\bar{K}$.

The simultaneous observation of two pseudoscalars is reported in three production mechanisms: π^-p [6,7]; radiative $J/\psi(1S)$ decay [8,9]; and $p\bar{p}$ annihilation at rest [11–14]. All of them give values for the masses, widths, and decay modes in reasonable agreement. However, Ref. [9] favors a state decaying into $K^*(892)\bar{K}$ at a lower mass than the state decaying into $a_0(980)\pi$, although agreement with MARK-III is not excluded. In $J/\psi(1S)$ radiative decay, the $\eta(1405)$ decays into $K\bar{K}\pi$ through $a_0(980)\pi$, and hence a signal is also expected in the $\eta\pi\pi$ mass spectrum. This was indeed observed by MARK III in $\eta\pi^+\pi^-$ [15], which reports a mass of 1400 MeV, in line with the existence of the $\eta(1405)$ decaying into $a_0(980)\pi$. BES [10] reports an enhancement in $K^+K^-\pi^0$ around 1.44 GeV in $J/\psi(1S)$ decay, recoiling against an ω (but not a ϕ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the $f_1(1420)$ (see below).

The $\eta(1405)$ is also observed in $p\bar{p}$ annihilation at rest into $\eta\pi^+\pi^-\pi^0\pi^0$, where it decays into $\eta\pi\pi$ [16]. The intermediate $a_0(980)\pi$ accounts for roughly half of the $\eta\pi\pi$ signal, in agreement with MARK III [15] and DM2 [4].

The $\eta(1295)$ has been observed by four π^-p experiments [7,17–19], and evidence is reported in $p\bar{p}$ annihilation [23–25]. In $J/\psi(1S)$ radiative decay, an $\eta(1295)$ signal is evident in the 0^{-+} $\eta\pi\pi$ wave of the DM2 data [9]. Also BaBar [20] reports evidence for a signal around 1295 MeV in B decays into $\eta\pi\pi K$. However, the existence of the $\eta(1295)$ is questioned in Refs. [21] and [22]. The authors claim a single pseudoscalar meson in the 1400 MeV region. This conclusion is based on properties of the wave functions in the 3P_0 model (and on an unpublished analysis of the annihilation $p\bar{p} \rightarrow 4\pi\eta$). The pseudoscalar signal around 1400 MeV is then attributed to the first radial excitation of the η .

Assuming establishment of the $\eta(1295)$, the $\eta(1475)$ could be the first radial excitation of the η' , with the $\eta(1295)$ being the first radial excitation of the η . Ideal mixing, suggested by the $\eta(1295)$ and $\pi(1300)$ mass degeneracy, would then imply that the second isoscalar in the nonet is mainly $s\bar{s}$, and hence couples to $K^*\bar{K}$, in agreement with properties of the $\eta(1475)$.

Also, its width matches the expected width for the radially excited $s\bar{s}$ state [26,27]. A study of radial excitations of pseudoscalar mesons [28] favors the $s\bar{s}$ interpretation of the $\eta(1475)$. However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable $s\bar{s}$ admixture also in the $\eta(1405)$.

The $K\bar{K}\pi$ and $\eta\pi\pi$ channels were studied in $\gamma\gamma$ collisions by L3 [29]. The analysis leads to a clear $\eta(1475)$ signal in $K\bar{K}\pi$, decaying into $K^*\bar{K}$, very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [29] did not observe the $\eta(1405)$, neither in $K\bar{K}\pi$ nor in $\eta\pi\pi$. The observation of the $\eta(1475)$, combined with the absence of an $\eta(1405)$ signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in $\gamma\gamma$ collisions, the L3 results [29] suggest that $\eta(1405)$ has a large gluonic content (see also Refs. [30] and [31]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in $\gamma\gamma \rightarrow \eta(1475) \rightarrow K_S^0 K^\pm \pi^\mp$ [32]. However, more data are required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [33], confirming the evidence of the $\eta(1475)$ observed by L3. The CLEO upper limit [32] for $\Gamma_{\gamma\gamma}(\eta(1475))$, and the L3 results [33], are consistent with the world average for the $\eta(1475)$ width.

BaBar [20] also reports the $\eta(1475)$ in B decays into $K\bar{K}\pi$ (and possibly $\eta\pi\pi$). Upper limits are given for $\eta(1405)$ decay into $K\bar{K}^*$. The data sample is not sufficient to identify a possible $\eta(1405)$ contribution into $\eta\pi\pi$.

The gluonium interpretation for the $\eta(1405)$ is not favored by lattice gauge theories which predict the 0^{-+} state above 2 GeV [34]. However, the $\eta(1405)$ is an excellent candidate for the 0^{-+} glueball in the fluxtube model [35]. In this model, the 0^{++} $f_0(1500)$ glueball is also naturally related to a 0^{-+} glueball with mass degeneracy broken in QCD. Also, Ref. [36] shows that the pseudoscalar glueball could lie at a lower mass than predicted from lattice calculation. In this model the $\eta(1405)$ appears as the natural glueball candidate (see also Refs. [37] and [38]). A detailed review of the experimental situation is available in Ref. [39].

Let us now deal with 1^{++} isoscalars. The $f_1(1420)$, decaying into $K^*\bar{K}$, was first reported in π^-p reactions at 4 GeV/c [40]. However, later analyses found that the 1400–1500 MeV region was far more complex [41–43]. A reanalysis of the MARK III data in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [8] shows the $f_1(1420)$ decaying into $K^*\bar{K}$. Also, a $C=+1$ state is observed in tagged $\gamma\gamma$ collisions (*e.g.*, Ref. [44]).

In $\pi^-p \rightarrow \eta\pi\pi n$ charge-exchange reactions at 8–9 GeV/c the $\eta\pi\pi$ mass spectrum is dominated by the $\eta(1440)$ and $\eta(1295)$ [17,45], and at 100 GeV/c Ref. [18] reports the $\eta(1295)$ and $\eta(1440)$ decaying into $\eta\pi^0\pi^0$ with a weak $f_1(1285)$ signal, and no evidence for the $f_1(1420)$.

Axial (1^{++}) mesons are not observed in $\bar{p}p$ annihilation at rest in liquid hydrogen, which proceeds dominantly through S -wave annihilation. However, in gaseous hydrogen, P -wave annihilation is enhanced and, indeed, Ref. [12] reports $f_1(1420)$ decaying into $K^*\bar{K}$. The $f_1(1420)$, decaying into $K\bar{K}\pi$, is also seen in pp central production, together with the $f_1(1285)$. The latter decays via $a_0(980)\pi$, and the former only via $K^*\bar{K}$, while the $\eta(1440)$ is absent [46,47]. The $K_S K_S \pi^0$ decay mode of the $f_1(1420)$ establishes unambiguously $C=+1$. On the other hand, there is no evidence for any state decaying into $\eta\pi\pi$ around 1400 MeV, and hence the $\eta\pi\pi$ mode of the $f_1(1420)$ must be suppressed [48].

We now turn to the experimental evidence for the $f_1(1510)$. Two states, the $f_1(1420)$ and $f_1(1510)$, decaying into $K^*\bar{K}$, compete for the $s\bar{s}$ assignment in the 1^{++} nonet. The $f_1(1510)$ was seen in $K^-p \rightarrow \Lambda K\bar{K}\pi$ at 4 GeV/c [49], and at 11 GeV/c [50]. Evidence is also reported in π^-p at 8 GeV/c, based on the phase motion of the 1^{++} $K^*\bar{K}$ wave [43]. A somewhat broader 1^{++} signal is also observed in $J/\psi(1S)$ radiative decay into $\eta\pi^+\pi^-$ [51].

The absence of $f_1(1420)$ in K^-p [50] argues against the $f_1(1420)$ being the $s\bar{s}$ member of the 1^{++} nonet. However, the $f_1(1420)$ was reported in K^-p but not in π^-p [52], while two experiments do not observe the $f_1(1510)$ in K^-p [52,53]. The latter is also not seen in radiative $J/\psi(1S)$ decay [8,9] and possibly [10], central collisions [47], or $\gamma\gamma$ collisions [54], although, surprisingly for an $s\bar{s}$ state, a signal is reported in 4π decays [55]. These facts lead to the conclusion that $f_1(1510)$ is not well established [56].

Assigning the $f_1(1420)$ to the 1^{++} nonet, one finds a nonet mixing angle of $\sim 50^\circ$ [56]. However, arguments favoring the $f_1(1420)$ being a hybrid $q\bar{q}g$ meson, or a four-quark state, were put forward in Refs. [57] and [58], respectively, while Ref. [59] argued for a molecular state formed by the π orbiting in a P -wave around an S -wave $K\bar{K}$ state.

Summarizing, there is convincing evidence for the $f_1(1420)$ decaying into $K^*\bar{K}$, and for two pseudoscalars in the $\eta(1440)$ region, the $\eta(1405)$ and $\eta(1475)$, decaying into $a_0(980)\pi$ and $K^*\bar{K}$, respectively. The $f_1(1510)$ is not well established.

1425 ± 7	800	10,12 BAILLON	67	HBC	$0 \bar{p} p \rightarrow K \bar{K} \pi \pi$

1 From fit to the $a_0(980)\pi^0$ partial wave.

2 Best fit with a single Breit Wigner.

3 Decaying dominantly directly to $K^+ K^- \pi^0$.

4 Decaying into $(K\bar{K})_S \pi$, $(K\pi)_S \bar{K}$, and $a_0(980)\pi$.

5 From fit to the $a_0(980)\pi^0$ partial wave. Cannot rule out a $a_0(980)\pi^1$ partial wave.

6 Excluded from averaging because averaging would be meaningless.

7 Best fit with a single Breit Wigner.

8 This peak in the $\gamma\rho$ channel may not be related to the $\eta(1405)$.

9 Estimated by us from various fits.

10 These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to $\eta(1475)$.

11 Systematic uncertainty not evaluated.

12 From best fit of 0^-+ partial wave, 50% $K^*(892)K$, 50% $a_0(980)\pi$.

- 25 Using the data of BAILLON 67 on $\bar{p}p \rightarrow K\bar{K}\pi$.
 26 Assuming that the $a_0(980)$ decays only into $K\bar{K}$.
 27 Assuming that the $a_0(980)$ decays only into $\eta\pi$.
 28 Statistical error only.
 29 Assuming that the $a_0(980)$ decays only into $\eta\pi$.
 30 Using $B(J/\psi \rightarrow \gamma\eta(1405) \rightarrow \gamma K\bar{K}\pi) = 4.2 \times 10^{-3}$ and $B(J/\psi \rightarrow \gamma\eta(1405) \rightarrow \gamma\gamma\rho^0) = 6.4 \times 10^{-5}$ and assuming that the $\gamma\rho^0$ signal does not come from the $f_1(1420)$.
 31 Using preliminary Crystal Barrel data.
 32 Assuming that the $\eta(1405)$ decays are saturated by the $\pi\pi\eta$, $K\bar{K}\pi$ and $\rho\rho$ modes.
 33 Calculated by us from $B(J/\psi \rightarrow \eta(1405)\gamma \rightarrow \phi\gamma\gamma) < 0.82 \times 10^{-4}$ and $B(J/\psi \rightarrow \eta(1405)\gamma \rightarrow \rho^0\gamma\gamma) = (1.07 \pm 0.11) \times 10^{-4}$.

 $\rho(1450)$

$$I^G(J^{PC}) = 1^+(1^{--})$$

See our mini-review under the $\rho(1700)$.

 $\rho(1450)$ MASS

VALUE (MeV)	DOCUMENT ID	COMMENT
1465 ± 25 OUR ESTIMATE		This is only an educated guess; the error given is larger than the error on the average of the published values.

 $\eta\rho^0$ MODE

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••			
1497 ± 14	¹ AKHMETSHIN 01B	CMD2	$e^+e^- \rightarrow \eta\gamma$
1421 ± 15	² AKHMETSHIN 00D	CMD2	$e^+e^- \rightarrow \eta\pi^+\pi^-$
1470 ± 20	ANTONELLI 88	DM2	$e^+e^- \rightarrow \eta\pi^+\pi^-$
1446 ± 10	FUKUI 88	SPEC	8.95 $\pi^-p \rightarrow \eta\pi^+\pi^-n$

¹ Using the data of AKHMETSHIN 01B on $e^+e^- \rightarrow \eta\gamma$, AKHMETSHIN 00D and ANTONELLI 88 on $e^+e^- \rightarrow \eta\pi^+\pi^-$.

² Using the data of ANTONELLI 88, DOLINSKY 91, and AKHMETSHIN 00D. The energy-independent width of the $\rho(1450)$ and $\rho(1700)$ mesons assumed.

 $\omega\pi$ MODE

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••				
1582 ± 17 ± 25	2382	³ AKHMETSHIN 03B	CMD2	$e^+e^- \rightarrow \pi^0\pi^0\gamma$
1349 ± 25 ± $\frac{10}{5}$	341	⁴ ALEXANDER 01B	CLE2	$B \rightarrow D^{(*)}\omega\pi^-$
1523 ± 10		⁵ EDWARDS 00A	CLE2	$\tau^- \rightarrow \omega\pi^- \nu_\tau$
1463 ± 25		⁶ CLEGG 94	RVUE	
1250		⁷ ASTON 80C	OMEG	20–70 $\gamma p \rightarrow \omega\pi^0 p$
1290 ± 40		⁷ BARBER 80C	SPEC	3–5 $\gamma p \rightarrow \omega\pi^0 p$

³ Using the data of AKHMETSHIN 03B and BISELLO 91B assuming the $\omega\pi^0$ and $\pi^+\pi^-$ mass dependence of the total width. $\rho(1700)$ mass and width fixed at 1700 MeV and 240 MeV, respectively.

⁴ Using Breit-Wigner parameterization of the $\rho(1450)$ and assuming the $\omega\pi^-$ mass dependence for the total width.

⁵ Mass-independent width parameterization. $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.

⁶ Using data from BISELLO 91B, DOLINSKY 86 and ALBRECHT 87L.

⁷ Not separated from $b_1(1235)$, not pure $J^P = 1^-$ effect.

²⁵Breit-Wigner, solution 1, PWA ambiguous.

²⁶K-matrix pole from combined analysis of $\pi^-p \rightarrow \pi^0\pi^0 n, \pi^-p \rightarrow K\bar{K}n, \pi^+\pi^- \rightarrow \pi^+\pi^-, \bar{p}p \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0 \pi^0, K^+K_S^0 \pi^0$ at rest, $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^-\pi^0, K_S^0 K_S^0 \pi^0$ at rest.

²⁷Supersedes BARBERIS 99 and BARBERIS 99B.

²⁸T-matrix pole on sheet --+.

²⁹T-matrix pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AMSLER 94d.

³⁰Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.

³¹From a simultaneous analysis of the annihilations $\bar{p}p \rightarrow 3\pi^0, \pi^0\eta\eta$.

³²Reanalysis of ANISOVICH 94 data.

³³From central value and spread of two solutions. Breit-Wigner mass.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 11.4$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_4	-83

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 14.0$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
~ 18	1.2M	24,25 ACHASOV	03D RVUE	0.44-2.00 e ⁺ e ⁻ → π ⁺ π ⁻ π ⁰
32 ± 1		24 HENNER	02 RVUE	1.2-2.0 e ⁺ e ⁻ → ρπ, ωππ

23 From the combined fit of ANTONELLI 92, ACHASOV 01E, ACHASOV 02E, and ACHASOV 03D data on the π⁺π⁻π⁰ and ANTONELLI 92 on the ωπ⁺π⁻ final states. Supersedes ACHASOV 99E and ACHASOV 02E.
 24 Assuming that the ω(1650) decays into ρπ and ωππ only.
 25 Calculated by us from the cross section at the peak.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.9$ for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATIONAn overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 14.7$ for 7 degrees of freedom.The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\rho(1700)$

$$I^G(J^{PC}) = 1^+(1^{--})$$

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated May 2010 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation [3], as well as that of $e^+e^- \rightarrow \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on 4π -systems produced in e^+e^- annihilation, and in τ -decays (τ decays to 4π , and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ -like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \rightarrow 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two 1^- states is provided by [7] in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)², and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in π^-p charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \rightarrow \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\bar{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\bar{K}$ decay mode [12–14]. High-statistics studies of the decays $\tau \rightarrow \pi\pi\nu_\tau$ [15,16], and $\tau \rightarrow 4\pi\nu_\tau$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the τ mass. A recent very-high-statistics study of the $\tau \rightarrow \pi\pi\nu_\tau$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in τ decays.

The structure of these ρ states is not yet completely clear. Barnes [19] and Close [20] claim that $\rho(1450)$ has a mass consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$ -hybrid

mixture. Donnachie [21] argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has been observed by [22] in $e^+e^- \rightarrow 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \rightarrow 4\pi$ decays. Alexander [23] observes the $\rho(1450) \rightarrow \omega\pi$ decay mode in B -meson decays, however, does not find $\rho(1700) \rightarrow \omega\pi^0$. A similar conclusion is made by [24], who studied the process $e^+e^- \rightarrow \omega\pi^0$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\bar{p}n$ and $\bar{p}p$ annihilation [25,26], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC} = 1^{--}$ earlier observed by [27] (referred to as $C(1480)$) and recently confirmed by [28]. While [29] shows that it may be a threshold effect, [5] and [30] suggest two independent vector states with this decay mode. The $C(1480)$ has not been seen in the $\bar{p}p$ [31] and e^+e^- [32,33] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [28]. Note that [28] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [34–40] may be interpreted in terms of either $J^P = 1^-$ $\rho(770) \rightarrow \omega\pi$ production [41], or $J^P = 1^+$ $b_1(1235)$ production [39,40]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [42] showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

Recently [43] reported a very broad 1^{--} resonance-like K^+K^- state in $J/\psi \rightarrow K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [44–46] suggest its exotic structure (molecular or multiquark), while [47] and [48] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. We quote [43] as $X(1575)$ in the section “Further States.”

Evidence for ρ -like mesons decaying into 6π states was first noted by [49] in the analysis of 6π mass spectra from e^+e^- annihilation [50,51] and diffractive photoproduction [52]. Clegg [49] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [53]. The relativistic quark model [54] predicts the 2^3D_1 state with $J^{PC} = 1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

The E687 Collaboration at Fermilab reported an observation of a narrow-dip structure at 1.9 GeV in the $3\pi^+3\pi^-$ diffractive photoproduction [55]. A similar effect of the dip in the cross section of $e^+e^- \rightarrow 6\pi$ around 1.9 GeV has been earlier reported by DM2 [51], where 6π included both $3\pi^+3\pi^-$ and $2\pi^+2\pi^-\pi^0$. Later the dip in the R value (the total cross section of $e^+e^- \rightarrow$ hadrons divided by the cross section of $e^+e^- \rightarrow \mu^+\mu^-$) was

Meson Particle Listings

 $\rho(1700)$

observed by [56], again around 1.9 GeV. This energy is close to the $N\bar{N}$ threshold, which hints at the possible relation between the dip and $N\bar{N}$, *e.g.*, the frequently discussed narrow $N\bar{N}$ resonance or just a threshold effect. Such behaviour is also characteristic of exotic objects like vector $q\bar{q}$ hybrids. Note that [57] failed to find this state in the reaction $\bar{n}p \rightarrow 3\pi^+2\pi^-\pi^0$. A reanalysis of the E687 data by [58] shows that a dip may arise due to interference of a narrow object with a broad $\rho(1700)$ independently of the nature of the former. BaBar studied the processes $e^+e^- \rightarrow 3\pi^+3\pi^-$ and $e^+e^- \rightarrow 2\pi^+2\pi^-2\pi^0$ using the radiative return, and observed a structure around 1.9 GeV in both final states [59]. The data are not well described by a single Breit-Wigner state, and a good fit is achieved while taking into account the interference of such a structure with a Jacob-Slansky amplitude for continuum. The mass of this state obtained by BaBar is consistent with [56] and [55], but the width is substantially larger. Recently [28] observed a structure at 1.9 GeV in the radiative return to the $\phi\pi$ final state, with a much smaller width of 48 ± 17 MeV consistent with that of [56,58]. We list these observations under a separate particle $\rho(1900)$, which needs confirmation.

¹In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.

²This state may be different from $f_0(1710)$, see CLOSE 05.

³ $J^P = 0^+$.

⁴T-matrix pole.

⁵Supersedes BARBERIS 99 and BARBERIS 99B.

⁶ $J^P = 0^+$, supersedes by ARMSTRONG 89D.

⁷No J^{PC} determination.

⁸ $J^P = 2^+$.

⁹Breit-Wigner mass.

¹⁰Systematic errors not estimated.

¹¹K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K\bar{K}n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p}p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p}n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.

¹²Decaying to $f_0(1370)\pi\pi$.

¹³ $J^P = 0^+$.

¹⁴Not seen by AMSLER 02.

¹⁵T-matrix pole, assuming $J^P = 0^+$.

¹⁶No J^{PC} determination.

¹⁷No J^{PC} determination, width not determined.

¹⁸From a fit to the 0^+ partial wave.

¹⁹ALDE 92D combines all the GAMS-2000 data.

²⁰ $J^P = 2^+$, superseded by FRENCH 99.

²¹From an analysis ignoring interference with $f_2'(1525)$.

²²From an analysis including interference with $f_2'(1525)$.

²³Superseded by ALDE 92D.

²⁴Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.

²⁵ $J^P = 2^+$ preferred.

²⁶From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.

²⁷Superseded by LONGACRE 86.

- 220 $\frac{+100}{-70}$ 53,54 EDWARDS 82D CBAL $J/\psi \rightarrow \gamma 2\eta$
- 200 $\frac{+156}{-9}$ 55 ETKIN 82B MPS 23 $\pi^- p \rightarrow n 2K_S^0$
- 28 In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
- 29 Breit-Wigner width.
- 30 $J^P = 0^+$.
- 31 T-matrix pole.
- 32 Supersedes BARBERIS 99 and BARBERIS 99b.
- 33 $J^P = 0^+$, superseded by ARMSTRONG 89D.
- 34 No J^{PC} determination.
- 35 $J^P = 2^+$.
- 36 No J^{PC} determination.
- 37 Systematic errors not estimated.
- 38 This state may be different from $f_0(1710)$, see CLOSE 05.
- 39 (Solution 1)
- 40 K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \bar{K} n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- 41 (Solution 1)
- 42 Decaying to $f_0(1370) \pi \pi$.
- 43 $J^P = 0^+$.
- 44 Not seen by AMSLER 02.
- 45 T-matrix pole, assuming $J^P = 0^+$
- 46 No J^{PC} determination.
- 47 From a fit to the 0^+ partial wave.
- 48 ALDE 92D combines all the GAMS-2000 data.
- 49 $J^P = 2^+$, (0^+ excluded).
- 50 From an analysis ignoring interference with $f_2'(1525)$.
- 51 From an analysis including interference with $f_2'(1525)$.
- 52 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
- 53 $J^P = 2^+$ preferred.
- 54 From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
- 55 From an amplitude analysis of the $K_S^0 K_S^0$ system, superseded by LONGACRE 86.

OMITTED FROM SUMMARY TABLE

Needs confirmation. Seen by BAl 03F and ABLIKIM 05R in radiative decays of the J/ψ . Evidence for a threshold enhancement in the $p\bar{p}$ mass spectrum was also reported by ABE 02K, AUBERT, B 05L, and WANG 05A in $B^+ \rightarrow p\bar{p}K^+$, WANG 05A in $B^0 \rightarrow p\bar{p}K_S^0$, ABE 02W in $\bar{B}^0 \rightarrow p\bar{p}D^0$, and WEI 08 in $B^+ \rightarrow p\bar{p}\pi^+$ decays. Not seen by ATHAR 06 in $\Upsilon(1S) \rightarrow p\bar{p}\gamma$.

$f_2(1910)$

$I^G(J^{PC}) = 0^+(2^{++})$

OMITTED FROM SUMMARY TABLE

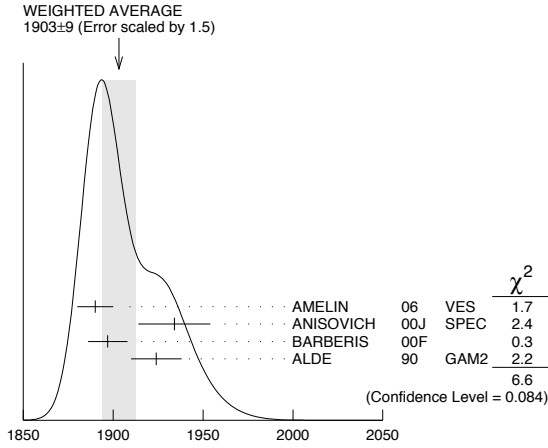

We list here three different peaks with close masses and widths seen in the mass distributions of $\omega\omega$, $\eta\eta'$, and K^+K^- final states. ALDE 91B argues that they are of different nature.

$f_2(1910)$ MASS

$f_2(1910)$ $\omega\omega$ MODE

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
1903 ± 9 OUR AVERAGE	Error includes scale factor of 1.5. See the ideogram below.		
1890 ± 10	¹ AMELIN 06	VES	36 $\pi^- p \rightarrow \omega\omega n$
1934 ± 20	ANISOVICH 00J	SPEC

2307 ± 6	ALPER	80	CNTR	0	62 $\pi^- p \rightarrow K^+ K^- n$
----------	-------	----	------	---	------------------------------------

- $I(J^P) = 1(5^-)$ from simultaneous analysis of $p\bar{p} \rightarrow \pi^- \pi^+$ and $\pi^0 \pi^0$.
- $I = 0(1)$; $J^P = 5^-$ from Barrelet-zero analysis.
- $I(J^P) = 1(5^-)$ from amplitude analysis.
- From the combined analysis of ANISOVICH 00J, ANISOVICH 01D, ANISOVICH 01E, and ANISOVICH 02.
- Isospins 0 and 1 not separated.
- From a fit to the total elastic cross section.
- Referred to as U or U region by ALSPECTOR 73.
- For $I = 1 \overline{N}N$.
- No evidence for this bump seen in the $\bar{p}p$ data of CHAPMAN 71B. Narrow state not confirmed by OH 73 with more data.

Meson Particle Listings

 K^\pm

STRANGE MESONS
($S = \pm 1, C = B = 0$)

$K^+ = u\bar{s}, K^0 = d\bar{s}, \bar{K}^0 = \bar{d}s, K^- = \bar{u}s,$ similarly for K^{*} 's

 K^\pm $I(J^P) = \frac{1}{2}(0^-)$ **THE CHARGED KAON MASS**

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV } (S = 2.4), \quad (1)$$

where the error has been increased by the scale factor S . The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV}, \quad (2)$$

$$\chi^2 = 22.9 \text{ for } 5 \text{ D.F.}, \text{ Prob.} = 0.04\%,$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$

$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV } (S = 1.5) \quad \text{GALL 88}$$

$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$

$$\chi^2 = 21.2 \text{ for } 1 \text{ D.F.}, \text{ Prob.} = 0.0004\%, \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2 .

The GALL 88 measurement was made using four different kaonic atom transitions, $K^- \text{Pb } (9 \rightarrow 8)$, $K^- \text{Pb } (11 \rightarrow 10)$, $K^- \text{W } (9 \rightarrow 8)$, and $K^- \text{W } (11 \rightarrow 10)$. The m_{K^\pm} values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their $K^- \text{Pb } (9 \rightarrow 8)$ m_{K^\pm} is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007, \quad (4)$$

$$\chi^2 = 7.0 \text{ for } 3 \text{ D.F.}, \text{ Prob.} = 7.2\%.$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by $S=1.5$ to obtain their published error ± 0.011 shown in Eq. (3) above and used in the Particle Listings average.

Figure 1: Ideogram of m_{K^\pm} mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ measurement yield two well-separated peaks. One might suspect the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the $K^- \text{Pb } (9 \rightarrow 8)$ transition, we have separated the CHENG 75 data, which also used $K^- \text{Pb}$, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the $K^- \text{Pb } (9 \rightarrow 8)$ transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the $K^- \text{Pb } (9 \rightarrow 8)$ transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the $K^- \text{Pb } (9 \rightarrow 8)$ transition produces the most consistent set of data, but that excluding only the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ transition or DENISOV 91 also produces acceptable probabilities.

Table 1: m_{K^\pm} averages for some combinations of Fig. 1 data.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no K^- Pb(9→8)
493.687 ± 0.006	14.6	11	20	no GALL 88 K^- Pb(9→8)
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ -ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 m_{K^\pm} values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 → 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 → 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: m_{K^\pm} averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9→8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9→8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C . The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C , which is good agreement with the calculated energy.

While we suspect that the GALL 88 K^- Pb (9 → 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

Revised November 2009 by L. Littenberg (BNL) and G. Valencia (Iowa State University).

A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–14]. Activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for CP violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \rightarrow \mu e$. Category 2 includes processes such as $K^+ \rightarrow \pi^+ \nu \bar{\nu}$, which is sensitive to $|V_{td}|$. Much of the interest in Category 3 is focused on the decays $K_L \rightarrow \pi^0 \ell \bar{\ell}$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes $K_L \rightarrow \pi^0 \gamma \gamma$ and $K_L \rightarrow \ell^+ \ell^- \gamma$. The former is important in understanding a CP -conserving contribution to $K_L \rightarrow \pi^0 \ell^+ \ell^-$, whereas the latter could shed light on long distance contributions to $K_L \rightarrow \mu^+ \mu^-$.

The interplay between Categories 2-4 can be illustrated in Fig. 1. The modes $K \rightarrow \pi \nu \bar{\nu}$ are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters, they also constrain new interactions. The modes $K_L \rightarrow \pi^0 e^+ e^-$ and $K_L \rightarrow \mu^+ \mu^-$ are also sensitive to CKM parameters. However, they suffer from a series of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

Figure 1: Role of rare kaon decays in determining the unitarity triangle. The solid arrows point to auxiliary modes needed to interpret the main results, or potential backgrounds to them.

B. Explicit violations of the Standard Model: Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to left-handed fermions with electroweak strength and without mixing angles yields $B(K_L \rightarrow \mu e) = 4.7 \times 10^{-12} (148 \text{ TeV}/M_X)^4$ [4]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \rightarrow \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis a vis LFV. The decays $K_L \rightarrow \mu^\pm e^\mp$ and $K^+ \rightarrow \pi^+ e^\mp \mu^\pm$ (or $K_L \rightarrow \pi^0 e^\mp \mu^\pm$) provide complementary information on potential family number violating interactions, since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays [15,16] also exist. Related searches in μ and τ processes are discussed in our section “Tests of Conservation Laws.”

Table 1: Searches for lepton flavor violation in K decay

Mode	90% CL		
	upper limit	Exp't	Yr./Ref.
$K^+ \rightarrow \pi^+ e^- \mu^+$	1.2×10^{-11}	BNL-865	2005/Ref. 17
$K^+ \rightarrow \pi^+ e^+ \mu^-$	5.2×10^{-10}	BNL-865	2000/Ref. 15
$K_L \rightarrow \mu e$	4.7×10^{-12}	BNL-871	1998/Ref. 18
$K_L \rightarrow \pi^0 e \mu$	7.6×10^{-11}	KTeV	2008/Ref. 19
$K_L \rightarrow \pi^0 \pi^0 e \mu$	1.7×10^{-10}	KTeV	2008/Ref. 19

Physics beyond the SM is also pursued through the search for $K^+ \rightarrow \pi^+ X^0$, where X^0 is a very light, long-lived particle (e.g., hyperphoton, axion, familon, etc.). The 90% CL upper limit on this process is 7.3×10^{-11} [20].

C. Measurements of Standard Model parameters:

In the SM, the decay $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,21,22]. This permits a precise calculation [23] of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [24,25].

