⁵ Using measurements or limits from AQUINES 06.
⁶ Using $B(D_s^+ \rightarrow \phi\pi^+) = (4.4 \pm 0.6)\%$ from PDG 06.
⁷ Supersedes ARTUSO 05B. Combining inclusive ϕ , D_s , and B measurements. Using $B(D_s^+ \rightarrow \phi\pi^+) = 4.4 \pm 0.6\%$ from PDG 06.
⁸ Uses a model-dependent estimate $B(B_s \rightarrow D_s X) = (92 \pm 11)\%$.
⁹ From a measurement of $\sigma(e^+e^- \rightarrow B_s^*\bar{B}_s^*) / \sigma(e^+e^- \rightarrow B_s^{(*)}\bar{B}_s^{(*)})$ at $\sqrt{s} = 10.86$ GeV.
¹⁰ Assuming that the observed events are solely due to the $\Upsilon(5S)$ resonance.
¹¹ ARTUSO 05B reports $[\Gamma(\Upsilon(10860) \rightarrow D_s \text{ anything} + \text{c.c.})/\Gamma_{\text{total}}] \times [B(D_s^+ \rightarrow \phi\pi^+)] = 0.0198 \pm 0.0019 \pm 0.0038$ which we divide by our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

Meson Particle Listings

Non- $q\bar{q}$ Candidates,

NON- $q\bar{q}$ CANDIDATES

We include here reference lists on gluonium and other non- $q\bar{q}$ candidates. For a review see PDG 06, Journal of Physics, G **33** 1 (2006). See also the "Note on scalar mesons" in the $f_0(600)$ Particle Listings, our note "New charmonium-like states" in PDG 08, Physics Letters **B667** 1 (2008), and the extensive chapter on Spectroscopy in N. Brambilla et al. (Quarkonium Working Group), to be published in the Eur. Phys. J. in 2010.

938.2796 ± 0.0027	COHEN 73	RVUE	1973 CODATA value

$|m_p - m_{\bar{p}}|/m_p$

A test of CPT invariance. Note that the comparison of the \bar{p} and p charge-to-mass ratio, given in the next data block, is much better determined.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
< 2 × 10⁻⁹	90	¹ HORI 06	SPEC	$\bar{p}e^-$ He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
< 1.0 × 10 ⁻⁸	90	¹ HORI 03	SPEC	$\bar{p}e^-$ ⁴ He, $\bar{p}e^-$ ³ He
< 6 × 10 ⁻⁸	90	¹ HORI 01	SPEC	$\bar{p}e^-$ He atom
< 5 × 10 ⁻⁷		² TORII 99	SPEC	$\bar{p}e^-$ He atom

¹HORI 01, HORI 03, and HORI 06 use the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 99 (see below) to get their results. Their results are not independent of the HORI 01, HORI 03, and HORI 06 values for $|q_p + q_{\bar{p}}|/e$, below.

²TORII 99 uses the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for $|q_p + q_{\bar{p}}|/e$, below.

\bar{p}/p CHARGE-TO-MASS RATIO, $|\frac{q_{\bar{p}}}{m_{\bar{p}}}|/(\frac{q_p}{m_p})$

A test of CPT invariance. Listed here are measurements involving the inertial masses. For a discussion of what may be inferred about the ratio of \bar{p} and p gravitational masses, see ERICSON 90; they obtain an upper bound of 10⁻⁶-10⁻⁷ for violation of the equivalence principle for \bar{p} 's.

VALUE	DOCUMENT ID	TECN	COMMENT
0.99999999991 ± 0.00000000009	GABRIELSE 99	TRAP	Penning trap
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1.0000000015 ± 0.0000000011	³ GABRIELSE 95	TRAP	Penning trap
1.0000000023 ± 0.0000000042	⁴ GABRIELSE 90	TRAP	Penning trap

³Equation (2) of GABRIELSE 95 should read $M(\bar{p})/M(p) = 0.999\,999\,9985(11)$ (G. Gabrielse, private communication).

⁴GABRIELSE 90 also measures $m_{\bar{p}}/m_{e^-} = 1836.152660 \pm 0.000083$ and $m_p/m_{e^-} = 1836.152680 \pm 0.000088$. Both are completely consistent with the 1986 CODATA (COHEN 87) value for m_p/m_{e^-} of 1836.152701 ± 0.000037.

$(\frac{q_{\bar{p}}}{m_{\bar{p}}} - \frac{q_p}{m_p}) / \frac{q_p}{m_p}$

A test of CPT invariance. Taken from the \bar{p}/p charge-to-mass ratio, above.

VALUE	DOCUMENT ID
(-9 ± 9) × 10⁻¹¹ OUR EVALUATION	

$|q_p + q_{\bar{p}}|/e$

A test of CPT invariance. Note that the comparison of the \bar{p} and p charge-to-mass ratios given above is much better determined. See also a similar test involving the electron.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
< 2 × 10⁻⁹	90	⁵ HORI 06	SPEC	$\bar{p}e^-$ He atom
• • • We do not use the following data for averages, fits, limits, etc. • • •				
< 1.0 × 10 ⁻⁸	90	⁵ HORI 03	SPEC	$\bar{p}e^-$ ⁴ He, $\bar{p}e^-$ ³ He
< 6 × 10 ⁻⁸	90	⁵ HORI 01	SPEC	$\bar{p}e^-$ He atom
< 5 × 10 ⁻⁷		⁶ TORII 99	SPEC	$\bar{p}e^-$ He atom
< 2 × 10 ⁻⁵		⁷ HUGHES 92	RVUE	

⁵HORI 01, HORI 03, and HORI 06 use the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 99 (see above) to get their results. Their results are not independent of the HORI 01, HORI 03, and HORI 06 values for $|m_p - m_{\bar{p}}|/m_p$, above.

⁶TORII 99 uses the more-precisely-known constraint on the \bar{p} charge-to-mass ratio of GABRIELSE 95 (see above) to get this result. This is not independent of the TORII 99 value for $|m_p - m_{\bar{p}}|/m_p$, above.

⁷HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

$|q_p + q_e|/e$

See DYLLA 73 for a summary of experiments on the neutrality of matter. See also "n CHARGE" in the neutron Listings.

VALUE	DOCUMENT ID	COMMENT
< 1.0 × 10⁻²¹	⁸ DYLLA 73	Neutrality of SF ₆
• • • We do not use the following data for averages, fits, limits, etc. • • •		
< 3.2 × 10 ⁻²⁰	⁹ SENGUPTA 00	binary pulsar
< 0.8 × 10 ⁻²¹	MARINELLI 84	Magnetic levitation

⁸Assumes that $q_n = q_p + q_e$.

⁹SENGUPTA 00 uses the difference between the observed rate of rotational energy loss by the binary pulsar PSR B1913+16 and the rate predicted by general relativity to set this limit. See the paper for assumptions.

Baryon Particle Listings

 ρ

¹⁰DMITRIEV 03 calculates this limit from the limit on the electric dipole moment of the ¹⁹⁹Hg atom.

¹¹This WILKENING 84 value includes a finite-size effect and a magnetic effect.

¹²This WILKENING 84 value is more cautious than the other and excludes the finite-size effect, which relies on uncertain nuclear integrals.

 ρ ELECTRIC POLARIZABILITY α_p

For a very complete review of the "polarizability of the nucleon and Compton scattering," see SCHUMACHER 05. His recommended values for the proton are $\alpha_p = (12.0 \pm 0.6) \times 10^{-4} \text{ fm}^3$ and $\beta_p = (1.9 \pm 0.6) \times 10^{-4} \text{ fm}^3$, almost exactly our averages.

VALUE (10^{-4} fm^3)	DOCUMENT ID	TECN	COMMENT
12.0 ± 0.6 OUR AVERAGE

11.82 ± 0.98 +0.52 -0.98	¹⁴ BLANPIED 01	LEGS	$\rho(\vec{\gamma}, \gamma), \rho(\vec{\gamma}, \pi^0), \rho(\vec{\gamma}, \pi^+)$
11.9 ± 0.5 ± 1.3	¹⁵ OLMOSDEL... 01	CNTR	γp Compton scattering
12.1 ± 0.8 ± 0.5	¹⁶ MACGIBBON 95	RVUE	global average
• • • We do not use the following data for averages, fits, limits, etc. • • •			
11.7 ± 0.8 ± 0.7	¹⁷ BARANOV 01	RVUE	Global average
12.5 ± 0.6 ± 0.9	MACGIBBON 95	CNTR	γp Compton scattering
9.8 ± 0.4 ± 1.1	HALLIN 93	CNTR	γp Compton scattering
10.62 +1.25 +1.07 -1.19 -1.03	ZIEGER 92	CNTR	γp Compton scattering
10.9 ± 2.2 ± 1.3	¹⁸ FEDERSPIEL 91	CNTR	γp Compton scattering

¹³BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_N = (13.0 \pm 1.9 +3.9) \times 10^{-4} \text{ fm}^3$ and $\beta_N = (-1.8 \pm 1.9 +2.1) \times 10^{-4} \text{ fm}^3$.

¹⁴BLANPIED 01 gives $\alpha_p + \beta_p$ and $\alpha_p - \beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.

¹⁵This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4} \text{ fm}^3$. See the paper for a discussion.

¹⁶MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.

¹⁷BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

¹⁸FEDERSPIEL 91 obtains for the (static) electric polarizability α_p , defined in terms of the induced electric dipole moment by $\mathbf{D} = 4\pi\epsilon_0\alpha_p\mathbf{E}$, the value $(7.0 \pm 2.2 \pm 1.3) \times 10^{-4} \text{ fm}^3$.

 ρ MAGNETIC POLARIZABILITY β_p

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint $\bar{\alpha} + \bar{\beta} = (14.2 \pm 0.5) \times 10^{-4} \text{ fm}^3$. Errors here are anticorrelated with those on $\bar{\alpha}_p$ due to this constraint.

²¹This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4} \text{ fm}^3$. See the paper for a discussion.

²²MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.

²³BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

 ρ CHARGE RADIUS

This is the rms charge radius, $\sqrt{\langle r^2 \rangle}$.

VALUE (fm)	DOCUMENT ID	TECN	COMMENT
0.8768 ± 0.0069	MOHR 08	RVUE	2006 CODATA value

²⁴ ESCHRICH 01 actually gives $\langle r^2 \rangle = (0.69 \pm 0.06 \pm 0.06) \text{ fm}^2$.			

 ρ MEAN LIFE

A test of baryon conservation. See the "p Partial Mean Lives" section below for limits for identified final states. The limits here are to "anything" or are for "disappearance" modes of a bound proton (p) or (n). See also the 3ν modes in the "Partial Mean Lives" section. Table 1 of BACK 03 is a nice summary.

LIMIT (years)	PARTICLE	CL%	DOCUMENT ID	TECN	COMMENT
>5.8 × 10²⁹	n	90	²⁵ ARAKI 06	06	KLND $n \rightarrow$ invisible

²⁵ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the s shell of ¹²C.

²⁶AHMED 04 looks for γ rays from the de-excitation of a residual ¹⁵O* or ¹⁵N* following the disappearance of a neutron or proton in ¹⁶O.

²⁷BACK 03 looks for decays of unstable nuclides left after N decays of parent ¹²C, ¹³C, ¹⁶O nuclei. These are "invisible channel" limits.

²⁸ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.

²⁹AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.

³⁰BERNABEI 00B looks for the decay of a ¹²⁸₅₃ nucleus following the disappearance of a proton in the otherwise-stable ¹²⁹Xe nucleus.

³¹EVANS 77 looks for the daughter nuclide ¹²⁹Xe from possible ¹³⁰Te decays in ancient Te ore samples.

³²This mean-life limit has been obtained from a half-life limit by dividing the latter by $\ln(2) = 0.693$.

³³FLEROV 58 looks for the spontaneous fission of a ²³²Th nucleus after the disappearance of one of its nucleons.

 \bar{p} MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also " \bar{p} Partial Mean Lives" after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is 7×10^5 years, for $\bar{p} \rightarrow e^- \gamma$. We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>8 × 10 ⁵	90		³⁴ GEER 00D	00D	\bar{p}/p ratio, cosmic rays
>0.28			GABRIELSE 90	TRAP	Penning trap
>0.08			BELL 79	CNTR	Storage ring
>1 × 10 ⁷	90	1	GOLDEN 79	SPEC	\bar{p}/p ratio, cosmic rays
>3.7 × 10 ⁻³			BREGMAN 78	CNTR	Storage ring

³⁴GEER 00D uses agreement between a model of galactic \bar{p} production and propagation and the observed \bar{p}/p cosmic-ray spectrum to set this limit.

p DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i , where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

Mode	Partial mean life (10^{30} years)	Confidence level

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ/B_i , where τ is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

³⁹ In estimating the background, this HIRATA 89c limit (as opposed to the later limits of WALL 00b and MCGREW 99) does not take into account present understanding that the flux of ν_μ originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here.

⁴⁰ We have calculated 90% CL limit from 1 confined event.

⁴¹ We have converted 2 possible events to 90% CL limit.

⁴² We have converted half-life to 90% CL mean life.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

n MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

Table with columns: VALUE (u), DOCUMENT ID, TECN, COMMENT. Lists CODATA values for the neutron mass.

Baryon Particle Listings

*n**n* MASS (MeV)

The mass is known much more precisely in *u* (atomic mass units) than in MeV. The conversion from *u* to MeV, $1\text{ u} = 931.494028 \pm 0.000023\text{ MeV}/c^2$ (MOHR 08, the 2006 CODATA value), involves the relatively poorly known electronic charge.

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
939.565346 ± 0.000023	MOHR	08	RVUE 2006 CODATA value
• • • We do not use the following data for averages, fits, limits, etc. • • •			
939.565360 ± 0.000081	MOHR	05	RVUE 2002 CODATA value
939.565331 ± 0.000037	¹ KESSLER	99	SPEC $np \rightarrow d\gamma$
939.565330 ± 0.000038	MOHR	99	RVUE 1998 CODATA value
939.56565 ± 0.00028	^{2,3} DIFILIPPO	94	TRAP Penning trap
939.56563 ± 0.00028	COHEN	87	RVUE 1986 CODATA value
939.56564 ± 0.00028	^{3,4} GREENE	86	SPEC $np \rightarrow d\gamma$
939.5731 ± 0.0027	³ COHEN	73	RVUE 1973 CODATA value

¹ We use the 1998 CODATA *u*-to-MeV conversion factor (see the heading above) to get this mass in MeV from the much more precisely measured KESSLER 99 value of $1.00866491637 \pm 0.0000000082\text{ u}$.

² The mass is known much more precisely in *u*: $m = 1.0086649235 \pm 0.0000000023\text{ u}$. We use the 1986 CODATA conversion factor to get the mass in MeV.

³ These determinations are not independent of the $m_n - m_p$ measurements below.

⁴ The mass is known much more precisely in *u*: $m = 1.008664919 \pm 0.000000014\text{ u}$.

 \bar{n} MASS

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT
939.485 ± 0.051	59	⁵ CRESTI	86	HBC $\bar{p}p \rightarrow \bar{n}n$

⁵ This is a corrected result (see the erratum). The error is statistical. The maximum systematic error is 0.029 MeV.

 $(m_n - m_{\bar{n}})/m_n$

A test of *CPT* invariance. Calculated from the *n* and \bar{n} masses, above.

⁶ Calculated by us from the MOHR 08 ratio $m_n/m_p = 1.00137841918(46)$. In *u*, $m_n - m_p = 1.38844920(46) \times 10^{-3}\text{ u}$.