BNL-787 observed two candidate events [26,27] in the clean high π^+ momentum and one event [28] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [20] and three more in the low-momentum region [29] yielding a branching ratio of $(1.73^{+1.15}_{-1.05}) \times 10^{-10}$ [30]. A new experiment, NA62, with a sensitivity goal of $\sim 10^{-12}$ /event was proposed [31] at CERN in 2005. It has been approved and is scheduled to run in 2011. In the future, this mode may provide grounds for precision tests of flavor dynamics [32]. The branching ratio can be written in terms of the very well-measured K_{e3} rate as [2]:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) = \frac{\alpha^2 B(K^+ \rightarrow \pi^0 e^+ \nu)}{V_{us}^2 2\pi^2 \sin^4 \theta_W} \times \sum_{l=e,\mu,\tau} |V_{cs}^* V_{cd} X_{NL}^\ell + V_{ts}^* V_{td} X(m_t)|^2 \quad (1)$$

to eliminate the *a priori* unknown hadronic matrix element. Isospin breaking corrections to the ratio of matrix elements reduce this rate by 10% [33,23]. In Eq. (1), the Inami-Lim function $X(m_t)$ is of order 1 [34], and X_{NL}^ℓ is several hundred times smaller. This form exhibits the strong dependence of this branching ratio on $|V_{td}|$. QCD corrections, which mainly affect X_{NL}^ℓ , lead to a residual error of $< 5\%$ for the decay amplitude [11,22,35,36]. Evaluating the constants in Eq. (1), one can cast this result in terms of the CKM parameters λ , V_{cb} , $\bar{\rho}$ and $\bar{\eta}$ (see our Section on “The Cabibbo-Kobayashi-Maskawa mixing matrix”) [11]:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2], \quad (2)$$

where $\rho_c \equiv 1 + (\frac{2}{3} X_{NL}^e + \frac{1}{3} X_{NL}^\tau) / (|V_{cb}|^2 X(m_t)) \approx 1.4$ and $\sigma \equiv 1 / (1 - \frac{1}{2} \lambda^2)^2$. Thus, $B(K^+ \rightarrow \pi^+ \nu \bar{\nu})$ determines an ellipse in the $\bar{\rho}$, $\bar{\eta}$ plane with center $(\rho_c, 0)$ and semi-axes $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$ and $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$. Current constraints on the CKM parameters lead to a predicted branching ratio $(8.5 \pm 0.7) \times 10^{-11}$ [36], near the lower end of the measurement of BNL-787 and 949.

The decay $K_L \rightarrow \mu^+ \mu^-$ also has a short distance contribution sensitive to the CKM parameter $\bar{\rho}$, given by [11]:

$$B_{SD}(K_L \rightarrow \mu^+ \mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho_c' - \bar{\rho})^2 \quad (3)$$

where ρ_c' depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for $K_L \rightarrow \gamma \gamma$ to be $B_{abs}(K_L \rightarrow \mu^+ \mu^-) =$

$(6.64 \pm 0.07) \times 10^{-9}$; and it almost completely saturates the observed rate $B(K_L \rightarrow \mu^+ \mu^-) = (6.84 \pm 0.11) \times 10^{-9}$ [37]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [38], but can be estimated with certain assumptions [39,40]. The decay $K_L \rightarrow e^+ e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \rightarrow e^+ e^-) \sim 9 \times 10^{-12}$ [38,41], is in good agreement with the BNL-871 measurement, $(8.7^{+5.7}_{-4.1}) \times 10^{-12}$ [42].

D. Searches for direct CP violation: The mode $K_L \rightarrow \pi^0 \nu \bar{\nu}$ is dominantly *CP*-violating and free of hadronic uncertainties [2,43,44]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode $K^+ \rightarrow \pi^+ \nu \bar{\nu}$. The branching ratio is given approximately by Ref. 11:

$$B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2. \quad (4)$$

With current constraints on the CKM parameters this leads to a predicted branching ratio $(2.6 \pm 0.3) \times 10^{-11}$ [14]. The 90% CL bound on $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ provides a nearly model-independent bound $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.46 \times 10^{-9}$ [45]. KEK-391a, which began data-taking in early 2004, has published a result of $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq 6.7 \times 10^{-8}$ [46] based on partial data. Very recently a preliminary result on the remainder of the data yielded $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq 6.8 \times 10^{-8}$ [47]. The KOTO experiment, whose initial goal is to reach the 10^{-11} /event level, is under construction at J-PARC [48].

There has been much theoretical work on possible contributions to rare *K* decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [49].

The decay $K_L \rightarrow \pi^0 e^+ e^-$ also has sensitivity to the CKM parameter η through its *CP*-violating component. There are both direct and indirect *CP*-violating amplitudes which can interfere. The direct *CP*-violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect *CP*-violating amplitude can be inferred from a measurement of $K_S \rightarrow \pi^0 e^+ e^-$. The complete *CP*-violating contribution to the rate can be written as [50]:

$$B_{CPV} \approx 10^{-12} \left[15.7 |a_S|^2 \pm 1.45 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right) |a_S| + 0.129 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right)^2 \right] \quad (5)$$

where the three terms correspond to the indirect *CP* violation, the interference, and the direct *CP* violation respectively. The parameter a_S has been extracted by NA48 from a measurement of the decay $K_S \rightarrow \pi^0 e^+ e^-$ with the result $|a_S| = 1.06^{+0.26}_{-0.21} \pm 0.07$ [51]. With current constraints on the CKM parameters this implies that

$$B_{CPV} \approx (17.2 \pm 9.4 + 4.7) \times 10^{-12}. \quad (6)$$

Meson Particle Listings

K^\pm

The indirect CP violation is larger than the direct CP violation. While the sign of the interference is *a priori* unknown, arguments in favor of a positive sign have been put forward in Ref. 52 and Ref. 53. NA48 has also obtained the value $a_s = 1.54^{+0.40}_{-0.32} \pm 0.06$ [54] from a measurement of the $K_S \rightarrow \pi^0 \mu^+ \mu^-$ rate, in agreement with the value extracted from $K_S \rightarrow \pi^0 e^+ e^-$

$K_L \rightarrow \pi^0 \gamma \gamma$ also has a CP -conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low $m_{\gamma\gamma}$ region of the $K_L \rightarrow \pi^0 \gamma \gamma$ spectrum. The rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \rightarrow \pi^0 \gamma \gamma$ are well described in chiral perturbation theory in terms of three (*a priori*) unknown parameters [55,56].

Both KTeV and NA48 have studied the mode $K_L \rightarrow \pi^0 \gamma \gamma$, reporting similar results. KTeV finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\text{stat}} \pm 0.05_{\text{sys}}) \times 10^{-6}$ [57], while NA48 finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\text{stat}} \pm 0.03_{\text{sys}} \pm 0.03_{\text{norm}}) \times 10^{-6}$ [58]. Both experiments are consistent with a negligible rate in the low $m_{\gamma\gamma}$ region, suggesting a very small CP -conserving component $B_{\text{CP}}(K_L \rightarrow \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$ [52,56,58]. There remains some model dependence in the estimate of the dispersive part of the CP -conserving $K_L \rightarrow \pi^0 e^+ e^-$ [52].

The related process, $K_L \rightarrow \pi^0 \gamma e^+ e^-$, is potentially an additional background in some region of phase space [59]. This process has been observed with a branching ratio of $(1.62 \pm 0.14_{\text{stat}} \pm 0.09_{\text{sys}}) \times 10^{-8}$ [60].

The decay $K_L \rightarrow \gamma \gamma e^+ e^-$ constitutes the dominant background to $K_L \rightarrow \pi^0 e^+ e^-$. It was first observed by BNL-845 [61], and subsequently confirmed with a much larger sample by FNAL-799 [62]. It has been estimated that this background will enter at about the 10^{-10} level [63,64], comparable to or larger than the signal level. Because of this, the observation of $K_L \rightarrow \pi^0 e^+ e^-$ at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 52 and references cited therein.

The 90% CL upper bound for the process $K_L \rightarrow \pi^0 e^+ e^-$ is 2.8×10^{-10} [64]. For the closely related muonic process, the published upper bound is $B(K_L \rightarrow \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$ [65], compared with the SM prediction of $(1.5 \pm 0.3) \times 10^{-11}$ [66] (assuming positive interference between the direct- and indirect- CP violating components). KTeV has additional data corresponding to about a factor 1.3 in sensitivity for the latter reaction that is under analysis.

A study of $K_L \rightarrow \pi^0 \mu^+ \mu^-$ has indicated that it might be possible to extract the direct CP -violating contribution by a joint study of the Dalitz plot variables and the components of the μ^+ polarization [67]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two $K_L \rightarrow \pi^0 \ell^+ \ell^-$ modes complements the $K \rightarrow \pi \nu \bar{\nu}$ measurements in constraining physics beyond the SM [68].

E. Other long distance dominated modes:

The decays $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ ($\ell = e$ or μ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [69,70]. Ref. 50 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections.

The related rare hyperon decay mode $\Sigma^+ \rightarrow p \mu^+ \mu^-$, has been recently observed by the HyperCP collaboration [71]. The observed rate is in rough agreement with the standard model expectation [72] but the three events that have been observed cluster at a common $m_{\mu\mu}$ invariant mass and this can be interpreted as evidence for a new particle X^0 . The existing measurements of $K^+ \rightarrow \pi^+ \mu^+ \mu^-$ rule out a scalar X^0 and the new bounds, $B(K_L \rightarrow \pi^0 \pi^0 \mu^+ \mu^-) < 9.44 \times 10^{-11}$ [73] and $B(K_L \rightarrow \pi^0 \pi^0 \gamma \gamma) < 2.4 \times 10^{-7}$ [74] aim at closing the possibility of a pseudoscalar X^0 [75].

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes $K_L \rightarrow \ell^+ \ell^- \gamma$ [76,77], and $K_L \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$ for $\ell, \ell' = e$ or μ [16,78–80]. All these results are used to test hadronic models and could further our understanding of the long distance component in $K_L \rightarrow \mu^+ \mu^-$.

Meson Particle Listings

 K^\pm **K^\pm DECAY MODES** K^- modes are charge conjugates of the modes below.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Leptonic and semileptonic modes		
Γ_1 $K^+ \rightarrow e^+ \nu_e$	$(1.584 \pm 0.020) \times 10^{-5}$	
Γ_2 $K^+ \rightarrow \mu^+ \nu_\mu$	$(63.55 \pm 0.11) \%$	S=1.2
Γ_3 $K^+ \rightarrow \pi^0 e^+ \nu_e$	$(5.07 \pm 0.04) \%$	S=2.1
Called K_{e3}^+ .		
Γ_4 $K^+ \rightarrow \pi^0 \mu^+ \nu_\mu$	$(3.353 \pm 0.034) \%$	S=1.8
Called $K_{\mu 3}^+$.		
Γ_5 $K^+ \rightarrow \pi^0 \pi^0 e^+ \nu_e$	$(2.2 \pm 0.4) \times 10^{-5}$	
Γ_6 $K^+ \rightarrow \pi^+ \pi^- e^+ \nu_e$	$(4.09 \pm 0.10) \times 10^{-5}$	
Γ_7 $K^+ \rightarrow \pi^+ \pi^- \mu^+ \nu_\mu$	$(1.4 \pm 0.9) \times 10^{-5}$	
Γ_8 $K^+ \rightarrow \pi^0 \pi^0 \pi^0 e^+ \nu_e$	$< 3.5 \times 10^{-6}$	CL=90%
Hadronic modes		
Γ_9 $K^+ \rightarrow \pi^+ \pi^0$	$(20.66 \pm 0.08) \%$	S=1.2
Γ_{10} $K^+ \rightarrow \pi^+ \pi^0 \pi^0$	$(1.761 \pm 0.022) \%$	S=1.1
Γ_{11} $K^+ \rightarrow \pi^+ \pi^+ \pi^-$	$(5.59 \pm 0.04) \%$	S=1.3
Leptonic and semileptonic modes with photons		
Γ_{12} $K^+ \rightarrow \mu^+ \nu_\mu \gamma$	[a,b] $(6.2 \pm 0.8) \times 10^{-3}$	
Γ_{13} $K^+ \rightarrow \mu^+ \nu_\mu \gamma (\text{SD}^+)$	[c,d] $(1.33 \pm 0.22) \times 10^{-5}$	
Γ_{14} $K^+ \rightarrow \mu^+ \nu_\mu \gamma (\text{SD}^+ \text{INT})$	[c,d] $< 2.7 \times 10^{-5}$	CL=90%
Γ_{15} $K^+ \rightarrow \mu^+ \nu_\mu \gamma (\text{SD}^- + \text{SD}^- \text{INT})$	[c,d] $< 2.6 \times 10^{-4}$	CL=90%
Γ_{16} $K^+ \rightarrow e^+ \nu_e \gamma$	$(9.4 \pm 0.4) \times 10^{-6}$	
Γ_{17} $K^+ \rightarrow \pi^0 e^+ \nu_e \gamma$	[a,b] $(2.56 \pm 0.16) \times 10^{-4}$	
Γ_{18} $K^+ \rightarrow \pi^0 e^+ \nu_e \gamma (\text{SD})$	[c,d] $< 5.3 \times 10^{-5}$	CL=90%
Γ_{19} $K^+ \rightarrow \pi^0 \mu^+ \nu_\mu \gamma$	[a,b] $(1.5 \pm 0.4) \times 10^{-5}$	
Γ_{20} $K^+ \rightarrow \pi^0 \pi^0 e^+ \nu_e \gamma$	$< 5 \times 10^{-6}$	CL=90%
Hadronic modes with photons or $\ell\bar{\ell}$ pairs		
Γ_{21} $K^+ \rightarrow \pi^+ \pi^0 \gamma$	[a,b] $(2.75 \pm 0.15) \times 10^{-4}$	
Γ_{22} $K^+ \rightarrow \pi^+ \pi^0 \gamma (\text{DE})$	[b,e] $(4.3 \pm 0.7) \times 10^{-6}$	
Γ_{23} $K^+ \rightarrow \pi^+ \pi^0 \pi^0 \gamma$	[a,b] $(7.6 \pm 3.0) \times 10^{-6}$	
Γ_{24} $K^+ \rightarrow \pi^+ \pi^+ \pi^- \gamma$	[a,b] $(1.04 \pm 0.31) \times 10^{-4}$	
Γ_{25} $K^+ \rightarrow \pi^+ \gamma \gamma$	[b] $(1.10 \pm 0.32) \times 10^{-6}$	
Γ_{26} $K^+ \rightarrow \pi^+ 3\gamma$	[b] $< 1.0 \times 10^{-4}$	CL=90%
Γ_{27} $K^\pm \rightarrow \pi^+ e^+ e^- \gamma$	$(1.19 \pm 0.13) \times 10^{-8}$	
Leptonic modes with $\ell\bar{\ell}$ pairs		
Γ_{28} $K^+ \rightarrow e^+ \nu_e \nu \bar{\nu}$	$< 6 \times 10^{-5}$	CL=90%
Γ_{29} $K^+ \rightarrow \mu^+ \nu_\mu \nu \bar{\nu}$	$< 6.0 \times 10^{-6}$	CL=90%

Γ_{47} $K^+ \rightarrow \mu^+ \bar{\nu}_e$	L [f] $< 3.3 \times 10^{-3}$	CL=90%
Γ_{48} $K^+ \rightarrow \pi^0 e^+ \bar{\nu}_e$	L $< 3 \times 10^{-3}$	CL=90%
Γ_{49} $K^+ \rightarrow \pi^+ \gamma$	[g] $< 2.3 \times 10^{-9}$	CL=90%

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] See the "Note on $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$ Form Factors" in the π^\pm Particle Listings for definitions and details.

[d] Structure-dependent part.

[e] Direct-emission branching fraction.

[f] Derived from an analysis of neutrino-oscillation experiments.

[g] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 13 branching ratios uses 32 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 51.8$ for 25 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹⁰The ratio is defined to include internal-bremsstrahlung, ignoring direct-emission contributions. AMBROSINO 09E determined the ratio from the measurement of $\Gamma(K \rightarrow e\nu(\gamma))$, $E_\gamma < 10$ MeV / $\Gamma(K \rightarrow \mu\nu(\gamma))$. 89.8% of $K \rightarrow e\nu(\gamma)$ events had $E_\gamma < 10$ MeV.

0.53 ± 0.22 ⁵⁰ ROMANO 71 HLBC $+ E_\gamma > 30$ MeV

1.2 ± 0.8 BELLOTTI 67 HLBC $E_\gamma > 30$ MeV

⁴⁶ AKIMENKO 07 provides values for three kinematic regions. For averaging, we use value with $E_\gamma > 10$ MeV and $0.6 < \cos(\theta_{e\gamma}) < 0.9$.

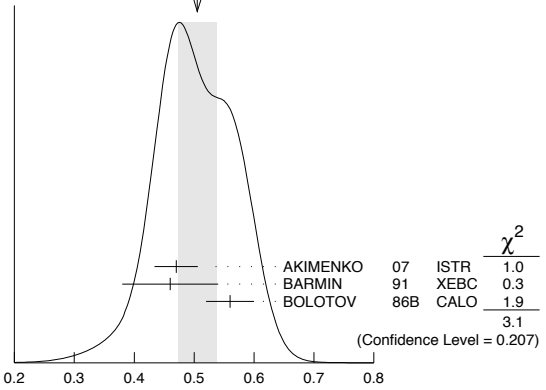

⁴⁷ BARMIN 91 quotes branching ratio $\Gamma(K \rightarrow e \pi^0 \nu_\ell \gamma)/\Gamma_{all}$. The measured normalization is $[\Gamma(K \rightarrow e \pi^0 \nu) + \Gamma(K \rightarrow \pi^+ \pi^+ \pi^-)]$. For comparison with other experiments we used $\Gamma(K \rightarrow e \pi^0 \nu)/\Gamma_{all} = 0.0482$ to calculate the values quoted here.

⁴⁸ $\cos(\theta_{e\gamma})$ between 0.6 and 0.9.

⁴⁹ First LJUNG 73 value is for $\cos(\theta_{e\gamma}) < 0.9$, second value is for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9 for comparison with ROMANO 71.

⁵⁰ Both ROMANO 71 values are for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest E_γ cut for Summary Table value. See ROMANO 71 for E_γ dependence.

< 500	90	0		KLEMS	71	OSPK + $T_\pi < 117$ MeV
-100 ± 600				CHEN	68	OSPK + T_π 60–90 MeV

⁵⁵ KITCHING 97 is extrapolated from their model-independent branching fraction $(6.0 \pm 1.5 \pm 0.7) \times 10^{-7}$ for $100 \text{ MeV}/c < P_{\pi^+} < 180 \text{ MeV}/c$ using Chiral Perturbation Theory.

⁵⁶ ARTAMONOV 05 limit assumes ChPT with $\tilde{c} = 1.8$ with unitarity corrections. With $\tilde{c} = 1.6$ and no unitarity corrections they obtain $< 2.3 \times 10^{-8}$ at 90% CL. This partial branching ratio is predicted to be 6.10×10^{-9} and 0.49×10^{-9} for the cases with and without unitarity correction.

81 COOPER 82 limit on $\bar{\nu}_e$ observation is here interpreted as a limit on lepton number violation in the absence of mixing.

 $\Gamma(\pi^+\gamma)/\Gamma_{\text{total}}$ Γ_{49}/Γ

Violates angular momentum conservation and gauge invariance. Current interest in this decay is as a search for non-commutative space-time effects as discussed in ARTAMONOV 05 and for exotic physics such as a vacuum expectation value of a new vector field, non-local Superstring effects, or departures from Lorentz invariance, as discussed in ADLER 02b.

 K^\pm DALITZ PLOT PARAMETERS FOR
 $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^\pm \rightarrow \pi^\pm \pi^\pm \pi^\mp$, $K^\pm \rightarrow \pi^0 \pi^0 \pi^\pm$, and $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\begin{aligned} |M|^2 \propto & 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[\frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2 \\ & + j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[\frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2 \\ & + f \frac{(s_2 - s_1)(s_3 - s_0)}{m_{\pi^+}^2 m_{\pi^+}^2} + \dots, \end{aligned} \quad (1)$$

where $m_{\pi^+}^2$ has been introduced to make the coefficients g , h , j , and k dimensionless, and

$$\begin{aligned} s_i &= (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i, \quad i = 1, 2, 3, \\ s_0 &= \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2). \end{aligned}$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g , h , and k must be the same for $K^+ \rightarrow \pi^+ \pi^+ \pi^-$ as for $K^- \rightarrow \pi^- \pi^- \pi^+$.

Since different experiments use different forms for $|M|^2$, in order to compare the experiments we have converted to g , h , j , and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y , a_t , a_u , or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

¹⁰⁰ BATLEY 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value $g = 0.626 \pm 0.007$ to obtain $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$. Neglects any possible charge asymmetries in higher order slope parameters h or k .

¹⁰¹ Asymmetry obtained assuming that $g_+ + g_- = 2 \times 0.652$ (PDG 02) and that asymmetries in h and k are zero.

¹⁰² Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters h or k are neglected.

ALTERNATIVE PARAMETRIZATIONS OF $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$ DALITZ PLOT

The following functional form for the matrix element suggested by $\pi\pi$ rescattering in $K^+ \rightarrow \pi^+ \pi^+ \pi^- \rightarrow \pi^+ \pi^0 \pi^0$ is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element = $M_0 + M_1$ where $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$ with $u = (s_3 - s_0)/(m_{\pi^+})^2$, $v = (s_2 - s_1)/(m_{\pi^+})^2$ and where M_1 takes into account the non-analytic piece due to $\pi\pi$ rescattering amplitudes a_0 and a_2 ; The parameters g_0 and h' are related to the parameters g and h of the matrix element squared given in the previous section by the approximations $g_0 \sim g^{PDG}$ and $h' \sim h^{PDG} - (g/2)^2$ and $k_0 \sim k^{PDG}$.

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGGER 09 to extract g_{BB} and h'_{BB} .

 $K_{\ell 3}^\pm$ AND $K_{\ell 3}^0$ FORM FACTORS

Updated October 2009 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to $K \rightarrow \pi \ell \nu$ decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments, discussed immediately below, measure f_+ and f_- , while $K_{e 3}$ experiments, discussed further below, are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

$K_{\mu 3}$ Experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t , *i.e.*,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm(t/m_{\pi^+}^2)]. \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (*i.e.*, $\lambda_- = 0$).

There are two equivalent parametrizations commonly used in these analyses:

(1) **λ_+ , $\xi(0)$ parametrization.** Older analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$).

(2) **λ_+ , λ_0 parametrization.** More recent $K_{\mu 3}$ analyses have parametrized in terms of the form factors f_+ and f_0 , which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

Meson Particle Listings

K^\pm

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)] . \quad (5)$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the $(\lambda_+, \xi(0))$ parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the $K_{\mu 3}^0$ parameters, correlations, and conversion between parametrizations.

Quadratic Parametrization. More recent high-statistics experiments have included a quadratic term in the expansion of $f_+(t)$,

$$f_+(t) = f_+(0) \left[1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2}(t/m_{\pi^+}^2)^2 \right] . \quad (6)$$

If there is a non-vanishing quadratic term, then λ_+ of Eq. (2) represents the average slope, which is then different from λ'_+ . Our convention is to include the factor $\frac{1}{2}$ in the quadratic term, and to use m_{π^+} even for K_{e3}^+ and $K_{\mu 3}^+$ decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the “ K_{e3}^\pm and $K_{\mu 3}^0$ Form Factors” sections of the Listings.

Pole Parametrization: The pole model describes the t -dependence of $f_+(t)$ and $f_0(t)$ in terms of the exchange of the lightest vector and scalar K^* mesons with masses M_v and M_s , respectively:

$$f_+(t) = f_+(0) \left[\frac{M_v^2}{M_v^2 - t} \right] , \quad f_0(t) = f_0(0) \left[\frac{M_s^2}{M_s^2 - t} \right] . \quad (7)$$

Dispersive Parametrization [7,8]. This approach uses dispersive techniques and the known low-energy K - π phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[\frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right] ; \quad (8)$$

$$f_0(t) = f_+(0) \exp \left[\frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right] , \quad (9)$$

where Λ_+ is the slope of the vector form factor, and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$ is the logarithm of the scalar form factor at the Callan-Treiman point. The functions $H(t)$ and $G(t)$ are dispersive integrals.

K_{e3} Experiments: Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ can be assumed to be linear in t , in which case the linear coefficient λ_+ of Eq. (2) is determined, or quadratic, in which case the linear coefficient λ'_+ and quadratic coefficient λ''_+ of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5)\nu \\ + (2f_T/m_K)(P_K)_\lambda (P_\pi)_\mu \bar{\ell} \sigma_{\lambda\mu} (1 + \gamma_5)\nu , \quad (10)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

Fits for K_{e3} Form Factors. For K_{e3} data, we determine best values for the three parametrizations: linear (λ_+) , quadratic $(\lambda'_+, \lambda''_+)$ and pole (M_v) . For $K_{\mu 3}$ data, we determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$ and pole (M_v, M_s) . We then assume $\mu - e$ universality so that we can combine K_{e3} and $K_{\mu 3}$ data, and again determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$, and pole (M_v, M_s) . When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two K_{e3} cases where there is only one parameter: linear (λ_+) and pole (M_v) .

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter λ''_+ is highly correlated with the linear parameter λ'_+ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming $\mu - e$ universality. The “Meson Summary Tables” show all of the results assuming $\mu - e$ universality, but most results not assuming $\mu - e$ universality are given only in the Listings.

 K_{A4}^\pm FORM FACTORS

Based on the parametrizations of AMOROS 99, the K_{A4}^\pm form factors can be expressed as

$$F_s = f_s + f'_s q^2 + f''_s q^4 + f'_e S_e / 4m_\pi^2$$

$$F_p = f_p + f'_p q^2$$

$$G_p = g_p + g'_p q^2$$

$$H_p = h_p + h'_p q^2$$

where $q^2 = (S_\pi / 4m_\pi^2)$, S_π is the invariant mass squared of the dipion, and S_e is the invariant mass squared of the dilepton.

T-VIOLATION PARAMETER IN K^0 - \bar{K}^0 MIXING

The asymmetry $A_T = \frac{\Gamma(\bar{K}^0 \rightarrow K^0) - \Gamma(K^0 \rightarrow \bar{K}^0)}{\Gamma(\bar{K}^0 \rightarrow K^0) + \Gamma(K^0 \rightarrow \bar{K}^0)}$ must vanish if T invariance holds.

ASYMMETRY A_T IN K^0 - \bar{K}^0 MIXING

VALUE (units 10^{-3})	EVTS	DOCUMENT ID	TECN
6.6±1.3±1.0	640k	1 ANGELOPOU... 98E	CPLR

¹ ANGELOPOULOS 98E measures the asymmetry $A_T = \frac{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}$ as a function of the neutral-kaon eigentime τ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\bar{p} \rightarrow K^- \pi^+ K^0$ and $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 01B, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T -violating $\Delta S = \Delta S$ conserving parameter (for its definition, see Review below) $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated October 2009 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

CPT theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in $K^0 - \bar{K}^0$ system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where M and Γ are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [4] for notations and previous literature), allows a very accurate test of CPT symmetry; indeed since CPT requires $M_{11} = M_{22}$ and $\Gamma_{11} = \Gamma_{22}$, the mass and width eigenstates, $K_{S,L}$, have a CPT -violating piece, δ , in addition to the usual CPT -conserving parameter ϵ :

$$K_{S,L} = \frac{1}{\sqrt{2(1+|\epsilon_{S,L}|^2)}} \left[(1+\epsilon_{S,L}) K^0 + (1-\epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta.$$

Using the phase convention $\Im(\Gamma_{12}) = 0$, we determine the phase of ϵ to be $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$. Imposing unitarity to an arbitrary combination of K^0 and \bar{K}^0 wave functions, we obtain the Bell-Steinberger relation [5] connecting CP and CPT violation in the mass matrix to CP and CPT violation in the decay; in fact, neglecting $\mathcal{O}(\epsilon)$ corrections to the coefficient of the CPT -violating parameter, δ , we can write [4]

$$\left[\frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{SW} \right] \left[\frac{\Re(\epsilon)}{1+|\epsilon|^2} - i\Im(\delta) \right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f),$$

where $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$. We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \mathcal{B}(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^-(\gamma), 3\pi^0, \pi^0 \pi^+ \pi^-(\gamma),$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 4 has been updated by using the recent measurements of K_L branching ratios from KTeV [6] and NA48 [7,8])

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.013) + i(1.061 \pm 0.014)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.007) + i(0.471 \pm 0.007)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 7 \times 10^{-6} \text{ at } 95\% \text{ CL}.$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-),$$

Meson Particle Listings

 K^0

where x_+ (x_-) describes the violation of the $\Delta S = \Delta Q$ rule in CPT -conserving (violating) decay amplitudes, and y parametrizes CPT violation for $\Delta S = \Delta Q$ transitions. Taking advantage of their tagged $K^0(\bar{K}^0)$ beams, CPLEAR has measured $\Im(x_+)$, $\Re(x_-)$, $\Im(\delta)$, and $\Re(\delta)$ [10]. These determinations have been improved in Ref. 4 by including the information $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$, where $A_{L,S}$ are the K_L and K_S semileptonic charge asymmetries, respectively, from the PDG [11] and KLOE [12]. Here we are also including the T -violating asymmetry measurement from CPLEAR [13].

Table 1: Values, errors, and correlation coefficients for $\Re(\delta)$, $\Im(\delta)$, $\Re(x_-)$, $\Im(x_+)$, and $A_S + A_L$ obtained from a combined fit, including KLOE [4] and CPLEAR [13].

	value	Correlations coefficients
$\Re(\delta)$	$(3.0 \pm 2.3) \times 10^{-4}$	1
$\Im(\delta)$	$(-0.66 \pm 0.65) \times 10^{-2}$	-0.21 1
$\Re(x_-)$	$(-0.30 \pm 0.21) \times 10^{-2}$	-0.21 -0.60 1
$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38 -0.14 0.47 1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10 -0.63 0.99 0.43 1

The value $A_S + A_L$ in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\begin{aligned} & \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) (\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta))) \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) ((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))) . \end{aligned} \quad (6)$$

Defining

$$\alpha_{\pi\ell\nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \rightarrow \pi\ell\nu) \Im(\delta) , \quad (7)$$

we find:

$$\alpha_{\pi\ell\nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5} .$$

Inserting the values of the α parameters into Eq. (2), we find

$$\begin{aligned} \Re(\epsilon) &= (161.2 \pm 0.6) \times 10^{-5} , \\ \Im(\delta) &= (-0.6 \pm 1.9) \times 10^{-5} . \end{aligned} \quad (8)$$

The complete information on Eq. (8) is given in Table 2.

Table 2: Summary of results: values, errors, and correlation coefficients for $\Re(\epsilon)$, $\Im(\delta)$, $\Re(\delta)$, and $\Re(x_-)$.

	value	Correlations coefficients
$\Re(\epsilon)$	$(161.2 \pm 0.6) \times 10^{-5}$	+1
$\Im(\delta)$	$(-0.6 \pm 1.9) \times 10^{-5}$	+0.26 1
$\Re(\delta)$	$(2.5 \pm 2.3) \times 10^{-4}$	+0.08 -0.09 1
$\Re(x_-)$	$(-4.2 \pm 1.7) \times 10^{-3}$	+0.13 0.17 -0.43 1

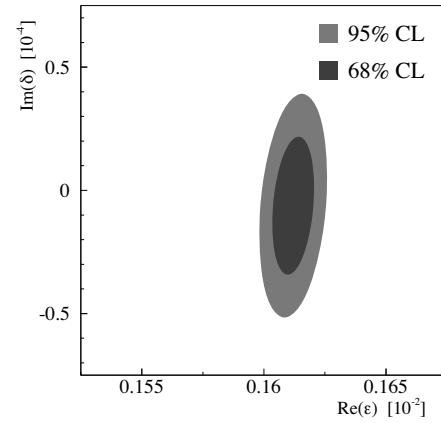

Figure 1: Top: allowed region at 68% and 95% C.L. in the $\Re(\epsilon)$, $\Im(\delta)$ plane. Bottom: allowed region at 68% and 95% C.L. in the ΔM , $\Delta\Gamma$ plane. Latest KTeV preliminary results not included in these figures.

Now the agreement with CPT conservation, $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$, is at 30% C.L.

The allowed region in the $\Re(\epsilon) - \Im(\delta)$ plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

The process giving the largest contribution to the size of the allowed region is $K_L \rightarrow \pi^+\pi^-$, through the uncertainty on ϕ_{+-} .