⁷ Calculated by us from the MOHR 05 ratio $m_n/m_p = 1.00137841870 \pm 0.0000000058$. In *u*, $m_n - m_p = (1.3884487 \pm 0.0000006) \times 10^{-3}\text{ u}$.

⁸ Calculated by us from the MOHR 99 ratio $m_n/m_p = 1.00137841887 \pm 0.0000000058$. In *u*, $m_n - m_p = (1.3884489 \pm 0.0000006) \times 10^{-3}\text{ u}$.

⁹ Calculated by us from the COHEN 87 ratio $m_n/m_p = 1.001378404 \pm 0.000000009$. In *u*, $m_n - m_p = 0.001388434 \pm 0.000000009\text{ u}$.

n MEAN LIFE

We now compile only direct measurements of the lifetime, not those inferred from decay correlation measurements. For the average, we only use measurements with an error less than 10 s.

The most recent result, that of SEREBROV 05 (for a more detailed account, see SEREBROV 08A), is so far from other results that it makes no sense to include it in the average. It is up to workers in this field to resolve this issue. Until this major disagreement is understood our present average of $885.7 \pm 0.8\text{ s}$ must be suspect.

For recent reviews of neutron physics, see NICO 05A, SEVERIJNS 06, ABELE 08, and NICO 09.

Limits on lifetimes for *bound* neutrons are given in the section "*p* PARTIAL MEAN LIVES."

¹⁴ LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

¹⁵ This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

n MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron, $\langle r_n^2 \rangle$, is related to the neutron-electron scattering length b_{ne} by $\langle r_n^2 \rangle = 3(m_e a_0/m_n)b_{ne}$, where m_e and m_n are the masses of the electron and neutron, and a_0 is the Bohr radius. Numerically, $\langle r_n^2 \rangle = 86.34 b_{ne}$, if we use a_0 for a nucleus with infinite mass.

LIMIT ON *nπ* OSCILLATIONS

Mean Time for *nπ* Transition in Vacuum

A test of $\Delta B=2$ baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for *nπ* oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for $n \rightarrow \pi$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\bar{B}_f [f_1(q^2)\gamma_\lambda + i f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5q_\lambda] B_i. \quad (1)$$

Here B_i and \bar{B}_f are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1 , f_2 , g_1 , and g_3 account for vector, induced tensor (“weak magnetism”), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V , and g_1 reduces to the axial-vector coupling constant g_A . The latter coefficients are related by Cabibbo’s theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an e^\pm is emitted, and gives a very small correction, which can be estimated by PCAC [4], for μ^\pm modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f}, \quad (2)$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2 , it is necessary to modify the form factors at $q^2 = 0$ by a “dipole” q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}. \quad (3)$$

The presence of a “triple correlation” term in the transition probability, proportional to $\text{Im}(g_A/g_V)$ and of the form

$$\sigma_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (4)$$

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \quad (5)$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \bar{B}_f (A - B\gamma_5) B_i, \quad (6)$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \hat{\omega}_f \cdot \hat{\omega}_i + (1 - \gamma)(\hat{\omega}_f \cdot \hat{\mathbf{n}})(\hat{\omega}_i \cdot \hat{\mathbf{n}}) + \alpha(\hat{\omega}_f \cdot \hat{\mathbf{n}} + \hat{\omega}_i \cdot \hat{\mathbf{n}}) + \beta \hat{\mathbf{n}} \cdot (\hat{\omega}_f \times \hat{\omega}_i), \quad (7)$$

where $\hat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\hat{\omega}_i$ and $\hat{\omega}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α , β , and γ are defined as

$$\begin{aligned} \alpha &= 2 \text{Re}(s^*p)/(|s|^2 + |p|^2), \\ \beta &= 2 \text{Im}(s^*p)/(|s|^2 + |p|^2), \\ \gamma &= (|s|^2 - |p|^2)/(|s|^2 + |p|^2), \end{aligned} \quad (8)$$

where $s = A$ and $p = |\mathbf{p}_f| B/(E_f + m_f)$; here E_f and \mathbf{p}_f are the energy and momentum of the final baryon. The parameters α , β , and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \quad (9)$$

If the hyperon polarization is \mathbf{P}_Y , the polarization \mathbf{P}_B of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \hat{\mathbf{n}}) + \gamma\hat{\mathbf{n}} \times (\mathbf{P}_Y \times \hat{\mathbf{n}})}{1 + \alpha\mathbf{P}_Y \cdot \hat{\mathbf{n}}}. \quad (10)$$

Here \mathbf{P}_B is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\hat{\mathbf{n}}$ from the hyperon rest frame, in which $\hat{\mathbf{n}}$ and \mathbf{P}_Y are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin \phi. \quad (11)$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α , ϕ , and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore

that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s|e^{i\delta_s} \text{ and } p = |p|e^{i\delta_p}, \quad (12)$$

where δ_s and δ_p are the pion-baryon s - and p -wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p). \quad (13)$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \rightarrow p\pi^-$ decay, the value of Δ may be compared with the s - and p -wave phase shifts in low-energy π^-p scattering, and the results are consistent with T invariance.

See also the note on "Radiative Hyperon Decays" in the Ξ^0 Listings in this *Review*.

-1.263 ± 0.016	36 KROPF	74 RVUE	n decay alone
-1.250 ± 0.009	36 KROPF	74 RVUE	n decay + nuclear ft

- 31 This is the combined result of ABELE 02 and ABELE 97D.
- 32 MOSTOVOI 01 measures the two P -odd correlations A and B , or rather SA and SB , where S is the n polarization, in free neutron decay.
- 33 YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.
- 34 These experiments measure the absolute value of g_A/g_V only.
- 35 KROHN 75 includes events of CHRISTENSEN 70.
- 36 KROPF 74 reviews all data through 1972.

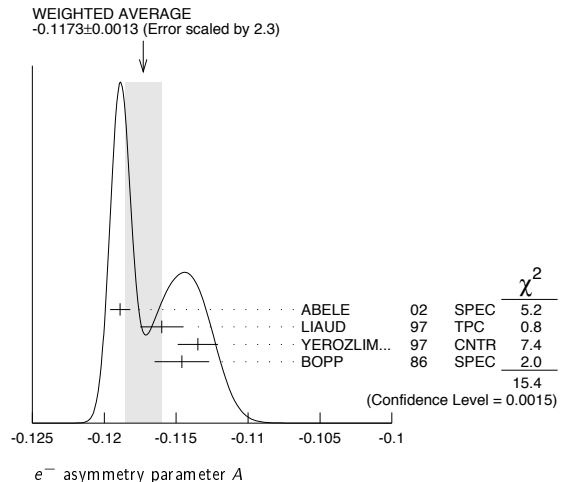

e^- ASYMMETRY PARAMETER A

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model, A is related to $\lambda \equiv g_A/g_V$ by $A = -2\lambda(\lambda + 1) / (1 + 3\lambda^2)$; this assumes that g_A and g_V are real.

- 38 YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.
- 39 MOSTOVOI 01 calculates this from its measurement of $\lambda = g_A/g_V$ above.
- 40 These results are not corrected for radiative effects and weak magnetism, but the corrections are small compared to the errors.

Baryon Particle Listings

n

 \mathcal{T}_e ASYMMETRY PARAMETER B

This is the neutron-spin antineutrino-momentum correlation coefficient. In the Standard Model, B is related to $\lambda \equiv g_A/g_V$ by $B = 2\lambda(\lambda - 1) / (1 + 3\lambda^2)$; this assumes that g_A and g_V are real.

0.9876 ± 0.0004	⁴¹ MOSTOVOI 01	CNTR	Inferred

⁴¹ MOSTOVOI 01 calculates this from its measurement of $\lambda = g_A/g_V$ above.

PROTON ASYMMETRY PARAMETER C

Describes the correlation between the neutron spin and the proton momentum. In the Standard Model, C is related to $\lambda \equiv g_A/g_V$ by $C = -x_c(A + B) = x_c 4\lambda/(1 + 3\lambda^2)$, where $x_c = 0.27484$ is a kinematic factor; this assumes that g_A and g_V are real.

VALUE	DOCUMENT ID	TECN	COMMENT

 $e\text{-}\mathcal{T}_e$ ANGULAR CORRELATION COEFFICIENT a

For a review of past experiments and plans for future measurements of the a parameter, see WIETFELDT 05. In the Standard Model, a is related to $\lambda \equiv g_A/g_V$ by $a = (1 - \lambda^2) / (1 + 3\lambda^2)$; this assumes that g_A and g_V are real.

-0.1045 ± 0.0014	⁴² MOSTOVOI 01	CNTR	Inferred

⁴² MOSTOVOI 01 calculates this from its measurement of $\lambda = g_A/g_V$ above.

 ϕ_{AV} , PHASE OF g_A RELATIVE TO g_V

Time reversal invariance requires this to be 0 or 180°. This is related to D given in the next data block and $\lambda \equiv g_A/g_V$ by $\sin(\phi_{AV}) = D(1+3\lambda^2)/2\lambda$; this assumes that g_A and g_V are real.

-27 ± 50	⁴⁴ EROZOLIM... 74	CNTR	Cold n , polarized
-11 ± 17	STEINBERG 74	CNTR	Cold n , polarized

⁴⁴ EROZOLIMSKII 78 says asymmetric proton losses and nonuniform beam polarization may give a systematic error up to 30×10^{-4} , thus increasing the EROZOLIMSKII 74 error to 50×10^{-4} . STEINBERG 74 and STEINBERG 76 estimate these systematic errors to be insignificant in their experiment.

TRIPLE CORRELATION COEFFICIENT R

Another test of time-reversal invariance. R measures the polarization of the electron in the direction perpendicular to the plane defined by the neutron spin and the electron momentum. $R = 0$ for T invariance.

VALUE	DOCUMENT ID	TECN	COMMENT
+0.008 ± 0.015 ± 0.005			
	⁴⁵ KOZELA 09	CNTR	Mott polarimeter

⁴⁵ KOZELA 09 also measures the polarization of the electron along the direction of the neutron spin. This is nonzero in the Standard Model; the correlation coefficient is $N = +0.056 \pm 0.011 \pm 0.005$.

n REFERENCES

We have omitted some papers that have been superseded by later experiments. See our earlier editions.

N AND Δ RESONANCES

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The conventional (*i.e.*, Breit-Wigner) masses, pole positions, widths, and elasticities of the N and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. Partial-wave analyses have also been performed on much smaller data sets to get $N\eta$, ΛK , and ΣK branching fractions. Other branching fractions come from isobar-model analyses of $\pi N \rightarrow N\pi\pi$ data. Finally, many $N\gamma$ branching fractions have been determined from photoproduction experiments (see Sec. III).

Table 1 lists all the N and Δ entries in the Baryon Listings and gives our evaluation of the status of each, both overall and channel by channel. Only the "established" resonances (overall status 3 or 4 stars) appear in the Baryon Summary Table. We generally consider a resonance to be established only if it has been seen in at least two independent analyses of elastic scattering and if the relevant partial-wave amplitudes do not behave erratically or have large errors.

We have, in this 2006 *Review*, made slight adjustments to our estimates of N and Δ masses, widths, and elasticities.

II. Using the N and Δ listings

Written 2002 by G. Höhler (University of Karlsruhe) and R.L. Workman, (George Washington University).

In the inelastic region, a resonance is associated with a cluster of poles on different Riemann sheets. If one of these poles is located near the real axis and far enough from branch points, it will be strongly dominant. If one of the final-state particles itself has a strong decay, it is also necessary to consider branch points in the lower half plane that belong to thresholds for two-particle final states; see for example Refs. 3 and 4.

Table 1. The status of the N and Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

Particle	$L_{2I,2J}$	Overall status	Status as seen in —

- **** Existence is certain, and properties are at least fairly well explored.
 *** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.
 ** Evidence of existence is only fair.
 * Evidence of existence is poor.

Baryon Particle Listings

N 's and Δ 's, $N(1440)$

Our Particle Listings and Summary Tables include pole parameters for the N and Δ resonances. However, the Breit-Wigner parameters are most often quoted and are used in model-based studies of the baryons and associated reaction dynamics. Problems associated with this choice were discussed in our 2000 edition [5]. Here we just point out that the use of Breit-Wigner parameters for complicated structures, such as the $N(1440)$, should be avoided. In this case, the method used in Ref. 4 is suitable for the analysis.

In the search for “missing” quark-model states, indications of new structures occasionally are found. Often these are associated (if possible) with the one- and two-star states listed in Table 1. We caution against this: The status of the one- and two-star states found in the Karlsruhe-Helsinki (KH80) [2] and Carnegie-Mellon/Berkeley (CMB80) [6] fits is now doubtful. Predictions for π^+p spin-rotation parameters from those fits are in significant disagreement with recent ITEP/PNPI measurements [7], whereas the predictions of Ref. 8 are good. This discrepancy has been associated in Ref. 7 with the behavior of a zero trajectory at a “critical point” (see Sec. 2.1.1 of Ref. 2) near a pion lab momentum of 0.8 GeV/c. According to Ref. 7, the effect on the 4-star resonances $\Delta(1905)$ and $\Delta(1950)$ is small, but the effect on the 3-star resonances $\Delta(1920)$ and $\Delta(1930)$ is large. For a study of the approximation made in Ref. 7 and of problems with some higher resonances, the detailed treatment of zero trajectories in Ref. 9 is relevant. This problem should also be considered in any multi-channel analysis that uses the KH80 and CMB80 amplitudes as input.

III. Electromagnetic interactions

Revised 2003 by R.L. Workman (George Washington University).

Nearly all the entries in the Listings concerning electromagnetic properties of the N and Δ resonances are $N\gamma$ couplings. These couplings, the helicity amplitudes $A_{1/2}$ and $A_{3/2}$, have been obtained in partial-wave analyses of single-pion photoproduction, η photoproduction, and Compton scattering. Most photoproduction analyses have taken the existence, masses, and widths of the resonances from the $\pi N \rightarrow \pi N$ analyses, and have only determined the $N\gamma$ couplings. This approach is only applicable to resonances with a significant $N\pi$ coupling. A brief description of the various methods of analysis of photoproduction data may be found in our 1992 edition [10].

Our Listings omit a number of analyses that are now obsolete. Most of the older results may be found in our 1982 edition [11]. The errors quoted for the couplings in the Listings are calculated in different ways in different analyses and therefore should be used with care. In general, the systematic differences between the analyses caused by using different parameterization schemes are probably more indicative of the true uncertainties than are the quoted errors.

Probably the most reliable analyses, for most resonances, are ARAI 80, CRAWFORD 80, AWAJI 81, FUJII 81, CRAWFORD 83, and ARNDT 96. There is an update to the Crawford

analysis [1]. The errors we give on $N\gamma$ couplings are a combination of the stated statistical errors on the analyses and the systematic differences between them. The analyses are given equal weight, except ARNDT 96 is weighted, rather arbitrarily, by a factor of two because its data set is at least 50% larger than those of the other analyses and contains many new high-quality measurements. The $\Delta(1232)$ and $N(1535)$ are special cases and are discussed in the 2002 *Review* [12].

The Baryon Summary Table gives $N\gamma$ branching fractions for those resonances whose couplings are considered to be reasonably well established. The $N\gamma$ partial width Γ_γ is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k^2}{\pi} \frac{2M_N}{(2J+1)M_R} [|A_{1/2}|^2 + |A_{3/2}|^2] .$$

Here M_N and M_R are the nucleon and resonance masses, J is the resonance spin, and k is the photon c.m. decay momentum.

See our 2002 *Review* [12] for some further discussion.