The limits on $\Im(\delta)$ and $\Re(\delta)$ can be used to constrain the $K^0 - \bar{K}^0$ mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)].$$

The allowed region in the $\Delta M = (m_{K^0} - m_{\bar{K}^0})$, $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$ plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 11) and in the limit $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$ we obtain

$$-5.1 \times 10^{-19} \text{ GeV} < m_{K^0} - m_{\bar{K}^0} < 5.1 \times 10^{-19} \text{ GeV} \text{ at } 95 \% \text{ C.L.}$$

Adding the preliminary KTeV results on $\phi_{\pi^+\pi^-}$ and $\Delta\phi$ [14,15] we obtain: $\Re(\epsilon) = (161.2 \pm 0.6) \times 10^{-5}$, $\Im(\delta) = (-0.6 \pm 1.4) \times 10^{-5}$, leading to

$$-4.0 \times 10^{-19} \text{ GeV} < m_{K^0} - m_{\bar{K}^0} < 4.0 \times 10^{-19} \text{ GeV} \text{ at } 95 \% \text{ C.L.}$$

- ² AMBROSINO 06H uses Bell-Steinberger relations with the following measurements: $B(K_L^0 \rightarrow \pi^+\pi^-)$ in AMBROSINO 06F, $B(K_S^0 \rightarrow \pi^0\pi^0\pi^0)$ in AMBROSINO 05B, the K_S^0 -semileptonic charge asymmetry in AMBROSINO 06E, and K^0 -semileptonic results in ANGELOPOULOS 98F.
³ LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG 04 and APOSTOLAKIS 99B.

CPT-VIOLATION PARAMETERS

In $K^0 - \bar{K}^0$ mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter δ specifies the *CPT*-violating part.

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of *CP T*-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

REAL PART OF δ

A nonzero value violates *CPT* invariance.

- ⁸ AMBROSINO 06H uses Bell-Steinberger relations with the following measurements: $B(K_L^0 \rightarrow \pi^+\pi^-)$ in AMBROSINO 06F, $B(K_S^0 \rightarrow \pi^0\pi^0\pi^0)$ in AMBROSINO 05B, the K_S^0 -semileptonic charge asymmetry in AMBROSINO 06E, and K^0 -semileptonic results in ANGELOPOULOS 98F.
⁹ LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG 04 and APOSTOLAKIS 99B.
¹⁰ APOSTOLAKIS 99B assumes only unitarity and combines CPLEAR and other results.
¹¹ If $\Delta S = \Delta Q$ is not assumed, ANGELOPOULOS 98F finds $\text{Im}\delta = (-15 \pm 23 \pm 3) \times 10^{-3}$.
¹² DEMIDOV 95 reanalyzes data from HART 73 and NIEBERGALL 74.

Re(η)

A non-zero value would violate *CPT* invariance in $\Delta S = \Delta Q$ amplitude. $\text{Re}(\eta)$ is the following combination of K_{e3} decay amplitudes:

$$\text{Re}(\eta) = \text{Re} \left(\frac{A(K^0 \rightarrow e^-\pi^+\bar{\nu}_e) + A(K^0 \rightarrow e^+\pi^-\nu_e)}{A(K^0 \rightarrow e^-\pi^+\bar{\nu}_e) + A(K^0 \rightarrow e^+\pi^-\nu_e)} \right)$$

VALUE (units 10^{-3})	EVTS	DOCUMENT ID	TECN

K_S^0 MEAN LIFE

For earlier measurements, beginning with BOLDT 58B, see our 1986 edition, Physics Letters **170B** 130 (1986).

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. The result labeled "OUR FIT Assuming $CP T$ " ["OUR FIT Not assuming $CP T$ "] includes all measurements except those with the comment "Not assuming $CP T$ " ["Assuming $CP T$ "]. Measurements with neither comment do not assume CPT and enter both fits.

1 This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes $CP T$. This τ_S value is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$

measurement in the K_L^0 listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.396$.

2 The two ALAVI-HARATI 03 values use the same data. The first enters the "assuming $CP T$ " fit and the second enters the "not assuming $CP T$ " fit.

3 This ALAVI-HARATI 03 fit has Δm , ϕ_{+-} , and τ_{K_S} free. See ϕ_{+-} in the " K_L CP violation" section for correlation information.

4 ARONSON 82 find that K_S^0 mean life may depend on the kaon energy.

5 CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348) / \Delta m] 10^{10} / \text{s}$, or, in terms of mean life, CARITHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} \text{ s})$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5292 \pm 0.0009) (10^{10} \text{ } \hbar \text{ s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

6 HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-} . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

7 Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

K_S^0 DECAY MODES

Γ_{14}	$\pi^0 \mu^+ \mu^-$	SI	$(2.9^{+1.5}_{-1.2}) \times 10^{-9}$	

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as $0.666 \cdot B(\pi^\pm e^\mp \nu_e)$.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.1$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $(\delta x_i \delta x_j) / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

••• We do not use the following data for averages, fits, limits, etc. •••

¹⁷ BATLEY 05 is obtained by measuring the interference parameters in $K_S, K_L \rightarrow \pi^+ \pi^- \pi^0$: $\text{Re}(\lambda) = 0.038 \pm 0.008 \pm 0.006$ and $\text{Im}(\lambda) = -0.013 \pm 0.005 \pm 0.004$; the correlation coeff. between $\text{Re}(\lambda)$ and $\text{Im}(\lambda)$ is 0.66 (statistical only).

¹⁸ ADLER 97b find the CP-conserving parameters $\text{Re}(\lambda) = (28 \pm 7 \pm 3) \times 10^{-3}$, $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$. They estimate $B(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)$ from $\text{Re}(\lambda)$ and the K_L^0 decay parameters. See also ANGELOPOULOS 98c.

¹⁹ ZOU 96 is from the the measured quantities $|\rho_{+-0}| = 0.039^{+0.009}_{-0.006} \pm 0.005$ and $\phi_\rho = (-9 \pm 18)^\circ$.

²⁰ ADLER 96E is from the measured quantities $\text{Re}(\lambda) = 0.036 \pm 0.010^{+0.002}_{-0.003}$ and $\text{Im}(\lambda)$ consistent with zero. Note that the quantity λ is the same as ρ_{+-0} used in other footnotes.

²¹ THOMSON 94 calculates this branching ratio from their measurements $|\rho_{+-0}| = 0.035^{+0.019}_{-0.011} \pm 0.004$ and $\phi_\rho = (-59 \pm 48)^\circ$ where $|\rho_{+-0}| e^{i\phi_\rho} = A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, I = 2) / A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)$.

²⁸ AMBROSINO 08c reports $(2.26 \pm 0.12 \pm 0.06) \times 10^{-6}$ from a measurement of $[\Gamma(K_S^0 \rightarrow \gamma\gamma)/\Gamma_{\text{total}}] \times [B(K_S^0 \rightarrow \pi^0\pi^0)]$ assuming $B(K_S^0 \rightarrow \pi^0\pi^0) = (30.69 \pm 0.05) \times 10^{-2}$.

²⁹ LAI 03 reports $[\Gamma(K_S^0 \rightarrow \gamma\gamma)/\Gamma_{\text{total}}] / [B(K_S^0 \rightarrow \pi^0\pi^0)] = (8.84 \pm 0.18 \pm 0.10) \times 10^{-6}$

which we multiply by our best value $B(K_S^0 \rightarrow \pi^0\pi^0) = (30.69 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³⁰ BARR 95B result is calculated using $B(K_L \rightarrow \gamma\gamma) = (5.86 \pm 0.17) \times 10^{-4}$.

³¹ BARR 95B quotes this as the combined BARR 95B + BURKHARDT 87 result after rescaling BURKHARDT 87 to use same branching ratios and lifetimes as BARR 95B.

7.2 ± 1.4		75	AKHMETSHIN	99 CMD2	Tagged K_S^0 using $\phi \rightarrow K_L^0 K_S^0$
---------------	--	----	------------	---------	---

³² Reconstructed from $K^0(\bar{K}^0)(t) \rightarrow \pi e \nu$ distributions using PDG values of $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$, $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$ s and $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

³³ Obtained by imposing $\sum_i B(K_S^0 \rightarrow i) = 1$, where i runs over all the four branching ratios $\pi^+\pi^-$, $\pi^0\pi^0$, $\pi e \nu$, and $\pi \mu \nu$. Input value of $B(K_S^0 \rightarrow \pi^+\pi^-) / B(K_S^0 \rightarrow \pi^0\pi^0)$

from AMBROSINO 06c is used. To derive $\Gamma(K_S^0 \rightarrow \pi^+\pi^-) / \Gamma(K_S^0 \rightarrow \pi^+\pi^- e \nu)$, lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+\pi^-)$ branching ratio measurement.

³⁴ Uses the PDG 00 value for $B(K_S^0 \rightarrow \pi^+\pi^-)$.

 $\Gamma(\pi^\pm \mu^\mp \nu_\mu)/\Gamma_{\text{total}}$ Γ_9/Γ

The PDG 06 value below has not been measured but is computed to be 0.666 times the $K_S \rightarrow \pi^\pm e^\mp \nu_e$ branching fraction. It is included in the fit that constrains the four branching ratios $\pi^+\pi^-$, $\pi^0\pi^0$, $\pi e \nu$, and $\pi \mu \nu$ to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the $\pi^+\pi^-$ and $\pi^0\pi^0$ modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

 K_S^0 FORM FACTORS

For discussion, see note on K_{e3} form factors in the K^\pm section of the Particle Listings above. Because the semileptonic branching fraction is smaller in K_S^0 than K_L^0 by the ratio of the mean lives, the K_S^0 semileptonic form factor has so far been measured only in the K_{e3} mode using the linear expansion $f_+(t) = f_+(0) (1 + \lambda_+ t / m_\pi^2)$, which gives the vector form factor $f_+(t)$ relative to its value at $t = 0$.

CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \rightarrow \pi^+\pi^-\pi^0$ have isospin $I = 0, 1, 2$, and 3 . The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \rightarrow \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \rightarrow \pi^+\pi^-\pi^0)}{A(K_L \rightarrow \pi^+\pi^-\pi^0)}. \quad (1)$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \rightarrow \pi^0\pi^0\pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0} , η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \rightarrow \pi^0\pi^0\pi^0)}{A(K_L \rightarrow \pi^0\pi^0\pi^0)}. \quad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\begin{aligned} \eta_{+-0} &= \eta_{000} \\ &= \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \end{aligned} \quad (3)$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \rightarrow 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\text{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\text{Im}(\eta_{+-0})$ and $\text{Im}(\eta_{000})$ and so as limits on the CP -violating phase of the decay amplitude a_1 .

CP-VIOLATION PARAMETERS IN K_S^0 DECAY

$$A_S = [\Gamma(K_S^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_S^0 \rightarrow \pi^+ e^- \bar{\nu}_e)] / \text{SUM}$$

Such asymmetry violates CP . If CPT is assumed then $A_S = 2 \text{Re}(\epsilon)$.

$$I(J^P) = \frac{1}{2}(0^-)$$

$$m_{K_L^0} - m_{K_S^0}$$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. The result labeled "OUR FIT Assuming CPT " ["OUR FIT Not assuming CPT "] includes all measurements except those with the comment "Not assuming CPT " ["Assuming CPT "]. Measurements with neither comment do not assume CPT and enter both fits.

- ALAVI-HARATI 03 fit Δm and $\tau_{K_S^0}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. CPT is assumed. See " K_S^0 Mean Life" section for correlation information.
- The two ALAVI-HARATI 03 values use the same data. The first enters the "Assuming CPT " fit and the second enters the "Not assuming CPT " fit. They use 40-160 GeV K beams.
- ALAVI-HARATI 03 fit Δm , ϕ_{+-} , and $\tau_{K_S^0}$ simultaneously. See ϕ_{+-} in the " K_L CP violation" section for correlation information.
- Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20-160 GeV K beams.
- GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$, i.e. assumes CPT . 20-160 GeV K beams.
- These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
- GJESDAL 74 uses charge asymmetry in K_S^0 decays.
- ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.
- Uses \bar{K}_{e3}^0 and K_{e3}^0 strangeness tagging at production and decay. Assumes CPT conservation on $\Delta S = -\Delta Q$ transitions.
- ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.
- ARONSON 82 find that Δm may depend on the kaon energy.
- ARONSON 70 and CARNEGIE 71 use K_S^0 mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K_S^0 mean life or in η_{+-} .

K_L^0 MEAN LIFE

VALUE (10^{-8} s)	EVTS	DOCUMENT ID	TECN	COMMENT
5.116 ± 0.020		OUR FIT		
5.099 ± 0.021		OUR AVERAGE		
5.072 ± 0.011 ± 0.035	13M	13 AMBROSINO 06	KLOE	$\sum_i B_i = 1$
5.092 ± 0.017 ± 0.025	15M	AMBROSINO 05c	KLOE	
5.154 ± 0.044	0.4M	VOSBURGH 72	CNTR	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
5.15 ± 0.14		DEVLIN 67	CNTR	

13 AMBROSINO 06 uses $\phi \rightarrow K_L K_S$ with K_L tagged by $K_S \rightarrow \pi^+ \pi^-$. The four major K_L BR's are measured, the small remainder ($\pi^+ \pi^-, \pi^0 \pi^0, \gamma \gamma$) is taken from PDG 04. This KLOE K_L lifetime is obtained by imposing $\sum_i B_i = 1$. The correlation matrix among the four measured K_L BR's and this K_L lifetime is

	K_{e3}	$K_{\mu 3}$	$3\pi^0$	$\pi^+ \pi^- \pi^0$	τ_{K_L}
K_{e3}	1	-0.25	-0.56	-0.07	0.25
$K_{\mu 3}$		1	-0.43	-0.20	0.33
$3\pi^0$			1	-0.39	-0.21
$\pi^+ \pi^- \pi^0$				1	-0.39
τ_{K_L}					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is $(5.084 \pm 0.023) \times 10^{-8}$ s.

K_L^0 DECAY MODES

Mode	Fraction (Γ_i/Γ)	Scale factor/Confidence level

Γ_{36}	$\pi^0\pi^0\mu^\pm e^\mp$	LF	< 1.7	CL=90%

- [a] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \rightarrow \pi^+\pi^-\gamma$ (DE).
- [c] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [d] See the Particle Listings below for the energy limits used in this measurement.
- [e] Allowed by higher-order electroweak interactions.
- [f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a $\chi^2 = 37.3$ for 17 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

V_{ud}, V_{us} , THE CABIBBO ANGLE, AND CKM UNITARITY

Updated November 2009 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters (λ, A, ρ, η) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by λ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle, $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$. Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Unfortunately, the precise value of λ has been somewhat controversial in the past, with kaon decays suggesting [4] $\lambda \simeq 0.220$, while hyperon decays [5] and indirect determinations via nuclear β -decays imply a somewhat larger $\lambda \simeq 0.225 - 0.230$. That discrepancy is often discussed in terms of a deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1. \quad (2)$$

For many years, using a value of V_{us} derived from $K \rightarrow \pi e \nu$ (K_{e3}) decays, that sum was consistently 2-2.5 sigma below unity, a potential signal [6] for new physics effects. Below, we discuss the current status of V_{ud} , V_{us} , and their associated unitarity test in Eq. (2). (Since $|V_{ub}|^2 \simeq 1 \times 10^{-5}$ is negligibly small, it is ignored in this discussion.)

Meson Particle Listings

 K_L^0 V_{ud}

The value of V_{ud} has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of V_{ud} comes from superallowed nuclear beta-decays [6] ($0^+ \rightarrow 0^+$ transitions). Measuring their half-lives, t , and Q values which give the decay rate factor, f , leads to a precise determination of V_{ud} via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \text{RC})} \quad (3)$$

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays. The most recent analysis of Hardy and Towner [10, 11] gives a weighted average (with errors combined in quadrature) of

$$V_{ud} = 0.97425(22) \text{ (superallowed)}, \quad (4)$$

which, assuming unitarity, corresponds to $\lambda = 0.2255(10)$. The new average value of V_{ud} is shifted upward compared to our 2007 value of 0.97418(27) primarily because of improvements in the experimental ft values and nuclear isospin breaking corrections employed. We note, however, that the possibility of additional nuclear coulombic corrections has been raised recently [12].

Combined measurements of the neutron lifetime, τ_n , and the ratio of axial-vector/vector couplings, $g_A \equiv G_A/G_V$, via neutron decay asymmetries can also be used to determine V_{ud} :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects have been recently updated and their error was reduced by about a factor of 2 [9], leading to a ± 0.0002 theoretical uncertainty in V_{ud} (common to all V_{ud} extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 885.7(8) \text{ sec} \\ g_A^{\text{ave}} &= 1.2695(29) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9746(4)_{\tau_n(18)} g_A(2)_{\text{RC}} \quad (7)$$

with the error dominated by g_A uncertainties (which have been expanded due to experimental inconsistencies). We note that a recent precise measurement [13] of $\tau_n = 878.5(7)(3)$ sec is also inconsistent with the world average from this *Review* and would lead to a considerably larger $V_{ud} = 0.9786(4)(18)(2)$. Alternatively, accepting the recent shorter lifetime measurement as correct, and employing it along with the value of V_{ud} in Eq. (4), leads to $g_A = 1.2763(7)$, which is outside of the range of Eq. (6) but in good accord with the most recent direct measurements of g_A [14]. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the

uncertainties in g_A and τ_n , potentially making them the best way to determine V_{ud} .

The recently completed PIBETA experiment at PSI measured the very small ($\mathcal{O}(10^{-8})$) branching ratio for $\pi^+ \rightarrow \pi^0 e^+ \nu_e$ with about $\pm 1/2\%$ precision. Their result gives [15]

$$V_{ud} = 0.9749(26) \left[\frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$ [7], rather than the experimental branching ratio from this *Review* of $1.230(4) \times 10^{-4}$ which would lower the value to $V_{ud} = 0.9728(30)$. Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

 V_{us}

$|V_{us}|$ may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used $K\ell 3$ decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here, ℓ refers to either e or μ , G_F is the Fermi constant, M_K is the kaon mass, S_{EW} is the short-distance radiative correction, δ_K^ℓ is the mode-dependent long-distance radiative correction, $f_+(0)$ is the calculated form factor at zero momentum transfer for the $\ell\nu$ system, and I_K^ℓ is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays, δ_{SU2} is the deviation from one of the ratio of $f_+(0)$ for the charged to neutral kaon decay; it is zero for the neutral kaon. C^2 is 1 (1/2) for neutral (charged) kaon decays. Most determinations of $|V_{us}|$ have been based only on $K \rightarrow \pi e \nu$ decays; $K \rightarrow \pi \mu \nu$ decays have not been used because of large uncertainties in I_K^μ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for S_{EW} , δ_K^ℓ , δ_{SU2} , and $f_+(0)$.

Many new measurements during the last few years have resulted in a significant shift in V_{us} . Most importantly, recent measurements of the $K \rightarrow \pi e \nu$ branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [16] in the charged kaon system and then by KTeV [17,18] in the neutral kaon system; subsequent measurements were made by KLOE [19–22], NA48 [23–25], and ISTRA+ [26]. Current averages (*e.g.*, by the PDG [27] or Flavianet [28]) of the semileptonic branching fractions are based only on recent, high-statistics experiments where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [29] and form factors [30–34], have resulted in improved precision for all of the experimental inputs

to V_{us} . Precise measurements of form factors for $K_{\mu 3}$ decay now make it possible to use both semileptonic decay modes to extract V_{us} .

Following the analysis of the Flavianet group [28], one finds the values of $|V_{us}|f_+(0)$ in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.21664(48). \quad (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [35], as well as $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$, the expectation for $f_+(0)|V_{us}|$ assuming unitarity, based on $|V_{ud}| = 0.9742 \pm 0.0003$, $|V_{ub}| = (3.6 \pm 0.7) \times 10^{-3}$, and the lattice calculation of $f_+(0) = 0.9644 \pm 0.0049$ [36] (Lattice calculations of $f_+(0)$ have improved significantly in recent years, and therefore replace the classic calculation of Leutwyler and Roos [37].) Combining the result in Eq. (10) with the above value of $f_+(0)$ gives

$$|V_{us}| = \lambda = 0.2246 \pm 0.0012. \quad (11)$$

Table 1: $|V_{us}|f_+(0)$ from $K\ell 3$.

Decay Mode	$ V_{us} f_+(0)$
$K^\pm e 3$	0.2173 ± 0.0008
$K^\pm \mu 3$	0.2176 ± 0.0011
$K_L e 3$	0.2163 ± 0.0006
$K_L \mu 3$	0.2168 ± 0.0007
$K_S e 3$	0.2154 ± 0.0013
Average	0.2166 ± 0.0005

Figure 1: Comparison of determinations of $|V_{us}|f_+(0)$ from this review (labeled 2009), from the PDG 2002, and with the prediction from unitarity using $|V_{ud}|$ and the lattice calculation of $f_+(0)$ [36]. For $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$, the inner error bars are from the quoted uncertainty in $f_+(0)$; the total uncertainties include the $|V_{ud}|$ and $|V_{ub}|$ errors.

A value of V_{us} can also be obtained from a comparison of the radiative inclusive decay rates for $K \rightarrow \mu\nu(\gamma)$ and $\pi \rightarrow \mu\nu(\gamma)$ combined with a lattice gauge theory calculation of f_K/f_π via [42]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.2387(4) \left[\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3337(46), \quad (13)$$

which averages in the KLOE result [43], $B(K \rightarrow \mu\nu(\gamma)) = 63.66(9)(15)\%$ and [44]

$$f_K/f_\pi = 1.189(7) \quad (14)$$

along with the value of V_{ud} in Eq. (4) leads to

$$|V_{us}| = 0.2259(5)(13). \quad (15)$$

It should be mentioned that hyperon decay fits suggest [5]

$$|V_{us}| = 0.2250(27) \text{ Hyperon Decays} \quad (16)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a recent representative effort [45] that incorporates SU(3) breaking found $V_{us} = 0.226(5)$. Similarly, inclusive strangeness changing tau decays give [46]

$$|V_{us}| = 0.2208(34) \text{ Tau Decays} \quad (17)$$

where the central value depends on the strange quark mass. However, a recent BaBar study [47] of $\tau \rightarrow K\nu/\tau \rightarrow \pi\nu$ using the lattice value of f_K/f_π from Eq. (14) finds $V_{us} = 0.2255(24)$, in good agreement with other determinations.

Employing the value of V_{ud} in Eq. (4) and $V_{us} = 0.2252(9)$, the average of the $K\ell 3$ (Eq. (11)) and $K\mu 2$ (Eq. (15)) determinations of V_{us} , leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(4)(4). \quad (18)$$

where the first error is the uncertainty from $|V_{ud}|^2$ and the second error is the uncertainty from $|V_{us}|^2$.

CKM Unitarity Constraints

The current good experimental agreement with unitarity, $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(6)$, provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays, K decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant, $G_\mu = 1.166371(6) \times 10^{-5} \text{GeV}^{-2}$.

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary

Meson Particle Listings

 K_L^0

muon decay $\mu^+ \rightarrow e^+ \nu_e \bar{\nu}_\mu$) and (2) new heavy quark mixing V_{uD} [51]. Other examples in the literature [52,53] include Z_χ boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

Exotic Muon Decays

If additional lepton flavor violating decays such as $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$ (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays $\Gamma(\text{exotic } \mu \text{ decays})$, they should be subtracted before the extraction of G_μ and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9989 \quad (19)$$

or

$$BR(\text{exotic } \mu \text{ decays}) < 0.001 . \quad (20)$$

This bound is a factor of 10 better than the direct experimental bound on $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$.

New Heavy Quark Mixing

Heavy D quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as E_6 grand unification. Their mixing with ordinary quarks gives rise to V_{uD} which is constrained by unitarity (one sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - |V_{uD}|^2 > 0.9989 \\ |V_{uD}| < 0.03 . \quad (21)$$

A similar constraint applies to heavy neutrino mixing and the couplings $V_{\mu N}$ and V_{eN} .

⁷⁵ Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT h " and "QUADRATIC COEFFICIENT k " below.) Correlations prevent us from averaging results of fits not including g , h , and k terms.

⁷⁶ BISI 74 value comes from quadratic fit with quad. term consistent with zero. g error is thus larger than if linear fit were used.

⁷⁷ BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable K_L^0 momentum spectrum of second experiment (had same beam).

-6.1 ± 0.9 ± 0.5	14.7M	⁸⁰ LAI	01B NA48
-3.3 ± 1.1 ± 0.7	5M	^{80,81} SOMALWAR	92 E731

⁷⁹ Result obtained using Cl3pl model of CABIBBO 05 to include $\pi\pi$ rescattering effects. The systematic error includes an external error of 1.06×10^{-3} from the parametrization input of $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$ from BATLEY 06B.

⁸⁰ LAI 01B and SOMALWAR 92 results do not include $\pi\pi$ final state rescattering effects.

⁸¹ SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ definitions.

K_L^0 FORM FACTORS

For discussion, see note on form factors in the K^\pm section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$$f_0(t) = f_+(t) + f_-(t) t / (m_{K^0}^2 - m_{\pi^+}^2)$$

t = momentum transfer to the π .

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0 :

$$f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$$

For quadratic expansion

$$f_+(t) = f_+(0) (1 + \lambda'_+ t / m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2 / m_{\pi^+}^4)$$

Meson Particle Listings

K_L^0

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_+ .

NA48 (K_{e3}) and ISTRA quadratic expansion coefficients are converted with $\lambda'_+ PDG = \lambda_+ NA48$ and $\lambda''_+ PDG = 2 \lambda'_+ NA48$

$\lambda'_+ PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$ and

$\lambda''_+ PDG = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_+ ISTRA$

ISTRA linear expansion coefficients are converted with $\lambda_+ PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$ and $\lambda_0 PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0 ISTRA$

The pole parametrization is

$$f_+(t) = f_+(0) \left(\frac{M_V^2}{M_V^2 - t} \right)$$

$$f_0(t) = f_0(0) \left(\frac{M_S^2}{M_S^2 - t} \right)$$

where M_V and M_S are the vector and scalar pole masses.

The dispersive parametrization is

$$f_+(t) = f_+(0) \exp \left[\frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right];$$

$$f_0(t) = f_0(0) \exp \left[\frac{t}{m_K^2 - m_\pi^2} (\ln[C] - G(t)) \right],$$

where Λ_+ is the slope parameter and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$ is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$ and $G(t)$ are dispersive integrals.

The following abbreviations are used:

- DP = Dalitz plot analysis.
- PI = π spectrum analysis.
- MU = μ spectrum analysis.
- POL = μ polarization analysis.
- BR = $K_{\mu 3}^0 / K_{e 3}^0$ branching ratio analysis.
- E = positron or electron spectrum analysis.
- RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K_{e 3}^0$ DECAY)

 $\alpha_{K^*}^{\text{eff}}$ DECAY FORM FACTOR FOR $K_L \rightarrow e^+ e^- e^+ e^-$

$\alpha_{K^*}^{\text{eff}}$ is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two $e^+ e^-$ pairs here compared with one in $e^+ e^- \gamma$ decays, a factorized expression is used for the $e^+ e^- e^+ e^-$ decay form factor.

CP VIOLATION IN K_L DECAYS

Updated May 2010 by L. Wolfenstein (Carnegie-Mellon University), T.G. Trippe (LBNL), and C.-J. Lin (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K , D , B , and B_s mesons is given in “ CP Violation in Meson Decays” by D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters is given in a book by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays, and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$, and in the nonleptonic decay $K_L^0 \rightarrow 2\pi$. The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) = |\eta_{+-}| e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) = |\eta_{00}| e^{i\phi_{00}} \quad (1c)$$

CP violation can occur either in the $K^0 - \bar{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the $K^0 - \bar{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle. \quad (2)$$

If CP invariance held, we would have $q = p$ so that K_S would be CP -even and K_L CP -odd. (We define $|\bar{K}^0\rangle$ as $CP |K^0\rangle$.) CP violation in $K^0 - \bar{K}^0$ mixing is then given by the parameter $\tilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})}. \quad (3)$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I}, \quad (4)$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP -violating

observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon'. \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = i e^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon. \quad (5d)$$

In Eqs. (5a), small corrections [3] of order $\epsilon' \times \text{Re}(A_2/A_0)$ are neglected, and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities $\text{Im } A_0$, $\text{Im } A_2$, and $\text{Im } \tilde{\epsilon}$ depend on the choice of phase convention, since one can change the phases of K^0 and \bar{K}^0 by a transformation of the strange quark state $|s\rangle \rightarrow |s\rangle e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set $\text{Im } A_0$ or $\text{Im } A_2$ or $\text{Im } \tilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice $\text{Im } A_0 = 0$ is called the Wu-Yang phase convention [4], in which case $\epsilon = \tilde{\epsilon}$. The value of ϵ' is independent of phase convention, and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero, and that CP violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.51 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of $\pi - \pi$ scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of ϵ' and of η_{+-} and η_{00} , the CP -violation parameters in the decays $K_S \rightarrow \pi^+ \pi^- \pi^0$ [7], and $K_S \rightarrow \pi^0 \pi^0 \pi^0$ [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase ϕ_{SW} . An important point for the analysis is that $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) , including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}(\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

Meson Particle Listings

 K_L^0

$$\phi_\epsilon = (43.5 \pm 0.7)^\circ, \quad (8b)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.65 \pm 0.26) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.7)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.2 \pm 0.4)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct CP violation, as indicated by ϵ'/ϵ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of A_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation [see “Tests of Conservation Laws”].

2. Fits for K_L^0 CP -violation parameters:

In recent years, K_L^0 CP -violation experiments have improved our knowledge of CP -violation parameters, and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP -violation parameters in $K_L^0 \rightarrow \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S , and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \rightarrow \pi\pi$ branching fractions.

Fits to ϕ_{+-} , ϕ_{00} , $\Delta\phi$, Δm , and τ_S data: These are joint fits to the data on ϕ_{+-} , ϕ_{00} , the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K_L^0 - K_S^0$ mass difference Δm , and the K_S^0 mean life τ_S , including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S . Some measurements of τ_S are correlated with Δm . The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Listings, and the τ_S section of the K_S^0 Listings.

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S , with additional terms specifying the dependence of the value on Δm and τ_S . These cases lead to diagonal bands in Figs. [1] and [2]. The KTeV experiment [10] quotes its results as values of ϕ_{+-} , Δm , and τ_S with correlations, leading to the ellipses labeled “b.”

The data on τ_S , Δm , and ϕ_{+-} shown in Figs. [1] and [2] are combined with data on ϕ_{00} and $\phi_{00} - \phi_{+-}$ in two fits, one without assuming CPT , and the other with this assumption. The results without assuming CPT are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left(\frac{2\Delta m}{\Delta\Gamma} \right) = \tan^{-1} \left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

In Figs. [1] and [2], ϕ_{SW} is shown as narrow bands labeled “j.”

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the $\chi^2 = 1$ contour of the fit result. Color version at end of book.

Table 1: References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Listings, and the τ_S section of the K_S Listings.

Table 2 column 2, “Fit w/o CPT ,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the $\chi^2 = 1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the

Figure 2: ϕ_{+-} vs τ_s . τ_s measurements appear as vertical bands spanning $\tau_s \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the fit result’s $\chi^2 = 1$ contour. Color version at end of book.

x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the ϕ_{SW} bands.

If CPT invariance and unitarity are assumed, then by Eq. (6a), the phase of ϵ is constrained to be approximately equal to

$$\phi_{\text{SW}} = (43.5165 \pm 0.0002)^\circ + 54.1(\Delta m - 0.5290)^\circ + 32.0(\tau_s - 0.8958)^\circ \quad (10)$$

where we have linearized the Δm and τ_s dependence of Eq. (9). The error ± 0.0002 is due to the uncertainty in τ_L . Here Δm has units $10^{10} \hbar \text{s}^{-1}$ and τ_s has units 10^{-10}s .

If in addition we use the observation that $\text{Re}(\epsilon'/\epsilon) \ll 1$ and $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'}$ given in Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3 \text{Im} \left(\frac{\epsilon'}{\epsilon} \right) \\ &\approx -3 \text{Re} \left(\frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{\text{SW}}$.

Table 2: Fit results for ϕ_{+-} , Δm , τ_s , ϕ_{00} , $\Delta\phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the CPT assumption.

# Deg. Free.	13	17

In the fit assuming CPT , we constrain $\phi_\epsilon = \phi_{\text{SW}}$ using the linear expression in Eq. (10), and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 10. Some additional data for which the authors assumed CPT are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/ CPT ,” and the correlation matrix is shown in Table 4. The Δm precision is improved by the CPT assumption.

Table 3: Correlation matrix for the results of the fit without the CPT assumption

	ϕ_{+-}	Δm	τ_s	ϕ_{00}	$\Delta\phi$	ϕ_ϵ

Fits for ϵ'/ϵ , $|\eta_{+-}|$, $|\eta_{00}|$, and $B(K_L \rightarrow \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ . Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes (τ_L , τ_S), and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[\frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the CP -violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K_L^0 \rightarrow \pi^+\pi^-)$ and $B(K_L^0 \rightarrow \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K_S^0 values from this edition, are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$, which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 10. Thus, the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 10 values) are used along with the K_L^0 and K_S^0 mean lives and the $K_S^0 \rightarrow \pi\pi$ branching fractions to compute the K_L^0 branching ratio $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$. This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 10. Thus, the K_L^0 branching ratio fit values in this edition include the results of the direct measurement of $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ . Most individual measurements of $|\eta_{+-}|$ and $|\eta_{00}|$ enter our fits directly via the corresponding measurements of $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$, and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

 CP -VIOLATION PARAMETERS IN K_L^0 DECAYS**CHARGE ASYMMETRY IN $K_{\mu 3}^0$ DECAYS**

Such asymmetry violates CP . It is related to $\text{Re}(\epsilon)$.