 $N(1440)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ARNDT 06 also finds a second-sheet pole with real part = 1388 MeV, $-2 \times$ imaginary part = 165 MeV, and residue with modulus 86 MeV and phase = -46 degrees.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 04 also finds a second-sheet pole with real part = 1385 MeV, $-2 \times$ imaginary part = 166 MeV, and residue with modulus 82 MeV and phase = -51° .
- ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV, $-2 \times$ imaginary part = 210 MeV, and residue with modulus 92 MeV and phase = -54° .
- ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, $-2 \times$ imaginary part = 256 MeV, and residue = $(78-153i)$ MeV.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620) S_{31}$ coupling to $\Delta(1232)\pi$.

N(1520) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\pi$	0.55 to 0.65
Γ_2 $N\eta$	(2.3 ± 0.4) × 10 ⁻³
Γ_3 $N\pi\pi$	40-50 %
Γ_4 $\Delta\pi$	15-25 %
Γ_5 $\Delta(1232)\pi, S\text{-wave}$	5-12 %
Γ_6 $\Delta(1232)\pi, D\text{-wave}$	10-14 %
Γ_7 $N\rho$	15-25 %
Γ_8 $N\rho, S=1/2, D\text{-wave}$	
Γ_9 $N\rho, S=3/2, S\text{-wave}$	
Γ_{10} $N\rho, S=3/2, D\text{-wave}$	
Γ_{11} $N(\pi\pi)_{S\text{-wave}}^{I=0}$	<8 %
Γ_{12} $p\gamma$	0.46-0.56 %
Γ_{13} $p\gamma, \text{helicity}=1/2$	0.001-0.034 %
Γ_{14} $p\gamma, \text{helicity}=3/2$	0.44-0.53 %
Γ_{15} $n\gamma$	0.30-0.53 %
Γ_{16} $n\gamma, \text{helicity}=1/2$	0.04-0.10 %
Γ_{17} $n\gamma, \text{helicity}=3/2$	0.25-0.45 %

 $N(1520)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The ratio of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$.

 $N(1535)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- KRUSCHE 97 fits with the mass fixed at 1544 MeV.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The best value ARMSTRONG 99B obtains is ≈ 0.55 ; this assumes S_{11} dominance in the reaction $p(e, e'p)\eta$ at $Q^2 = 4$ (GeV/c)².
- This STAROSTIN 03 value is an estimate made using simplest assumptions.
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(20 \pm 15)^\circ$.
- BENMERROUCHE 91 uses an effective Lagrangian approach to analyze η photoproduction data.
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(20 \pm 20)^\circ$.

 $N(1650)$ FOOTNOTES

- ARNDT 95 finds two distinct states.
- BATINIC 95 finds two distinct states. This second resonance was associated with the $N(2090) S_{11}$.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(25 \pm 20)^\circ$.
- This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(30 \pm 25)^\circ$.

 $N(1675)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- SAXON 80 finds the coupling phase is near 90°.
- LONGACRE 77 considers this coupling to be well determined.

Coupling to ΛK not required in the analyses of SAXON 80 or BELL 83.				

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620) S_{31}$ coupling to $\Delta(1232)\pi$.

$N(1680)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.

$N(1700) D_{13}$ $I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various partial-wave analyses do not agree very well.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

N(1700) FOOTNOTES

- The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
- The range given is from the four best solutions.

$N(1710)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\pi$	10-20 %
Γ_2 $N\eta$	(6.2 \pm 1.0) %
Γ_3 $N\omega$	(13.0 \pm 2.0) %
Γ_4 ΛK	5-25 %
Γ_5 ΣK	
Γ_6 $N\pi\pi$	40-90 %
Γ_7 $\Delta\pi$	15-40 %
Γ_8 $\Delta(1232)\pi, P$ -wave	
Γ_9 $N\rho$	5-25 %
Γ_{10} $N\rho, S=1/2, P$ -wave	
Γ_{11} $N\rho, S=3/2, P$ -wave	
Γ_{12} $N(\pi\pi)_{S\text{-wave}}^{I=0}$	10-40 %
Γ_{13} $p\gamma$	0.002-0.05 %
Γ_{14} $p\gamma, \text{helicity}=1/2$	0.002-0.05 %
Γ_{15} $n\gamma$	0.0-0.02 %
Γ_{16} $n\gamma, \text{helicity}=1/2$	0.0-0.02 %

$N(1710)$ FOOTNOTES

- BATINIC 95 finds a second state with a 6 MeV mass difference.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

N(1720) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ _i /Γ)
Γ ₁ Nπ	10-20 %
Γ ₂ Nη	(4.0 ± 1.0) %
Γ ₃ ΛK	1-15 %
Γ ₄ ΣK	
Γ ₅ Nππ	>70 %
Γ ₆ Δπ	
Γ ₇ Δ(1232)π, P-wave	
Γ ₈ Nρ	70-85 %
Γ ₉ Nρ, S=1/2, P-wave	
Γ ₁₀ Nρ, S=3/2, P-wave	
Γ ₁₁ N(ππ) _{S-wave} ^{j=0}	
Γ ₁₂ pγ	0.003-0.10 %
Γ ₁₃ pγ, helicity=1/2	0.003-0.08 %
Γ ₁₄ pγ, helicity=3/2	0.001-0.03 %
Γ ₁₅ nγ	0.002-0.39 %
Γ ₁₆ nγ, helicity=1/2	0.0-0.002 %
Γ ₁₇ nγ, helicity=3/2	0.001-0.39 %

$N(1720)$ FOOTNOTES

- ¹ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ³ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ⁴ LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$$I(J^P) = \frac{1}{2}(\frac{7}{2}^+) \text{ Status: } **$$

OMITTED FROM SUMMARY TABLE

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various analyses do not agree very well with one another.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

OMITTED FROM SUMMARY TABLE

There is some evidence for two resonances in this wave between 1800 and 2200 MeV (see CUTKOSKY 80). However, the solution of HOEHLER 79 is quite different.

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

N(2080) FOOTNOTES

- CUTKOSKY 80 finds a lower mass D_{13} resonance, as well as one in this region. Both are listed here.
- The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \rightarrow \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

 $N(2090)$ FOOTNOTES

¹ LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 Partial-Wave Analyses**

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an *N*(3245), an *N*(3690), and an *N*(3755), each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an *N*(3030), deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 *L*_{1,15} state below.

⁴ This ARNDT 95 value is in error, as pointed out by HOHLER 01. The corrected value is in line with the ARNDT 91 value (R.A. Arndt, private communication).

 $\Delta(1232)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

Mode	Fraction (Γ_j/Γ)
Γ_1 $N\pi$	100 %
Γ_2 $N\gamma$	0.52–0.60 %
Γ_3 $N\gamma$, helicity=1/2	0.11–0.13 %
Γ_4 $N\gamma$, helicity=3/2	0.41–0.47 %

 $\Delta(1600) P_{33}$

$$I(J^P) = \frac{3}{2}(\frac{3}{2}^+) \text{ Status: } ***$$

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various analyses are not in good agreement.

$\Delta(1600)$ FOOTNOTES

- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \rightarrow \Sigma^+ K^+ K^+$ data of WINNIK 77 around 1920 MeV.
- LONGACRE 77 considers this coupling to be well determined.
- WADA 84 is inconsistent with other analyses — see the Note on N and Δ Resonances.

$\Delta(1620)$ FOOTNOTES

- CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620) S_{31}$ coupling to $\Delta(1232)\pi$.

 $\Delta(1700)$ FOOTNOTES

- Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.
- LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- LONGACRE 77 considers this coupling to be well determined.

$\Delta(1750)$ FOOTNOTES

- ¹ CHEW 80 reports four resonances in the P_{31} wave — see also the $\Delta(1910)$. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.
- ² ARNDT 04 gives no corresponding Breit-Wigner parameters for this state, because the mass so obtained is about 500 MeV higher than that suggested by the position of the pole.

 $\Delta(1900)$ FOOTNOTES

- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 $\Delta(1905)$, $\Delta(1910)$ $\Delta(1905)$ FOOTNOTES

- ¹ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
² See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
³ LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$\Delta(1910)$ FOOTNOTES

- 1 CHEW 80 reports four resonances in the P_{31} wave — see also the $\Delta(1750)$. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.
- 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

$\Delta(1950)$ FOOTNOTES

- From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 $\Delta(2150)$ FOOTNOTES

¹ CHEW 80 reports two S_{31} resonances in this mass region. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The $\Delta(2850)$ has been resolved into the $\Delta(2750) l_{3,13}$ and $\Delta(2950) K_{3,15}$. The $\Delta(3230)$ is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

EXOTIC BARYONS

PENTAQUARKS

Written May 2008 by C.G. Wohl (LBNL).

See pp. 1019–1022 of the 2006 *Review* [1] for the evidence for the $\Theta(1540)$, $\Phi(1860)$, and $\Theta_c(3100)$, and for the early unsuccessful attempts to confirm them. The table below lists papers published since then giving results of further unsuccessful searches. There are experiments at high energies and low; in new reactions and old; there are experiments—some by the same groups that claimed the original discoveries—with orders-of-magnitude greater statistics than before; there are experiments that find 100,000 $\Lambda(1520)$ s in $\bar{K}N$, but no hint of a $\Theta(1540)$ in KN . Many of the experiments search over large ranges of mass. The limits on production of a pentaquark given in the

last column of the table are at 90 or 95% confidence level; the cross-section limits are in some cases now fractions of a nanobarn. The limits often involve assumptions about the width of the pentaquark, its production angular distribution, or other matters. There is not room (or reason) to give here all the details—for which, see the papers.

There are two or three recent experiments that find weak evidence for signals near the nominal masses, but there is simply no point in tabulating them in view of the overwhelming evidence that the claimed pentaquarks do not exist. The only advance in particle physics thought worthy of mention in the American Institute of Physics “Physics News in 2003” was a false alarm. The whole story—the discoveries themselves, the tidal wave of papers by theorists and phenomenologists that followed, and the eventual “undiscovery”—is a curious episode in the history of science.

Table 1: Unsuccessful searches for pentaquarks. There are ten more unsuccessful searches for the $\Theta(1540)$, nine for the $\Phi(1860)$, and three for the $\Theta_c(3100)$ listed in our 2006 edition [1].

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p , n , and Λ moments as input. In this model, the moments are [1]

$$\begin{aligned} \mu_p &= (4\mu_u - \mu_d)/3 & \mu_n &= (4\mu_d - \mu_u)/3 \\ \mu_{\Sigma^+} &= (4\mu_u - \mu_s)/3 & \mu_{\Sigma^-} &= (4\mu_d - \mu_s)/3 \\ \mu_{\Xi^0} &= (4\mu_s - \mu_u)/3 & \mu_{\Xi^-} &= (4\mu_s - \mu_d)/3 \\ \mu_\Lambda &= \mu_s & \mu_{\Sigma^0} &= (2\mu_u + 2\mu_d - \mu_s)/3 \\ \mu_{\Omega^-} &= 3\mu_s \end{aligned}$$

and the $\Sigma^0 \rightarrow \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}.$$

The quark moments that result from this model are $\mu_u = +1.852 \mu_N$, $\mu_d = -0.972 \mu_N$, and $\mu_s = -0.613 \mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.5$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

⁷ Changed by us from $\Gamma(p e^- \bar{\nu}_e)/\Gamma(N\pi)$ assuming the authors used $\Gamma(p\pi^-)/\Gamma_{\text{total}} = 2/3$.

⁸ Changed by us from $\Gamma(p e^- \bar{\nu}_e)/\Gamma(N\pi)$ because $\Gamma(p e^- \nu)/\Gamma(p\pi^-)$ is the directly measured quantity.

¹⁰CHAUVAT 85 actually gives $\alpha_+(\bar{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$. Assumes polarization is same in $\bar{p}p \rightarrow \bar{\Lambda}X$ and $pp \rightarrow \Lambda X$. Tests of this assumption, based on C-invariance and fragmentation, are satisfied by the data.

g_A / g_V FOR Λ → pe⁻ν_e

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. The measurements all assume that the form factor $g_2 = 0$. See also the footnote on DWORKIN 90.

¹¹The tabulated result assumes the weak-magnetism coupling $w \equiv g_W(0)/g_V(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 measures w to be 0.15 ± 0.30 , and then $g_A/g_V = -0.731 \pm 0.016$.

¹²This experiment measures only the absolute value of g_A/g_V .

Baryon Particle Listings

Λ 's and Σ 's

Λ AND Σ RESONANCES

Introduction: The only new data entries in this 2006 *Review* are two measurements of the $\Lambda(1520) \rightarrow \Lambda\gamma$ branching fraction and measurements of the $\Sigma(1385) \rightarrow \Lambda\gamma$ and $\Sigma^- \gamma$ branching fractions. The field remains at a standstill. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1 , the amplitude for $K^- p \rightarrow \bar{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the “first” particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points “up”), then any Σ at resonance will point “up” and any Λ at resonance will point “down” (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\bar{K}N \rightarrow \Lambda\pi$ and $\bar{K}N \rightarrow \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is “up”? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or - sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

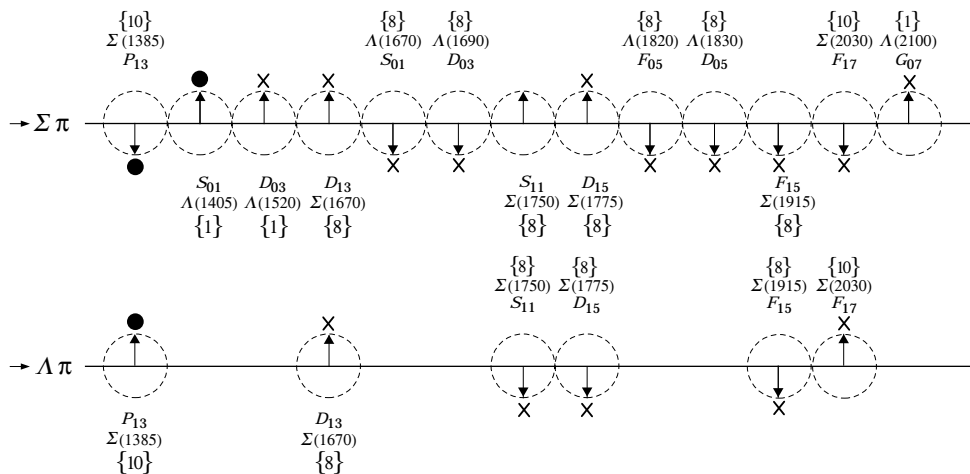

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\bar{K}N \rightarrow \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a \bullet , are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an \times .

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

**** Existence is certain, and properties are at least fairly well explored.
 *** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.
 ** Evidence of existence is only fair.
 * Evidence of existence is poor.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The Σ(1385) and Λ(1405) of course lie below the $\bar{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case

of Λ(1520) and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the Σ(1670).

Λ(1405) S_{01}
 $I(J^P) = 0(\frac{1}{2}^-)$ Status: ****

It seems to be the universal opinion of the chiral-unitary community that there are two poles in the 1400-MeV region. For discussions and earlier references, see for example MAGAS 05 and JIDO 03. ZYCHOR 08 presents experimental evidence against the two-pole model, but this is disputed by GENG 07A. See also REVAI 09, which finds little basis for choosing between one- and two-pole models.

See also the “Note on the Λ(1405)” in our 2000 edition, *The European Physical Journal* **C15** 1 (2000).

A single, ordinary three-quark Λ(1405) fits nicely into a $J^P = 1/2^-$ SU(4) $\bar{4}$ multiplet, whose other members are the $\Lambda_c(2595)^+$, $\Xi_c(2790)^+$, and $\Xi_c(2790)^0$; see Fig. 1 of our note on “Charmed Baryons.”