 $A_L =$ weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was δ_L or δ . We use A_L for consistency with B^0 asymmetry notation and with recent K_S^0 notation.

PARAMETERS FOR $K_L^0 \rightarrow 2\pi$ DECAY

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0)$$

The fitted values of $|\eta_{+-}|$ and $|\eta_{00}|$ given below are the results of a fit to $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and $\text{Re}(\epsilon'/\epsilon)$. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from the fitted values of the $K_L^0 \rightarrow \pi\pi$ and $K_S^0 \rightarrow \pi\pi$ branching ratios and the K_L^0 and K_S^0 lifetimes. This information is included as data in the $|\eta_{+-}|$ and $|\eta_{00}|$ sections with a Document ID "BRFIT." See the note "CP violation in K_L decays" above for details.

 $|\eta_{00}| = |A(K_L^0 \rightarrow 2\pi^0) / A(K_S^0 \rightarrow 2\pi^0)|$

VALUE (units 10^{-3})	DOCUMENT ID	TECN	COMMENT
2.221 ± 0.011 OUR FIT	Error includes scale factor of 1.8.

2.95 ± 0.63	128 CHOLLET 70	OSP K	Cu reg., 4γ 's

127 Error is statistical only.

128 CHOLLET 70 gives $|\eta_{00}| = (1.23 \pm 0.24) \times (\text{regeneration amplitude, } 2 \text{ GeV}/c \text{ Cu})/10000\text{mb}$. WOLFF 71 gives $|\eta_{00}| = (1.13 \pm 0.12) \times (\text{regeneration amplitude, } 2 \text{ GeV}/c \text{ Cu})/10000\text{mb}$. We compute both $|\eta_{00}|$ values for (regeneration amplitude, $2 \text{ GeV}/c \text{ Cu}) = 24 \pm 2\text{mb}$. This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm et al., Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

 $|\eta_{+-}| = |A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)|$

129 Value obtained from the NA48 measurements of $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)/\Gamma(K_L^0 \rightarrow \pi e \nu_e)$ and $\tau_{K_S^0}$ and KLOE measurements of $B(K_S^0 \rightarrow \pi^+ \pi^-)$ and $\tau_{K_L^0}$. $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)$ is defined to include the inner bremsstrahlung component $\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \gamma(\text{IB}))$ but exclude the direct emission component $B(K_S^0 \rightarrow \pi^+ \pi^- (\text{DE}))$. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

130 AMBROSINO 06F uses KLOE branching ratios and τ_L together with τ_S from PDG 04. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

131 ALEXOPOULOS 04 $|\eta_{+-}|$ uses their $K_L^0 \rightarrow \pi\pi$ branching fractions, $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}$ s from the average of KTeV and NA48 τ_S measurements, and assumes that $\Gamma(K_S^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi e \nu_e)$ giving $B(K_S^0 \rightarrow \pi e \nu_e) = 0.118\%$. Their $|\eta_{+-}|$ is not directly used in our fit, but enters our fit via their branching ratio measurements.

132 APOSTOLAKIS 99C report $(2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934]) \times 10^{-3}$. We evaluate for our 2006 best value $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

133 ADLER 95B report $(2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926]) \times 10^{-3}$. We evaluate for our 1996 best values $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \text{hs}^{-1}$ and $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$ s. Superseded by APOSTOLAKIS 99C.

 $|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$

This expression is a very good approximation, good to about one part in 10^{-4} because of the small measured value of $\phi_{00} - \phi_{+-}$ and small theoretical ambiguities.

• • • We do not use the following data for averages, fits, limits, etc. • • •

134 This is the square root of the ratio R given by BURKHARDT 88 and BARR 93D.

135 This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

136 We calculate $|\eta_{00}/\eta_{+-}| = 1 - 3(\epsilon'/\epsilon)$ from WOODS 88 (ϵ'/ϵ) value.

 $\text{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$

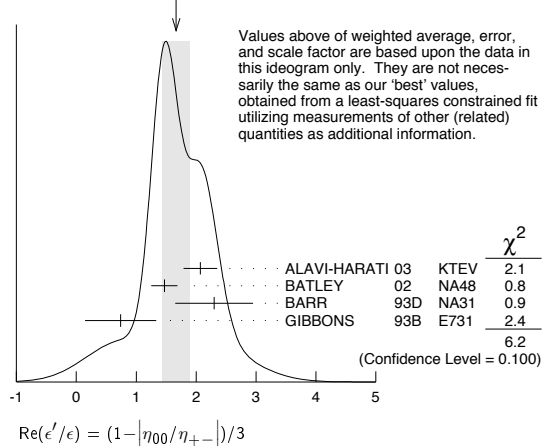

We have neglected terms of order $\omega \cdot \text{Re}(\epsilon'/\epsilon)$, where $\omega = \text{Re}(A_2)/\text{Re}(A_0) \approx 1/22$. If included, this correction would lower $\text{Re}(\epsilon'/\epsilon)$ by about 0.04×10^{-3} . See SOZZI 04.

137 These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ only.

138 This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

139 These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.

WEIGHTED AVERAGE
1.67 ± 0.23 (Error scaled by 1.4) ϕ_{+-} , PHASE OF η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K_L^0 - K_S^0$ mass difference in units 10^{10}hs^{-1} and τ_S is the K_S mean life in units 10^{-10} s. We also give the regeneration phase ϕ_r in the comments below.

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. Most experiments in this section are included in both the "Not Assuming CPT" and "Assuming CPT" fits. In the latter fit, they have little direct influence on ϕ_{+-} because their errors are large compared to that assuming CPT, but they influence Δm and τ_S through their dependencies on these parameters, which are given in the footnotes. Only ALAVI-HARATI 03 is excluded from the "Assuming CPT" fit because we explicitly include their Δm and τ_S measurements which assume CPT.

44.2 ± 2.8 ± 0.2	152	CARTHERS	75	SPEC C regenerator

140 ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ and τ_{K_S} measurements in the K_L^0 and K_S^0 sections respectively. The correlation coefficients are $\rho(\phi_{+-}, \Delta m) = +0.955$, $\rho(\phi_{+-}, \tau_{K_S}) = -0.871$, and $\rho(\tau_{K_S}, \Delta m) = -0.840$. *CPT* is not assumed. Uses scintillator Pb regenerator.

141 APOSTOLAKIS 99c measures $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.

142 SCHWINGENHEUER 95 measures $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

143 These experiments measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude.

144 GIBBONS 93 measures $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports ϕ_{+-} (42.2 ± 1.4)°. They measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.

145 CAROSI 90 measures $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

146 GEWENIGER 74B measures $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.

147 ADLER 96c measures $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

148 ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review D54 1 (1996)).

149 ADLER 95B measures $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

150 ADLER 92B quote separately two systematic errors: ± 0.4 from their experiment and ± 1.0 degrees due to the uncertainty in the value of Δm .

151 KARLSSON 90 systematic error does not include regeneration phase uncertainty.

152 CARTHERS 75 measures $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f = -40.9 \pm 2.6$ °.

 ϕ_{00} , PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
43.52 ± 0.05 OUR FIT	Error includes scale factor of 1.1. Assuming <i>CPT</i>		
43.7 ± 0.8 OUR FIT	Error includes scale factor of 1.2. Not assuming <i>CPT</i>		
44.5 ± 2.3 ± 0.6	153	CAROSI	90 NA31

• • • We do not use the following data for averages, fits, limits, etc. • • •

41.6 ± 5.9 ± 0.2	154	ANGELOPOU...	98 CPLR
50.8 ± 7.1 ± 1.7	155	ADLER	96B CPLR Sup. by ANGELOPOULOS 98
47.4 ± 1.4 ± 0.9	156	KARLSSON	90 E731

153 CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

154 ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values. The τ_S dependence is negligible.

155 ADLER 96B identified initial neutral kaon individually as being a K^0 or a \bar{K}^0 . The systematic uncertainty is ± 1.5 ° combined in quadrature with ± 0.8 ° due to Δm .

156 KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00} - \phi_{+-}$ and $\text{Re } \epsilon'/\epsilon$, and small theoretical ambiguities.

43.51 ± 0.05 OUR FIT	Error includes scale factor of 1.1. Assuming <i>CPT</i>	
43.5 ± 0.7 OUR FIT	Error includes scale factor of 1.3. Not assuming <i>CPT</i>	
43.5136 ± 0.0002 ± 0.0533	157	SUPERWEAK 10 Assuming <i>CPT</i>

157 SUPERWEAK 10 is a fake measurement used to impose the *CPT* or Superweak constraint $\phi_{+-} = \phi_{\text{SW}} = \tan^{-1}[2 \frac{\Delta m}{\hbar} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$. This "measurement" is linearized using values near the RPP 2004 edition values of Δm , τ_S and τ_L , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 10 measures $\phi_\epsilon = (43.51647 \pm 0.00020) + 54.1 [\Delta m - 0.5290] + 32.0 [\tau_S - 0.8958]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8953 \pm 0.0005$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

DECAY-PLANE ASYMMETRY IN $\pi^+\pi^-e^+e^-$ DECAYS

This is the *CP*-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where ϕ is the angle between the e^+e^- and $\pi^+\pi^-$ planes in the K_L^0 rest frame.

¹⁶²SUPERWEAK 10 is a fake experiment to constrain $\phi_{00} - \phi_{+-}$ to a small value as described in the note "CP violation in K_L decays."

¹⁶³ALAVI-HARATI 03 fit Re(ϵ'/ϵ), Im(ϵ'/ϵ), Δm , τ_{K_S} , and ϕ_{+-} simultaneously, not assuming CPT. Phase difference is obtained from $\phi_{00} - \phi_{+-} \approx -3\text{Im}(\epsilon'/\epsilon)$ for small $|\epsilon'/\epsilon|$.

¹⁶⁴This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

¹⁶⁵GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K_S^0 mean life) and mass difference (see the section on $m_{K_L^0} - m_{K_S^0}$).

¹⁶⁶CAROSI 90 is excluded from the fit because it is not independent of ϕ_{+-} and ϕ_{00} values.

PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of CPT. The Superweak phase $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$ where $\Delta m = m_{K_L^0} - m_{K_S^0}$ and $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L\tau_S)$.

¹⁷⁸Footnote 10 of HILL 67 should read +0.58, not -0.58 (private communication) CHO 70 is analysis of unambiguous events in new data and HILL 67.

¹⁷⁹BALDO-CEOLIN 65 gives x and θ converted by us to Re(x) and Im(x).

¹⁸⁰FRANZINI 65 gives x and θ for Re(x) and Im(x). See SCHMIDT 67.

Meson Particle Listings

$K_L^0, K_S^0(800)$

Table listing meson particles with columns for author, experiment, and location. Includes entries like VOSBURGH, BALATS, BARMIN, etc.

Table listing meson particles with columns for author, experiment, and location. Includes entries like AUERBACH, FIRESTONE, BEHR, etc.

$K_0^*(800)$ Or κ

$I(J^P) = \frac{1}{2}(0^+)$

OMITTED FROM SUMMARY TABLE Needs confirmation. See the mini-review on scalar mesons under $f_0(600)$ (see the index for the page number).

$K_0^*(800)$ MASS

Table showing mass values, EVTS, DOCUMENT ID, TECN, and COMMENT for K0*(800). Includes entries like 672 ± 40, 841 ± 30, etc.

- 1 S-matrix pole. GUO 06 in a chiral unitary approach report a mass of 757 ± 33 MeV and a width of 558 ± 82 MeV.
2 A fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model with mass and width of the $K_0^*(800)$ from ABLIKIM 06c well describes the left slope of the $K_S^0 \pi^-$ invariant mass spectrum in $\tau^- \rightarrow K_S^0 \pi^- \nu_\tau$ decay studied by EPIFANOV 07.
3 S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.
4 Not seen by KOPP 01 using 7070 events of $D^0 \rightarrow K^- \pi^+ \pi^0$. LINK 02e and LINK 05i show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$ in their high statistics analysis of $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$.
5 AUBERT 07t does not find evidence for the charged $K_0^*(800)$ using 11k events of $D^0 \rightarrow K^- K^+ \pi^0$.
6 S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.
7 T-matrix pole.
8 A Breit-Wigner mass and width.
9 S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the κ an s-dependent width with an Adler zero near threshold.
10 Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.
11 S-matrix pole.
12 Using ASTON 88.
13 T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.
14 T-matrix pole. Reanalysis of ASTON 88 data.
15 Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

$K_0^*(800)$ WIDTH

Table showing width values, EVTS, DOCUMENT ID, TECN, and COMMENT for K0*(800). Includes entries like 550 ± 34, 618 ± 90, etc.

OTHER RELATED PAPERS

Table listing other related papers with columns for author, experiment, and location. Includes entries like HAYAKAWA, LITTENBERG, RITCHIE, etc.

Meson Particle Listings

 $K_0^*(800)$, $K^*(892)$

- ¹⁶ S-matrix pole.
¹⁷ A fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model with mass and width of the $K_0^*(800)$ from ABLIKIM 06c well describes the left slope of the $K_0^*(800)$ invariant mass spectrum in $\tau^- \rightarrow K_0^*(800) \pi^- \nu_\tau$ decay studied by EPIFANOV 07.
¹⁸ S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.
¹⁹ Not seen by KOPP 01 using 7070 events of $D^0 \rightarrow K^- \pi^+ \pi^0$. LINK 02e and LINK 05i show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$ in their high statistics analysis of $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$.
²⁰ AUBERT 07t does not find evidence for the charged $K_0^*(800)$ using 11k events of $D^0 \rightarrow K^- K^+ \pi^0$.
²¹ S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.
²² T-matrix pole.
²³ A Breit-Wigner mass and width.
²⁴ S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the π s-dependent width with an Adler zero near threshold.
²⁵ Statistical error only. A fit to the Dalitz plot including the $K_0^*(800)^\pm$, $K^*(892)^\pm$, and ϕ resonances modeled as Breit-Wigners. A significant S-wave can be also modeled as a non-resonant contribution.
²⁶ Using ASTON 88.
²⁷ T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.
²⁸ T-matrix pole. Reanalysis of ASTON 88 data.
²⁹ Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

WEIGHTED AVERAGE
895.94 ± 0.22 (Error scaled by 1.4)

- Inclusive reaction. Complicated background and phase-space effects.
- Mass errors enlarged by us to Γ/\sqrt{N} . See note.
- Number of events in peak reevaluated by us.
- K-matrix pole.
- From a partial wave amplitude analysis.
- From a fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model.
- Systematic uncertainties not estimated.
- From the pole position of the $K\pi$ vector form factor in the complex s-plane and using EPIFANOV 07 data.
- Reanalysis of EPIFANOV 07 using resonance chiral theory.
- Calculated by us from the shift by 4.7 ± 0.9 MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.

- ¹¹ With mass and width of the $K^*(1410)$ fixed at 1412 MeV and 227 MeV, respectively.
¹² From the isobar model with a complex pole for the κ .
¹³ Fit to $K\pi$ mass spectrum includes a non-resonant scalar component.
¹⁴ From pole extrapolation.
¹⁵ This value comes from a fit with χ^2 of 178/117.

 $K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple “realistic” tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

WEIGHTED AVERAGE
48.7 ± 0.7 (Error scaled by 1.6)**NEUTRAL ONLY (MeV)**

- ¹⁸ Width errors enlarged by us to $4 \times \Gamma/\sqrt{N}$; see note.
¹⁹ Inclusive reaction. Complicated background and phase-space effects.
²⁰ Number of events in peak reevaluated by us.
²¹ K-matrix pole.
²² From a partial wave amplitude analysis.
²³ From a fit in the $K_S^0(800) + K^*(892) + K^*(1410)$ model.
²⁴ Systematic uncertainties not estimated.
²⁵ From the pole position of the $K\pi$ vector form factor in the complex s -plane and using EPIFANOV 07 data.
²⁶ Reanalysis of EPIFANOV 07 using resonance chiral theory.
²⁷ With mass and width of the $K^*(1410)$ fixed at 1412 MeV and 227 MeV, respectively.
²⁸ From the isobar model with a complex pole for the κ .
²⁹ Fit to $K\pi$ mass spectrum includes a non-resonant scalar component.
³⁰ This value comes from a fit with χ^2 of 178/117.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s -dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.

² From the isobar model with a complex pole for the κ .

³ From a non-parametric analysis.

⁴ A Breit-Wigner mass and width.

⁵ S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the κ with an s -dependent width and an Adler zero near threshold.

⁶ S-matrix pole. Using ASTON 88 and assuming $K_0^*(800)$, $K_0^*(1950)$.

⁷ Using ASTON 88 and assuming $K_0^*(800)$.

⁸ T-matrix pole. Reanalysis of ASTON 88 data.

⁹ Breit-Wigner fit. Using ASTON 88.

¹⁰ Assuming a low-mass scalar $K\pi$ resonance, $\kappa(800)$.

¹¹ T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.

¹² J^P not determined, could be $K_2^*(1430)$.

¹³ T-matrix pole.

¹⁴ Uses a model for the background, without this background they get a mass 1340 MeV, where the phase shift passes 90° .

¹⁵ Mass defined by pole position.

¹⁶ From elastic $K\pi$ partial-wave analysis.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 20.2$ for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$I^G(J^{PC}) = ?^?(?^{??})$$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several ($\Lambda \bar{p}$ + pions) and ($\bar{\Lambda} p$ + pions) states in Σ^- Be reactions by BOURQUIN 86 and in $n p$ and $n A$ reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers ($B=0, Q=+1, S=-1$ for $\Lambda \bar{p} \pi^+ \pi^+$ and $I \geq 3/2$ for $\Lambda \bar{p} \pi^-$). Needs confirmation.

²BARLAG 90c estimates the systematic error to be negligible.

D^+ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Inclusive modes		
Γ_1 e^+ semileptonic	(16.07 ± 0.30) %

[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[b] These subfractions of the $K^-2\pi^+$ mode are uncertain: see the Particle Listings.

[c] Submodes of the $D^+ \rightarrow K^-2\pi^+\pi^0$ and $K_S^0 2\pi^+\pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[d] The unseen decay modes of the resonances are included.

[e] This is *not* a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+\ell^+\ell^-$ final state.

[f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[g] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 23 branching ratios uses 36 measurements and one constraint to determine 15 parameters. The overall fit has a $\chi^2 = 35.8$ for 22 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

DALITZ PLOT ANALYSIS FORMALISM

Written January 2006 by D. Asner (Pacific Northwest National Laboratory)

Introduction: Weak nonleptonic decays of D and B mesons are expected to proceed dominantly through resonant two-body decays [1]; see Ref. [2] for a review of resonance phenomenology. The amplitudes are typically calculated with the Dalitz-plot analysis technique [3], which uses the minimum number of independent observable quantities. For three-body decays of a spin-0 particle to all pseudo-scalar final states, D or $B \rightarrow abc$, the decay rate [4] is

$$\Gamma = \frac{1}{(2\pi)^3 32\sqrt{s^3}} |\mathcal{M}|^2 dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where m_{ij} is the invariant mass of particles i and j . The coefficient of the amplitude includes all kinematic factors, and $|\mathcal{M}|^2$ contains the dynamics. The scatter plot in m_{ab}^2 versus m_{bc}^2 is the Dalitz plot. If $|\mathcal{M}|^2$ is constant, the kinematically allowed region of the plot will be populated uniformly with events. Any variation in the population over the Dalitz plot is due to dynamical rather than kinematical effects. It is straightforward to extend the formalism beyond three-body final states. For N -body final states with only spin-0 particles, phase space has dimension $3N - 7$. Other decays of interest include one vector particle or a fermion/anti-fermion pair (*e.g.*, $B \rightarrow D^* \pi \pi$, $B \rightarrow \bar{K}_c p \pi$, $B \rightarrow K \ell \ell$) in the final state. For the first case, phase space has dimension $3N - 5$, and for the latter two the dimension is $3N - 4$.

Formalism: The amplitude for the process, $R \rightarrow rc, r \rightarrow ab$ where R is a D or B , r is an intermediate resonance, and a, b, c are pseudo-scalars, is given by

$$\begin{aligned} \mathcal{M}_r(J, L, l, m_{ab}, m_{bc}) &= \sum_\lambda \langle ab|r_\lambda \rangle T_r(m_{ab}) \langle cr_\lambda|R_J \rangle \quad (2) \\ &= Z(J, L, l, \vec{p}, \vec{q}) B_L^R(|\vec{p}|) B_L^R(|\vec{q}|) T_r(m_{ab}). \end{aligned}$$

The sum is over the helicity states λ of r , J is the total angular momentum of R (for D and B decays, $J=0$), L is the orbital angular momentum between r and c , l is the orbital angular momentum between a and b (the spin of r), \vec{p} and \vec{q} are the momenta of c and of a in the r rest frame, Z describes the

Meson Particle Listings

D^\pm

angular distribution of the final-state particles, B_L^R and B_L' are the barrier factors for the production of rc and of ab , and T_r is the dynamical function describing the resonance r . The amplitude for modeling the Dalitz plot is a phenomenological object. Differences in the parametrizations of Z , B_L , and T_r , as well as in the set of resonances r , complicate the comparison of results from different experiments.

Usually the resonances are modeled with a Breit-Wigner form, although some more recent analyses use a K -matrix formalism [5,6,7] with the P -vector approximation [8] to describe the $\pi\pi$ S-wave.

The nonresonant (NR) contribution to $D \rightarrow abc$ is parametrized as constant (S-wave) with no variation in magnitude or phase across the Dalitz plot. The available phase space is much greater for B decays, and the nonresonant contribution to $B \rightarrow abc$ requires a more sophisticated parametrization. Theoretical models of the NR amplitude [9-12] do not reproduce the distributions observed in the data. Experimentally, several parametrizations have been used [13,14].

Barrier Factor B_L : The maximum angular momentum L in a strong decay is limited by the linear momentum q . Decay particles moving slowly with an impact parameter (meson radius) d of order 1 fm have difficulty generating sufficient angular momentum to conserve the spin of the resonance. The Blatt-Weisskopf [15,16] functions B_L , given in Table 1, weight the reaction amplitudes to account for this spin-dependent effect. These functions are normalized to give $B_L = 1$ for $z = (|q|d)^2 = 1$. Another common formulation, B_L' , also in Table 1, is normalized to give $B_L' = 1$ for $z = z_0 = (|q_0|d)^2$ where q_0 is the value of q when $m_{ab} = m_r$.

Table 1: Blatt-Weisskopf barrier factors.

L	$B_L(q)$	$B_L'(q, q_0)$
0	1	1
1	$\sqrt{\frac{2z}{1+z}}$	$\sqrt{\frac{1+z_0}{1+z}}$
2	$\sqrt{\frac{13z^2}{(z-3)^2+9z}}$	$\sqrt{\frac{(z_0-3)^2+9z_0}{(z-3)^2+9z}}$

where $z = (|q|d)^2$ and $z_0 = (|q_0|d)^2$

Angular distribution: The tensor or Zemach formalism [17,18] and the helicity formalism [19,18] yield identical descriptions of the angular distributions for the decay process $R \rightarrow rc, r \rightarrow ab$ when a, b and c all have spin-0. The angular distributions for $L = 0, 1$, and 2 are given in Table 2. For final-state particles with non-zero spin (e.g., radiative decays), the helicity formalism is required.

Table 2: Angular distributions for $L = 0, 1, 2$ where θ is the angle between particles a and c in the rest frame of resonance r , $\sqrt{1+\zeta^2} = E_r/m_{ab}$ is a relativistic correction, and $E_r = (m_R^2 + m_{ab}^2 - m_c^2)/2m_R$.

$J \rightarrow L + l$	Angular distribution
$0 \rightarrow 0+0$	uniform
$0 \rightarrow 1+1$	$(1+\zeta^2) \cos^2 \theta$
$0 \rightarrow 2+2$	$\left(\zeta^2 + \frac{3}{2}\right)^2 (\cos^2 \theta - 1/3)^2$

Dynamical Function T_r : The dynamical function T_r is derived from the S -matrix formalism. In general, the amplitude that a final state f couples to an initial state i is $S_{fi} = \langle f|S|i\rangle$, where the scattering operator S is unitary and satisfies $SS^\dagger = S^\dagger S = I$. The Lorentz-invariant transition operator \hat{T} is defined by separating the probability that $f = i$, yielding

$$S = I + 2iT = I + 2i\{\rho\}^{1/2} \hat{T} \{\rho\}^{1/2}, \quad (3)$$

where I is the identity operator, ρ is the diagonal phase-space matrix, with $\rho_{ii} = 2q_i/m$, and q_i is the momentum of a in the r rest frame for decay channel i . In the single-channel S-wave case, $S = e^{2i\delta}$ satisfies unitarity and

$$\hat{T} = \frac{1}{\rho} e^{i\delta} \sin \delta. \quad (4)$$

There are three common formulations of the dynamical function. The Breit-Wigner formalism—the first term in a Taylor expansion about a T -matrix pole—is the simplest formulation. The K -matrix formalism [5] is more general (allowing more than one T -matrix pole and coupled channels while preserving unitarity). The Flatté distribution [20] is used to parametrize resonances near threshold and is equivalent to a one-pole, two-channel K -matrix.

Breit-Wigner Formulation: The common formulation of a Breit-Wigner resonance decaying to spin-0 particles a and b is

$$T_r(m_{ab}) = \frac{1}{m_r^2 - m_{ab}^2 - im_r \Gamma_{ab}(q)}. \quad (5)$$

The “mass-dependent” width Γ is

$$\Gamma = \Gamma_r \left(\frac{q}{q_r}\right)^{2L+1} \left(\frac{m_r}{m_{ab}}\right) B_L'(q, q_0)^2, \quad (6)$$

and $B_L'(q, q_0)$ is the Blatt-Weisskopf barrier factor from Table 1. A Breit-Wigner parametrization best describes isolated, non-overlapping resonances far from the threshold of additional decay channels. For the ρ and $\rho(1450)$ a more complex parametrization suggested by Gounaris-Sakurai [21] is often used [22-26]. Unitarity can be violated when the dynamical function is parametrized as the sum of two or more overlapping Breit-Wigners. The proximity of a threshold to a resonance distorts the line shape from a simple Breit-Wigner. Here the Flatté formula provides a better description and is discussed below.

K -matrix Formalism: The T matrix can be written as

$$\hat{T} = (I - i\hat{K}\rho)^{-1}\hat{K}, \quad (7)$$

where \hat{K} is the Lorentz-invariant K -matrix describing the scattering process and ρ is the phase-space factor. Resonances appear as poles in the K -matrix:

$$\hat{K}_{ij} = \sum_{\alpha} \frac{\sqrt{m_{\alpha}\Gamma_{\alpha i}(m)m_{\alpha}\Gamma_{\alpha j}(m)}}{(m_{\alpha}^2 - m^2)\sqrt{\rho_i\rho_j}}. \quad (8)$$

The K -matrix is real by construction, and so the associated T -matrix respects unitarity.

For a single pole in a single channel, K is

$$K = \frac{m_0\Gamma(m)}{m_0^2 - m^2} \quad (9)$$

and

$$T = K(1 - iK)^{-1} = \frac{m_0\Gamma(m)}{m_0^2 - m^2 - im_0\Gamma(m)}, \quad (10)$$

which is the relativistic Breit-Wigner formula. For two poles in a single channel, K is

$$K = \frac{m_{\alpha}\Gamma_{\alpha}(m)}{m_{\alpha}^2 - m^2} + \frac{m_{\beta}\Gamma_{\beta}(m)}{m_{\beta}^2 - m^2}. \quad (11)$$

If m_{α} and m_{β} are far apart relative to the widths, the T matrix is approximately the sum of two Breit-Wigners, $T(K_{\alpha} + K_{\beta}) \approx T(K_{\alpha}) + T(K_{\beta})$, each of the form of Eq. (10). This approximation is not valid for two nearby resonances, in which case T can violate unitarity.

This formulation, which applies to S -channel production in two-body scattering, $ab \rightarrow cd$, can be generalized to describe the production of resonances in processes such as the decay of charm mesons. The key assumption here is that the two-body system described by the K -matrix does *not* interact with the rest of the final state [8]. The validity of this assumption varies with the production process and is appropriate for reactions such as $\pi^- p \rightarrow \pi^0 \pi^0 n$ and semileptonic decays such as $D \rightarrow K \pi \ell \nu$. The assumption may be of limited validity for production processes such as $p\bar{p} \rightarrow \pi\pi\pi$ or $D \rightarrow \pi\pi\pi$. In these cases, the two-body Lorentz-invariant amplitude, \hat{F} , is given by

$$\hat{F}_i = (I - i\hat{K}\rho)_{ij}^{-1}\hat{P}_j = (\hat{T}\hat{K}^{-1})_{ij}\hat{P}_j, \quad (12)$$

where P is the production vector that parametrizes the resonance production in the open channels.

For the $\pi\pi$ S-wave, a common formulation of the K -matrix [7,24,25] is

$$K_{ij}(s) = \left[\sum_{\alpha} \left(\frac{g_i^{(\alpha)} g_j^{(\alpha)}}{m_{\alpha}^2 - s} \right) + f_{ij}^{sc} \frac{1 - s_0^{sc}}{s - s_0^{sc}} \right] \left[\frac{(s - s_A m_{\pi}^2 / 2)(1 - s_{A0})}{(s - s_{A0})} \right]. \quad (13)$$

The factor $g_i^{(\alpha)}$ is the real coupling constant of the K -matrix pole m_{α} to meson channel i ; the parameters f_{ij}^{sc} and s_0^{sc} describe a smooth part of the K -matrix elements; the second factor in square brackets suppresses a false kinematical singularity near

the $\pi\pi$ threshold (the Adler zero); and the number 1 has units GeV^2 .

The production vector, with $i = 1$ denoting $\pi\pi$, is

$$P_j(s) = \left[\sum_{\alpha} \left(\frac{\beta_{\alpha} g_j^{(\alpha)}}{m_{\alpha}^2 - s} \right) + f_{1j}^{pr} \frac{1 - s_0^{pr}}{s - s_0^{pr}} \right] \left[\frac{(s - s_A m_{\pi}^2 / 2)(1 - s_{A0})}{(s - s_{A0})} \right]. \quad (14)$$

where the free parameters of the Dalitz plot fit are the complex production couplings β_{α} and the production-vector background parameters f_{1j}^{pr} and s_0^{pr} . All other parameters are fixed by scattering experiments. Ref. [6] describes the $\pi\pi$ scattering data with a 4-pole, 2-channel ($\pi\pi$, $K\bar{K}$) model, while Ref. [7] describes the scattering data with 5-pole, 5-channel ($\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta'\eta'$ and 4π) model. The former has been implemented by CLEO [27] and the latter by FOCUS [25] and BABAR [24]. In both cases, only the $\pi\pi$ channel was analyzed. A more complete coupled-channel analysis would simultaneously fit all final states accessible by rescattering.