$\Lambda(1405)$ FOOTNOTES

- ¹DALITZ 91 fits the HEMINGWAY 85 data.
- ²THOMAS 73 data is fit by CHAO 73 (see next section).
- ³The KIMURA 00 values are from fits A and B from a coupled-channel potential model using low-energy $\bar{K}N$ and $\Sigma\pi$ data, kaonic-hydrogen x-ray measurements, and our $\Lambda(1405)$ mass and width. The results bear mainly on the nature of the $\Lambda(1405)$: three-quark state or $\bar{K}N$ bound state.
- ⁴The MARTIN 81 fit includes the $K^\pm p$ forward scattering amplitudes and the dispersion relations they must satisfy.
- ⁵See also the accompanying paper of THOMAS 73.
- ⁶Data of SAKITT 65 are used in the fit by KITTEL 66.
- ⁷An asymmetric shape, with $\Gamma/2 = 41$ MeV below resonance, 14 MeV above.

$\Lambda(1520) D_{03}$

$$I(J^P) = 0(\frac{3}{2}^-) \text{ Status: } ***$$

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** 1 (1982).

Production and formation experiments agree quite well, so they are listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 26 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 17.6$ for 21 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma(\Sigma(1385)\pi(\rightarrow\Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$	DOCUMENT ID	TECN	COMMENT	Γ_5/Γ_3
The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$. Only the values of $(\Sigma(1385)\pi) / (\Lambda\pi\pi)$ given by MAST 73B and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{S\text{-wave}}$ state.

$\Lambda(1520)$ FOOTNOTES

- From the best-resolution sample of $\Lambda\pi\pi$ events only.
- The $\bar{K}N \rightarrow \Sigma\pi$ amplitude at resonance is $+0.46 \pm 0.01$.
- Assumes $\Gamma(N\bar{K})/\Gamma_{\text{total}} = 0.46 \pm 0.02$.
- Both $\Sigma(1385)\pi$ DS_{03} and $\Sigma(\pi\pi)$ DP_{03} contribute.
- The central bin (1514-1524 MeV) gives 0.74 ± 0.10 ; other bins are lower by 2-to-5 standard deviations.
- Much of the $\Sigma\pi\pi$ decay proceeds via $\Sigma(1385)\pi$.
- Assumes $\Gamma(N\bar{K})/\Gamma_{\text{total}} = 0.46$.
- Calculated from $\Gamma(\Lambda\gamma)/\Gamma_{\text{total}}$, assuming SU(3). Needed to constrain the sum of all the branching ratios to be unity.

 $\Lambda(1670)$ FOOTNOTES

- ¹ GARCIA-RECIO 03 gives pole, not Breit-Wigner, parameters, but the narrow width of the $\Lambda(1670)$ means there will be little difference.
² MARTIN 77 obtains identical resonance parameters from a T-matrix pole and from a Breit-Wigner fit.

 $\Lambda(1690)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\bar{K}$	20–30 %
Γ_2 $\Sigma\pi$	20–40 %
Γ_3 $\Lambda\pi\pi$	~ 25 %
Γ_4 $\Sigma\pi\pi$	~ 20 %
Γ_5 $\Lambda\eta$	
Γ_6 $\Sigma(1385)\pi, S$ -wave	

The above branching fractions are our estimates, not fits or averages.

 $\Lambda(1690)$ BRANCHING RATIOSThe sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

 $\Lambda(1690)$ FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another D_{03} Λ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.
² BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

$\Lambda(1820) F_{05}$

$$I(J^P) = 0(\frac{5}{2}^+) \text{ Status: } ***$$

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

VALUE				
$+0.065 \pm 0.029$	³ CAMERON	78	DPWA $K^- p \rightarrow \Sigma(1385)\pi$	

$\Lambda(1820)$ FOOTNOTES

- The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \rightarrow \Sigma \pi$ decay.
- The published sign has been changed to be in accord with the baryon-first convention.

$I(J^P) = 0(?)^?$ Status: *

OMITTED FROM SUMMARY TABLE

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5 , P_3+D_5 , or P_1+D_3 (BRANDSTETTER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\bar{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\bar{K}$ or $\Sigma\pi$. With new K^-n angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

 $\Lambda(2100) G_{07}$

$$I(J^P) = 0(\frac{7}{2}^-) \text{ Status: } ***$$

Discovered by COOL 66 and by WOHL 66. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** 1 (1986).

Baryon Particle Listings

$\Lambda(2100)$, $\Lambda(2110)$, $\Lambda(2325)$

$\Lambda(2100)$ FOOTNOTES

- The NAKKASYAN 75 values are from the two best solutions found. Each has the $\Lambda(2100)$ and one additional resonance (P_3 or F_5).
- Note that the three for BACCARI 77 entries are for three different waves.
- The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

$\Lambda(2325)$ D_{03}

$$I(J^P) = 0(\frac{3}{2}^-) \text{ Status: } *$$

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^-p \rightarrow \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^-p \rightarrow \bar{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

Γ_9 $p \mu^+ \mu^-$	$S1 (9 \pm 9 / -8) \times 10^{-8}$	

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.7$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ***

COURANT 63 and ALFF-STEINBERGER 65, using $\Sigma^0 \rightarrow \Lambda e^+ e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \rightarrow \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses $\Sigma^+, \Sigma^0, \Sigma^-,$ and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \rightarrow \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0 - Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma^0 \Lambda} / \mu_N)^2 \tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

Γ_5 $\Lambda e^- \bar{\nu}_e$	(5.73 ± 0.27) × 10 ⁻⁵

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 8.7$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_3	-64		
x_4	-77	0	
x_5	-5	0	0
	x_1	x_3	x_4

Σ^- BRANCHING RATIOS

-0.071 ± 0.012	51k	BANGERTER	69	HBC $K^- p$ 0.4 GeV/c

ϕ ANGLE FOR $\Sigma^- \rightarrow n \pi^-$

($\tan \phi = \beta / \gamma$)

VALUE (°)	EVTS	DOCUMENT ID	TECN	COMMENT
10 ± 15 OUR AVERAGE				
+ 5 ± 23	1092	⁶ BERLEY	70B	HBC n rescattering
14 ± 19	1385	BANGERTER	69B	HBC $K^- p$ 0.4 GeV/c

⁶ BERLEY 70b changed from -5 to +5° to agree with our sign convention.

g_A/g_V FOR $\Sigma^- \rightarrow n e^- \bar{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.340 ± 0.017 OUR AVERAGE				
+0.327 ± 0.007 ± 0.019	50k	⁷ HSUEH	88	SPEC Σ^- 250 GeV
+0.34 ± 0.05	4456	⁸ BOURQUIN	83c	SPEC SPS hyperon beam
0.385 ± 0.037	3507	⁹ TANENBAUM	74	ASPK

• • • We do not use the following data for averages, fits, limits, etc. • • •

⁷ The sign is, with our conventions, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

⁸ BOURQUIN 83c favors the positive sign by at least 2.6 standard deviations.

⁹ TANENBAUM 74 gives 0.435 ± 0.035 , assuming no q^2 dependence in g_A and g_V . The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \rightarrow n e^- \bar{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT

$\Sigma(1385) P_{13}$

$$I(J^P) = 1(\frac{3}{2}^+) \text{ Status: } ****$$

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P -wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P -wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S -wave results are given here.

 $\Sigma(1385)$ FOOTNOTES

- From fit to inclusive $\Lambda\pi$ spectrum.
- Includes data of HOLMGREN 77.
- The errors are statistical only. The resolution is not unfolded.
- The error is enlarged to Γ/\sqrt{N} . See the note on the $K^*(892)$ mass in the 1984 edition.
- From a fit to $\Lambda\pi^0$ with the width fixed at 34 MeV.
- From fit to inclusive $\Lambda\pi^0$ spectrum with the width fixed at 40 MeV.
- Redundant with data in the mass Listings.
- Results from $\Lambda\pi^+\pi^-$ and $\Lambda\pi^+\pi^-\pi^0$ combined by us.
- The error is enlarged to $4\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
- Consistent with +, 0, and − widths equal.
- We calculate this from the MOLCHANOV 04 upper limit of 9.5 keV on the $\Sigma^-\gamma$ width.
- We calculate this from the ARIK 77 upper limit of 24 keV on the $\Sigma^-\gamma$ width.
- An extrapolation of the parametrized amplitude below threshold.

$$I(J^P) = 1(?^?) \quad \text{Status: *}$$

OMITTED FROM SUMMARY TABLE

These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+p \rightarrow (Y\pi)K^+$ at 1.7 GeV/c. Also, the Y polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \rightarrow \Lambda K$ decay. However, such an explanation for the $(\Sigma^+\pi^0)K^+$ channel in terms of $\Delta(1650) \rightarrow \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^-p \rightarrow \Lambda\pi^0$.

ENGELEN 80 performs a multichannel analysis of $K^-p \rightarrow p\bar{K}^0\pi^-$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in $p\bar{K}^0$ which cannot be explained as a reflection of any competing channel.

PRAKHOV 04 sees no evidence for this or other light Σ resonances, aside from the $\Sigma(1385)$, in $K^-p \rightarrow \Lambda\pi^0\pi^0$.

ZYCHOR 06 finds peaks in $pp \rightarrow pK^+(\pi^\pm X^\mp)$ at $p_{beam} = 3.65$ GeV/c.

$\Sigma(1560)$ Bumps $I(J^P) = 1(?)^?$ Status: **

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^-p \rightarrow (\Lambda/\Sigma)\pi K\bar{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^\pm$ from the reaction $pp \rightarrow \Lambda\pi^+\pi^-X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\bar{K}N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$$I(J^P) = 1(\frac{3}{2}^-) \text{ Status: } *$$

OMITTED FROM SUMMARY TABLE

Seen in the isospin-1 $\bar{K}N$ cross section at BNL (LI 73, CARROLL 76) and in a partial-wave analysis of $K^-p \rightarrow \Lambda\pi^0$ for c.m. energies 1560–1600 MeV by LITCHFIELD 74. LITCHFIELD 74 finds $J^P = 3/2^-$. Not seen by ENGLER 78 or by CAMERON 78C (with larger statistics in $K_L^0 p \rightarrow \Lambda\pi^+$ and $\Sigma^0\pi^+$).

Neither OLMSTED 04 (in $K^-p \rightarrow \Lambda\pi^0$) nor PRAKHOV 04 (in $K^-p \rightarrow \Lambda\pi^0\pi^0$) see any evidence for this state.

$\Sigma(1580)$ FOOTNOTES

¹CARROLL 76 sees a total-cross-section bump with $(J+1/2) \Gamma_{el} / \Gamma_{total} = 0.06$.

²The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\bar{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

$\Sigma(1660)$ FOOTNOTES

- The evidence of KOISO 85 is weak.
- The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- From solution 1 of BAILLON 75; not present in solution 2.
- From solution 2 of PONTE 75; not present in solution 1.

THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma\pi/\Sigma\pi\pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^-p \rightarrow \pi^-\Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma\pi\pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma\pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13} . There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda\pi/\Sigma\pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

Baryon Particle Listings

 $\Sigma(1670)$ $\Sigma(1670) D_{13}$

$$I(J^P) = 1(\frac{3}{2}^-) \text{ Status: } ****$$

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

Results from production experiments are listed separately in the next entry.

0.081 \pm 0.016	⁶ CAMERON	77	DPWA $P\text{-wave}$ decay

 $\Sigma(1670)$ FOOTNOTES

- The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- Results are with and without an S_{11} $\Sigma(1620)$ in the fit.
- SIMS 68 uses only cross-section data. Result used as upper limit only.
- Ratio only for $\Sigma\pi\pi$ system in $l=1$, which cannot be $\Sigma(1385)$.
- Assuming the $\Lambda(1405)\pi$ cross-section bump is due only to $3/2^-$ resonance.
- The CAMERON 77 upper limit on $F\text{-wave}$ decay is 0.03.

$J^P = 3/2^+$		LEVEQUE	65	HBC	$\Lambda(1405) \pi$

 $\Sigma(1670)$ FOOTNOTES

- Total cross-section bump with $(J+1/2) \Gamma_{el} / \Gamma_{total} = 0.23$.
- Enhancements in $\Sigma\pi$ and $\Sigma\pi\pi$ cross sections.
- Backward production in the $\Lambda\pi^- K^+$ final state.
- Depending on production angle.
- APSELL 74, ESTES 74, and TIMMERMANS 76 find strong branching ratio dependence on production angle, as in earlier production experiments.

 $\Sigma(1690)$ FOOTNOTES
(PRODUCTION EXPERIMENTS)

- From $\pi^+ p \rightarrow (\Lambda\pi^+) K^+$, $J > 1/2$ is not required by the data.
- From $\pi^+ p \rightarrow (\Lambda\pi^+) (K\pi)^+$, $J > 1/2$ is indicated, but large background precludes a definite conclusion.
- See the $\Sigma(1670)$ Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the $\Sigma(1690)$.
- This analysis, which is difficult and requires several assumptions and shows no unambiguous $\Sigma(1690)$ signal, suggests $J^P = 5/2^+$. Such a state would lead all previously known Y^* trajectories.

 $\Sigma(1750) S_{11}$

$$I(J^P) = 1(\frac{1}{2}^-) \quad \text{Status: ***}$$

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\bar{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74). $\Sigma(1750)$ MASS

 $\Sigma(1770)$, $\Sigma(1775)$ $\Sigma(1770)$ FOOTNOTES

- ¹ Required to fit the isospin-1 total cross section of CARROLL 76 in the $\bar{K}N$ channel. The addition of new K^-p polarization and K^-n differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660) P_{11}$.
- ² From solution 1 of BAILLON 75; not present in solution 2.
- ³ Not required in KANE 74, which supersedes KANE 72.

$$\Sigma(1775) D_{15} \quad I(J^P) = 1(\frac{5}{2}^-) \text{ Status: } ****$$

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820)F_{05}$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

 $\Sigma(1775)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)
Γ_1 $N\bar{K}$	37-43%
Γ_2 $\Lambda\pi$	14-20%
Γ_3 $\Sigma\pi$	2-5%
Γ_4 $\Sigma(1385)\pi$	8-12%
Γ_5 $\Sigma(1385)\pi, D\text{-wave}$	
Γ_6 $\Lambda(1520)\pi$	17-23%
Γ_7 $\Sigma\pi\pi$	

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 63.9$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	-30			
x_3	-17	-21		
x_4	-37	-49	-14	
x_6	-81	6	8	16
	x_1	x_2	x_3	x_4

 $\Sigma(1775)$ BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too small.

 $\Sigma(1775)$ FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- ² This rate combines P -wave- and F -wave decays. The CAMERON 77 results for the separate P -wave- and F -wave decays are -0.303 ± 0.010 and -0.037 ± 0.014 . The published signs have been changed here to be in accord with the baryon-first convention.
- ³ The CAMERON 78 upper limit on G -wave decay is 0.03.
- ⁴ For about 3/4 of this, the $\Sigma\pi$ system has $l = 0$ and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has $l = 1$, which is about what is expected from the known $\Sigma(1775) \rightarrow \Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

$$I(J^P) = 1(\frac{3}{2}^+) \text{ Status: } ****$$

Discovered by COOL 66. For results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions in this region used to be listed in a separate entry immediately following. They may be found in our 1986 edition Physics Letters **170B** 1 (1986).