Flatté Formalism: The Flatté formulation is used when a second channel opens close to a resonance:

$$\hat{T}(m_{ab}) = \frac{1}{m_r^2 - m_{ab}^2 - i(\rho_1 g_1^2 + \rho_2 g_2^2)}, \quad (15)$$

where $g_1^2 + g_2^2 = m_0\Gamma_r$. This situation occurs in the $\pi\pi$ S-wave where the $f_0(980)$ is near the $K\bar{K}$ threshold, and in the $\pi\eta$ channel where the $a_0(980)$ also lies near the $K\bar{K}$ threshold. For the $a_0(980)$ resonance, the relevant coupling constants are $g_1 = g_{\pi\eta}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\eta}$ and $\rho_2 = \rho_{KK}$, where

$$\rho_{ab} = \sqrt{\left(1 - \left(\frac{m_a - m_b}{m_{ab}}\right)^2\right) \left(1 - \left(\frac{m_a + m_b}{m_{ab}}\right)^2\right)}. \quad (16)$$

For the $f_0(980)$ the relevant coupling constants are $g_1 = g_{\pi\pi}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\pi}$ and $\rho_2 = \rho_{KK}$. The charged and neutral K channels are usually assumed to have the same coupling constant but different phase space factors, due to $m_{K^+} \neq m_{K^0}$; the result is

$$\rho_{KK} = \frac{1}{2} \left(\sqrt{1 - \left(\frac{2m_{K^\pm}}{m_{KK}}\right)^2} + \sqrt{1 - \left(\frac{2m_{K^0}}{m_{KK}}\right)^2} \right). \quad (17)$$

Branching Ratios from Dalitz Plot Fits: A fit to the Dalitz plot distribution using either a Breit-Wigner or a K -matrix formalism factorizes into a resonant contribution to the amplitude \mathcal{M}_j and a complex coefficient, $a_j e^{i\delta_j}$, where a_j and δ_j are real. The definition of a rate of a single process, given a set of amplitudes a_j and phases δ_j , is the square of the relevant matrix element (see Eq. (1)). The ‘‘fit fraction’’ is usually defined as the integral over the Dalitz plot (m_{ab} vs. m_{bc}) of a single amplitude squared divided by the integral over the Dalitz plot of the square of the coherent sum of all amplitudes, or

$$\text{fit fraction}_j = \frac{\int |a_j e^{i\delta_j} \mathcal{M}_j|^2 dm_{ab}^2 dm_{bc}^2}{\int |\sum_k a_k e^{i\delta_k} \mathcal{M}_k|^2 dm_{ab}^2 dm_{bc}^2}, \quad (18)$$

Meson Particle Listings

D^\pm

where \mathcal{M}_j is defined in Eq. (2) and described in Ref. [28]. In general, the sum of the fit fractions for all components will not be unity due to interference.

When the K -matrix of Eq. (12) is used to describe a wave (e.g., the $\pi\pi$ S-wave), then \mathcal{M}_j refers to the entire wave. In this case, it may not be straightforward to separate \mathcal{M}_j into a sum of individual resonances unless these are narrow and well separated.

Reconstruction Efficiency and Resolution: The efficiency for reconstructing an event as a function of position on the Dalitz plot is in general non-uniform. Typically, a Monte Carlo sample generated with a uniform distribution in phase space is used to determine the efficiency. The variation in efficiency across the Dalitz plot varies with experiment and decay mode. Most recent analyses utilize a full GEANT [29] detector simulation.

Finite detector resolution can usually be safely neglected as most resonances are comparatively broad. Notable exceptions where detector resolution effects must be modeled are $\phi \rightarrow K^+K^-$, $\omega \rightarrow \pi^+\pi^-$, and $a_0 \rightarrow \eta\pi^0$. One approach is to convolve the resolution function in the Dalitz-plot variables m_{ab}^2 and m_{bc}^2 with the function that parametrizes the resonant amplitudes. In high-statistics data samples, resolution effects near the phase-space boundary typically contribute to a poor goodness of fit. The momenta of the final-state particles can be recalculated with a D or B mass constraint, which forces the kinematic boundaries of the Dalitz plot to be strictly respected. If the three-body mass is not constrained, then the efficiency (and the parametrization of background) may also depend on the reconstructed mass.

Backgrounds: The contribution of background to the D and B samples varies by experiment and final state. The background naturally falls into five categories: (i) purely combinatoric background containing no resonances; (ii) combinatoric background containing intermediate resonances, such as a real K^{*-} or ρ , plus additional random particles; (iii) final states containing identical particles as in $D^0 \rightarrow K_S^0\pi^0$ background to $D^0 \rightarrow \pi^+\pi^-\pi^0$ and $B \rightarrow D\pi$ background to $B \rightarrow K\pi\pi$; (iv) mistagged decays such as a real \overline{D}^0 or \overline{B}^0 incorrectly identified as a D^0 or B^0 ; and (v) particle misidentification of the decay products such as $D^+ \rightarrow \pi^-\pi^+\pi^+$ or $D_s^+ \rightarrow K^-K^+\pi^+$ reconstructed as $D^+ \rightarrow K^-\pi^+\pi^+$.

The contribution from combinatoric background with intermediate resonances is distinct from the resonances in the signal because the former do *not* interfere with the latter since they are not from true resonances. Similarly, $D^0 \rightarrow \rho\pi$ and $D^0 \rightarrow K_S^0\pi^0$ do not interfere since strong and weak transitions proceed on different time scales. The usual identification tag of the initial particle as a D^0 or a \overline{D}^0 is the charge of the distinctive slow pion in the decay sequence $D^{*+} \rightarrow D^0\pi_s^+$ or $D^{*-} \rightarrow \overline{D}^0\pi_s^-$. Another possibility is the identification or “tagging” of one of the D mesons from $\psi(3770) \rightarrow D^0\overline{D}^0$, as is done for B mesons from $\Upsilon(4S)$. The mistagged background is subtle and may be

mistakenly enumerated in the *signal* fraction determined by a D^0 mass fit. Mistagged decays contain true \overline{D}^0 's or \overline{B}^0 's and so the resonances in the mistagged sample exhibit interference on the Dalitz plot.

REVIEW OF D-MESON DALITZ PLOT ANALYSES

Revised April 2010 by D. Asner (Pacific Northwest National Laboratory)

The formalism of Dalitz-plot analysis is reviewed in the preceding note. Recent studies of multi-body decays of charm mesons probe a variety of physics, including γ/ϕ_3 , $D^0-\bar{D}^0$ mixing, searches for CP violation, doubly Cabibbo-suppressed decays, and properties of S-wave $\pi\pi$, $K\pi$, and $K\bar{K}$ resonances. In the following, we discuss: (1) $D^0 \rightarrow K_S^0\pi^+\pi^-$; (2) doubly Cabibbo-suppressed decays; and (3) CP violation. The properties of the light meson resonances determined in D-meson Dalitz-plot analyses are reported in the light unflavored meson section of this *Review*.

$D^0 \rightarrow K_S^0\pi^+\pi^-$: Several experiments have analyzed $D^0 \rightarrow K_S^0\pi^+\pi^-$ decay. A CLEO analysis [1] included ten resonances: $K_S^0\rho^0$, $K_S^0\omega$, $K_S^0f_0(980)$, $K_S^0f_2(1270)$, $K_S^0f_0(1370)$, $K^*(892)^-\pi^+$, $K_0^*(1430)^-\pi^+$, $K_2^*(1430)^-\pi^+$, $K^*(1680)^-\pi^+$, and the doubly Cabibbo-suppressed (DCS) mode $K^*(892)^+\pi^-$. The CLEO model does not provide a good description of higher-statistics BABAR and Belle data samples. An improved description is obtained in three ways: First, by adding more Breit-Wigner resonances. Second, following the methodology of FOCUS [2], by applying a K -matrix model [3–5] to the $\pi\pi$ S-wave [6,7]. Third, by adding a parameterization to the $K\pi$ S-wave motivated by the LASS experiment [8].

A BABAR analysis [7,9,10] added to the CLEO model the $K^*(1410)^-\pi^+$, $K_S^0\rho^0(1450)$, the DCS modes $K_0^*(1430)^+\pi^-$ and $K_2^*(1430)^+\pi^-$, and two Breit-Wigner $\pi\pi$ S-wave contributions. A Belle analysis [11–13] included all the components of BABAR and added two more DCS modes, $K^*(1410)^+\pi^-$ and $K^*(1680)^+\pi^-$. Recently, BABAR has modeled the $\pi\pi$ S-wave using a K -matrix model for the $\pi\pi$ and $K\pi$ S-waves [14].

The primary motivation for the analysis of the decay $D^0 \rightarrow K_S^0\pi^+\pi^-$ is to study $D^0 - \bar{D}^0$ oscillations and the CKM angles. The quasi-two-body intermediate states include both CP -even and CP -odd eigenstates as well as doubly Cabibbo-suppressed channels. Time-dependent analyses of the Dalitz plot from CLEO [15] and Belle [6] simultaneously determined the strong transition amplitudes and phases, the mixing parameters x and y without phase or sign ambiguity, and the CP -violating parameter $|q/p|$ and $\text{Arg}(q/p)$. See the note on “ $D^0 - \bar{D}^0$ Mixing” for a discussion.

The CKM angle γ/ϕ_3 [16] and the quark-mixing parameter $\cos 2\beta/\phi_1$ [17] can be determined using the decays $B^- \rightarrow D^{(*)}K^{(*)-}$ and $\bar{B}^0 \rightarrow Dh^0$, respectively, followed by the decay $D \rightarrow K_S^0\pi^+\pi^-$. The Belle and BABAR experiments measured γ/ϕ_3 (Belle [11–13] and BABAR [7,9,10,14,18]) and $\cos 2\beta/\phi_1$ (Belle [19], BABAR [20]). In these analyses, a large systematic

uncertainty in the relative phase between the D^0 and \bar{D}^0 amplitudes point by point across the Dalitz plot remains to be fully understood.

The quantum entangled production of $D^0\bar{D}^0$ pairs from $\psi(3770)$ enables a model-independent determination of the D^0/\bar{D}^0 relative phase. Studying CP -tagged Dalitz plots [21,22] provides sensitivity to the cosine of the relative phase, while studying double-tagged Dalitz plots [22] probes both the cosine and sine of the D^0/\bar{D}^0 phase difference. CLEO analyzed [23] the $D^0 \rightarrow K_S^0\pi^+\pi^-$ and $D^0 \rightarrow K_L^0\pi^+\pi^-$ samples using the CP -even tag modes K^+K^- , $\pi^+\pi^-$, $K_L^0\pi^0$ (vs. $K_S^0\pi^+\pi^-$ only), the CP -odd tag modes $K_S^0\pi^0$, $K_S^0\eta$, and the double-tag modes $(K_S^0\pi^+\pi^-)^2$ and $(K_S^0\pi^+\pi^-)(K_L^0\pi^+\pi^-)$. These measurements can reduce the model uncertainty on γ/ϕ_3 to about 3° .

Doubly Cabibbo-Suppressed Decays: There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of D mesons. The first consists of those in which the DCS and corresponding Cabibbo-favored (CF) decays populate distinct Dalitz plots; the pairs $D^0 \rightarrow K^+\pi^-\pi^0$ and $D^0 \rightarrow K^-\pi^+\pi^0$, or $D^+ \rightarrow K^+\pi^+\pi^-$ and $D^+ \rightarrow K^-\pi^+\pi^+$, are examples. Our average of three measurements of $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0)/\Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$ is $(2.20 \pm 0.10) \times 10^{-3}$. Our average of four measurements of $\Gamma(D^+ \rightarrow K^+\pi^-\pi^+)/\Gamma(D^+ \rightarrow K^-\pi^+\pi^+)$ is $(5.77 \pm 0.22) \times 10^{-3}$; see the Particle Listings.

The second class consists of decays in which the DCS and CF modes populate the same Dalitz plot; for example, $D^0 \rightarrow K^{*-}\pi^+$ and $D^0 \rightarrow K^{*+}\pi^-$ both contribute to $D^0 \rightarrow K_S^0\pi^+\pi^-$. In this class, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude and allows direct measurement of the relative strong phases between amplitudes. CLEO [1] and Belle [6] have measured the relative phase between $D^0 \rightarrow K^*(892)^+\pi^-$ and $D^0 \rightarrow K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3^{+15}_-5)^\circ$ and $(171.9 \pm 1.3)^\circ$ (statistical error only). These results are close to the 180° expected from Cabibbo factors and a small strong phase.

In addition, Belle [6] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, $K_2^*(1430)^+\pi^-$, $K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4\theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 . For $K^+\pi^-$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4\theta_c$. Similarly, BABAR [7] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The values for R in units of $\tan^4\theta_c$ are 3.45 ± 0.31 , 7.7 ± 3.0 , and 1.7 ± 1.7 , respectively. Recently, BABAR [14] has used a K -matrix formalism to describe the $\pi\pi$ S-wave in $K_S^0\pi^+\pi^-$. The reported values for R in units of $\tan^4\theta_c$ are 2.78 ± 0.11 , 0.5 ± 0.2 , and 1.4 ± 0.5 , respectively. The large differences in R among these final states could point to an interesting role for hadronic effects.

There are other ways, not involving DCS decays, in which D^0 and \bar{D}^0 singly Cabibbo-suppressed decays can populate the

Meson Particle Listings

 D^\pm

same Dalitz plot. Examples are D^0 and \bar{D}^0 decays to $K_S^0 K^+ \pi^-$, or to $K_S^0 K^- \pi^+$. These final states can be used to study D^0 - \bar{D}^0 mixing and the CKM angle γ/ϕ_3 .

CP Violation: In the limit of CP conservation, charge conjugate decays will have the same Dalitz-plot distribution. The $D^{*\pm}$ tag enables the discrimination between D^0 and \bar{D}^0 . The integrated CP violation across the Dalitz plot is determined in two ways. The first uses

$$\mathcal{A}_{CP} = \int \left(\frac{|\mathcal{M}|^2 - |\bar{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\bar{\mathcal{M}}|^2} \right) dm_{ab}^2 dm_{bc}^2 \bigg/ \int dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where \mathcal{M} and $\bar{\mathcal{M}}$ have the same normalization and represent the D^0 and \bar{D}^0 Dalitz-plot amplitudes for the three-body decay $D \rightarrow abc$, and m_{ab} (m_{bc}) is the invariant mass of ab (bc). The second uses the asymmetry in the efficiency-corrected D^0 and \bar{D}^0 yields,

$$\mathcal{A}_{CP} = \frac{N_{D^0} - N_{\bar{D}^0}}{N_{D^0} + N_{\bar{D}^0}}. \quad (2)$$

These expressions are less sensitive to CP violation than are the individual resonant submodes [24–26]. Our Particle Listings give limits on CP violation for 12 D^+ , 52 D^0 , and 13 D_S^+ decay modes. No evidence of CP violation has been observed in D -meson decays.

The possibility of interference between CP -conserving and CP -violating amplitudes provides a more sensitive probe of CP violation. The constraints on the square of the CP -violating amplitudes obtained in the resonant submodes of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ range from 3.5×10^{-4} to 28.4×10^{-4} at 95% confidence level [24]. A similar analysis has been performed by CLEO [25] searching for CP violation in $D^+ \rightarrow K^+ K^- \pi^+$. The constraints on the square of the CP -violating amplitudes in the resonant submodes range from 4×10^{-4} to 51×10^{-4} at 95%. BABAR finds no evidence for CP -violating amplitudes in the resonant submodes of $D^0 \rightarrow K^+ K^- \pi^0$ and $D^0 \rightarrow \pi^+ \pi^- \pi^0$ [26].

$D^+ D^-$ T-VIOLATING DECAY-RATE ASYMMETRIES

$A_{Tviol}(K_S^0 K^\pm \pi^+ \pi^-)$ in $D^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T -odd correlation of the K^+ , π^+ , and π^- momenta for the D^+ . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the D^- . $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D^+ decays (the Γ 's are partial widths). With $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ tests for T violation even with nonzero strong phases.

 D^0 - \bar{D}^0 MIXING

Revised April 2010 by D. Asner (Pacific Northwest National Laboratory)

The detailed formalism for $D^0 - \bar{D}^0$ mixing is presented in the note on “ CP Violation in Meson Decays” in this *Review*. For completeness, we present an overview here. The time evolution of the $D^0 - \bar{D}^0$ system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \left(\mathbf{M} - \frac{i}{2} \mathbf{\Gamma} \right) \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the \mathbf{M} and $\mathbf{\Gamma}$ matrices are Hermitian, and CPT invariance requires that $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$. The off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because CP violation is expected to be quite small here, it is convenient to label the mass eigenstates by the CP quantum number in the limit of CP conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left(\frac{q}{p} \right)^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}. \quad (3)$$

The normalization condition is $|p|^2 + |q|^2 = 1$. Our phase convention is $CP|D^0\rangle = +|\bar{D}^0\rangle$, and the sign is chosen so that D_1 has CP even, or nearly so.

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left(M - \frac{i}{2}\Gamma \right) \pm \frac{q}{p} \left(M_{12} - \frac{i}{2}\Gamma_{12} \right), \quad (4)$$

where $m_{1,2}$ and $\Gamma_{1,2}$ are the masses and widths of the $D_{1,2}$.

We define dimensionless mixing parameters x and y by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$. If CP is conserved, then M_{12} and Γ_{12} are real, $\Delta m = 2M_{12}$, $\Delta\Gamma = 2\Gamma_{12}$, and $p = q = 1/\sqrt{2}$. The signs of Δm and $\Delta\Gamma$ are to be determined experimentally.

The parameters x and y are measured in several ways. The most precise values are obtained using the time dependence of D decays. Since $D^0 - \bar{D}^0$ mixing is a small effect, the identifying tag of the initial particle as a D^0 or a \bar{D}^0 must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence $D^{*+} \rightarrow D^0\pi^+$ or $D^{*-} \rightarrow \bar{D}^0\pi^-$. In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the B -factories allow the production flavor to also be determined by fully reconstructing charm on the “other side” of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the D 's produced from $\psi(3770) \rightarrow D^0\bar{D}^0$ decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the D^0 and \bar{D}^0 do not travel far enough), the quantum-coherent $C = -1$ $\psi(3770) \rightarrow D^0\bar{D}^0$ state provides time-integrated sensitivity [2,3].

Time-Dependent Analyses: We extend the formalism of this *Review*'s note on “ CP Violation in Meson Decays.” In addition to the “right-sign” instantaneous decay amplitudes $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$ and $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$ for CP conjugate final states $f = K^+\pi^-, \dots$ and $\bar{f} = K^-\pi^+, \dots$, we include “wrong-sign” amplitudes $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral D -meson mean lifetime, $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\bar{D}^0\rangle$ state at $t = 0$, the time-dependent rates of decay to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f|H|D^0(t)\rangle|^2}{|\bar{A}_f|^2} = \left| \frac{q}{p} \right|^2 \left| g_+(t) \lambda_f^{-1} + g_-(t) \right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f}|H|\bar{D}^0(t)\rangle|^2}{|A_{\bar{f}}|^2} = \left| \frac{p}{q} \right|^2 \left| g_+(t) \lambda_{\bar{f}} + g_-(t) \right|^2. \quad (8)$$

where

$$\lambda_f \equiv q\bar{A}_f/pA_f, \quad \lambda_{\bar{f}} \equiv q\bar{A}_{\bar{f}}/pA_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} \left(e^{-iz_1 t} \pm e^{-iz_2 t} \right), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of D^0 and \bar{D}^0 would cancel between q/p and \bar{A}_f/A_f and leave λ_f unchanged. We expand $r(t)$ and $\bar{r}(t)$ to second order in x and y for modes in which the ratio of decay amplitudes, $R_D = |A_f/\bar{A}_f|^2$, is very small.

Semileptonic decays: Consider the final state $f = K^+\ell^-\bar{\nu}_\ell$, where $A_f = \bar{A}_{\bar{f}} = 0$ in the Standard Model. The final state f is only accessible through mixing and $r(t)$ is

$$r(t) = |g_-(t)|^2 \left| \frac{q}{p} \right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left| \frac{q}{p} \right|^2. \quad (11)$$

For $\bar{r}(t)$ q/p is replaced by p/q . In the Standard Model, CP violation in charm mixing is small and $|q/p| \approx 1$. In the limit of CP conservation, $r(t) = \bar{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left| \frac{q}{p} \right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} = \frac{1}{2} (x^2 + y^2). \quad (12)$$

Table 1: Results for R_M in D^0 semileptonic decays.

1996	E791 [9]	$K^+\ell^-\bar{\nu}_\ell$	$(1.1^{+3.0}_{-2.7}) \times 10^{-3}$	$< 5.0 \times 10^{-3}$
HFAG [10]			0.13 ± 0.27	

*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the BABAR result has been superseded by Ref. 1, and the Belle result has been superseded by Ref. 4.

Table 1 summarizes results for R_M from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is $R_M = (1.30 \pm 2.69) \times 10^{-4}$.

Wrong-sign decays to hadronic non- CP eigenstates: Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left| \frac{A_f}{\bar{A}_f} \right| \sim O(\tan^2 \theta_c), \quad (13)$$

where R_D is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate, δ_f is the strong phase difference between DCS and CF processes, and θ_c is the Cabibbo angle. The minus sign originates from the sign of V_{us} relative to V_{cd} .

We characterize the violation of CP with the real-valued parameters A_M , A_D , and ϕ . We adopt the parametrization (see Refs. 11 and 12)

$$\left| \frac{q}{p} \right|^2 = \sqrt{\frac{1+A_M}{1-A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left(\frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f+\phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left(\frac{(1-A_D)(1+A_M)}{(1+A_D)(1-A_M)} \right)^{1/4} e^{-i(\delta_f-\phi)}. \quad (16)$$

From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

and A_D is a measure of direct CP violation, while A_M is a measure of CP violation in mixing. The angle ϕ measures CP violation in interference between mixing and decay. While A_M is independent of the decay process, A_D and ϕ , in general, depend on f .

In general, $\lambda_{\bar{f}}$ and λ_f^{-1} are independent complex numbers. More detail on CP violation in meson decays can be found in Ref. 13. To leading order, for A_D and $A_M \ll 1$,

$$r(t) = e^{-t} \left[R_D(1+A_D) + \sqrt{R_D(1+A_M)(1+A_D)} y'_- t + \frac{1}{2}(1+A_M)R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[R_D(1-A_D) + \sqrt{R_D(1-A_M)(1-A_D)} y'_+ t + \frac{1}{2}(1-A_M)R_M t^2 \right] \quad (19)$$

Here

$$y'_\pm \equiv y' \cos \phi \pm x' \sin \phi = y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \quad (20)$$

where

$$x' \equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \quad y' \equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \quad (21)$$

and $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$ is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M , A_D , and ϕ are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left(R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

Meson Particle Listings

D^0

The ratio R is the most readily accessible experimental quantity. In Table 2 are also reported the measurements of R_D and A_D , and their HFAG average [10] from a general fit; all allow for both mixing and CP violation. Typically, the fit parameters are R_D , x'^2 , and y' . Table 3 summarizes the results for y' and x'^2 . Allowing for CP violation, the separate contributions to R can be extracted by fitting the $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^-\pi^+$ decay rates.

Table 2: Results for R , R_D , and A_D in $D^0 \rightarrow K^+\pi^-$.

Year	Exper.	$R(\times 10^{-3})$	$R_D(\times 10^{-3})$	$A_D(\%)$
2007	CDF [14]	4.15 ± 0.10	3.04 ± 0.55	—
2007	BABAR [15]	$3.53 \pm 0.08 \pm 0.04$	$3.03 \pm 0.16 \pm 0.10$	$-2.1 \pm 5.2 \pm 1.5$
2006	Belle [16]	$3.77 \pm 0.08 \pm 0.05$	3.64 ± 0.17	2.3 ± 4.7

2002	CLEO [20]	$K^{*+}\pi^-$	$0.5 \pm 0.2^{+0.6}_{-0.1}$
2001	CLEO [26]	$K^+\pi^-\pi^+\pi^-$	$0.44^{+0.13}_{-0.12} \pm 0.06$
2001	CLEO [27]	$K^+\pi^-\pi^0$	$0.43^{+0.11}_{-0.10} \pm 0.07$
1998	E791 [19]	$K^+\pi^-\pi^+\pi^-$	$0.25^{+0.36}_{-0.34} \pm 0.03$

Extraction of the mixing parameters x and y from the results in Table 3 requires knowledge of the relative strong phase $\delta_{K\pi}$. An interference effect that provides useful sensitivity to $\delta_{K\pi}$ arises in the decay chain $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+\pi^-)$, where f_{CP} denotes a CP -even or -odd eigenstate from D^0 decay, such as K^+K^- or $K_S^0\pi^0$, respectively [28]. Here, the amplitude relation

$$\sqrt{2} A(D_{\pm} \rightarrow K^-\pi^+) = A(D^0 \rightarrow K^-\pi^+) \pm A(\bar{D}^0 \rightarrow K^-\pi^+), \quad (24)$$

where D_{\pm} denotes a CP -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^-\pi^+)|^2 - |A(D_- \rightarrow K^-\pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^-\pi^+)|^2}. \quad (25)$$

This neglects CP violation and uses $\sqrt{R_D} \ll 1$.

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although x and y do not vary across the space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference δ from point to point to determine x and y .

A time-dependent analysis of $D^0 \rightarrow K^+\pi^-\pi^0$ from BABAR [24,29] determines the *relative* strong phase variation across the Dalitz plot and reports $x'' = (2.61^{+0.57}_{-0.68} \pm 0.39)\%$, and $y'' = (-0.06^{+0.55}_{-0.64} \pm 0.34)\%$, where x'' and y'' are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (26)$$

in parallel to x' , y' , and $\delta_{K\pi}$ of Eq. (21). Here $\delta_{K\pi\pi^0}$ is the remaining strong phase difference between the DCS $D^0 \rightarrow K^+\rho^-$ and the CF $\bar{D}^0 \rightarrow K^+\rho^-$ amplitudes and does not vary across the Dalitz plot. Both strong phases, $\delta_{K\pi}$ and $\delta_{K\pi\pi^0}$, can be determined from time-integrated CP asymmetries in correlated $D^0 \bar{D}^0$ produced at the $\psi(3770)$ [28,30].

Both the sign and magnitude of x and y without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody D^0 decays [31,21]. In $D^0 \rightarrow K_S^0\pi^+\pi^-$, the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of

the relative strong phases. CLEO [20] and Belle [21] have measured the relative phase between $D^0 \rightarrow K^*(892)^+\pi^-$ and $D^0 \rightarrow K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$ and $(171.9 \pm 1.3 \text{ (stat. only)})^\circ$, respectively. These results are close to the 180° expected from Cabibbo factors and a small strong phase. Table 5 summarizes the results from Belle [21] of a time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$.

Table 5: Results from Belle time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$ [21]. The errors are statistical, experimental systematic, and decay-model systematic, respectively.

Result	95% C.L. interval
No CP Violation	
$x = (0.80 \pm 0.29_{-0.07-0.14}^{+0.09+0.10})\%$	$(0.0, 1.6)\%$
$y = (0.33 \pm 0.24_{-0.12-0.08}^{+0.08+0.06})\%$	$(-0.34, 0.96)\%$
With CP Violation	
$x = (0.81 \pm 0.30_{-0.07-0.16}^{+0.10+0.09})\%$	$ x < 1.6\%$
$y = (0.37 \pm 0.25_{-0.13-0.08}^{+0.07+0.07})\%$	$ y < 1.04\%$
$ q/p = 0.86_{-0.29-0.03}^{+0.30+0.06} \pm 0.08$	
$\phi = (-14_{-18-3-4}^{+16+5+2})^\circ$	

In addition, Belle [21] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, $K_2^*(1430)^+\pi^-$, $K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4\theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 . For $K^+\pi^-$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4\theta_c$. Similarly, BABAR [22] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The values for R in units of $\tan^4\theta_c$ are 3.45 ± 0.31 , 7.7 ± 3.0 , and 1.7 ± 1.7 , respectively. Recently, BABAR [23] has used a K-matrix formalism to describe the $\pi\pi$ S-wave in $K_S^0\pi^+\pi^-$. The reported values for R in units of $\tan^4\theta_c$ are 2.78 ± 0.11 , 0.5 ± 0.2 , and 1.4 ± 0.5 , respectively. The large differences in R among these final states could point to an interesting role for hadronic effects.

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and \bar{f} , and $A_f = A_{\bar{f}}$ and $\bar{A}_{\bar{f}} = \bar{A}_f$. We denote final states with CP eigenvalues ± 1 by f_\pm and write λ_\pm for λ_{f_\pm} .

The quantity y may be measured by comparing the rate for D^0 decays to non- CP eigenstates such as $K^-\pi^+$ with decays to CP eigenstates such as K^+K^- [12]. If decays to K^+K^- have a shorter effective lifetime than those to $K^-\pi^+$, y is positive.

In the limit of slow mixing ($x, y \ll 1$) and the absence of direct CP violation ($A_D = 0$), but allowing for small indirect CP violation ($|A_M|, |\phi| \ll 1$), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{i\phi}. \quad (27)$$

Table 6: Results for y_{CP} from $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$.

*This measurement is included in the result reported by Ref. 32.

In this scenario, to a good approximation, the decay rates for states that are initially D^0 and \bar{D}^0 to a CP eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (28)$$

$$\bar{r}_\pm(t) \propto \exp(-t/\bar{\tau}_\pm), \quad (29)$$

where τ is measured in units of $1/\Gamma$.

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (30)$$

$$1/\bar{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (31)$$

The effective decay rate to a CP eigenstate combining both D^0 and \bar{D}^0 decays is

$$r_\pm(t) + \bar{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (32)$$

Here

$$y_{CP} = \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (33)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (34)$$

If CP is conserved, $y_{CP} = y$.

All measurements of y_{CP} and A_Γ are relative to the $D^0 \rightarrow K^-\pi^+$ decay rate. Table 6 summarizes the current status of measurements. Belle [35] and BaBar [32,34] have reported y_{CP} and the decay-rate asymmetry for CP even final states

$$A_\Gamma = \frac{\bar{\tau}_+ - \tau_+}{\bar{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\bar{\tau}_+)}{(1/\tau_+) + (1/\bar{\tau}_+)} \quad (35)$$

$$= \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (36)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (37)$$

If CP is conserved, $A_\Gamma = 0$. Recently, Belle [33] has reported y_{CP} for the final state $K_S^0K^+K^-$ which is dominated by the CP odd final state $K_S^0\phi$.

Meson Particle Listings

D^0

Substantial work on the time-integrated CP asymmetries in decays to CP eigenstates are consistent with no CP -violation at the few-percent level [40].

Coherent $D^0\bar{D}^0$ Analyses: Measurements of R_D , $\cos\delta_{K\pi}$, x , and y can be made simultaneously in a combined fit to the single-tag (ST) and double-tag (DT) yields, or individually by a series of “targeted” analyses [28,30].

The “comprehensive” analysis simultaneously measures mixing and DCS parameters by examining various ST and DT rates. Due to quantum correlations in the $C = -1$ and $C = +1$ $D^0\bar{D}^0$ pairs produced in the reactions $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$ and $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$, respectively, the time-integrated $D^0\bar{D}^0$ decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from $D^0\text{--}\bar{D}^0$ mixing.

The following categories of final states are considered:

f or \bar{f} : Hadronic states accessed from either D^0 or \bar{D}^0 decay but that are not CP eigenstates. An example is $K^-\pi^+$, which results from Cabibbo-favored D^0 transitions or DCS \bar{D}^0 transitions.

ℓ^+ or ℓ^- : Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent D^0 .

f_+ or f_- : CP -even and CP -odd eigenstates, respectively.

The decay rates for $D^0\bar{D}^0$ pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both $C = -1$ and $C = +1$, reproducing the work of Ref. 3. Such $D^0\bar{D}^0$ combinations, where both D final states are specified, are double tags. In addition, the rates for single tags, where either the D^0 or \bar{D}^0 is identified and the other neutral D decays generically are given in Ref. 2.

CLEO-c has reported results using 281 pb^{-1} of $e^+e^- \rightarrow \psi(3770)$ data [41,42], where the quantum-coherent $D^0\bar{D}^0$ pairs are in the $C = -1$ state. The values of y , R_M , and $\cos\delta_{K\pi}$ are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are $K^-\pi^+$ (f), $K^+\pi^-$ (\bar{f}), K^-K^+ (f_+), $\pi^+\pi^-$ (f_+), $K_S^0\pi^0\pi^0$ (f_+), $K_L^0\pi^0$ (f_+), $K_S^0\pi^0$ (f_-), $K_S^0\eta$ (f_-), and $K_S^0\omega$ (f_-). The two flavored final states, $K^-\pi^+$ and $K^+\pi^-$, can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one D is fully reconstructed in one of the hadronic modes listed above, and the other D is partially reconstructed, requiring that only an electron be found. When the electron is accompanied by a flavor tag ($D \rightarrow K^-\pi^+$ or $K^+\pi^-$), only the “right-sign” DT sample, where the electron and kaon charges are the same, is used.

The main results of the CLEO-c analysis are the determination of $\cos\delta_{K\pi} = 1.10 \pm 0.35 \pm 0.07$, and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [41,42]. In these fits, which allow $\cos\delta_{K\pi}$ and x^2 to be unphysical, the no-mixing result ($x = y = 0$) is excluded

at 5.0σ . Constraining $\cos\delta_{K\pi}$ and $\sin\delta_{K\pi}$ to $[-1, +1]$ —that is interpreting $\delta_{K\pi}$ as an angle—yields $\delta_{K\pi} = (22_{-12}^{+14+9})^\circ$. Note that measurements of y (Table 5 and Table 6) and y' (Table 3) contribute to the determination of $\delta_{K\pi}$.