 $\Sigma(1915)$ FOOTNOTES

- The two entries for CORDEN 77C are from two different acceptable solutions.
- Preferred solution 3; see CORDEN 76 for other possibilities.
- The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- The mass and width are fixed to the GOPAL 77 values due to the low elasticity.
- The published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(2070) F_{15}$

$I(J^P) = 1(\frac{5}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 with new $K^- p$ polarization and $K^- n$ angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of $\bar{K} N \rightarrow \Sigma \pi$.

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\bar{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\bar{K}N \rightarrow \Lambda\pi$, $\Sigma\pi$, and $N\bar{K}$, respectively, suggest two resonances around this mass.

 $\Sigma(3170)$ Bumps **$\Sigma(3170)$ Bumps** $I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \rightarrow Y^{*+} \pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 9 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 4.6$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

⁸ DAUBER 69 uses $\alpha_\Lambda = 0.647 \pm 0.020$.⁹ The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

RADIATIVE HYPERON DECAYS

Written September 2003 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i \rightarrow B_f \gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q = 0$, $\Delta S = 1$ transition, the angular distribution of the direction \hat{p} of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi} (1 + \alpha_\gamma \mathbf{P}_i \cdot \hat{p}). \quad (1)$$

Here \mathbf{P}_i is the polarization of the decaying hyperon, and α_γ is the asymmetry parameter. In terms of the form factors $F_1(q^2)$,

$F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_\lambda + iF_2(q^2)\sigma_{\lambda\mu}q^\mu + G(q^2)\gamma_\lambda\gamma_5,$$

 α_γ is

$$\alpha_\gamma = \frac{2\text{Re}[G(0)F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2}, \quad (2)$$

where $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = -\alpha_\gamma$ [1].

The angular distribution for the weak hadronic decay, $B_i \rightarrow B_f \pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_π . Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = +\alpha_\pi$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

$\Xi^0 \rightarrow \Lambda\gamma$ decay—The radiative decay $\Xi^0 \rightarrow \Lambda\gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \rightarrow p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_\Lambda = -\alpha_{\Xi\Lambda\gamma}$. Let α_- be the $\Lambda \rightarrow p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \rightarrow p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2} (1 - \alpha_{\Xi\Lambda\gamma} \alpha_- \cos\theta_{\Lambda p}) \quad (3)$$

for the angular distribution of the proton in the Λ frame. The only published measurement of $\alpha_{\Xi\Lambda\gamma}$ [4] got the sign wrong, as explained in an erratum 12 years later [5]. The corrected result is $\alpha_{\Xi\Lambda\gamma} = -0.43 \pm 0.44$.

$\Xi^0 \rightarrow \Sigma^0\gamma$ decay—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \rightarrow \Sigma^0\gamma$, $\Sigma^0 \rightarrow \Lambda\gamma$, $\Lambda \rightarrow p\pi^-$. Again, for an unpolarized Ξ^0 , the longitudinal polarization of the Σ^0 will be $P_\Sigma = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \rightarrow \Lambda\gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ , as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity +1/2, the probability amplitudes for positive and negative spin states of the Σ^0 along the Λ momentum are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity -1/2, the amplitudes are interchanged. If the Σ^0 has longitudinal polarization P_Σ , the probabilities for Λ helicities $\pm 1/2$ are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_\Sigma) \cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_\Sigma) \sin^2(\theta_{\Sigma\Lambda}/2), \quad (4)$$

and the longitudinal polarization of the Λ is

$$P_\Lambda = -P_\Sigma \cos\theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma} \cos\theta_{\Sigma\Lambda}. \quad (5)$$

Using Eq. (1) for the $\Lambda \rightarrow p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \rightarrow \Lambda\gamma$, $\Lambda \rightarrow p\pi^-$ chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}d\cos\theta_{\Lambda p}} = \frac{N}{4} (1 + \alpha_{\Xi\Sigma\gamma} \cos\theta_{\Sigma\Lambda} \alpha_- \cos\theta_{\Lambda p}). \quad (6)$$

The KTeV collaboration recently measured $\alpha_{\Xi\Sigma\gamma}$ to be -0.63 ± 0.09 [6]. The only other measurement has been withdrawn [7].

References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 40 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

⁸This LUK 00 value is for $\alpha(\Xi^+)\alpha_+(\bar{\Lambda})$. We assume CP conservation here by including it in the average for $\alpha(\Xi^-)\alpha_-(\Lambda)$. But see the second data block below for the CP test.

α FOR $\Xi^- \rightarrow \Lambda\pi^-$
 The above average, $\alpha(\Xi^-)\alpha_-(\Lambda) = -0.294 \pm 0.005$, where the error includes a scale factor of 1.7, divided by our current average $\alpha_-(\Lambda) = 0.642 \pm 0.013$, gives the following value for $\alpha(\Xi^-)$.

-0.458 ± 0.012 OUR EVALUATION Error includes scale factor of 1.8.

$\frac{[\alpha(\Xi^-)\alpha_-(\Lambda) - \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}{[\alpha(\Xi^-)\alpha_-(\Lambda) + \alpha(\Xi^+)\alpha_+(\bar{\Lambda})]}$
 This is zero if CP is conserved. The α 's are the decay-asymmetry parameters for $\Xi^- \rightarrow \Lambda\pi^-$ and $\Lambda \rightarrow p\pi^-$ and for $\Xi^+ \rightarrow \bar{\Lambda}\pi^+$ and $\bar{\Lambda} \rightarrow \bar{p}\pi^+$.

54 ± 30	356	¹² CARMONY 64B	HBC	

⁹From this result and α_Ξ , HUANG 04 gets $\beta_\Xi = -0.037 \pm 0.011 \pm 0.010$ and $\gamma_\Xi = 0.888 \pm 0.0004 \pm 0.006$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(4.6 \pm 1.4 \pm 1.2)^\circ$.

¹⁰From this result and α_Ξ , CHAKRAVORTY 03 obtains $\beta_\Xi = -0.025 \pm 0.042 \pm 0.006$ and $\gamma_\Xi = 0.889 \pm 0.001 \pm 0.007$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(3.17 \pm 5.28 \pm 0.73)^\circ$.

¹¹BENSINGER 85 used $\alpha_\Lambda = 0.642 \pm 0.013$.

¹²The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

g_A/g_V FOR $\Xi^- \rightarrow \Lambda e^-\bar{\nu}_e$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
-0.25 ± 0.05	1992	¹³ BOURQUIN 83	SPEC	SPS hyperon beam

¹³BOURQUIN 83 assumes that $g_2 = 0$. Also, the sign has been changed to agree with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on Ξ resonances has been added since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	$L_{2I,2J}$	Overall status	Status as seen in —				
			$\Xi\pi$	ΛK	ΣK	$\Xi(1530)\pi$	Other channels
$\Xi(1318)$	P_{11}	****					Decays weakly
$\Xi(1530)$	P_{13}	****	****				
$\Xi(1620)$		*	*				
$\Xi(1690)$		***		***	**		
$\Xi(1820)$	D_{13}	***	**	***	**	**	
$\Xi(1950)$		***	**	**		*	
$\Xi(2030)$	1	***		**	***		
$\Xi(2120)$		*		*			
$\Xi(2250)$		**					3-body decays
$\Xi(2370)$	1	**					3-body decays
$\Xi(2500)$		*		*			3-body decays

**** Existence is certain, and properties are at least fairly well explored.
 *** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.
 ** Evidence of existence is only fair.
 * Evidence of existence is poor.

Reference

- B.T. Meadows, in *Proceedings of the IVth International Conference on Baryon Resonances* (Toronto, 1980), ed. N. Isgur, p. 283.

$\Xi(1530) P_{13}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^+) \text{ Status: } ***$$

This is the only Ξ resonance whose properties are all reasonably well known. Assuming that the Λ_c^+ has $J^P = 1/2^+$, AUBERT 08AK, in a study of $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$, finds conclusively that the spin of the $\Xi(1530)^0$ is 3/2. In conjunction with SCHLEIN 63B and BUTTON-SHAFFER 66, this proves also that the parity is +.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$\Xi(1690)$

$I(J^P) = \frac{1}{2}(?)^?$ Status: ***

AUBERT 08AK, in a study of $\Lambda_c^+ \rightarrow \Xi^- \pi^+ K^+$, finds some evidence that the $\Xi(1690)$ has $J^P = 1/2^-$.

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma \bar{K}$ mass spectra in $K^- p \rightarrow (\Sigma \bar{K}) K \pi$ at 4.2 GeV/c. The data from the $\Sigma \bar{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda \bar{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ .

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda \bar{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0 \bar{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^- . The significance claimed is 6.7 standard deviations.

ADAMOVIICH 98 sees a peak of 1400 ± 300 events in the $\Xi^- \pi^+$ spectrum produced by 345 GeV/c Σ^- -nucleus interactions.

 $\Xi(1820) D_{13}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-) \text{ Status: } ***$$

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76C. TEODORO 78 favors $J=3/2$, but cannot make a parity discrimination. BIAGI 87C is consistent with $J=3/2$ and favors negative parity for this J value.

 $\Xi(1820)$ MASS

We only average the measurements that appear to us to be most significant and best determined.

- BIAGI 87 also sees weak signals in the in the $\Xi^- \pi^+ \pi^-$ channel at 1782.6 ± 1.4 MeV ($\Gamma = 6.0 \pm 1.5$ MeV) and 1831.9 ± 2.8 MeV ($\Gamma = 9.6 \pm 9.9$ MeV).
- BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV.
- From a fit to inclusive $\Xi \pi, \Xi \pi \pi$, and ΛK^- spectra.
- From a fit to inclusive $\Xi \pi$ and $\Xi \pi \pi$ spectra only.
- Including $\Xi \pi \pi$.
- DAUBER 69 uses in part the same data as SMITH 65c.
- For the decay mode $\Xi^- \pi^+ \pi^0$ only. This limit includes $\Xi(1530) \pi$.
- Or less. Upper limit for the 3-body decay.

Baryon Particle Listings

$\Xi(1950), \Xi(2030)$

$\Xi(1950)$

$$I(J^P) = \frac{1}{2}(?)^? \text{ Status: } ***$$

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a $\Xi(1950)$ in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

$\Xi(2030)$

$$I(J^P) = \frac{1}{2}(\geq \frac{5}{2})^? \text{ Status: } ***$$

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma \bar{K}$ and a weaker coupling to $\Lambda \bar{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi \pi \pi$ (or $\Xi(1530) \pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma) \bar{K} \pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

$\Xi(2120)$ FOOTNOTES

- ¹ CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\bar{\Lambda} K^+) X$ final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.
- ² GAY 76c sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u . This suggests an anomalous production mechanism if the $\Xi(2120)$ is real.

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in $\Lambda\bar{K}\pi$, $\Sigma\bar{K}\pi$, and $\Xi\pi\pi$ mass spectra. GOLDWASSER 70 sees a narrower bump in $\Xi\pi\pi$ at a higher mass. Not seen by HASSALL 81 with 45 events/ μb at 6.5 GeV/c. Seen by JENKINS 83. Perhaps seen by BIAGI 87.

Baryon Particle Listings

 Ω^- **Ω^- BARYONS**
($S = -3, I = 0$)

$$\Omega^- = sss$$

 Ω^-

$$I(J^P) = 0(\frac{3}{2}^+) \text{ Status: } ****$$

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$. AUBERT, BE 06 finds from the decay angular distributions of $\Xi_c^0 \rightarrow \Omega^- K^+$ and $\Omega_c^0 \rightarrow \Omega^- K^+$ that $J = 3/2$; this depends on the spins of the Ξ_c^0 and Ω_c^0 being $J = 1/2$, their supposed values.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

 Ω^- MASS

The fit assumes the Ω^- and $\bar{\Omega}^+$ masses are the same, and averages them together.

¹DIBIANCA 75 gives a mass for each event. We quote the average.

²The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L. Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.

³Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.

⁴The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^- \Xi Ag$.

A peak in the $\Omega^- \pi^+ \pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS

(C = +1)

$\Lambda_c^+ = udc, \Sigma_c^{++} = uuc, \Sigma_c^+ = udc, \Sigma_c^0 = ddc,$

$\Xi_c^+ = usc, \Xi_c^0 = dsc, \Omega_c^0 = ssc$

CHARMED BARYONS

Revised January 2010 by C.G. Wohl (LBNL).

There are 17 known charmed baryons, and four other candidates not well enough established to be promoted to the Summary Tables.* Fig. 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c differs from a Λ or a Σ only by the replacement of the s quark with a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c . Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ and Ω spectra.**

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells what charmed baryons to expect; this is essential, because few of the spin-parity values given in Fig. 1(a) have been measured. Rather, they have been assigned in accord with expectations of the theory. However, they are all very likely as shown (see below).

SU(4) multiplets—Baryons made from $u, d, s,$ and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3 \times 3 \times 3 = 10 + 8_1 + 8_2 + 1$ for the subset of baryons made from just $u, d,$ and s quarks, is $4 \times 4 \times 4 = 20 + 20'_1 + 20'_2 + \bar{4}$. Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. Figure 2(b) shows the 20'-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(c) shows the $\bar{4}$ multiplet, an inverted tetrahedron. One level up from the bottom level of each multiplet are the baryons with one c quark. All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet- Λ resonance calls for another 20'- or 20- or $\bar{4}$ -plet, respectively.

Fig. 1. (a) The known charmed baryons, and (b) the lightest “4-star” strange baryons. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the lightest Ω_c does not have $J = 3/2$. The $J^P = 1/2^+$ states, all tabbed with a circle, belong to the SU(4) multiplet that includes the nucleon; states with a circle with the same fill belong to the same SU(3) multiplet within that SU(4) multiplet. Similar remarks apply to the other states: same shape of tab, same SU(4) multiplet; same fill of that shape, same SU(3) multiplet. The $J^P = 1/2^-$ and $3/2^-$ states tabbed with triangles complete two SU(4) $\bar{4}$ multiplets.

Baryon Particle Listings

Charmed Baryons

The flavor symmetries shown in Fig. 2 are of course badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same $J^P = 1/2^+$ 20'-plet as the nucleon, a Λ_c , a Σ_c , two Ξ_c 's, and an Ω_c . Note that this Ω_c has $J^P = 1/2^+$ and is not in the same SU(4) multiplet as the famous $J^P = 3/2^+$ Ω^- .

Figure 2: SU(4) multiplets of baryons made of $u, d, s,$ and c quarks. (a) The 20-plet with an SU(3) decuplet on the lowest level. (b) The 20'-plet with an SU(3) octet on the lowest level. (c) The $\bar{4}$ -plet. Note that here and in Fig. 3, but not in Fig. 1, each charge state is shown separately.

Figure 3 shows in more detail the middle level of the 20'-plet of Fig. 2(b); it splits apart into two SU(3) multiplets, a $\bar{3}$ and a 6. The states of the $\bar{3}$ are antisymmetric under the interchange of the two light quarks (the $u, d,$ and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\bar{3}$.

Figure 3: The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 2(b). The Λ_c and Ξ_c tabbed with open circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) $\bar{3}$ -plet, as in (a) here. The $\Sigma_c, \Xi_c,$ and Ω_c tabbed with closed circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) 6-plet, as in (b) here. Together the nine particles complete the charm = +1 level of a $J^P = 1/2^+$ SU(4) 20'-plet, as in Fig. 2(b).

The observed spectra—(1) The parity of the lightest Λ_c is defined to be positive (as are the parities of the $p, n,$ and Λ); the limited evidence about its spin is consistent with $J = 1/2$. However, few of the J^P quantum numbers given in Fig. 1(a) have been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.[†] There are no surprises: the $J^P = 1/2^+$ states come first, then the $J^P = 3/2^+$ states . . .

(2) There is, however, evidence that many of the J^P assignments in Fig. 1(a) must be correct. As is well known, the successive mass differences between the $J^P = 3/2^+$ particles, the $\Delta(1232)^-, \Sigma(1385)^-, \Xi(1535)^-,$ and Ω^- , which lie along the lower left edge of the 20-plet in Fig. 2(a), should according to SU(3) be about equal; and indeed experimentally they nearly are. In the same way, the mass differences between the $J^P = 1/2^+$ $\Sigma_c(2455)^0, \Xi_c^0,$ and Ω_c^0 ,[‡] the particles along the left edge of Fig. 3(b), should be about equal—assuming, of course, that they *do* all have the same J^P . The measured differences are 124.1 ± 2.9 MeV and 117.3 ± 3.4 MeV—not perfect, but close. Similarly, the mass differences between the presumed $J^P = 3/2^+$ $\Sigma_c(2520)^0, \Xi_c(2645)^0,$ and $\Omega_c(2770)^0$ are 127.9 ± 0.8 MeV and 122.4 ± 3.1 MeV. In Fig. 1(a), these two sets of charm particles are tabbed with solid circles and solid squares.

(3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \rightarrow \Lambda_c^+ \pi \pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the “ Q ” is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s -wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P = 1/2^+$, makes $J^P = 1/2^-$ for the $\Lambda_c(2593)$.

(4) The heavier charmed baryons, such as the $J^P = 1/2^-$ and $3/2^-$ Λ_c 's, have much narrower widths than do their strange counterparts, such as the $\Lambda(1405)$ and $\Lambda(1520)$. The clean Λ_c spectrum has in fact been taken to settle the decades-long discussion about the nature of the $\Lambda(1405)$ —true 3-quark state or mere $\bar{K}N$ threshold effect?—unambiguously in favor of the first interpretation (which is not to say that the proximity of the $\bar{K}N$ threshold has no effect on the $\Lambda(1405)$). In fact, models of baryon-resonance spectroscopy should now *start* with the narrow charmed baryons, and work back to those broad old resonances.

Footnotes:

* The unpromoted states are a $\Lambda_c(2765)^+,$ a $\Xi_c(2930),$ a $\Xi_c(3055),$ and a $\Xi_c(3123)$. There is also weak evidence for a baryon with *two* c quarks, a Ξ_{cc}^+ at 3519 MeV. See the Particle Listings.

** For example, there are three Ω_c^0 states (properly symmetrized states of $ssc, scs,$ and css) corresponding to each Ω^- (sss) state.

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery

papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle has its mass as part of its name if and only if it decays strongly. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c' .

Λ_c^+

$I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The quark content is udc . The spin J has not actually been measured. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with the expected $J = 1/2$.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

Λ_c^+ MASS

Our value in 2004, 2284.9 ± 0.6 MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes $\Sigma_c-\Lambda_c^+$ and $\Lambda_c^{*+}-\Lambda_c^+$ mass-difference measurements, but this doesn't affect the Λ_c^+ mass. The new (in 2006) Λ_c^+ mass simply pushes all those other masses higher.

¹AUBERT,B 05s uses low-Q $\Lambda_c^0 K^+$ and $\Sigma^0 K_S^0 K^+$ decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the Λ_c^+ mass.

Λ_c^+ DECAY MODES

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements, below. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

[a] See the note on " Λ_c^+ Branching Fractions" below.

[b] This branching fraction includes all the decay modes of the final-state resonance.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 33 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 15.5$ for 22 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 Λ_c^+ BRANCHING FRACTIONS

Revised 2002 by P.R. Burchat (Stanford University).

Most Λ_c^+ branching fractions are measured relative to the decay mode $\Lambda_c^+ \rightarrow p K^- \pi^+$. However, there are no completely model-independent measurements of the absolute branching fraction for $\Lambda_c^+ \rightarrow p K^- \pi^+$. Here we describe the measurements that have been used to extract $B(\Lambda_c^+ \rightarrow p K^- \pi^+)$, the model-dependence of the results, and the method we have used to average the results.

ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92) measure $B(\bar{B} \rightarrow \Lambda_c^+ X) \cdot B(\Lambda_c^+ \rightarrow p K^- \pi^+)$ to be $(0.30 \pm 0.12 \pm 0.06) \%$ and $(0.273 \pm 0.051 \pm 0.039) \%$. Under the assumptions that decays of \bar{B} mesons to baryons are dominated by $\bar{B} \rightarrow \Lambda_c^+ X$ and that $\Lambda_c^+ X$ final states other than $\Lambda_c^+ \bar{N} X$ can be neglected, they also measure $B(\bar{B} \rightarrow \Lambda_c^+ X)$ to be $(6.8 \pm 0.5 \pm 0.3) \%$ (ALBRECHT 92O) and $(6.4 \pm 0.8 \pm 0.8) \%$ (CRAWFORD 92). Combining these results, we get $B(\Lambda_c^+ \rightarrow p K^- \pi^+) = (4.14 \pm 0.91) \%$. However, the assumption that \bar{B} decay modes to baryons other than $\Lambda_c^+ \bar{N} X$ are negligible is not on solid ground experimentally or theoretically [2]. Therefore, the branching fraction for $\Lambda_c^+ \rightarrow p K^- \pi^+$ given above may be low by some undetermined amount.

A second type of model-dependent determination of $B(\Lambda_c^+ \rightarrow p K^- \pi^+)$ is based on measurements by ARGUS (ALBRECHT 91G) and CLEO (BERGFELD 94) of $\sigma(e^+ e^- \rightarrow \Lambda_c^+ X) \cdot B(\Lambda_c^+ \rightarrow \Lambda \ell^+ \nu_\ell) = (4.15 \pm 1.03 \pm 1.18) \text{ pb}$ and $(4.77 \pm 0.25 \pm 0.66) \text{ pb}$. ARGUS (ALBRECHT 96E) and CLEO (AVERY 91) have also measured $\sigma(e^+ e^- \rightarrow \Lambda_c^+ X) \cdot B(\Lambda_c^+ \rightarrow p K^- \pi^+)$. The weighted average is $(11.2 \pm 1.3) \text{ pb}$.

From these measurements, we extract $R \equiv B(\Lambda_c^+ \rightarrow p K^- \pi^+) / B(\Lambda_c^+ \rightarrow \Lambda \ell^+ \nu_\ell) = 2.40 \pm 0.43$. We estimate the $\Lambda_c^+ \rightarrow p K^- \pi^+$ branching fraction from the equation

$$B(\Lambda_c^+ \rightarrow p K^- \pi^+) = R f F \frac{\Gamma(D \rightarrow X \ell^+ \nu_\ell)}{1 + |V_{cd}/V_{cs}|^2} \cdot \tau(\Lambda_c^+) , \quad (1)$$

where $f = B(\Lambda_c^+ \rightarrow \Lambda \ell^+ \nu_\ell) / B(\Lambda_c^+ \rightarrow X_s \ell^+ \nu_\ell)$ and $F = \Gamma(\Lambda_c^+ \rightarrow X_s \ell^+ \nu_\ell) / \Gamma(D^0 \rightarrow X_s \ell^+ \nu_\ell)$. When we use

Λ_c^+

$1+|V_{cd}/V_{cs}|^2 = 1.05$ and the world averages $\Gamma(D \rightarrow X\ell^+\nu_\ell) = (0.166 \pm 0.006) \times 10^{12} \text{ s}^{-1}$ and $\tau(\Lambda_c^+) = (0.192 \pm 0.005) \times 10^{-12} \text{ s}$, we calculate $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot fF$. Theoretical estimates for f and F are near 1.0 with significant uncertainties.

So, we have two results with significant model-dependence: $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (4.14 \pm 0.91)\%$ from \overline{B} decays, and $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot fF$ from semileptonic Λ_c^+ decays. If we set $fF = 1.0$ in the second result, and assign an uncertainty of 30% to each result to account for the unknown model-dependence, we get the consistent results $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (4.14 \pm 0.91 \pm 1.24)\%$ and $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (7.3 \pm 1.4 \pm 2.2)\%$. The weighted average of these two results is $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (5.0 \pm 1.3)\%$, where the uncertainty contains both the experimental uncertainty and the 30% estimate of model dependence in each result. We assigned the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \rightarrow pK^-\pi^+$ branching fraction in our 2000 *Review* [1].

A third type of measurement of $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$ has been published by CLEO (JAFPE 00). Under the assumption that a \overline{D} meson and an antiproton in opposite hemispheres is evidence for a Λ_c^+ in the hemisphere of the \overline{p} , the fraction of such $\overline{D}\overline{p}$ events with a $\Lambda_c^+ \rightarrow pK^-\pi^+$ decay can be used to determine the $\Lambda_c^+ \rightarrow pK^-\pi^+$ branching fraction. CLEO measures $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (5.0 \pm 1.3)\%$, which is coincidentally exactly the same value as our PDG 00 average given above. The quoted uncertainty includes significant contributions from model-dependent effects (*e.g.*, differences between the \overline{p} momentum spectrum in events with a Λ_c^+ and \overline{p} in the same hemisphere, and with a \overline{D} and \overline{p} in opposite hemispheres; extrapolation of the Λ_c^+ and \overline{D} momentum spectrum below the minimum value used for rejecting B decay products; and our limited understanding of backgrounds such as $D\overline{D}N\overline{p}$ events).

We have chosen to continue to assign the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \rightarrow pK^-\pi^+$ branching fraction (given as PDG 02 below). As was noted earlier, most of the other Λ_c^+ decay modes are measured relative to this mode.

New methods for measuring the Λ_c^+ absolute branching fractions have been proposed [2,3].

² JAFFE 00 assumes that a \overline{D} meson and an antiproton in opposite hemispheres tags for a Λ_c^+ in the hemisphere of the \overline{p} . The fraction of such $\overline{D}\overline{p}$ events with a $\Lambda_c^+ \rightarrow pK^-\pi^+$ decay then gives the $pK^-\pi^+$ branching fraction. See the paper for assumptions, caveats, etc.				
³ To extract $\Gamma(pK^-\pi^+)/\Gamma_{\text{total}}$, we use $B(\overline{B} \rightarrow \Lambda_c^+ X) \cdot B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (0.28 \pm 0.06)\%$, which is the average of measurements from ARGUS (ALBRECHT 88c) and CLEO (CRAWFORD 92).				
⁴ ALBRECHT 92o measures $B(\overline{B} \rightarrow \Lambda_c^+ X) = (6.8 \pm 0.5 \pm 0.3)\%$.				
⁵ CRAWFORD 92 measures $B(\overline{B} \rightarrow \Lambda_c^+ X) = (6.4 \pm 0.8 \pm 0.8)\%$.

Λ_c^+ DECAY PARAMETERS

See the note on "Baryon Decay Parameters" in the neutron Listings.

α FOR $\Lambda_c^+ \rightarrow \Lambda \pi^+$				
VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
-0.91 ± 0.15 OUR AVERAGE				
$-0.78 \pm 0.16 \pm 0.19$		LINK	06A	FOCS γA , $\bar{E}_\gamma \approx 180$ GeV
$-0.94 \pm 0.21 \pm 0.12$	414	22 BISHAI	95	CLE2 $e^+ e^- \approx \Upsilon(4S)$
-0.96 ± 0.42		ALBRECHT	92	ARG $e^+ e^- \approx 10.4$ GeV
-1.1 ± 0.4	86	AVERY	90b	CLEO $e^+ e^- \approx 10.6$ GeV

²² BISHAI 95 actually gives $\alpha = -0.94 \pm 0.21 \pm 0.12$ limit -1.0 . However, for $\alpha \approx -1.0$, some experiments should get unphysical values ($\alpha < -1.0$), and for averaging with other measurements such values (or errors that extend below -1.0) should *not* be chopped.

$\Lambda_c^+, \Lambda_c(2595)^+$

α FOR $\Lambda_c^+ \rightarrow \Sigma^+ \pi^0$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
$-0.45 \pm 0.31 \pm 0.06$	89	BISHAI	95	CLE2 $e^+e^- \approx \mathcal{T}(4S)$

α FOR $\Lambda_c^+ \rightarrow \Lambda e^+ \nu_e$

The experiments don't cover the complete (or same incomplete) $M(\Lambda e^+)$ range, but we average them together anyway.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
-0.86 ± 0.04 OUR AVERAGE				
$-0.86 \pm 0.03 \pm 0.02$	3201	23 HINSON	05	CLEO $e^+e^- \approx \mathcal{T}(4S)$
$-0.91 \pm 0.42 \pm 0.25$		24 ALBRECHT	94B	ARG $e^+e^- \approx 10$ GeV
$-0.82 \pm 0.09 \pm 0.06$ $-0.06 - 0.03$	700	25 CRAWFORD	95	CLE2 See HINSON 05
$-0.89 \pm 0.17 \pm 0.09$ $-0.11 - 0.05$	350	26 BERGFELD	94	CLE2 See CRAWFORD 95

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 23 HINSON 05 measures the form-factor ratio $R \equiv f_2/f_1$ for $\Lambda_c^+ \rightarrow \Lambda e^+ \nu_e$ events to be $-0.31 \pm 0.05 \pm 0.04$ and the pole mass to be $2.21 \pm 0.08 \pm 0.14$ GeV/c², and from these calculates α , averaged over q^2 , where $\langle q^2 \rangle = 0.67$ (GeV/c)².
- 24 ALBRECHT 94B uses Λe^+ and $\Lambda \mu^+$ events in the mass range $1.85 < M(\Lambda e^+) < 2.20$ GeV.
- 25 CRAWFORD 95 measures the form-factor ratio $R \equiv f_2/f_1$ for $\Lambda_c^+ \rightarrow \Lambda e^+ \nu_e$ events to be $-0.25 \pm 0.14 \pm 0.08$ and from this calculates α , averaged over q^2 , to be the above.
- 26 BERGFELD 94 uses Λe^+ events.

$\Lambda_c^+, \bar{\Lambda}_c^-$ CP-VIOLATING DECAY ASYMMETRIES

$(\alpha + \bar{\alpha})/(\alpha - \bar{\alpha})$ in $\Lambda_c^+ \rightarrow \Lambda \pi^+, \bar{\Lambda}_c^- \rightarrow \bar{\Lambda} \pi^-$

This is zero if CP is conserved.

VALUE	DOCUMENT ID	TECN	COMMENT
$-0.07 \pm 0.19 \pm 0.24$	LINK	06A	FOCS $\gamma A, \bar{E}_\gamma \approx 180$ GeV

$\Lambda_c(2595)^+$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ***

Seen in $\Lambda_c^+ \pi^+ \pi^-$ but not in $\Lambda_c^+ \pi^0$, so this is indeed an excited Λ_c^+ rather than a Σ_c^+ . The $\Lambda_c^+ \pi^+ \pi^-$ mode is largely, and perhaps entirely, $\Sigma_c \pi$, which is just at threshold; thus (assuming, as has not yet been proven, that the Σ_c has $J^P = 1/2^+$) the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405)$.

$\Lambda_c(2595)^+$ MASS

The mass is obtained from the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass-difference measurements below. But the mass may be 2 or 3 MeV lower: see the footnote to BLECHMAN 03 in the next data block.