Coherent $D^0\bar{D}^0$ production can also be used to determine the average strong phase difference, $\bar{\delta}_f$, and coherence factor, R_f , for a flavor-specific multibody final state, f , such as $K^-\pi^+\pi^0$ [43]. Determining the mixing parameters using multibody decays, without using knowledge of resonant substructure, requires both R_f and $\bar{\delta}_f$. Furthermore, the measurement of R_f improves the determination of the Unitarity Triangle angle γ [44,45]. The parameters $\bar{\delta}_f$ and R_f are defined by

$$R_f e^{-i\bar{\delta}_f} = \frac{\int \mathcal{A}_f(\mathbf{x})\mathcal{A}_{\bar{f}}(\mathbf{x})d\mathbf{x}}{A_f A_{\bar{f}}}. \quad (38)$$

Here $\mathcal{A}_f(\mathbf{x})$ ($\mathcal{A}_{\bar{f}}(\mathbf{x})$) is the amplitude for $D^0 \rightarrow f$ ($D^0 \rightarrow \bar{f}$) at a point in multibody phase space described by parameters \mathbf{x} , and $A_f^2 = \int |\mathcal{A}_f(\mathbf{x})|^2 d\mathbf{x}$. A value of R_f close to unity indicates that only a few intermediate states, with limited overlap in phase space, dominate the decay. Note that while $\bar{\delta}_{K\pi} = \delta_{K\pi}$ (defined in Eq. (13)), knowledge of the resonant substructure is required to relate $\bar{\delta}_{K\pi\pi^0}$ and $\bar{\delta}_{K3\pi}$ to $\delta_{K\pi\pi^0}$ (defined below Eq. (26)) and $\delta_{K3\pi}$, respectively.

CLEO-c has reported results for R_f and $\bar{\delta}_f$ ($f = K^-\pi^+\pi^0$, $K^-\pi^+\pi^+\pi^-$) using 818 pb^{-1} of $e^+e^- \rightarrow \psi(3770)$ data [46]. The DT rates of f tagged by f_\pm , f , or another flavor-specific final state with a kaon of the same sign, e.g. $K^-\pi^+\pi^0$ vs. $K^-\pi^+$, provide the sensitivity to the parameters [43]. A similar analysis strategy is adopted to that reported in Refs [41,42]. Two fits to the DT rates are performed with and without external constraints on the mixing parameters x , y , and $\delta_{K\pi}$. The results of these fits are shown in Table 7. The results of Ref. 46 are not yet included in the HFAG average [10].

Table 7: Results from CLEO-c for mixing parameters from coherent $D^0\bar{D}^0$ decays.

Parameter	Mixing constrained	Mixing unconstrained
$\delta_{K\pi}(\circ)$ [41,42]	22_{-16}^{+14}	< 75 @95% C.L.
$\delta_{K\pi}(\circ)$ [46]	$28.5_{-9.5}^{+9.6}$	50_{-28}^{+38}
x (%) [46]	0.96 ± 0.25	$-0.8_{-2.5}^{+2.9}$
y (%) [46]	0.81 ± 0.16	$0.7_{-2.7}^{+2.4}$
$R_{K\pi\pi^0}$ [46]	0.84 ± 0.07	$0.78_{-0.25}^{+0.11}$
$\bar{\delta}_{K\pi\pi^0}(\circ)$ [46]	47_{-17}^{+14}	59_{-28}^{+32}
$R_{K3\pi}$ [46]	$0.33_{-0.23}^{+0.26}$	$0.36_{-0.30}^{+0.24}$
$\bar{\delta}_{K3\pi}(\circ)$ [46]	-66_{-23}^{+26}	-62_{-53}^{+62}

Summary of Experimental Results: Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For $D^0 \rightarrow K^+\pi^-$, BABAR [15] and CDF [14] find evidence for oscillations with 3.9σ ($\Delta\text{Log}\mathcal{L}$) and 3.8σ (Bayesian), respectively. The most precise measurement for mixing parameters is from Belle [16], which excludes $x^2 = y' = 0$ at 2.1σ .

For y_{CP} in $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$, Belle [35] and BABAR [32] find 3.2σ and 4.1σ effects. The most sensitive measurement of y is in $D^0 \rightarrow K_S^0\pi^+\pi^-$ from Belle [21] and is only 1.2σ significant. In the same analysis, Belle also finds a 2.4σ result for x . The current situation would benefit from better knowledge of the strong phase difference $\delta_{K\pi}$ than provided by the current CLEO-c result [41,42]. This would allow one to unfold x and y from the $D^0 \rightarrow K^+\pi^-$ measurements of x'^2 and y' , and directly compare them to the $D^0 \rightarrow K_S^0\pi^+\pi^-$ results.

The experimental data consistently indicate that the D^0 and \bar{D}^0 do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to short-range processes, significant constraints on a variety of new physics models are obtained [47]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. However, recent evidence opens the window to searches for CP violation, which would provide unequivocal evidence of New Physics.

HFAG Averaging of Charm Mixing Results:

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of x , y , $\delta_{K\pi}$, $\delta_{K\pi\pi^0}$, R_D , $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$, $|q/p|$, and $\text{Arg}(q/p) \equiv \phi$. Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of $D^0 \rightarrow K^{(*)+}\ell^-\bar{\nu}$, K^+K^- , $\pi^+\pi^-$, $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, as well as CLEO-c results for double-tagged branching fractions measured at the $\psi(3770)$.

Figure 1: Two-dimensional 1σ - 5σ contours for (x, y) from measurements of $D^0 \rightarrow K^{(*)+}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [10]). Color version at end of book.

Table 8: HFAG Charm Mixing Average allowing for CP violation [10].

Parameter	HFAG average	95% C.L. interval
$x(\%)$	$0.98^{+0.24}_{-0.26}$	[0.46, 1.44]
$y(\%)$	0.83 ± 0.16	[0.51, 1.14]
$R_D(\%)$	0.337 ± 0.009	[0.320, 0.353]
$\delta_{K\pi}(\circ)$	$26.4^{+9.6}_{-9.9}$	[5.9, 45.8]
$\delta_{K\pi\pi^0}(\circ)$	$14.8^{+20.2}_{-22.1}$	[-30.3, 53.8]
$A_D(\%)$	-2.2 ± 2.4	[-6.9, 2.6]
$ q/p $	$0.86^{+0.18}_{-0.15}$	[0.60, 1.22]
$\phi(\circ)$	$-9.6^{+8.3}_{-9.5}$	[-22.1, 6.3]

For the global fit, confidence contours in the two dimensions (x, y) and $(|q/p|, \phi)$ are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to- 5σ contours. The fits exclude the no-mixing point ($x = y = 0$) at 10.2σ , whether or not CP violation is allowed. The parameters x and y differ from zero by 3.2σ and 4.8σ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 8.

Figure 2: Two-dimensional 1σ - 5σ contours for $(|q/p|, \text{Arg}(q/p))$ from measurements of $D^0 \rightarrow K^{(*)+}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [10]). Color version at end of book.

From the results of the HFAG averaging, the following can be concluded: (1) Since CP violation is small and y_{CP} is positive, the CP -even state is shorter-lived, as in the $K^0\bar{K}^0$

Meson Particle Listings

 D^0

system. (2) However, since x appears to be positive, the CP -even state is heavier, unlike in the $K^0\bar{K}^0$ system. (3) The strong phase difference $\delta_{K\pi}$ is unlikely to be small. (4) There is no evidence yet for CP -violation in the $D^0\bar{D}^0$ system. Observing CP -violation at the current level of sensitivity would indicate new physics.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on “ $D^0\text{-}\bar{D}^0$ Mixing,” above. The experiments usually present $x \equiv \Delta m/\Gamma$. Then $\Delta m = x \Gamma = x \hbar/\tau$.

⁵ The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^{*+} \pi^-$ and $\bar{D}^0 \rightarrow K^{*+} \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .

⁶ The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0 \text{ via } \bar{D}^0)/\Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+ \pi^- \pi^0$ and $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$ is assumed to be small. The width difference here is γ' , which is not the same as γ_{CP} in the note on $D^0\text{-}\bar{D}^0$ mixing.

⁷ LOWREY 09 uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^- \pi^+ \pi^0$ and $D^0 \rightarrow K^- \pi^- 2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $\Delta m = (2.34 \pm 0.61) \times 10^{10} \hbar s^{-1}$.

⁸ The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the $D^0\text{-}\bar{D}^0$ mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0)/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0\text{-}\bar{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03Z assumes the strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

⁹ This LINK 05H limit is inferred from the $D^0\text{-}\bar{D}^0$ mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0)/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0\text{-}\bar{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

¹⁰ This GODANG 00 limit is inferred from the $D^0\text{-}\bar{D}^0$ mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0)/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0\text{-}\bar{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

Meson Particle Listings
 D^0

- 11 AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on " D^0 - \bar{D}^0 Mixing," above.
- 12 This limit is inferred from R_M for $f = K^+ \pi^-$ and $f = K^+ \pi^- \pi^+ \pi^-$. See the note on " D^0 - \bar{D}^0 Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0 - \bar{D}^0 mixing.
- 13 This limit is inferred from R_M for $f = K^+ \ell^- \bar{\nu}_\ell$. See the note on " D^0 - \bar{D}^0 Mixing," above.
- 14 ANJOS 88C assumes that $y = 0$. See the note on " D^0 - \bar{D}^0 Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on " D^0 - \bar{D}^0 Mixing," above.

Due to the strong phase difference between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$, we exclude from the average those measurements of y' that are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0) / \Gamma(K^+ \pi^-)$ given near the end of this D^0 Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics, G 33 1 (2006)).

- 15 This combines the $y_{CP} = (\tau_{K^+ \pi^-} / \tau_{K^- \pi^+}) - 1$ using untagged $K^- \pi^+$ and $K^- K^+$ events of AUBERT 09A1 with the disjoint y_{CP} using tagged $K^- \pi^+$, $K^- K^+$, and $\pi^- \pi^+$ events of AUBERT 08U.
- 16 ZUPANC 09 uses a method based on measuring the mean decay time of $D^0 \rightarrow K_S^0 K^+ K^-$ events for different $K^+ K^-$ mass intervals.
- 17 STARIC 07 compares the lifetimes of D^0 decay to the CP eigenstates $K^+ K^-$ and $\pi^+ \pi^-$ with D^0 decay to $K^- \pi^+$.
- 18 The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$. This limit allows CP violation.
- 19 LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \rightarrow K^- K^+$ (CP even) decays and $D^0 \rightarrow K^- \pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)] / [\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- 20 CSORNA 02 measures the lifetime difference between $D^0 \rightarrow K^- K^+$ and $\pi^- \pi^+$ (CP even) decays and $D^0 \rightarrow K^- \pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)] / [\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- 21 The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0 \text{ via } \bar{D}^0) / \Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+ \pi^- \pi^0$ and $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$ is assumed to be small. The width difference here is y'' , which is not the same as y_{CP} in the note on D^0 - \bar{D}^0 mixing.
- 22 LOWREY 09 uses quantum correlations in $e^+ e^- \rightarrow D^0 \bar{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^- \pi^+ \pi^0$ and $D^0 \rightarrow K^- \pi^- \pi^+$. A fit that includes external measurements of charm mixing parameters gets $2y = (1.62 \pm 0.32) \times 10^{-2}$.
- 23 The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0) / \Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used

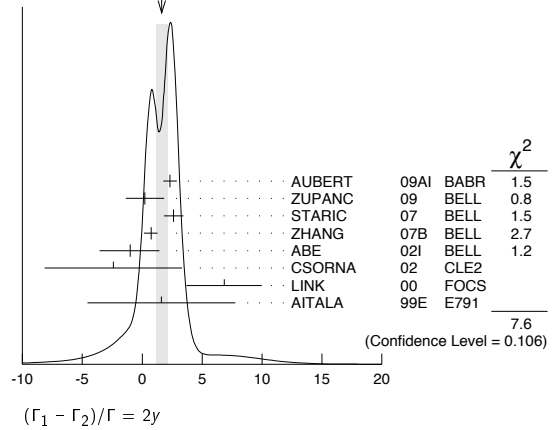

to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow CP violation. The phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. This is a measurement of y' and is not the same as the y_{CP} of our note above on " D^0 - \bar{D}^0 Mixing."

24 This value combines the results of AUBERT 08U and AUBERT 03P.

25 The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.

26 AUBERT 03P measures $Y \equiv 2\tau^0 / (\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \rightarrow K^- \pi^+$ (and $\bar{D}^0 \rightarrow K^+ \pi^-$) lifetime, and τ^+ and τ^- are the D^0 and \bar{D}^0 lifetimes to CP -even states (here $K^- K^+$ and $\pi^- \pi^+$). In the limit of CP conservation, $Y = y \equiv \Delta\Gamma / 2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

WEIGHTED AVERAGE
1.6 ± 0.5 (Error scaled by 1.4)

$|q/p|$

The mass eigenstates D_1^0 and D_2^0 are related to the $C = \pm 1$ states by $|D_{1,2}^0\rangle = p|D^0\rangle + q|\bar{D}^0\rangle$. See the note on " D^0 - \bar{D}^0 Mixing" above.

0.86 $^{+0.18}_{-0.15}$ OUR EVALUATION HFAG fit; see the note on " D^0 - \bar{D}^0 Mixing."

0.86 $^{+0.30 \pm 0.10}_{-0.29 - 0.08}$ 27 ZHANG 07B BELL $e^+ e^- \approx \Upsilon(4S)$

27 The phase of p/q is $(-14^{+16}_{-18} \pm 5)^\circ$. The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$. This value allows CP violation.

A_Γ

A_Γ is the decay-rate asymmetry for CP -even final states $A_\Gamma = (\bar{\tau}_+ - \tau_+) / (\bar{\tau}_+ + \tau_+)$. See the note on " D^0 - \bar{D}^0 Mixing" above.

1.4 ± 2.7 OUR AVERAGE

$\cos \delta$

δ is the $D^0 \rightarrow K^+ \pi^-$ relative strong phase.

1.03 $^{+0.31}_{-0.17}$ ± 0.06 28 ASNER 08 CLEO $e^+ e^- \rightarrow D^0 \bar{D}^0$, 3.77 GeV

28 ASNER 08 uses quantum correlations in $e^+ e^- \rightarrow D^0 \bar{D}^0$ at the $\psi(3770)$, where decay rates of CP -tagged $K\pi$ final states depend on $\cos \delta$ because of interfering amplitudes. The above measurement implies $|\delta| < 75^\circ$ with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds $\cos \delta = 1.10 \pm 0.35 \pm 0.07$. See also the note on " D^0 - \bar{D}^0 Mixing" p. 783 in our 2008 Review (PDG 08).

$D^0 \rightarrow K^- \pi^+ \pi^0$ COHERENCE FACTOR $R_{K\pi\pi^0}$

See the note on " D^0 - \bar{D}^0 Mixing" for the definition. $R_{K\pi\pi^0}$ can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states with limited interference.

0.78 $^{+0.11}_{-0.25}$ 29 LOWREY 09 CLEO $e^+ e^- \rightarrow D^0 \bar{D}^0$ at $\psi(3770)$

29 LOWREY 09 uses quantum correlations in $e^+ e^- \rightarrow D^0 \bar{D}^0$ at the $\psi(3770)$, where the decay rates of CP -tagged $K^- \pi^+ \pi^0$ final states depend on $R_{K\pi\pi^0}$ and $\delta_{K\pi\pi^0}$. A fit that includes external measurements of charm mixing parameters gets $R_{K\pi\pi^0} = 0.84 \pm 0.07$.

 D^0 DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

 Γ_{266} A dummy mode used by the fit. $(39.4 \pm 1.3) \%$ S=1.1

[a] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.

[b] This is the sum of our $K^- 2\pi^+ \pi^-, K^- 2\pi^+ \pi^- \pi^0, \bar{K}^0 2\pi^+ 2\pi^-, K^+ 2K^- \pi^+, 2\pi^+ 2\pi^-, 2\pi^+ 2\pi^- \pi^0, K^+ K^- \pi^+ \pi^-,$ and $K^+ K^- \pi^+ \pi^- \pi^0,$ branching fractions.[c] This is the sum of our $K^- 3\pi^+ 2\pi^-$ and $3\pi^+ 3\pi^-$ branching fractions.[d] The branching fractions for the $K^- e^+ \nu_e, K^*(892)^- e^+ \nu_e, \pi^- e^+ \nu_e,$ and $\rho^- e^+ \nu_e$ modes add up to $6.20 \pm 0.17 \%$.

[e] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[f] This is a doubly Cabibbo-suppressed mode.

[g] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[h] Submodes of the $D^0 \rightarrow K_S^0 \pi^+ \pi^- \pi^0$ mode with a K^* and/or ρ were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667 1** (2008), for those results.

[i] This branching fraction includes all the decay modes of the resonance in the final state.

[j] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.

[k] However, these upper limits are in serious disagreement with values obtained in another experiment.

[l] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[m] The value is for the sum of the charge states or particle/antiparticle states indicated.

[n] This limit is for either D^0 or \bar{D}^0 to $p e^-.$ [o] This limit is for either D^0 or \bar{D}^0 to $\bar{p} e^+.$

4.5 ± 0.8 ± 0.5	56	⁶³ ABACHI	88 HRS	$e^+ e^-$ 29 GeV
4.2 ± 0.4 ± 0.4	930	ADLER	88c MRK3	$e^+ e^-$ 3.77 GeV
4.1 ± 0.6	263 ± 17	⁶⁸ SCHINDLER	81 MRK2	$e^+ e^-$ 3.771 GeV
4.3 ± 1.0	130	⁶⁹ PERUZZI	77 LGW	$e^+ e^-$ 3.77 GeV

⁶¹ DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

⁶² This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

⁶³ ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97c use $D^*(2010)^+ \rightarrow D^0 \pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet ($\approx D^{*+}$ direction). The excess number of such π^+ 's over background gives the number of $D^*(2010)^+ \rightarrow D^0 \pi^+$ events, and the fraction with $D^0 \rightarrow K^- \pi^+$ gives the $D^0 \rightarrow K^- \pi^+$ branching fraction.

⁶⁴ ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\bar{B}^0 \rightarrow D^*(2010)^+ X \ell^- \bar{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

⁶⁵ COAN 98 assumes that $\Gamma(B \rightarrow \bar{D} X \ell^+ \nu) / \Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$, the last term accounting for $\bar{B} \rightarrow D_s^+ K X \ell^- \bar{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

⁶⁶ ALBRECHT 94 uses D^0 mesons from $\bar{B}^0 \rightarrow D^* \ell^- \bar{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

⁶⁷ This AKERIB 93 value includes radiative corrections; without them, the value is $0.0391 \pm 0.0008 \pm 0.0017$. AKERIB 93 is included in the CLEO average in ARTUSO 98.

⁶⁸ SCHINDLER 81 (MARK-2) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be $0.24 \pm 0.02 \text{ nb}$. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6 \text{ nb}$.

⁶⁹ PERUZZI 77 (MARK-1) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be $0.25 \pm 0.05 \text{ nb}$. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6 \text{ nb}$.

-1.7

93 BARLAG 92c computes the branching fraction using topological normalization.

 $\Gamma(K_S^0 \pi^+ \pi^- \pi^0)/\Gamma(K_S^0 \pi^+ \pi^-)$ Γ_{70}/Γ_{34}

Branching fractions for submodes of this mode with narrow resonances (the η , ω , η') are fairly well determined (see below). COFFMAN 92B gives fractions of K^* and ρ submodes, but with only 140 ± 28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

 <0.026 95 107 CRONIN-HEN..05 CLEO $e^+e^- \approx 10$ GeV
 107 The CRONIN-HENNESSY 05 fit here includes, in addition to the three $\rho\pi$ charged states, only the $f_0(980)\pi^0$ mode. See also the next entries for limits obtained in the same way for the $f_0(600)\pi^0$ mode and for an S -wave $\pi^+\pi^-$ parametrized using a K -matrix. Our $\rho\pi$ branching ratios, given above, use the fit with the K -matrix S wave.

WEIGHTED AVERAGE
0.1010±0.0016 (Error scaled by 1.4)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

 $\Gamma(K^+K^-)/\Gamma(\pi^+\pi^-)$ $\Gamma_{171}/\Gamma_{126}$ The unused results here are redundant with $\Gamma(K^+K^-)/\Gamma(K^-\pi^+)$ and $\Gamma(\pi^+\pi^-)/\Gamma(K^-\pi^+)$ measurements by the same experiments.

This is a limit on R_M without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

• • • We do not use the following data for averages, fits, limits, etc. • • •

122 The BITENC 08 right-sign sample includes about 15% of $D^0 \rightarrow K^-\pi^0 e^+\nu_e$ and other decays.

123 AITALA 96C uses $D^{*+} \rightarrow D^0\pi^+$ (and charge conjugate) decays to identify the charm at production and $D^0 \rightarrow K^-\ell^+\nu_\ell$ (and charge conjugate) decays to identify the charm at decay.

$\Gamma(K^+ \text{ or } K^*(892)^+ e^-\nu_e \text{ via } \bar{D}^0)/[\Gamma(K^-e^+\nu_e) + \Gamma(K^*(892)^-e^+\nu_e)]$		$\Gamma_{206}/(\Gamma_{18} + \Gamma_{20})$

This is R , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " D^0 - \bar{D}^0 Mixing," near the start of the D^0 Listings.

The experiments here use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born. The $D^0 \rightarrow K^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \rightarrow \bar{D}^0$ mixing followed by $\bar{D}^0 \rightarrow K^+\pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio R_D , and the following data block for limits on the mixing ratio R_M . See the section on CP -violating asymmetries near the end of this D^0 Listing for values of A_D , and the note on " D^0 - \bar{D}^0 Mixing" for limits on x' and y' .

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal **C3** 1 (1998)) and our 2006 edition (Journal of Physics, G **33** 1 (2006)).

<0.0092	95	141	BARATE	98W	ALEP e^+e^- at Z^0
<0.005	90	142	ANJOS	88c	E691 Photoproduction

136 This ZHANG 06 result allows CP violation, but the result does not change if CP violation is not allowed.

137 This LI 05A result allows CP violation. The limit becomes < 0.00042 (95% CL) if CP violation is not allowed.

138 LINK 05H obtains the same result whether or not CP violation is allowed.

139 This AUBERT 03Z result allows CP violation and assumes that the strong phase between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$ is small, and limits only $D^0 \rightarrow \bar{D}^0$ transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0016.

140 This GODANG 00 result allows CP violation and assumes that the strong phase between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$ is small, and limits only $D^0 \rightarrow \bar{D}^0$ transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0017.

141 This BARATE 98W result assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on " D^0 - \bar{D}^0 Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.036 (95%CL).

142 This ANJOS 88c result assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on " D^0 - \bar{D}^0 Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.019.

 $\Gamma(K_S^0\pi^+\pi^- \text{ in } D^0 \rightarrow \bar{D}^0)/\Gamma(K_S^0\pi^+\pi^-)$ Γ_{210}/Γ_{34}

This is R_M in the note on " D^0 - \bar{D}^0 Mixing" near the start of the D^0 Listings. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

<0.0085 90 150 AITALA 98 E791 π^- nucleus, 500 GeV

<0.0037 90 151 ANJOS 88c E691 Photoproduction

150 AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0 - \bar{D}^0 mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039 $^{+0.0036}_{-0.0032} \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$.$

151 This combines results of ANJOS 88c on $K^+\pi^-$ and $K^+\pi^+\pi^-$ (via \bar{D}^0) reported in the data block above (see footnotes there). It assumes no interference.

 $\Gamma(\mu^- \text{ anything via } \bar{D}^0)/\Gamma(\mu^+ \text{ anything})$ Γ_{219}/Γ_6

This is a D^0 - \bar{D}^0 mixing limit. See the somewhat better limits above.

 -0.080 ± 0.077 845 \pm 40 179 LI 05A BELL See ZHANG 06

175 This ZHANG 06 result allows mixing.

176 This LINK 05H result assumes no mixing. If mixing is allowed, it becomes $0.13 \pm 0.33 \pm 0.10$.

177 This AUBERT 03z limit assumes no mixing. If mixing is allowed, the 95% confidence-level interval is $(-2.8 < A_D < 4.9) \times 10^{-3}$.

178 This GODANG 00 result assumes no D^0 - \bar{D}^0 mixing; it becomes $-0.01 \pm 0.16 \pm 0.01$ when mixing is allowed.

179 This LI 05A result allows mixing.

D⁰- \bar{D}^0 T-VIOLATING DECAY-RATE ASYMMETRIES

D⁰ and \bar{D}^0 are distinguished by the charge of the parent D*: D⁰*+ → D⁰π⁺ and D⁰*- → D⁰π⁻.

A_{Tviol}(K⁺K⁻π⁺π⁻) in D⁰, \bar{D}^0 → K⁺K⁻π⁺π⁻

C_T ≡ $\bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T-odd correlation of the K⁺, π⁺, and π⁻ momenta for the D⁰. $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the \bar{D}^0 . A_T ≡ [Γ(C_T > 0) - Γ(C_T < 0)] / [Γ(C_T > 0) + Γ(C_T < 0)] would, in the absence of strong phases, test for T violation in D⁰ decays (the Γ's are partial widths). With $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, the asymmetry A_{Tviol} ≡ 1/2(A_T - \bar{A}_T) tests for T violation even with nonzero strong phases.

Table with 5 columns: VALUE, EVTS, DOCUMENT ID, TECN, COMMENT. Row 1: +0.010 ± 0.057 ± 0.037, 828 ± 46, LINK, 05E FOCS, γ A, E_γ ≈ 180 GeV

D⁰ CPT-VIOLATING DECAY-RATE ASYMMETRIES

A_{CP T}(K[±]π[±]) in D⁰ → K⁻π[±], \bar{D}^0 → K⁺π⁻

A_{CP T}(t) is defined in terms of the time-dependent decay probabilities P(D⁰ → K⁻π[±]) and $\bar{P}(\bar{D}^0 \rightarrow K^+ \pi^-)$ by A_{CP T}(t) = (P - \bar{P}) / (P + \bar{P}). For small mixing parameters x ≡ Δm/Γ and y ≡ ΔΓ/2Γ (as is the case), and times t, A_{CP T}(t) reduces to [y Re ξ - x Im ξ] Γt, where ξ is the CPT-violating parameter.

The following is actually y Re ξ - x Im ξ.

$D_1(2420)^0$ POLARIZATION AMPLITUDE A_{D_1}

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like $1 + A_{D_1} \cos^2 \theta_h$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1 \rightarrow D^* \pi$ and the $D^* \rightarrow D \pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give $A_{D_1} = 3$.

Meson Particle Listings

D_s^\pm

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$$D_s^+ = c\bar{s}, D_s^- = \bar{c}s, \text{ similarly for } D_s^{* \prime}s$$

D_s^\pm

$$J(P) = 0(0^-)$$

The angular distributions of the decays of the ϕ and $\bar{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\bar{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

D_s^\pm MASS

The fit includes $D_s^\pm, D^0, D_s^{*\pm}, D^{*0}, D_s^{* \prime\pm}, D_1(2420)^0, D_2^*(2460)^0$, and $D_{s1}(2536)^\pm$ mass and mass difference measurements. Measurements of the D_s^\pm mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

Γ_{52}	$2K_S^0 2\pi^+ \pi^-$	(8.4 ±3.5) $\times 10^{-4}$		Γ_{113}	A dummy mode used by the fit. (72.2 ±1.3) %
Hadronic modes without K 's					
Γ_{53}	$\pi^+ \pi^0$	< 6 $\times 10^{-4}$ CL=90%		[a] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non- τ) e^+ exclusive fractions — an $e^+ \nu_e$ with an $\eta, \eta', \phi, K^0, K^{*0},$ or $f_0(980)$ — is 6.90 ± 0.4 %	
Γ_{54}	$2\pi^+ \pi^-$	(1.10±0.06) %		[b] This fraction includes η from η' decays.	
Γ_{55}	$\rho^0 \pi^+$	(2.0 ±1.2) $\times 10^{-4}$		[c] Two times (to include μ decays) the $\eta' e^+ \nu_e$ branching fraction, plus the $\eta' \pi^+, \eta' \rho^+,$ and $\eta' K^+$ fractions, is (18.4 ± 2.3) %, which considerably exceeds the inclusive η' fraction of (11.7 ± 1.8) %. Our best guess is that the $\eta' \rho^+$ fraction, (12.5 ± 2.2) %, is too large.	
Γ_{56}	$\pi^+ (\pi^+ \pi^-)_{S\text{-wave}}$	[g] (9.2 ±0.6) $\times 10^{-3}$		[d] This branching fraction includes all the decay modes of the final-state resonance.	
Γ_{57}	$f_0(980) \pi^+, f_0 \rightarrow \pi^+ \pi^-$			[e] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.	
Γ_{58}	$f_0(1370) \pi^+, f_0 \rightarrow \pi^+ \pi^-$			[f] We decouple the $D_s^+ \rightarrow \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.	
Γ_{59}	$f_0(1500) \pi^+, f_0 \rightarrow \pi^+ \pi^-$			[g] This comes from a model-independent and a K -matrix parametrization of the $\pi^+ \pi^-$ S -wave and is a sum over several f_0 mesons.	
Γ_{60}	$f_2(1270) \pi^+, f_2 \rightarrow \pi^+ \pi^-$	(1.11±0.20) $\times 10^{-3}$		[h] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.	
Γ_{61}	$\rho(1450)^0 \pi^+, \rho^0 \rightarrow \pi^+ \pi^-$	(3.0 ±2.0) $\times 10^{-4}$		[i] The value is for the sum of the charge states or particle/antiparticle states indicated.	
Γ_{62}	$\pi^+ 2\pi^0$	(6.5 ±1.3) $\times 10^{-3}$			
Γ_{63}	$2\pi^+ \pi^- \pi^0$	—			
Γ_{64}	$\eta \pi^+$	[d] (1.56±0.20) %			
Γ_{65}	$\omega \pi^+$	[d] (2.3 ±0.6) $\times 10^{-3}$			
Γ_{66}	$3\pi^+ 2\pi^-$	(8.0 ±0.9) $\times 10^{-3}$			
Γ_{67}	$2\pi^+ \pi^- 2\pi^0$	—

Γ_{93}	$K^+ \omega \pi^+ \pi^-$	[d] < 5.4 $\times 10^{-3}$ CL=90%			

Using this, we have:

$$\begin{aligned} f(K_S^0 K_L^0) &= f(K_S^0) - f(K^+ K_S^0) - f(K^- K_S^0) - 2f(2K_S^0) \\ &\quad - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \\ &\quad - 2 \times (1.70 \pm 0.32) - (1.67 \pm 0.26) \\ &= (6.2 \pm 1.4)\% . \end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors will be secondary.

There is a check on our result: The ϕ inclusive branching fraction is $(15.7 \pm 1.0)\%$, of which 34%, or $(5.34 \pm 0.34)\%$ of D_s^+ decays, produces a $K_S^0 K_L^0$. Our $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$ has to be at least this large—and it is.

We now make a table. The first column gives the various particle pairings; here we use $f(K^+ \bar{K}^0) = 2f(K^+ K_S^0)$, and likewise for $f(K^- K^0)$. The second column gives the inclusive branching fractions; the third column gives the fractions for $K^+ K^-$ and $K_S^0 K_L^0$ from $\phi \ell^+ \nu$ decay; the last column subtracts these off to get the purely hadronic $K\bar{K}$ inclusive fractions.

$K^+ K^-$	15.8 (0.7)%	2.44 (0.14)%	13.4 (0.7)%
$K^+ \bar{K}^0$	11.6 (1.0)		11.6 (1.0)
$K^- K^0$	3.8 (0.8)		3.8 (0.8)
$K_S^0 K_S^0 + K_L^0 K_L^0$	3.4 (0.64)		3.4 (0.64)
$K_S^0 K_L^0$	6.2 (1.4)	1.69 (0.10)	4.5 (1.4) .

The values in the last column are shown in Fig. 1. Their sum is $(36.7 \pm 2.1)\%$.

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

$K^+ K^-$ modes—The sum of measured $K^+ K^- \pi^+$, $K^+ K^- \pi^+ \pi^0$, and $K^+ K^- 2\pi^+ \pi^-$ branching fractions is $(12.0 \pm 0.6)\%$. That leaves $(1.4 \pm 0.9)\%$ for the $K^+ K^- \pi^+ 2\pi^0$ mode, which is the only other $K^+ K^-$ mode with three or fewer pions. In Fig. 1, this unmeasured part of the $K^+ K^-$ bin is shaded.