$\Lambda_c(2595)^+$ DECAY MODES

$\Lambda_c^+ \pi \pi$ and its submode $\Sigma_c(2455) \pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

Mode	Fraction (Γ_i/Γ)
$\Gamma_1 \Lambda_c^+ \pi^+ \pi^-$	[a] $\approx 67\%$
$\Gamma_2 \Sigma_c(2455)^{++} \pi^-$	$24 \pm 7\%$
$\Gamma_3 \Sigma_c(2455)^0 \pi^+$	$24 \pm 7\%$
$\Gamma_4 \Lambda_c^+ \pi^+ \pi^-$ 3-body	$18 \pm 10\%$
$\Gamma_5 \Lambda_c^+ \pi^0$	[b] not seen
$\Gamma_6 \Lambda_c^+ \gamma$	not seen

[a] Assuming isospin conservation, so that the other third is $\Lambda_c^+ \pi^0 \pi^0$.

[b] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+ .

$\Lambda_c(2765)^+$
or $\Sigma_c(2765)$

 $I(J^P) = ?(??)$ Status: *

OMITTED FROM SUMMARY TABLE

A broad, statistically significant peak (997^{+141}_{-129} events) seen in $\Lambda_c^+ \pi^+ \pi^-$. However, nothing at all is known about its quantum numbers, including whether it is a Λ_c^+ or a Σ_c , or whether the width might be due to overlapping states.

 $\Lambda_c(2765)^+$ MASS

The mass is obtained from the $\Lambda_c(2765)^+ - \Lambda_c^+$ mass-difference measurement below.

$\Lambda_c(2880)^+$

 $I(J^P) = 0(\frac{5}{2}^+)$ Status: ***

A narrow peak seen in $\Lambda_c^+ \pi^+ \pi^-$ and in pD^0 . It is not seen in pD^+ , and therefore it is probably a Λ_c^+ and not a Σ_c . The evidence for spin $5/2$ comes from the $\Sigma_c(2455)\pi$ decay angular distribution, and the evidence for parity $+$ comes from agreement of the $\Sigma_c(2520)/\Sigma_c(2455)$ branching ratio with a prediction of heavy quark symmetry (see MIZUK 07).

$\Sigma_c(2520)$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ***

Seen in the $\Lambda_c^+ \pi^+$ mass spectrum. The natural assignment is that this is the $J^P = 3/2^+$ excitation of the $\Sigma_c(2455)$, the charm counterpart of the $\Sigma(1385)$, but neither J nor P has been measured.

$\Sigma_c(2520)$ MASSES

The masses are obtained from the mass-difference measurements that follow.

Baryon Particle Listings

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+) \text{ Status: } ***$$

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of $I, J,$ or P has actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

2460 ± 25	82	BIAGI	83 SPEC	Σ^- Be 135 GeV

¹ The systematic error was (wrongly) given the other way round in LESIAK 05; see the erratum.
² Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^- \pi^+ \pi^+$ mass spectrum. COTEUS 87 sees two peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \rightarrow \Sigma^0 K^- \pi^+ \pi^+ \rightarrow (\Lambda \gamma) K^- \pi^+ \pi^+$, with the γ unseen. The combined significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

According to the quark model, the Ξ_c^0 (quark content dsc) and Ξ_c^+ form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I , J , or P has actually been measured.

Ξ_c^0 MASS

The fit uses the Ξ_c^0 and Ξ_c^+ mass and mass-difference measurements.

$$\Xi_c^{'+}$$

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+) \text{ Status: } ** *$$

The $\Xi_c^{'+}$ and $\Xi_c^{'0}$ presumably complete the SU(3) sextet whose other members are the Σ_c^{++} , Σ_c^+ , Σ_c^0 , and Ω_c^0 ; see Fig. 3 in the Note on Charmed Baryons just before the Λ_c^+ Listings. The quantum numbers given above come from this presumption but have not been measured.

$\Xi_c^{'+}$ MASS

The mass is obtained from the mass-difference measurement that follows.

 $\Xi_c(2790)$

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^-) \text{ Status: } ***$$

A peak seen in the $\Xi_c' \pi$ mass spectrum. The simplest assignment, based on the mass, width, and decay mode, is that this belongs in the same SU(4) multiplet as the $\Lambda(1405)$ and the $\Lambda_c(2595)^+$, but the spin and parity have not been measured.

 $\Xi_c(2790)$ MASSES

The masses are obtained from the mass-difference measurements that follow.

$\Omega_c(2770)^0$

$I(J^P) = 0(\frac{3}{2}^+)$ Status: * * *

The natural assignment is that this goes with the $\Sigma_c(2520)$ and $\Xi_c(2645)$ to complete the lowest mass $J^P = \frac{3}{2}^+$ SU(3) sextet, part of the SU(4) 20-plet that includes the $\Delta(1232)$. But J and P have not been measured.

$\Omega_c(2770)^0$ MASS

The mass is obtained from the mass-difference measurement that follows.

VALUE (MeV)	DOCUMENT ID
2765.9 ± 2.0 OUR FIT	Error includes scale factor of 1.2.

$I(J^P) = ?(??)$ Status: *

OMITTED FROM SUMMARY TABLE

This would presumably be an isospin-1/2 particle, a $ccu \Xi_{cc}^{++}$ and a $ccd \Xi_{cc}^+$. However, opposed to the evidence cited below, the BABAR experiment has found no evidence for a Ξ_{cc}^+ in a search in $\Lambda_c^+ K^- \pi^+$ and $\Xi_c^0 \pi^+$ modes, and no evidence of a Ξ_{cc}^{++} in $\Lambda_c^+ K^- \pi^+ \pi^+$ and $\Xi_c^0 \pi^+ \pi^+$ modes (AUBERT,B 06D). Nor has the BELLE experiment found any evidence for a Ξ_{cc}^+ in the $\Lambda_c^+ K^- \pi^+$ mode (CHISTOV 06).

 Λ_b^0 MEAN LIFE

See b -baryon Admixture section for data on b -baryon mean life average over species of b -baryon particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

 Λ_b^0 DECAY MODES

The branching fractions $B(b\text{-baryon} \rightarrow \Lambda \ell^- \bar{\nu}_\ell \text{ anything})$ and $B(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell \text{ anything})$ are not pure measurements because the underlying measured products of these with $B(b \rightarrow b\text{-baryon})$ were used to determine $B(b \rightarrow b\text{-baryon})$, as described in the note "Production and Decay of b -Flavored Hadrons."

For inclusive branching fractions, e.g., $\Lambda_b \rightarrow \bar{\Lambda}_c \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction (Γ_i/Γ)	Confidence level

 b -baryon ADMIXTURE ($\Lambda_b, \Xi_b, \Sigma_b, \Omega_b$) b -baryon ADMIXTURE MEAN LIFE

Each measurement of the b -baryon mean life is an average over an admixture of various b -baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b -baryon mean life. More b -baryon flavor specific channels are not included in the measurement.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- Measured mean life using fully reconstructed $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$ decays.
- Measured mean life using fully reconstructed $\Lambda_b^0 \rightarrow J/\psi \Lambda$ decays.
- Measured using semileptonic decays $\Lambda_b(0) \rightarrow \Lambda_c^+ \mu \nu X, \Lambda_c^+ \rightarrow K_S^0 p$.
- Measured using $\Lambda \ell^-$ decay length.
- Measured using $p \ell^-$ decay length.
- Measured using $\Lambda_c \ell^-$ and $\Lambda \ell^+ \ell^-$.
- Measured using the excess of $\Lambda \ell^-$, lepton impact parameter.
- Measured using $\Lambda_c \ell^-$.
- This ABREU 99w result is the combined result of the $\Lambda \ell^-$, $p \ell^-$, and excess $\Lambda \mu^-$ impact parameter measurements.
- ABREU 93f superseded by ABREU 96D.
- AKERS 93 superseded by AKERS 96.
- BUSKULIC 92i superseded by BUSKULIC 95L.

 b -baryon ADMIXTURE DECAY MODES ($\Lambda_b, \Xi_b, \Sigma_b, \Omega_b$)

These branching fractions are actually an average over weakly decaying b -baryons weighted by their production rates in Z decay (or high-energy $p\bar{p}$), branching ratios, and detection efficiencies. They scale with the LEP b -baryon production fraction $B(b \rightarrow b\text{-baryon})$ and are evaluated for our value $B(b \rightarrow b\text{-baryon}) = (9.2 \pm 1.8)\%$.

The branching fractions $B(b\text{-baryon} \rightarrow \Lambda \ell^- \bar{\nu}_\ell \text{ anything})$ and $B(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell \text{ anything})$ are not pure measurements because the underlying measured products of these with $B(b \rightarrow b\text{-baryon})$ were used to determine $B(b \rightarrow b\text{-baryon})$, as described in the note "Production and Decay of b -Flavored Hadrons."

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

MAGNETIC MONOPOLES

Written in September 2009 by D. Milstead (Stockholm Univ.) and E.J. Weinberg (Columbia Univ.).

The symmetry between electric and magnetic fields in the sourcefree Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles, even though there is at present no strong theoretical motivation for these.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi} \frac{\hat{\mathbf{r}}}{r^2}. \quad (1)$$

Any vector potential \mathbf{A} whose curl is equal to \mathbf{B} must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π . Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges Q_E^{\min} and Q_M^{\min} obeying

$$Q_E^{\min} Q_M^{\min} = 2\pi. \quad (2)$$

(For monopoles which also carry an electric charge, called dyons, the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r} \times \mathbf{v} - 4\pi Q_E Q_M \hat{\mathbf{r}} \quad (3)$$

Requiring the radial component of \mathbf{L} to be quantized in half-integer units yields Eq. (2).

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [2,3]. For example, a monopole could have both a

U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. (2) and conclude that Q_M must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [4] and Polyakov [5], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field ϕ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, ϕ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle\phi\rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of ϕ in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of ϕ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\text{mon}} \sim \frac{4\pi M_V}{e^2}. \quad (4)$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the electroweak theory, with SU(2) × U(1) broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\text{SU}(5) \xrightarrow{M_X} \text{SU}(3) \times \text{SU}(2) \times \text{U}(1) \xrightarrow{M_W} \text{SU}(3) \times \text{U}(1) \quad (5)$$

has a monopole [6] with $Q_M = 2\pi/e$ and mass

$$M_{\text{mon}} \sim \frac{4\pi M_X}{g^2}, \quad (6)$$

Searches Particle Listings

Magnetic Monopole Searches

where g is the $SU(5)$ gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\text{mon}} \sim 10^{17} - 10^{18}$ GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an $SO(10)$ theory with

$$SO(10) \xrightarrow{M_1} SU(4) \times SU(2) \times SU(2) \xrightarrow{M_2} SU(3) \times SU(2) \times U(1) \quad (7)$$

there is a monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [7].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon-monopole scattering. The surprising feature, pointed out by Callan [8] and Rubakov [9], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as $p + \text{monopole} \rightarrow e^+ + \pi^0 + \text{monopole}$ are essentially geometric; *i.e.*, $\sigma_{\Delta B} \beta \sim 10^{-27} \text{ cm}^2$, where $\beta = v/c$. Note, however, that intermediate mass monopoles arising at later stages of symmetry breakings, such as the doubly charged monopoles of the $SO(10)$ theory, do not catalyze baryon number violation.

1. Production and Annihilation

GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [10] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [11]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

2. Astrophysical and Cosmological Bounds

If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu\text{G}$. A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\text{mag}} \sim \begin{cases} 10^{-3}c \left(\frac{10^{17} \text{ GeV}}{M} \right)^{1/2}, & M \lesssim 10^{11} \text{ GeV} \\ c, & M \gtrsim 10^{11} \text{ GeV} \end{cases} \quad (8)$$

Accelerating these monopoles drains energy from the magnetic field. Parker [12] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. 13 for details), this Parker bound is

$$F < \begin{cases} 10^{-15} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \lesssim 10^{17} \text{ GeV} \\ 10^{-15} \left(\frac{M}{10^{17} \text{ GeV}} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}, & M \gtrsim 10^{17} \text{ GeV} \end{cases} \quad (9)$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [14],

$$F < \left[\frac{M}{10^{17} \text{ GeV}} + (3 \times 10^{-6}) \right] 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (10)$$

Considering magnetic fields in galactic clusters gives a bound [15] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction Ω_M of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\text{uniform}} = 1.3 \times 10^{-16} \Omega_M \left(\frac{10^{17} \text{ GeV}}{M} \right) \left(\frac{v}{10^{-3}c} \right) \text{ cm}^{-2} \text{ sr}^{-1} \text{ sec}^{-1}. \quad (11)$$

If we assume that $\Omega_M \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of Ω_M , and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released

in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [16–20], white dwarfs [21], and Jovian planets [22] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}\text{cm}^2}\right) \sim (10^{-18} - 10^{-29})\text{cm}^{-2}\text{sr}^{-1}\text{sec}^{-1}. \quad (12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of Eq. (12).

3. Searches for Magnetic Monopoles

To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24}Q_M^D$ [23] (where Q_M^D is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass¹ [24]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [25]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

4. Search Techniques

Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [26,27].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum

Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a magnetic field.

5. Searches for Monopoles Bound in Matter

Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [28]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [28].

6. Searches in Cosmic Rays

Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of these searches, the cross section for the catalysis process is either set to zero [29–31] or assigned a modest value (1mb) [32]. Searches which explicitly exploit the expected catalysed decays are discussed in the next section.

Although early cosmic ray searches using the induction technique [33] and NTDs [34] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim 10000\text{m}^2$ for an isotropic flux. As shown in Fig. 1, this experiment has so far provided the most extensive β -dependent flux limits for GUT monopoles with Dirac charge [32]. Also shown are limits from an experiment at the OHYA mine in Japan [29], which used a 2000m^2 array of NTDs.

In Fig. 1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO and OYHA flux limits, results from the SLIM [30] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV). The Radio Ice Cerenkov Experiment (RICE) at the South Pole have also provided flux limits of $\sim 10^{-18} \text{cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ (not shown) for intermediate mass monopoles [31]. This work was sensitive to ultrarelativistic monopoles ($10^7 \lesssim \gamma \lesssim 10^{12}$), and the

¹ Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

Searches Particle Listings

Magnetic Monopole Searches

limits were extracted assuming a monopole energy 10^{16} GeV. In addition to the aforementioned flux limits for monopoles with the Dirac charge, the OHYA experiment also presented limits for monopoles with charges up to $3Q_M^D$, as did the the SLIM experiment.

Figure 1: Upper flux limits for (a) GUT monopoles as a function of β (b) Monopoles as a function of mass for $\beta > 0.05$.

7. Searches via the Catalysis of Nucleon-Decay

Searches have also been performed for evidence of the catalysed decay of a nucleon, as predicted by the Callan-Rubakov mechanism. Searches have been made at a range of experiments which are sensitive to the induced nucleon decay of a passing monopole. For example, searches have been made with the Soudan [35] and Macro [36] experiments, using tracking detectors. Searches at Kamiokande [37], IMB [38] and the underwater Lake Baikal experiment [39] which exploit the Cerenkov effect have also been made. The resulting β -dependent flux limits from these experiments, which typically vary between $6 \times 10^{-17} - 9 \times 10^{-14} \text{cm}^{-2}\text{sr}^{-1}\text{s}^{-1}$ [25], are sensitive to the assumed values of the catalysis cross sections.

8. Searches at Colliders

Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

9. Direct Searches at Colliders

Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded

mass regions. A conservative approach with as little model-dependence as possible is thus to present the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 2 for recent results from high energy colliders.

Figure 2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made at the Tevatron by the CDF [40] and E882 [41] experiments. Complementary approaches were used; the CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Considered together, the searches provide a sensitivity to monopoles with charges between Q_M^D and $6Q_M^D$ and masses up to around 900 GeV. Earlier searches at the Tevatron, such as Ref. 42, used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [43] and searches for trapped monopoles [44].