$K^+ \bar{K}^0$ modes—Twice the sum of measured $K^+ K_S^0$ and $K^+ K_S^0 \pi^+ \pi^-$ branching fractions is $(4.9 \pm 0.3)\%$. This leaves $(6.7 \pm 1.0)\%$ for the unmeasured $K^+ \bar{K}^0$ modes (there are four such modes with three or fewer pions). This is shaded in the figure.

$K^- K^0$ modes—Twice the $K^- K_S^0 2\pi^+$ fraction is $(3.28 \pm 0.24)\%$, which leaves about $(0.5 \pm 0.8)\%$ for $K^- K^0 2\pi^+ \pi^0$, the only other $K^- K^0$ mode with three or fewer pions.

$K^0 \bar{K}^0$ modes—The only measurement of $K^0 \bar{K}^0$ decays is of the $2K_S^0 2\pi^+ \pi^-$ fraction, $(0.084 \pm 0.035)\%$; so nearly everything is shaded here. However, most of the $K_S^0 K_L^0$ fraction is accounted for by ϕ decays (see below).

Inclusive hadronic η , ω , η' , and ϕ fractions: These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2) η mesons that are included in the inclusive η' fraction; and (3) $K^+ K^-$ and $K_S^0 K_L^0$ from ϕ decays:

$$\begin{aligned} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\ &\quad - f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \end{aligned}$$

$$\begin{aligned} f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.03 f(\eta' \text{ inclusive}) \\ &= (5.7 \pm 1.4)\% \end{aligned}$$

$$\begin{aligned} f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \end{aligned}$$

$$\begin{aligned} f(\phi \text{ hadronic, } \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) \\ &\quad - f(\phi \ell^+ \nu)] = (1.8 \pm 0.2)\% . \end{aligned}$$

The factors 0.65, 0.03, and 0.17 are the $\eta' \rightarrow \eta$, $\eta' \rightarrow \omega$, and $\phi \not\rightarrow K\bar{K}$ branching fractions. Figure 1 shows the results; the sum is $(34.2 \pm 3.9)\%$, which is about equal to the hadronic $K\bar{K}$ total.

Note that the bin marked ϕ near the top of Fig. 1 includes neither the $\phi \ell^+ \nu$ decays nor the 83% of other ϕ decays that produce a $K\bar{K}$ pair. Compared to the size of that ϕ bin, there is twice as much ϕ in the $K_S^0 K_L^0$ bin, and nearly three times as much in the $K^+ K^-$ bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

η modes—The sum of $\eta \pi^+$, $\eta \rho^+$, and ηK^+ branching fractions is $(10.6 \pm 0.8)\%$, which leaves a good part of the inclusive hadronic η fraction, $(17.0 \pm 3.1)\%$, to be accounted for. This is shaded in the figure.

ω modes—The sum of $\omega \pi^+$, $\omega \pi^+ \pi^0$, and $\omega 2\pi^+ \pi^-$ fractions is $(4.6 \pm 0.9)\%$, which is nearly as large as the inclusive hadronic ω fraction, $(5.7 \pm 1.4)\%$.

η' modes—The sum of $\eta' \pi^+$, $\eta' \rho^+$, and $\eta' K^+$ fractions is $(16.5 \pm 2.2)\%$, which is much larger than the inclusive hadronic η' fraction, $(9.7 \pm 1.9)\%$. If an exclusive measurement is at fault, it almost has to be the $\eta' \rho^+$ fraction, which is $(12.5 \pm 2.2)\%$. It has been suggested that some of this signal might instead be misidentified kinematic reflections of other modes [2].

Cabibbo-suppressed modes: Remaining is $(9.1 \pm 4.5)\%$ for hadronic Cabibbo-suppressed modes having no η , ω , η' , or ϕ . The contributions are:

$K^0 + \text{pions}$ —Above, we found that $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$; subtracting leptonic contributions leaves $(1.20 \pm 0.24)\%$. The hadronic single- K^0 fraction is twice this, $(2.40 \pm 0.48)\%$.

$K^+ + \text{pions}$ —The $K^+ \pi^0$ and $K^+ \pi^+ \pi^-$ fractions sum to $(0.77 \pm 0.05)\%$. Much of the $K^+ n\pi$ modes, where $n \geq 3$, is already in the η , ω , and η' bins, and the rest is not measured. The total K^+ fraction wanted here is probably in the 1-to-2% range.

Multi-pions —The $2\pi^+ \pi^-$, $\pi^+ 2\pi^0$, and $3\pi^+ 2\pi^-$ fractions total $(2.6 \pm 0.2)\%$. Modes not measured might double this.

Meson Particle Listings

 D_s^\pm

The sum of the three contributions is certainly not inconsistent with the Cabibbo-suppressed total of $(9.1 \pm 4.5)\%$. The sum of actually measured fractions is $(4.2 \pm 0.2)\%$.

A model: With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [2]. Consider, say, the $D_s^+ \rightarrow K\bar{K}\pi$ charge modes: the $K^+K^-\pi^+$ branching fraction is measured, the $K^+\bar{K}^0\pi^0$ and $K^0\bar{K}^0\pi^+$ fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for $D_s^+ \rightarrow K\bar{K}\pi$ decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that $D_s^+ \rightarrow K\bar{K}\pi$ decay is dominated by $\phi\pi^+$, $K^+\bar{K}^{*0}$, and $K^{*+}\bar{K}^0$ submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of D_s^+ decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of π^+ , K_S^0 , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

Leptonic and semileptonic modes

DECAY CONSTANTS OF CHARGED PSEUDO-SCALAR MESONS

Revised April 2010 by J. Rosner (Univ. Chicago) and S. Stone (Syracuse Univ.)

Introduction. Charged mesons formed from a quark and an anti-quark can decay to a charged lepton and a neutrino when these objects annihilate via a virtual W boson [1]. Fig. 1 illustrates this process for the purely leptonic decay of a D^+ meson.

Figure 1: The annihilation process for pure D^+ leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual W^+ to the $\ell^+\nu$ final states occur for the π^+ , K^+ , D_s^+ , and B^+ mesons. (Charge-conjugate particles and decays are implied.) Let P be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 m_P \left(1 - \frac{m_\ell^2}{m_P^2}\right)^2 |V_{q_1 q_2}|^2. \quad (1)$$

Here m_P is the P mass, m_ℓ is the ℓ mass, $V_{q_1 q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks $q_1 \bar{q}_2$ in P , and G_F is the Fermi coupling constant. The parameter f_P is the decay constant, and is related to the wave-function overlap of the quark and antiquark.

The decay P^\pm starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the ℓ^\pm must then also be left-handed or right-handed, respectively. In the $m_\ell = 0$ limit, the decay is forbidden, and can only occur as a result of the finite ℓ mass. This helicity suppression is the origin of the m_ℓ^2 dependence of the decay width.

There is a complication in measuring purely leptonic decay rates. The process $P \rightarrow \ell\nu\gamma$ is not simply a radiative correction, although radiative corrections contribute. The P can make a transition to a virtual P^* , emitting a real photon, and the P^* decays into $\ell\nu$, avoiding helicity suppression. The importance of this amplitude depends on the decaying particle and the detection technique. The $\ell\nu\gamma$ rate for a heavy particle such as B decaying into a light particle such as a muon can be larger than the width without photon emission [2]. On the other hand, for decays into a τ^\pm , the helicity suppression is mostly broken and these effects appear to be small.

Measurements of purely leptonic decay branching fractions and lifetimes allow experimental determination of the product $|V_{q_1 q_2}| f_P$. If the CKM element is well known from other measurements, then f_P can be well measured. If, on the other hand, the CKM element is not well measured, having theoretical input on f_P can allow a determination of the CKM element. The

importance of measuring $\Gamma(P \rightarrow \ell\nu)$ depends on the particle being considered. For the B system, f_B is crucial for extracting information on the fundamental CKM parameters from measurements of $B^0\text{-}\bar{B}^0$ mixing. Knowledge of f_{B_s} is also needed, but it cannot be directly measured as the B_s is neutral, so the violation of the SU(3) relation $f_{B_s} = f_B$ must be estimated theoretically. This difficulty does not occur for D mesons as both the D^+ and D_s^+ are charged, allowing direct measurement of SU(3) breaking and a direct comparison with theory.

For B^- and D_s^+ decays, the existence of a charged Higgs boson (or any other charged object beyond the Standard Model) would modify the decay rates; however, this would not necessarily be true for the D^+ [3,4]. More generally, the ratio of $\tau\nu$ to $\mu\nu$ decays can serve as one probe of lepton universality [3,5].

As $|V_{ud}|$ has been quite accurately measured in superallowed β decays [6], with a value of 0.97425(22) [7], measurements of $\Gamma(\pi^+ \rightarrow \mu^+\nu)$ yield a value for f_π . Similarly, $|V_{us}|$ has been well measured in semileptonic kaon decays, so a value for f_K from $\Gamma(K^- \rightarrow \mu^-\bar{\nu})$ can be compared to theoretical calculations. Lattice gauge theory calculations, however, have been claimed to be very accurate in determining f_K , and these have been used to predict $|V_{us}|$ [8].

Charmed mesons. We review current measurements, starting with the charm system. The CLEO collaboration has performed the only measurement of the branching fraction for $D^+ \rightarrow \mu^+\nu$ [9]. CLEO uses e^+e^- collisions at the $\psi(3770)$ resonant energy where D^-D^+ pairs are copiously produced. They fully reconstruct one of the D mesons, find a candidate muon track of opposite sign to this tag, and then use kinematical constraints to infer the existence of a missing neutrino and hence the $\mu\nu$ decay of the other D . They find $\mathcal{B}(D^+ \rightarrow \mu^+\nu) = (3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$. We use the well-measured D^+ lifetime of 1.040(7) ps, and assuming $|V_{cd}|$ equals $|V_{us}| = 0.2246(12)$ [7] minus higher order correction terms [10], we find $|V_{cd}| = 0.2245(12)$. (The errors on these quantities are included in the systematic error.) The CLEO branching fraction result then translates into a value of

$$f_{D^+} = (206.7 \pm 8.5 \pm 2.5) \text{ MeV}. \quad (2)$$

This result includes a 1% correction (reduction) of the rate due to the presence of the radiative $\mu^+\nu\gamma$ final state based on the estimate by Dobrescu and Kronfeld [11].

Before we compare this result with theoretical predictions, we discuss the D_s^+ . Measurements of $f_{D_s^+}$ have been made by several groups and are listed in Table 1 [12–16]. We exclude values [17–21] obtained by normalizing to D_s^+ decay modes (mentioned in the 2008 version of this Review) that are not well defined. Many measurements, for example, used the $\phi\pi^+$ mode. This decay is a subset of the $D_s^+ \rightarrow K^+K^-\pi^+$ channel which has interferences from other modes populating the K^+K^- mass region near the ϕ , the most prominent of which is the $f_0(980)$. Thus the extraction of effective $\phi\pi^+$ rate is sensitive to the mass resolution of the experiment and the cuts used to define the ϕ mass region [22,23].

Meson Particle Listings

 D_s^\pm

Table 1: Experimental results for $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$, $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$, and $f_{D_s^+}$. Numbers for $f_{D_s^+}$ have been extracted using updated values for masses and $|V_{cs}|$ (see text); radiative corrections have been included. Common systematic errors in the CLEO results have been taken into account.

Experiment	Mode	$\mathcal{B} \times 10^{-2}$	$f_{D_s^+}$ (MeV)
CLEO-c [12]	$\mu^+\nu$	$(0.565 \pm 0.045 \pm 0.017)$	$257.6 \pm 10.3 \pm 4.3$

The CLEO and Belle $\mu^+\nu$ results rely on fully reconstructing all the final state particles except for the neutrino and using a missing-mass technique to infer the existence of the neutrino. CLEO uses $e^+e^- \rightarrow D_s D_s^*$ collisions at 4170 MeV, while Belle uses $e^+e^- \rightarrow DKn\pi D_s^*$ collisions at energies near the $\Upsilon(4S)$.

When selecting the $\tau^+ \rightarrow \pi^+\bar{\nu}$ and $\tau^+ \rightarrow \rho^+\bar{\nu}$ decay modes, CLEO uses both calculation of the missing-mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged D_s^- and the τ^+ decay products. The $\tau^+ \rightarrow e^+\nu\bar{\nu}$ mode, however, uses only extra energy. BaBar measures $\Gamma(D_s^+ \rightarrow \tau^+\nu)/\Gamma(D_s^+ \rightarrow \bar{K}^0 K^+)$ using the $\tau^+ \rightarrow e^+\nu\bar{\nu}$ mode. Here the D_s^- tag is formed similarly to Belle by finding events with a D a K and pions opposite a single positron and little extra energy. Then the analysis is performed selecting modes with a $\bar{K}^0 K^+$ consistent with arising from the decay of a D_s^+ . (The fourth error in Table 1 on their measurement reflects the uncertainty due to the PDG value of $\mathcal{B}(D_s^+ \rightarrow \bar{K}^0 K^+)$.)

We extract the decay constant from the measured branching ratios using the D_s^+ mass of 1.96849(34) GeV, the τ^+ mass of 1.77684(17) GeV, and a lifetime of 0.500(7) ps. We use the first order correction $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$ [10]; taking $|V_{ud}| = 0.97425(22)$ [6], and $|V_{cb}| = 0.04$ from an average of exclusive and inclusive semileptonic B decay results as discussed in Ref. [24], we find $|V_{cs}| = 0.97345(22)$. Our experimental average,

$$f_{D_s^+} = (257.5 \pm 6.1) \text{ MeV}, \quad (3)$$

uses only those results that are included in Table 1. We have again included the radiative correction of 1% in the $\mu^+\nu$ rates listed in the table estimated by Dobrescu and Kronfeld [11] (the $\tau^+\nu$ rates need not be corrected). Other theoretical calculations show that the $\gamma\mu^+\nu$ rate is a factor of 40–100 below the $\mu^+\nu$ rate for charm [25].

Two ratios are of particular interest. The ratio of decay constants for the $\tau^+\nu : \mu^+\nu$ modes is $f_{D_s^+}(\tau^+\nu)/f_{D_s^+}(\mu^+\nu) = 0.98 \pm 0.05$, and the ratio of D_s^+ to D^+ decay constants is $f_{D_s^+}/f_{D^+} = 1.25 \pm 0.06$. Table 2 compares the experimental $f_{D_s^+}$ with theoretical calculations [26–36]. While most theories give values lower than the $f_{D_s^+}$ measurement, the errors are sufficiently large, in most cases, to declare success. An unquenched lattice calculation [26], however, differs by 2.4 standard deviations [37]. Remarkably it agrees with f_{D^+} and consequently disagrees in the ratio $f_{D_s^+}/f_{D^+}$, with less significance as the error in f_{D^+} is substantial.

The Fermilab-MILC result has been updated; the preliminary values for f_{D^+} and $f_{D_s^+}$ were raised by 10 MeV and 11 MeV, respectively [27]. These changes bring the predictions for both numbers within errors of experiment.

Akeroyd and Chen [38] pointed out that leptonic decay widths are modified in two-Higgs-doublet models (2HDM). Specifically, for the D^+ and D_s^+ , Eq. (1) is modified by a factor r_q multiplying the right-hand side [39]:

$$r_q = \left[1 + \left(\frac{1}{m_c + m_q} \right) \left(\frac{M_{D_q}}{M_{H^+}} \right)^2 \left(m_c - \frac{m_q \tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right) \right]^2, \quad (4)$$

where M_{H^+} is the charged Higgs mass, M_{D_q} is the mass of the D meson (containing the light quark q), m_c is the charm quark mass, m_q is the light-quark mass, and $\tan \beta$ is the ratio of the vacuum expectation values of the two Higgs doublets. In models where the fermion mass arises from coupling to more than one vacuum expectation value ϵ_0 can be non-zero, perhaps as large as 0.01. For the D^+ , $m_d \ll m_c$, and the change due to the H^+ is very small. For the D_s^+ , however, the effect can be substantial.

A major concern is the need for the Standard Model (SM) value of $f_{D_s^+}$. We can take that from a theoretical model. Our most aggressive choice is that of the unquenched lattice calculation [26], because they claim the smallest error. Since the charged Higgs would lower the rate compared to the SM, in principle, experiment gives a lower limit on the charged Higgs mass. However, the value for the predicted decay constant using this model is 2.4 standard deviations *below* the measurement, implying that (a) either the model of Ref. 26 is not representative; (b) no value of m_{H^+} in the two-Higgs doublet model will satisfy the constraint at 99% confidence level; or (c) there is new physics, different from the 2HDM, that interferes constructively with the SM amplitude such as in the R-parity-violating model of Akeroyd and Recksiegel [40]. New physics can affect the $\mu^+\nu$ and $\tau^+\nu$ final states differently and thus these should be studied separately [39].

To sum up, the situation is not clear. To set limits on new physics we need an accurate calculation of $f_{D_s^+}$ and more precise measurements would also be useful.

The B meson. The Belle and BaBar collaborations have found evidence for $B^- \rightarrow \tau^-\bar{\nu}$ decay in $e^+e^- \rightarrow B^- B^+$ collisions at the $\Upsilon(4S)$ energy. The analysis relies on reconstructing a hadronic or semi-leptonic B decay tag, finding a τ candidate in the remaining track and or photon candidates, and examining the extra energy in the event which should be close to zero for a real τ decay opposite a B meson tag. The results are listed in Table 3.

There are large backgrounds under the signals in all cases. The systematic errors are also quite large, on the order of 20%. Thus the significances are not that large. Belle quotes 3.5σ and 3.8σ for their hadronic and semileptonic tags, respectively, while BaBar quotes 2.8σ for their combined result. We note that the four central values are remarkably close to the average considering the large errors on all the measurements. More accuracy would be useful to investigate the effects of new physics. Here the effect of a charged Higgs is different as it can either increase or decrease the expected SM branching ratio.

Meson Particle Listings

 D_s^\pm

Table 3: Experimental results for $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$. We have computed an average for the two Belle measurements assuming that the systematic errors are fully correlated.

Experiment	Tag	$\mathcal{B} \times 10^{-4}$
Belle [41]	Hadronic	$(1.79^{+0.56}_{-0.49} \text{ } ^{+0.46}_{-0.51})$
Belle [42]	Semileptonic	$(1.65^{+0.38}_{-0.37} \text{ } ^{+0.35}_{-0.34})$
Belle	Our Average	$(1.70^{+0.47}_{-0.46})$
BaBar [43]	Hadronic	$(1.8^{+0.9}_{-0.8} \pm 0.4)$
BaBar [44]	Semileptonic	$(1.7 \pm 0.8 \pm 0.4)$
BaBar [44]	Average	$(1.8^{+1.0}_{-0.9})$
	Our Average	$(1.72^{+0.43}_{-0.42})$

The factor r in the 2HDM that multiplies the right side of Eq. (1) is given in terms of the B meson mass, M_B , by [3,39]

$$r = \left(1 - \frac{\tan^2 \beta}{1 + \epsilon_0 \tan \beta} \frac{M_B^2}{m_{H^+}^2} \right)^2. \quad (5)$$

We can derive limits in the 2HDM $\tan\beta$ - m_{H^+} plane. Again, we need to know the SM prediction of this decay rate. We ascertain this value using Eq. (1). Here theory provides a value of $f_B = (193 \pm 11)$ MeV [45]. We also need a value for $|V_{ub}|$. Here significant differences arise between using inclusive charmless semileptonic decays and the exclusive decay $B \rightarrow \pi \ell^+ \nu$ [46]. We find that the inclusive decays give rise to a value of $|V_{ub}| = (4.21 \pm 0.25) \times 10^{-3}$, while the $\pi \ell^+ \nu$ measurements yield $|V_{ub}| = (3.50 \pm 0.35) \times 10^{-3}$. Taking an average over inclusive and exclusive determinations, and enlarging the error using the PDG prescription because the results differ, we find $|V_{ub}| = (3.97 \pm 0.55) \times 10^{-3}$, where the error is dominantly theoretical. We thus arrive at the SM prediction for the $\tau^- \bar{\nu}$ branching fraction of $(1.04 \pm 0.31) \times 10^{-4}$.

Taking the ratio of the experimental value to the predicted branching ratio at its 90% c.l. *upper* limit and using Eq. (5) with ϵ_0 set to zero, we find that we can limit $M_{H^+} / \tan\beta > 3.3$ GeV. The 90% c.l. *lower* limit also permits us to exclude the region 3.8 GeV $< M_{H^+} / \tan\beta < 18.0$ GeV [47]. Considering the large uncertainties on V_{ub} and the branching ratio measurements, this should be taken more as indication of what the data can eventually tell us when and if the situation improves.

Charged pions and kaons. We now discuss the determination of charged pion and kaon decay constants. The sum of branching fractions for $\pi^- \rightarrow \mu^- \bar{\nu}$ and $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$ is 99.98770(4)%. The two modes are difficult to separate experimentally, so we use this sum, with Eq. (1) modified to include photon emission and radiative corrections [48]. The branching fraction together with the lifetime 26.033(5) ns gives

$$f_{\pi^-} = (130.41 \pm 0.03 \pm 0.20) \text{ MeV}. \quad (6)$$

The first error is due to the error on $|V_{ud}|$, 0.97425(22) [6]; the second is due to the higher-order corrections, and is much larger.

Similarly, the sum of branching fractions for $K^- \rightarrow \mu^- \bar{\nu}$ and $K^- \rightarrow \mu^- \bar{\nu} \gamma$ is 63.55(11)%, and the lifetime is 12.3840(193) ns [49]. Measurements of semileptonic kaon decays provide a value for the product $f_+(0)|V_{us}|$, where $f_+(0)$ is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. We use a value for $f_+(0)|V_{us}|$ of 0.21664(48) [49]. The $f_+(0)$ must be determined theoretically. We follow Blucher and Marciano [7] in using the lattice calculation $f_+(0) = 0.9644 \pm 0.0049$ [50], since it appears to be more precise than the classic Leutwyler-Roos calculation $f_+(0) = 0.961 \pm 0.008$ [51]. The result is $|V_{us}| = 0.2246 \pm 0.0012$, which is consistent with the hyperon decay value of 0.2250 ± 0.0027 [52]. We derive

$$f_{K^-} = (156.1 \pm 0.2 \pm 0.8 \pm 0.2) \text{ MeV}. \quad (7)$$

The first error is due to the error on Γ ; the second is due to the CKM factor $|V_{us}|$, and the third is due to the higher-order corrections. The largest source of error in these corrections depends on the QCD part, which is based on one calculation in the large N_c framework. We have doubled the quoted error here; this would probably be unnecessary if other calculations were to come to similar conclusions. A large part of the additional uncertainty vanishes in the ratio of the K^- and π^- decay constants, which is

$$f_{K^-}/f_{\pi^-} = 1.197 \pm 0.002 \pm 0.006 \pm 0.001. \quad (8)$$

The first error is due to the measured decay rates; the second is due to the uncertainties on the CKM factors; the third is due to the uncertainties in the radiative correction ratio.

These measurements have been used in conjunction with calculations of f_K/f_π in order to find a value for $|V_{us}|/|V_{ud}|$. Two recent lattice predictions of f_K/f_π are 1.189 ± 0.007 [26] and $1.192 \pm 0.007 \pm 0.006$ [53]. Together with the precisely measured $|V_{ud}|$, this gives an independent measure of $|V_{us}|$ [8,49].

$6.8 \pm 1.1 \pm 1.8$	553	⁶ HEISTER 02i	ALEP Z decays

⁴ WIDHALM 08 gets $f_{D_s} = (275 \pm 16 \pm 12)$ MeV from the branching fraction.
⁵ PEDLAR 07A also fits μ^+ and τ^+ events together and gets an effective $\mu^+ \nu_\mu$ branching fraction of $(6.38 \pm 0.59 \pm 0.33) \times 10^{-3}$
⁶ This HEISTER 02i result is not actually an independent measurement of the absolute $\mu^+ \nu_\mu$ branching fraction, but is in fact based on our $\phi\pi^+$ branching fraction of 3.6 ± 0.9%, so it cannot be included in our overall fit. HEISTER 02i combines its $D_s^+ \rightarrow \tau^+ \nu_\tau$ and $\mu^+ \nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.

$\Gamma(\mu^+ \nu_\mu)/\Gamma(\phi\pi^+)$		Γ_{20}/Γ_{32}	
VALUE	EVTS	DOCUMENT ID	TECN COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••			
$0.143 \pm 0.018 \pm 0.006$	489 ± 55	⁷ AUBERT 07v	BABR $e^+ e^- \approx \Upsilon(4S)$
$0.23 \pm 0.06 \pm 0.04$	18	⁸ ALEXANDROV 00	BEAT π^- nucleus, 350 GeV
$0.173 \pm 0.023 \pm 0.035$	182	⁹ CHADHA 98	CLE2 $e^+ e^- \approx \Upsilon(4S)$
$0.245 \pm 0.052 \pm 0.074$	39	¹⁰ ACOSTA 94	CLE2 See CHADHA 98

⁷ AUBERT 07v gets $f_{D_s} = (283 \pm 17 \pm 16)$ MeV, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = (4.71 \pm 0.46)\%$.
⁸ ALEXANDROV 00 uses $f_D^2/f_{D_s}^2 = 0.82 \pm 0.09$ from a lattice-gauge-theory calculation to get the relative numbers of $D^+ \rightarrow \mu^+ \nu_\mu$ and $D_s^+ \rightarrow \mu^+ \nu_\mu$ events. The present result leads to $f_{D_s} = (323 \pm 44 \pm 36)$ MeV.
⁹ CHADHA 98 obtains $f_{D_s} = (280 \pm 19 \pm 28 \pm 34)$ MeV from this measurement, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.036 \pm 0.009$.
¹⁰ ACOSTA 94 obtains $f_{D_s} = (344 \pm 37 \pm 52 \pm 42)$ MeV from this measurement, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.037 \pm 0.009$.

$7.4 \pm 2.8 \pm 2.4$	16	¹⁵ ACCIARRI 97f	L3 $D_s^{*+} \rightarrow \gamma D_s^+$ from Z's

¹¹ ALEXANDER 09, NAIK 09A, and ONYISI 09 use different τ decay modes and are independent. The three papers combined give $f_{D_s} = (259.7 \pm 7.8 \pm 3.4)$ MeV.
¹² ECKLUND 08 and PEDLAR 07A are independent: ECKLUND 08 uses $\tau^+ \rightarrow e^+ \nu_e \bar{\nu}_\tau$ events, PEDLAR 07A uses $\tau^+ \rightarrow \pi^+ \bar{\nu}_\tau$ events.
¹³ HEISTER 02i combines its $D_s^+ \rightarrow \tau^+ \nu_\tau$ and $\mu^+ \nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.
¹⁴ This ABBIENDI 01L value gives a decay constant f_{D_s} of $(286 \pm 44 \pm 41)$ MeV.
¹⁵ The second ACCIARRI 97f error here combines in quadrature systematic (0.016) and normalization (0.018) errors. The branching fraction gives $f_{D_s} = (309 \pm 58 \pm 33 \pm 38)$ MeV.

5.50 ± 0.23 ± 0.16	22 ALEXANDER 08	CLEO	$e^+ e^-$ at 4.17 GeV

²²ALEXANDER 08 uses single- and double-tagged events in an overall fit. The correlation matrix for the branching fractions is used in the fit.

 $\Gamma(\phi\pi^+)/\Gamma_{\text{total}}$ Γ_{32}/Γ

The results here are model-independent. For earlier, model-dependent results, see our PDG 06 edition. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+$, $\phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.

3.9 +5.1 +1.8
-1.9 -1.1

26 BAI 95c BES $e^+ e^-$ 4.03 GeV

²³This AUBERT 06N measurement uses $\bar{B}^0 \rightarrow D_s^{(*)-} D^{(*)+}$ and $B^- \rightarrow D_s^{(*)-} D^{(*)0}$ decays, including some from other papers. However, the result is independent of AUBERT 05V.

²⁴AUBERT 05V uses the ratio of $B^0 \rightarrow D^{*-} D_s^{*+}$ events seen in two different ways, in both of which the $D^{*-} \rightarrow \bar{D}^0 \pi^-$ decay is fully reconstructed: (1) The $D_s^{*+} \rightarrow D_s^+ \gamma$, $D_s^+ \rightarrow \phi\pi^+$ decay is fully reconstructed. (2) The number of events in the D_s^+ peak in the missing mass spectrum against the $D^{*-} \gamma$ is measured.

²⁵ARTUSO 96 uses partially reconstructed $\bar{B}^0 \rightarrow D^{*+} D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^- \rightarrow \phi\pi^-)/\Gamma(D^0 \rightarrow K^- \pi^+)$ of $0.92 \pm 0.20 \pm 0.11$.

²⁶BAI 95c uses $e^+ e^- \rightarrow D_s^+ D_s^-$ events in which one or both of the D_s^\pm are observed to obtain the first model-independent measurement of the $D_s^+ \rightarrow \phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^\pm)$. However, with only two “doubly-tagged” events, the statistical error is very large.

 $\Gamma(\phi\pi^+, \phi \rightarrow K^+ K^-)/\Gamma(K^+ K^- \pi^+)$ Γ_{33}/Γ_{31}

This is the “fit fraction” from the Dalitz-plot analysis. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+$, $\phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.

 $\Gamma(\pi^+(\pi^+\pi^-)_{S\text{-wave}})/\Gamma(2\pi^+\pi^-)$ Γ_{56}/Γ_{54}

This is the "fit fraction" from the Dalitz-plot analysis. See also KLEMP 08, which uses 568 $D^+ \rightarrow 3\pi$ decays (over 280 background events) from FNAL E791 to study various parametrizations of the decay amplitudes. The emphasis there is more on S-wave $\pi\pi$ decay products — 20 different solutions are given — than on D_S^+ fit fractions.

0.830 ± 0.009 ± 0.019	³⁰ AUBERT	09o	BABR Dalitz fit, ≈ 10.5k evts
0.8704 ± 0.0560 ± 0.0438	³¹ LINK	04	FOCS Dalitz fit, 1475 ± 50 evts
³⁰ AUBERT 09o gives the amplitude and phase of the $\pi^+\pi^-$ S-wave in 29 $\pi^+\pi^-$ invariant-mass bins.			
³¹ LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full $\pi\pi$ S-wave isoscalar scattering amplitude to describe the $\pi^+\pi^-$ S-wave component of the $\pi^+\pi^+\pi^-$ state. The fit fraction given above is a sum over five f_0 mesons, the $f_0(980)$, $f_0(1300)$, $f_0(1200-1600)$, $f_0(1500)$, and $f_0(1750)$. See LINK 04 for details and discussion.

 $D_s^+ - D_s^-$ T-VIOLATING DECAY-RATE ASYMMETRIES

$A_{T\text{viol}}(K_S^0 K^\pm\pi^+\pi^-)$ in $D_s^\pm \rightarrow K_S^0 K^\pm\pi^+\pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T -odd correlation of the K^+ , π^+ , and π^- momenta for the D_s^+ . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the D_s^- . $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D_s^\pm decays (the Γ 's are partial widths). With $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, the asymmetry $A_{T\text{viol}} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ tests for T violation even with nonzero strong phases.

$\Gamma_2 D_s^+ \pi^0$ (5.8 ± 0.7) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_2 \begin{bmatrix} -100 \\ x_1 \end{bmatrix}$$

 $D_{s1}(2536)^\pm$

$$J(J^P) = 0(1^+)$$

J, P need confirmation.

Seen in $D^*(2010)+K^0$, $D^*(2007)^0K^+$, and $D_s^\pm\pi^+\pi^-$. Not seen in D^+K^0 or D^0K^+ . $J^P = 1^+$ assignment strongly favored.

 $D_{s1}(2536)^\pm$ MASS

The fit includes $D^\pm, D^0, D_s^\pm, D^{*\pm}, D^{*0}, D_s^{*\pm}, D_1(2420)^0, D_2^*(2460)^0$, and $D_{s1}(2536)^\pm$ mass and mass difference measurements.

Many measurements of *B* decays involve admixtures of *B* hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: “ B^\pm/B^0 Admixture” for $\Upsilon(4S)$ results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. B^0 - \bar{B}^0 mixing data are found in the B^0 section, while B_s^0 - \bar{B}_s^0 mixing data and B - \bar{B} mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. *CP*-violation data are found in the B^\pm, B^0 , and B^\pm/B^0 Admixture sections. *b*-baryons are found near the end of the Baryon section. Recently, we also created a new section: “ V_{cb} and V_{ub} CKM Matrix Elements.”

The organization of the *B* sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS

Updated March 2010 by Y. Kwon (Yonsei U., Seoul, Korea), G. Punzi (U. and INFN, Pisa, Italy), and J.G. Smith (U. of Colorado, Boulder, CO, USA).

The *b* quark belongs to the third generation of quarks and is the weak-doublet partner of the *t* quark. The existence of the third-generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix (“CKM” matrix), and confirmed four years later by the first observation of a $b\bar{b}$ meson [2]. In the KM model, *CP* violation is explained within the Standard Model (SM) by an irreducible phase of the 3×3 unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the *b* quark is the lighter element of the third-generation quark doublet, the decays of *b*-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a 3×3 unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large *CP* asymmetries, can be observed in the weak decays of *b*-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of *CP* violation in *B* meson decays. A crucial milestone was the first observation of *CP* violation in the *B* meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter $\sin 2\beta$ ($= \sin 2\phi_1$) [5], almost four decades after the discovery of a small *CP* asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and *CP* violation can be found elsewhere in this Review [6,7].

Recent developments in the physics of *b*-hadrons include the observation of direct *CP* violation, results for rare higher-order weak decays, investigations of heavier *b*-hadrons (B_s^0 , B_c , baryons, excited states), measurement of the B_s^0 -mixing frequency, increasingly accurate determinations of the CKM matrix parameters.

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss *b*-quark production and current results on spectroscopy

Meson Particle Listings

b-flavored hadrons

and lifetimes of *b*-flavored hadrons. We then discuss some basic properties of *B*-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of *B*-mesons. There are separate mini-reviews for $B\bar{B}$ mixing [8] and the extraction of the CKM matrix elements V_{cb} and V_{ub} from *B*-meson decays [9] in this *Review*.

Theory and terminology: The ground states of *b*-flavored hadrons decay via weak interactions. In most hadrons, the *b*-quark is accompanied by light-partner quarks (*d*, *u*, or *s*), and the decay modes are well described by the decay of the *b* quark (spectator model) [10]. The dominant decay mode of a *b* quark is $b \rightarrow cW^{*-}$ (referred to as a “tree” or “spectator” decay), where the virtual *W* materializes either into a pair of leptons $\ell\bar{\nu}$ (“semileptonic decay”), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from W^* to form one of the final state hadrons are suppressed by a factor $\sim (1/3)^2$, because the colors of the two quarks from different sources must match (“color-suppression”).

Many aspects of *B* decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 9. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used, where, in analogy with semileptonic decays, two-body hadronic decays of *B* mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant $b \rightarrow cW^{*-}$ decays), and the other the hadronization of the remaining $\bar{u}d$ (or $\bar{c}s$) system from the virtual W^- . Qualitatively, for a *B* decay with a large energy release, the $\bar{u}d$ pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [12]. There are several common implementations of these ideas for hadronic *B* decays, the most common of which are QCD factorization (QCDF) [13], perturbative QCD (pQCD) [14], and soft collinear effective theory (SCET) [15].

The transition $b \rightarrow u$ is suppressed by $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$ relative to $b \rightarrow c$ transitions, and gives way to rarer decay modes, *e.g.*, loop-induced $b \rightarrow s$ decays. The transition $b \rightarrow s$ is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex diagrams (denoted “penguin” decays). The rates for such processes are comparable or larger than CKM-suppressed $b \rightarrow u$ processes. Penguin processes involving $b \rightarrow d$ transitions are also possible, and have recently been observed [16,17]. Other decay processes discussed in this *Review* include *W*-exchange (a *W* is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark, similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual *W*, which then decays).

Production and spectroscopy: The bound states of a \bar{b} antiquark and a *u*, *d*, *s*, or *c* quark are referred to as the B_u (B^+), B_d (B^0), B_s^0 , and B_c^+ mesons, respectively. The B_c^+ is the heaviest of the ground-state *b*-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [18], but its mass was accurately determined only in 2006, from the fully reconstructed mode $B_c^+ \rightarrow J/\psi\pi^+$ [19].

The first excited meson is called the B^* meson, while B^{**} is the generic name for the four orbitally excited ($L = 1$) *B*-meson states that correspond to the *P*-wave mesons in the charm system, D^{**} . Excited states of the B_s^0 meson are similarly named B_s^{*0} and B_s^{**0} . Of the possible bound $\bar{b}b$ states, the Υ series (S-wave) and the χ_b (P-wave) are well studied. The pseudoscalar ground state η_b has been observed only recently by BaBar [20] (and confirmed by CLEO [21]), indirectly through the decay $\Upsilon(3S) \rightarrow \gamma\eta_b$. See Ref. 22 for classification and naming of these and other states.

Experimental studies of *b* decays have been performed in e^+e^- collisions at the $\Upsilon(4S)$ (ARGUS, CLEO, Belle, BaBar) and $\Upsilon(5S)$ (CLEO, Belle) resonances, as well as at higher energies, at the *Z* resonance (SLC, LEP) and in $p\bar{p}$ collisions (Tevatron). The $e^+e^- \rightarrow b\bar{b}$ production cross-section at the *Z*, $\Upsilon(4S)$, and $\Upsilon(5S)$ resonances are about 6.6 *nb*, 1.1 *nb*, and 0.3 *nb* respectively. High-energy hadron collisions produce *b*-flavored hadrons of all species with much larger cross-sections: $\sigma(p\bar{p} \rightarrow bX, |y| < 1) \sim 30 \mu\text{b}$ at the Tevatron ($\sqrt{s} = 1.96 \text{ TeV}$), and even higher at the energies of the LHC pp collider (up to a factor of ten at $\sqrt{s} = 14 \text{ TeV}$).

BaBar and Belle have accumulated respectively 560 fb^{-1} and 1020 fb^{-1} of data, of which 433 fb^{-1} and 710 fb^{-1} respectively at the $\Upsilon(4S)$ resonance, while CDF and D0 have currently accumulated about 7 fb^{-1} each. These numbers imply that the majority of *b*-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower efficiency. Only the few decay modes for which triggering and reconstruction are easiest have been studied so far in hadron collisions. Up to now, these have included final states with leptons, and exclusive modes with all charged particles in the final state. In contrast, detectors operating at e^+e^- colliders (“B-Factories”) have a high efficiency for most decays, and have provided large samples of a rich variety of decays of B^0 and B^+ mesons.

In hadron collisions, most production happens as $b\bar{b}$ pairs, either via *s*-channel production or gluon-splitting, with a smaller fraction of single *b*-quarks produced by flavor excitation. The total *b*-production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [23], more accurate input parameters, and more advanced calculations [24], the discrepancy between theory and data is now much reduced, although the presence of inconsistencies among existing measurements makes further studies desirable.

Each quark of a $b\bar{b}$ pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced b/\bar{b} quark (“flavor tag” or “charge tag”) from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced b -quarks typically peaks near the b -quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter, that are important to resolve the fast oscillations of B_s^0 mesons.

In e^+e^- colliders, since the B mesons are very slow in the $\Upsilon(4S)$ rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of CP violation. At KEKB, the boost is $\beta\gamma = 0.43$, and the typical B -meson decay length is dilated from $\approx 20 \mu\text{m}$ to $\approx 200 \mu\text{m}$. PEP-II uses a slightly larger boost, $\beta\gamma = 0.55$. The two B mesons produced in $\Upsilon(4S)$ decay are in a coherent quantum state, which makes it easier than in hadron collision to infer the charge state of one B meson from observation of the other; however, the coherence also requires to determine the decay time of both mesons, rather than just one, in order to perform time-dependent CP -violation measurements.

For the measurement of branching fractions, the initial composition of the data sample must be known. The $\Upsilon(4S)$ resonance decays predominantly to $B^0\bar{B}^0$ and B^+B^- ; the current experimental upper limit for non- $B\bar{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level (CL) [25]. The only known modes of this category are decays to lower Υ states and a pion pair, recently observed with branching fractions of order 10^{-4} [26]. The ratio f_+/f_0 of the fractions of charged to neutral B productions from $\Upsilon(4S)$ decays has been measured by CLEO, BaBar, and Belle in various ways, typically based on pairs of isospin-related decays of B^+ and B^0 , such that it can be assumed that $\Gamma(B^+ \rightarrow x^+) = \Gamma(B^0 \rightarrow x^0)$. In this way, the ratio of the number of events observed in these modes is proportional to $(f_+\tau_+)/ (f_0\tau_0)$ [27–30]. BaBar has also performed an independent measurement of f_0 with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed $B^0 \rightarrow D^{*-}\ell^+\nu$ decays [31]. The combined result, from the current average of τ_+/τ_0 , is $f_+/f_0 = 1.068 \pm 0.029$ [32]. This number is currently a bit less consistent with equal production of B^+B^- and $B^0\bar{B}^0$ pairs than it used to be in the past (deviates from unity by 2.5σ), but we still assume $f_+/f_0 = 1$ in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the B^+ and B^0 masses: our fit of CLEO, ARGUS, and CDF measurements yields $m(B^0) = 5279.50 \pm 0.33 \text{ MeV}/c^2$, $m(B^+) = 5279.13 \pm 0.31 \text{ MeV}/c^2$, and $m(B^0) - m(B^+) = 0.37 \pm 0.24 \text{ MeV}/c^2$.

CLEO and Belle have also collected some data at the $\Upsilon(5S)$ resonance [34,35], Belle in particular has been taking a large

fraction of its recent data at this resonance, and accumulated more than 100 fb^{-1} at the time of this writing. This resonance does not provide the simple final states of the $\Upsilon(4S)$: there are seven possible final states with a pair of non-strange B mesons and three with a pair of strange B mesons ($B_s^*\bar{B}_s^*$, $B_s^*\bar{B}_s^0$, and $B_s^0\bar{B}_s^0$). The fraction of events with a pair of B_s^0 mesons over the total number of events with a pair of b -flavored hadrons has been measured to be $f_s[\Upsilon(5S)] = 0.193 \pm 0.029$, of which 90% is made of $B_s^{*0}\bar{B}_s^{*0}$ events. A few branching fractions of the B_s^0 have been measured in this way, and if a precise knowledge of f_s can be reached, they could be made the most accurate. A few new B_s^0 modes have been observed that are difficult to reconstruct in hadron colliders, and the most precise mass measurement of the B_s^{*0} meson has been obtained [35,36]. However, the small boost of B_s^0 mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the Z peak.

In high-energy collisions, the produced b or \bar{b} quarks can hadronize with different probabilities into the full spectrum of b -hadrons, either in their ground or excited states. Table 1 shows the measured fractions f_d , f_u , f_s , and f_{baryon} of B^0 , B^+ , B_s^0 , and b baryons, respectively, in an unbiased sample of weakly decaying b hadrons produced at the Z resonance and in $p\bar{p}$ collisions [32]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of B_c mesons. The observed yields of B_c mesons at the Tevatron [18], provide an estimate $f_c = 0.2\%$, in agreement with expectations [37], which is below the current experimental uncertainties in the other fractions.

The combined values assume identical hadronization in $p\bar{p}$ collisions and in Z decay. These could in principle differ, because of the different momentum distributions of the b -quark in these processes; the sample used in the $p\bar{p}$ measurements has momenta close to the b mass, rather than $m_Z/2$. A test of the agreement between production fractions may be given by comparison of values of the average time-integrated mixing probability parameter $\bar{\chi} = f_d\chi_d + f_s\chi_s$ [8], which is an important input in the determination of the world-averages of production fractions. The current measurements of $\bar{\chi}$ from LEP and Tevatron differ by 1.8σ [32]. This slight discrepancy causes a larger uncertainty in the combined fractions in Table 1. With the availability of increasing large samples of b -flavored mesons and baryons at $p\bar{p}$ colliders, the limited knowledge of these fractions has become an important limiting factor in the determination of their branching fractions.

Excited B -meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the $B^{*-}B$ mass difference is $45.78 \pm 0.35 \text{ MeV}/c^2$. Evidence for B^{**} ($L=1$) production has been initially obtained at LEP [38], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been recently obtained at the Tevatron, allowing separation of

Meson Particle Listings

b-flavored hadrons

Table 1: Fractions of weakly-decaying *b*-hadron species in $Z \rightarrow b\bar{b}$ decay and in $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV.

<i>b</i> hadron	Fraction at Z [%]	Fraction at $p\bar{p}$ [%]	Combined [%]
B^+, B^0	40.2 ± 0.9	33.2 ± 3.0	40.0 ± 1.2
B_s^0	10.5 ± 0.9	12.2 ± 1.4	11.5 ± 1.3
<i>b</i> baryons	9.1 ± 1.5	21.4 ± 6.8	8.5 ± 2.1

the narrow states B_1 and B_2^* , and at CDF also a measurement of the B_2^* width [39].

Also the narrow B_s^{**} states, first sighted by OPAL as a single broad enhancement in the B^+K mass spectrum [40], have now been clearly observed and separately measured at the Tevatron [41]: $M(B_{s1}) = 5829.4 \pm 0.7$ MeV/ c^2 (CDF) and $M(B_{s2}^*) = 5839.7 \pm 0.7$ MeV/ c^2 (CDF), $M(B_{s2}^*) = 5839.6 \pm 1.1 \pm 0.7$ MeV/ c^2 (D0).

Baryon states containing a *b* quark are labeled according to the same scheme used for non-*b* baryons, with the addition of a *b* subscript [22]. For many years, the only well-established *b* baryon was the Λ_b^0 (quark composition *udb*), with only indirect evidence for Ξ_b (*dsb*) production from LEP [42]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron. Clear signals of four strongly-decaying baryon states, $\Sigma_b^+, \Sigma_b^{*+}$ (*uub*), $\Sigma_b^-, \Sigma_b^{*-}$ (*ddb*) have been obtained by CDF in $\Lambda_b^0\pi^\pm$ final states [43]. The strange bottom baryon Ξ_b^\pm has been observed in the exclusive mode $\Xi_b^\pm \rightarrow J/\psi\Xi^\pm$ by D0 [44], and CDF [45] that also measured its lifetime individually for the first time (was previously only known from a mix). The relative production of Ξ_b and Λ_b baryons has been found to be consistent with the B_s to B_d production ratio [44]. Observation of the doubly-strange bottom baryon Ω_b^- has been published by both D0 [46] and CDF [47]. The masses measured by the two experiments show however a large discrepancy that still needs to be resolved. Apart from this discrepancy, the masses of all these new baryons have been measured to a precision of a few MeV/ c^2 , and found to be in agreement with predictions from HQET.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in *CP* violation, such as the determination of V_{cb} and $B_s^0\bar{B}_s^0$ mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus, the lifetimes of all mesons and baryons containing *b* quarks would be equal. Non-spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for *b*-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variations in the *b* system are expected to be significantly smaller; on the order of 10% or less [48]. We expect:

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s^0) > \tau(\Lambda_b^0) \gg \tau(B_c^+). \quad (1)$$

In the B_c^+ , both quarks can decay weakly, resulting in a much shorter lifetime.

Measurements of the lifetimes of the different *b*-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the *b* sector. Over the past years, the precision of silicon vertex detectors and the increasing availability of fully-reconstructed samples yielded measurements with much-reduced statistical and systematic uncertainties, at the 1% level. The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in this mini-review Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [32].

Table 2: Summary of inclusive and exclusive world-average *b*-hadron lifetime measurements. For the two B_s^0 averages, see text below.

Particle	Lifetime [ps]
B^+	1.638 ± 0.011
B^0	1.525 ± 0.009
B_s^0 (flavor-specific)	1.417 ± 0.042
B_s^0 ($1/\Gamma_s$)	$1.472^{+0.024}_{-0.026}$
B_c^+	0.453 ± 0.041
Λ_b^0	$1.391^{+0.038}_{-0.037}$
Ξ_b^-	$1.56^{+0.27}_{-0.25}$
Ω_b^-	$1.13^{+0.53}_{-0.40}$
Ξ_b mixture	$1.49^{+0.19}_{-0.18}$
<i>b</i> -baryon mixture	1.345 ± 0.032
<i>b</i> -hadron mixture	1.568 ± 0.009

The short B_c^+ lifetime is in good agreement with predictions [49]. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.071 \pm 0.009, \quad \frac{\tau_{B_s^0}}{\tau_{B^0}} = 0.965 \pm 0.017,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.912 \pm 0.025,$$

while theory makes the following predictions [48,50]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02, \quad \frac{\tau_{B_s^0}}{\tau_{B^0}} = 1.00 \pm 0.01, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of B^+ to B^0 is measured to better than 1%, and is significantly different from one, in agreement with predictions [48]. Conversely, the ratio of B_s^0 to B^0 lifetimes is expected to be very close to one, but exhibits a 2.5σ deviation. The Λ_b lifetime has a history of discrepancies. Predictions used to be higher than data, before the introduction of higher-order effects lowered them. The recent measurements, from CDF on the exclusive $J/\psi\Lambda$ mode [51], and from D0 [52] on both semileptonic and $J/\psi\Lambda$ mode, disagree at the 3σ level. The most recent CDF measurement [53] appears to improve the agreement with theory again.

Neutral B mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths Γ_L and Γ_H . The SM predicts a non-zero width difference $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$ for both B_s and B_d . For B_d , $\Delta\Gamma_d/\Gamma_d$ is expected to be $\sim 0.2\%$. Analysis of BaBar and DELPHI data on CP -specific modes of the B^0 yield a combined result: $\Delta\Gamma_d/\Gamma_d = 0.009 \pm 0.037$ [32]. The issue is much more interesting for the B_s , since the SM expectation for $\Delta\Gamma_s/\Gamma_s$ is of order 10%. This potentially non-negligible difference requires care when defining the B_s^0 lifetime. As indicated in Table 2, two different lifetimes are defined for the B_s^0 meson: one is defined as $1/\Gamma_s$, where Γ_s is the average width of the two mass eigenstates $(\Gamma_L + \Gamma_H)/2$; the other is obtained from “flavor-specific” decays (*e.g.*, semileptonic) and depends both on Γ_s and $\Delta\Gamma_s$. Experimentally, the quantity $\Delta\Gamma_s$ can be accessed by measuring lifetimes in decays into CP eigenstates, which are expected to be close approximations to the mass eigenstates. This has been done with the $J/\psi\phi$ mode, where the two CP eigenstates are distinguished by angular distributions, and in $B_s^0 \rightarrow K^+K^-$ which is dominated by a single CP -state. The current experimental information is dominated by CDF and D0 measurements on the $J/\psi\phi$ mode. By appropriately combining all published measurements of $J/\psi\phi$ lifetimes and flavor-specific lifetimes, the HFAG group obtains a world-average $\Delta\Gamma_s/\Gamma_s = 0.092^{+0.051}_{-0.054}$ [32]; the quoted uncertainties are, however, non-Gaussian, and a better representation of the current uncertainty is given by the 95% CL interval: $-0.020 < \Delta\Gamma_s/\Gamma_s < 0.193$ [32], which is compatible with zero; the latest theoretical predictions yield $\Delta\Gamma_s/\Gamma_s = 0.147 \pm 0.060$ [54], in agreement with the experiment within the large uncertainties on both. From the theoretical point of view, the best quantity to use is $\Delta\Gamma_s/\Delta M_s$, which is much less affected by hadronic uncertainties: $\Delta\Gamma_s/\Delta M_s = (49.7 \pm 9.4) \times 10^{-4}$ [54]. Exploiting the very accurate measurement of ΔM_s now available [58], this can be turned into a SM prediction with just 20% uncertainty: $\Delta\Gamma_s/\Gamma_s = 0.127 \pm 0.024$. This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of Tevatron samples. Further improvements may come from $B_s^0 \rightarrow K^+K^-$, and alternative (model-dependent) determinations via the $B_s^0 \rightarrow D_s^{(*)+}D_s^{(*)-}$ branching fraction [57].

The width difference $\Delta\Gamma_s$ is connected to the B_s^0 mixing phase ϕ_s by $\Delta\Gamma_s = \Gamma_{12} \cos \phi_s$, where Γ_{12} is the off-diagonal term of the decay matrix [6,8,54]. Both CDF [55] and D0 [56] have produced CL contours in the $(\phi_s, \Delta\Gamma)$ plane from their measurements, and both observe a mild deviation, in the same direction, from the expectation of the Standard model of a phase ϕ_s close to zero. They have combined their measurements from samples of 2.8 fb^{-1} each to make a Tevatron average, obtaining a deviation from predictions at a level slightly above 2σ [33]. The possibility of a large value of ϕ_s has attracted significant interest, as it would be a very clean evidence for the

existence of new sources of CP violation beyond the standard model, and is currently a target of active investigation.

B meson decay properties: Semileptonic B decays $B \rightarrow X_c \ell \nu$ and $B \rightarrow X_u \ell \nu$ provide an excellent way to measure the magnitude of the CKM elements $|V_{cb}|$ and $|V_{ub}|$ respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used, and the nature of uncertainties are quite complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system $X_{c(u)}$ is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of B semileptonic decays and the extraction of $|V_{cb}|$ and $|V_{ub}|$ is given elsewhere in this *Review* [9].

On the other hand, hadronic decays of B are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Pure-penguin decays were first established by the observation of $B \rightarrow K^* \gamma$ [59]. Some observed decay modes such as $B^0 \rightarrow D_s^- K^+$, may be interpreted as evidence of a W -exchange process [60]. The recent evidence for the decay $B^+ \rightarrow \tau^+ \nu$ from Belle [61] and BaBar [62] is the first sign of a pure annihilation decay. There is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [63].

Hadronic decays:

Most of the hadronic B decays involve $b \rightarrow c$ transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic B decays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of B -factory detectors, a substantial fraction of hadronic B decay events can be fully reconstructed. Because of the kinematic constraint of $\Upsilon(4S)$, the energy sum of the final-state particles of a B meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables, ΔE (energy difference) and M_B (B candidate mass with a beam-energy constraint) are very effective for suppressing combinatorial background both from $\Upsilon(4S)$ and $e^+e^- \rightarrow q\bar{q}$ continuum events. In particular, the energy-constraint in M_B improves the signal resolution by almost an order of magnitude.

b-flavored hadrons

The kinematically clean environment of B meson decays provides an excellent opportunity to search for new states. For instance, quark-level $b \rightarrow c\bar{c}s$ decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow charm-strange state $D_{sJ}^*(2317)$ [64], and CLEO observed a similar state $D_{sJ}(2460)$ [65]. However, the properties of these new states were not well known until Belle observed $B \rightarrow DD_{sJ}^*(2317)$ and $B \rightarrow DD_{sJ}(2460)$, which helped identify some quantum numbers of $D_{sJ}(2460)$ [66]. Further studies of $D_{sJ}^{(*)}$ meson production in B decays have been made by Belle and BaBar. In particular, BaBar has observed $B \rightarrow D_{sJ}^*(2317)^+\bar{D}^{(*)}$ ($D_{sJ}^*(2317)^+ \rightarrow D_s^+\pi^0$) and $B \rightarrow D_{sJ}(2460)^+\bar{D}^{(*)}$ ($D_{sJ}(2460)^+ \rightarrow D_s^+\pi^0, D_s^+\gamma$) decays. The angular analysis of $B \rightarrow D_{sJ}(2460)^+\bar{D}$ with $D_{sJ}(2460)^+ \rightarrow D_s^+\gamma$ supports the $J^P = 1^+$ assignment for $D_{sJ}(2460)$. With a sample of 449 million $B\bar{B}$ pairs, Belle has observed a new D_{sJ} meson produced in $B^+ \rightarrow \bar{D}^0 D_{sJ} \rightarrow \bar{D}^0 D^0 K^+$ [67]. The mass and width of this state are measured to be $2708 \pm 9^{+11}_{-10}$ MeV/ c^2 and $108 \pm 23^{+36}_{-31}$ MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be 1^- .

A variety of exotic particles have been discovered in B decays. Belle found the $X(3872)$ state [68], confirmed by CDF [69] and BaBar [71]. Belle has observed a near-threshold enhancement in the $\omega J/\psi$ invariant mass for $B \rightarrow K\omega J/\psi$ decays [72]. BaBar has studied $B \rightarrow J/\psi\pi^+\pi^-K$, finding an excess of $J/\psi\pi^+\pi^-$ events with a mass just above 4.2 GeV/ c^2 ; this is consistent with the $Y(4260)$ that was observed by BaBar in ISR (Initial State Radiation) events [74]. A Belle study of $B \rightarrow K\pi^\pm\psi'$ [75] finds a state called $Z^\pm(4430)$ that decays to $\pi^\pm\psi'$. Since it is charged, it could not be a charmonium state. This state was searched for by BaBar with similar sensitivity but was not found [76]. More details about these exotic states are described in a separate mini-review [77] in this *Review*.

There have been hundreds of publications on hadronic B decays to open-charm and charmonium final states mostly from the B -factory experiments. These results are nicely summarized in a recent report by HFAG [32].

Rare B decays: All B -meson decays that do not occur through the $b \rightarrow c$ transition are usually called rare B decays. These include both semileptonic and hadronic $b \rightarrow u$ decays that are suppressed at leading order by the small CKM matrix element V_{ub} , as well as higher-order $b \rightarrow s(d)$ processes such as electroweak and gluonic penguin decays.

Charmless B meson decays into two-body hadronic final states such as $B \rightarrow \pi\pi$ and $K\pi$ are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct CP violations. Since the final state particles in these decays tend to have larger momenta than average B decay products, the event environment is cleaner than for $b \rightarrow c$ decays. Branching fractions are typically around 10^{-5} . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently,

comparable samples of the modes with all charged final particles have been reconstructed in $p\bar{p}$ collisions by CDF by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the B_s^0 , in final states $\phi\phi$ [78], K^+K^- [79], and $K^-\pi^+$ [80], and of charmless decays of the Λ_b^0 baryon [80]. Charmless B_s^0 modes are related to corresponding B^0 modes by U-spin symmetry, and are determined by similar amplitudes. Combining the observables from B_s^0 and B^0 modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [99].

Because of relatively high-momenta for final state particles, the dominant source of background in e^+e^- collisions is $q\bar{q}$ continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the four experiments.

BaBar [81] and Belle [82] have observed the decays $B^+ \rightarrow \bar{K}^0 K^+$ and $B^0 \rightarrow K^0 \bar{K}^0$. The world-average branching fractions are $\mathcal{B}(B^0 \rightarrow K^0 \bar{K}^0) = (0.96^{+0.20}_{-0.18}) \times 10^{-6}$ and $\mathcal{B}(B^+ \rightarrow \bar{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$. These are the first observations of hadronic $b \rightarrow d$ transitions, with significance $> 5\sigma$ for all four measurements. CP asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including $B^0 \rightarrow K^+\pi^-$ have contributions from both $b \rightarrow u$ tree and $b \rightarrow sg$ penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct CP violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [83], Belle [84], and CDF [85] have measured the direct CP violating asymmetry in $B^0 \rightarrow K^+\pi^-$ decays. The BaBar and Belle measurements constitute observation of direct CP violation with a significance of more than 5σ . The world average for this quantity is now rather precise, -0.098 ± 0.013 . There are sum rules that relate the decay rates and decay-rate asymmetries between the four $K\pi$ charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct CP violation in three other decays: $B^+ \rightarrow \rho^0 K^+$ [86], $B^+ \rightarrow \eta K^+$ [87], and $B^0 \rightarrow \eta K^{*0}$ [88]. The significance is typically $3-4\sigma$, though with the most recent BaBar measurement [87], this significance for the $B^+ \rightarrow \eta K^+$ decay is now more than 4σ . In at least the first two cases, a large direct CP violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay $B^0 \rightarrow \pi^+\pi^-$ can be used to extract the CKM angle α . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [89] can be used to untangle the penguin complications. The decay $B^0 \rightarrow \pi^0\pi^0$, which is now measured by both BaBar and Belle, is crucial in this analysis. Unfortunately the amount of

penguin pollution in the $B \rightarrow \pi\pi$ system is rather large. In the past few years, measurements in the $B^0 \rightarrow \rho\rho$ system have produced more precise values of α , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the $B^0 \rightarrow \rho^0\rho^0$ branching fraction. The average of recent measurements from BaBar and Belle BaBar [90] yields a branching fraction of $(0.73 \pm 0.28) \times 10^{-6}$. This is only 3% of the $\rho^+\rho^-$ branching fraction, much smaller than the corresponding ratio in the $\pi\pi$ system.

The decay $B \rightarrow a_1\pi$ has been seen by BaBar. An analysis of the time evolution of this decay [91] together with measurements of other related decays has recently been used to measure the CKM angle α [92] in agreement with the more precise measurements from the $\rho\rho$ system.

Since $B \rightarrow \rho\rho$ has two vector mesons in the final state, the CP eigenvalue of the final state depends on the longitudinal polarization fraction f_L for the decay. Therefore, a measurement of f_L is needed to extract the CKM angle α . Both BaBar and Belle have measured the f_L for the decays $\rho^+\rho^-$ and $\rho^+\rho^0$ and in both cases the measurements show $f_L > 0.9$, making a complete angular analysis unnecessary.

By analyzing the angular distributions of the B decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in B decays. Decays that are penguin-dominated surprisingly have values of f_L near 0.5. The list of such decays has now grown to include $B \rightarrow \phi K^*$, $B \rightarrow \rho K^*$, and $B \rightarrow \omega K^*$. The reasons for this ‘‘polarization puzzle’’ are not fully understood. A detailed description of the angular analysis of B decays to two vector mesons can be found in a separate mini-review [93] in this *Review*.

There has been substantial progress in measurements of many other rare- B decays. The decay $B \rightarrow \eta'K$ stood out as the largest rare- B decay for many years. The reasons for the large rate are now largely understood [13,94]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include $K\pi\pi$ (three charge states) [95], KKK (four charge states) [96], and $K^*\pi\pi$ (two charged states) [97]. Many of these analyses now include quite sophisticated Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay $B^+ \rightarrow K^+K^-\pi^+$ by BaBar [98], noteworthy because an even number of kaons is typically indicative of suppressed $b \rightarrow d$ transitions as discussed above.

Belle [61] and BaBar [62] have found evidence for $B^+ \rightarrow \tau^+\nu$ with a combined branching fraction of $(180 \pm 50) \times 10^{-6}$ in good agreement with the value expected in the SM. This is the first evidence for a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs. $\tan\beta$ is excluded by the limit on this mode.

Electroweak penguin decays:

More than a decade has passed since the CLEO experiment first observed an exclusive radiative $b \rightarrow s\gamma$ transition, $B \rightarrow K^*(892)\gamma$ [59], thus providing the first evidence for the one-loop

FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [100] with an average branching fraction $\mathcal{B}(B^0 \rightarrow K^{*0}\gamma) = (43.3 \pm 1.5) \times 10^{-6}$, and have added several new decay modes such as $B \rightarrow K_1\gamma$, $K_2^*(1430)\gamma$, *etc.* [101]. With a sample of 24 fb^{-1} at $\Upsilon(5S)$, Belle observed a radiative penguin decay of B_s^0 in $\phi\gamma$ mode with a branching fraction $(57_{-19}^{+22}) \times 10^{-6}$ [102].

Compared to $b \rightarrow s\gamma$, the $b \rightarrow d\gamma$ transitions such as $B \rightarrow \rho\gamma$, are suppressed by the small CKM element V_{td} . Both Belle and BaBar have observed these decays [16,17]. The world average $\mathcal{B}(B \rightarrow (\rho, \omega)\gamma) = (1.28 \pm 0.21) \times 10^{-6}$. This can be used to calculate $|V_{td}/V_{ts}|$ [103]; the measured values are $0.233_{-0.032}^{+0.033}$ from BaBar [17] and $0.195_{-0.024}^{+0.025}$ from Belle [16].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [104]. However, due to the uncertainties in the hadronization, only the inclusive $b \rightarrow s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. By combining the measurements of $B \rightarrow X_s\gamma$ from CLEO, BaBar, and Belle experiments [105,106], HFAG obtains the new average: $\mathcal{B}(B \rightarrow X_s\gamma) = (3.55 \pm 0.24 \pm 0.09) \times 10^{-4}$ [107]. Consistent results have been reported by ALEPH for inclusive b -hadrons produced at the Z . The measured branching fraction can be compared to theoretical calculations. Recent calculations of $\mathcal{B}(b \rightarrow s\gamma)$ in NNLO level predict the values of $(3.15 \pm 0.23) \times 10^{-4}$ [108] and $(2.98 \pm 0.26) \times 10^{-4}$ [109], where the latter is calculated with a cut $E_\gamma \geq 1.6 \text{ GeV}$.