The only LEP-2 search was made by OPAL [45] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to ~ 45 GeV. The L6-MODAL experiment [46] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [47]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [48] and PETRA [49]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [50,51].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beam pipe which had been used by the H1 experiment at HERA [52]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

10. Indirect Searches at Colliders

It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [53,54]. Photon-based searches were made by the D0 [55] and L3 [56] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

¹ ABBIENDI 08 assume production of spin 1/2 monopoles with effective charge $g\beta$ ($n=1$), via $e^+e^- \rightarrow \gamma^* \rightarrow M\bar{M}$, so that the cross section is proportional to $(1 + \cos^2\theta)$. There is no γ information for such highly saturated tracks, so a parabolic track in the jet chamber is projected onto the xy plane. Charge per hit in the chamber produces a clean separation of signal and background.

² ABULENCIA 06k searches for high-ionizing signals in CDF central outer tracker and time-of-flight detector. For Drell-Yan $M\bar{M}$ production, the cross section limit implies $M > 360$ GeV at 95% CL.

³ AKTAS 05A model-dependent limits as a function of monopole mass shown for arbitrary mass of 60 GeV. Based on search for stopped monopoles in the H1 Al beam pipe.

⁴ AKTAS 05A limits with assumed elastic spin 0 monopole pair production.

⁵ AKTAS 05A limits with assumed inelastic spin 1/2 monopole pair production.

⁶ KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Cross section results moderately model dependent; interpretation as a mass lower limit depends on possibly invalid perturbation expansion.

⁷ KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.

⁸ KALBFLEISCH 00 result is for aluminum.

⁹ KALBFLEISCH 00 result is for beryllium.

¹⁰ HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.

¹¹ Multiphoton events.

¹² Cherenkov radiation polarization.

¹³ Re-examines CERN neutrino experiments.

¹⁶ BALESTRA 08 exposed of nuclear track detector modules totaling 400 m² for 4 years at the Chacaltaya Laboratory (5230 m) in search for intermediate-mass monopoles with $\beta > 0.05$. The analysis is mainly based on three CR39 modules. For $M > 5 \times 10^{13}$ GeV there can be upward-going monopoles as well, hence the flux limit is half that obtained for less massive monopoles. Previous experiments (e.g. MACRO and OHYA (ORITO 91)) had set limits only for $M > 1 \times 10^9$ GeV.

¹⁷ HOGAN 08 limit on relativistic monopoles is based on nonobservation of radio Cherenkov signals at the South Pole.

¹⁸ AMBROSIO 02b direct search final result for $m \geq 10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from $\beta=4 \times 10^{-5}$ ($3.1 \times 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$) to $\beta=1 \times 10^{-4}$ ($2.1 \times 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$). Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.

¹⁹ AMBROSIO 02c limit for catalysis of nucleon decay with catalysis cross section of ≈ 1 mb. The flux limit increases by ~ 3 at the higher β limit, and increases to $1 \times 10^{-14} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$ if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m² sr.

See key on page 405

Searches Particle Listings Magnetic Monopole Searches

- ²⁰ AMBROSIO 02b result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 02b.
- ²¹ AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at $\beta=1.1 \times 10^{-4}$, goes through a minimum at 0.61×10^{-15} near $\beta=(1.1-2.7) \times 10^{-3}$, then rises to 0.84×10^{-15} at $\beta=0.1$. The global limit in this region is below the Parker bound at 10^{-15} . Less stringent limits are established for $4 \times 10^{-5} < \beta < 1 \times 10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.
- ²² AHLEN 94 limit for dyons extends down to $\beta=0.9E-4$ and a limit of $1.3E-14$ extends to $\beta = 0.8E-4$. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.
- ²³ Catalysis of nucleon decay; sensitive to assumed catalysis cross section.
- ²⁴ ORITO 91 limits are functions of velocity. Lowest limits are given here.
- ²⁵ Used DKMPR mechanism and Penning effect.
- ²⁶ Assumes monopole attaches fermion nucleus.
- ²⁷ Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.
- ²⁸ Based on lack of high-energy solar neutrinos from catalysis in the sun.
- ²⁹ Anomalous long-range α (^4He) tracks.
- ³⁰ CABRERA 82 candidate event has single Dirac charge within $\pm 5\%$.
- ³¹ ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

- ³² Catalysis of nucleon decay.
- ³³ ADAMS 93 limit based on "survival and growth of a small galactic seed field" is 10^{-16} ($m/10^{17}$ GeV) $\text{cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. Above 10^{17} GeV, limit 10^{-16} (10^{17} GeV/m) $\text{cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.
- ³⁴ Re-evaluates PARKER 70 limit for GUT monopoles.

I.1. Introduction: Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [1]. Supersymmetry also provides a framework for the unification of particle physics and gravity [2–5], which is governed by the Planck energy scale, $M_P \approx 10^{19}$ GeV (where the gravitational interactions become comparable in magnitude to the gauge interactions). In particular, it is possible that supersymmetry will ultimately explain the origin of the large hierarchy of energy scales from the W and Z masses to the Planck scale [6–10]. This is the so-called *gauge hierarchy*. The stability of the gauge hierarchy in the presence of radiative quantum corrections is not possible to maintain in the Standard Model, but can be maintained in supersymmetric theories.

If supersymmetry were an exact symmetry of nature, then particles and their superpartners (which differ in spin by half a unit) would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the supersymmetry breaking is *soft* [11,12], and the corresponding supersymmetry-breaking mass parameters are no larger than a few TeV. In particular, soft-supersymmetry-breaking terms of the Lagrangian are either linear, quadratic, or cubic in the fields, with some restrictions elucidated in Ref. 11. The impact of such terms becomes negligible at energy scales much larger than the size of the supersymmetry-breaking masses. The most interesting theories of this type are theories of “low-energy” (or “weak-scale”) supersymmetry, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking [7–10]. The latter is characterized by the Standard Model Higgs vacuum expectation value, $v \simeq 246$ GeV.

Although there are no unambiguous experimental results (at present) that require the existence of new physics at the TeV-scale, expectations of the latter are primarily based on three theoretical arguments. First, a *natural* explanation (*i.e.*, one that is stable with respect to quantum corrections) of the gauge hierarchy demands new physics at the TeV-scale [10]. Second, the unification of the three Standard Model gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the Standard Model (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of

the Standard Model, where supersymmetric masses lie below a few TeV, provides simple example of successful gauge coupling unification [13]. Third, the existence of dark matter, which makes up approximately one quarter of the energy density of the universe, cannot be explained within the Standard Model of particle physics [14]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called *WIMP miracle*, which is reviewed in Ref. 15). The lightest supersymmetric particle is a promising (although not the unique) candidate for the dark matter [16,17]. Further aspects of dark matter can be found in Ref. 18.

I.2. Structure of the MSSM: The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the fields of the two-Higgs-doublet extension of the Standard Model and adding the corresponding supersymmetric partners [19,20]. The corresponding field content of the MSSM and their gauge quantum numbers are shown in Table 1. The electric charge $Q = T_3 + \frac{1}{2}Y$ is determined in terms of the third component of the weak isospin (T_3) and the U(1) hypercharge (Y).

Table 1: The fields of the MSSM and their $SU(3) \times SU(2) \times U(1)$ quantum numbers are listed. Only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs super-multiplet, there is a corresponding anti-particle multiplet of charge-conjugated fermions and their associated scalar partners.

Field Content of the MSSM					
Super-Multiplets	Boson Fields	Fermionic Partners	SU(3)	SU(2)	U(1)
gluon/gluino	g	\tilde{g}	8	1	0
gauge/gaugino	W^\pm, W^0	$\tilde{W}^\pm, \tilde{W}^0$	1	3	0
	B	\tilde{B}	1	1	0
slepton/lepton	$(\tilde{\nu}, \tilde{e}^-)_L$	$(\nu, e^-)_L$	1	2	-1
	\tilde{e}_R^-	e_R^-	1	1	-2
squark/quark	$(\tilde{u}_L, \tilde{d}_L)$	$(u, d)_L$	3	2	1/3
	\tilde{u}_R	u_R	3	1	4/3
	\tilde{d}_R	d_R	3	1	-2/3
Higgs/higgsino	(H_d^0, H_d^-)	$(\tilde{H}_d^0, \tilde{H}_d^-)$	1	2	-1
	(H_u^+, H_u^0)	$(\tilde{H}_u^+, \tilde{H}_u^0)$	1	2	1

The gauge super-multiplets consist of the gluons and their *gluino* fermionic superpartners, and the $SU(2) \times U(1)$ gauge bosons and their *gaugino* fermionic superpartners. The Higgs multiplets consist of two complex doublets of Higgs fields, their *higgsino* fermionic superpartners, and the corresponding antiparticle fields. The matter super-multiplets consist of three generations of left-handed and right-handed quarks and lepton fields, their scalar superpartners (squark and slepton fields), and the corresponding antiparticle fields. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of anomalies from the introduction of

the higgsino superpartners. Moreover, without a second Higgs doublet, one cannot generate mass for both “up”-type and “down”-type quarks (and charged leptons) in a way consistent with the supersymmetry [21–23].

A general supersymmetric Lagrangian is determined by three functions of the superfields (composed of the fields of the super-multiplets): the superpotential, the Kähler potential, and the gauge kinetic-energy function [5]. For *renormalizable* globally supersymmetric theories, minimal forms for the latter two functions are required in order to generate canonical kinetic energy terms for all the fields. A renormalizable superpotential, which is at most cubic in the superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and supersymmetry produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy $SU(3) \times SU(2) \times U(1)$ gauge invariance and $B-L$ conservation (where B = baryon number and L = lepton number). Finally, the most general soft-supersymmetry-breaking terms are added [11,12,24]. To generate nonzero neutrino masses, extra structure is needed as discussed in section I.8.

I.2.1. Constraints on supersymmetric parameters: If supersymmetry is associated with the origin of the electroweak scale, then the mass parameters introduced by the soft-supersymmetry-breaking must be generally on the order of 1 TeV or below [25] (although models have been proposed in which some supersymmetric particle masses can be larger, in the range of 1–10 TeV [26]). Some lower bounds on these parameters exist due to the absence of supersymmetric-particle production at current accelerators [27,28]. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [29–31].

For example, the Standard Model global fit to precision electroweak data is quite good [32]. If all supersymmetric particle masses are significantly heavier than m_Z (in practice, masses greater than 300 GeV are sufficient [33]), then the effects of the supersymmetric particles decouple in loop corrections to electroweak observables [34]. In this case, the Standard Model global fit to precision data, and the corresponding MSSM fit yield similar results. On the other hand, regions of parameter space with light supersymmetric particle masses (just above the present day experimental limits) can in some cases generate significant one-loop corrections, resulting in a slight improvement or worsening of the overall global fit to the electroweak data, depending on the choice of the MSSM parameters [35]. Thus, the precision electroweak data provide some constraints on the magnitude of the soft-supersymmetry-breaking terms.

There are a number of other low-energy measurements that are especially sensitive to the effects of new physics through virtual loops. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous

Searches Particle Listings

Supersymmetric Particle Searches

magnetic moment, $a_\mu \equiv \frac{1}{2}(g-2)_\mu$ [36], and to the inclusive decay rate for $b \rightarrow s\gamma$. The Standard Model prediction for a_μ (where the hadronic contribution is determined from all e^+e^- data) exhibits a 3.2σ deviation from the experimentally observed value [37]. The rare decay $b \rightarrow s\gamma$ also provides a sensitive probe to the virtual effects of new physics beyond the Standard Model. Recent experimental measurements of $B \rightarrow X_s + \gamma$ by the BELLE collaboration [38] are in very good agreement with the theoretical predictions of Ref. 39. In both cases, supersymmetric corrections can contribute an observable shift from the Standard Model prediction in some regions of the MSSM parameter space [40,41]. The absence of a *significant* deviation in these and other B -physics observables from their Standard Model predictions places interesting constraints on the low-energy supersymmetry parameters [42].

There is some tension between the expectation that supersymmetry-breaking is associated with the electroweak symmetry-breaking scale and the non-observation of supersymmetric particles in present day collider experiments [43]. In particular, the experimental lower bound on squark and gluino masses is already three to four times larger than the masses of the W and Z bosons [27]. The non-observation at LEP [44] of the Higgs boson [whose mass depends indirectly on the top-squark mass via radiative corrections, cf. Eq. (11)] adds to this tension [45]. The separation of scales that govern electroweak symmetry and supersymmetry breaking is an example of the *little hierarchy problem* [46]. It appears that the Higgs vacuum expectation value must be fine-tuned at the percent level in the MSSM, although one can imagine model extensions in which the degree of fine-tuning is relaxed [47].

I.2.2. R-parity and the lightest supersymmetric particle: As a consequence of $B-L$ invariance, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [48]. Note that this implies that all the ordinary Standard Model particles have even R parity, whereas the corresponding supersymmetric partners have odd R parity. The conservation of R parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (R-even) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [49]. (There are some model circumstances in which a colored gluino LSP is allowed [50], but we do not consider this possibility further here.) Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical

signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Moreover, as noted at the end of Section I, the LSP is a promising candidate for dark matter [16,17].

I.2.3. The goldstino and gravitino: In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the $SU(3) \times SU(2) \times U(1)$ gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the *goldstino* ($\tilde{G}_{1/2}$) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [51]. However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global supersymmetry. If supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity [52]. In models of spontaneously-broken supergravity, the goldstino is “absorbed” by the *gravitino* (\tilde{G}) [sometimes called $\tilde{g}_{3/2}$ in the older literature], the spin-3/2 superpartner of the graviton [53]. By this super-Higgs mechanism, the goldstino is removed from the physical spectrum and the gravitino acquires a mass ($m_{3/2}$). In processes with center-of-mass energy $E \gg m_{3/2}$, the goldstino–gravitino equivalence theorem [54] states that the interactions of the helicity $\pm\frac{1}{2}$ gravitino (whose properties approximate those of the goldstino) dominate those of the helicity $\pm\frac{3}{2}$ gravitino. The interactions of gravitinos with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles (see, *e.g.*, Ref. 55).

I.2.4. Hidden sectors and the structure of supersymmetry breaking [24]: It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken low-energy supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. A more viable scheme posits a theory consisting of at least two distinct sectors: a *hidden* sector consisting of particles that are completely neutral with respect to the Standard Model gauge group, and a *visible* sector consisting of the particles of the MSSM. There are no renormalizable tree-level interactions between particles of the visible and hidden sectors. Supersymmetry breaking is assumed to originate in the hidden sector, and its effects are transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional *messenger* sector). Two theoretical scenarios have been examined in detail: gravity-mediated and gauge-mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of *gravity-mediated* supersymmetry breaking, gravity is the messenger of supersymmetry breaking [56–58]. More precisely, supersymmetry

breaking is mediated by effects of gravitational strength (suppressed by inverse powers of the Planck mass). In this scenario, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are roughly gravitational in strength [2,59]. Such a gravitino typically plays no role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [60]).

In *gauge-mediated* supersymmetry breaking, gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where supersymmetry is broken, a messenger sector consisting of particles (messengers) with $SU(3) \times SU(2) \times U(1)$ quantum numbers, and the visible sector consisting of the fields of the MSSM [61–63]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Finally, supersymmetry breaking is transmitted to the MSSM via the virtual exchange of the messengers. In models of *direct gauge mediation*, the hidden sector fields also carry Standard Model quantum numbers, and no separate messenger sector is required [64]. The gravitino mass in these models is typically in the eV range (although in some cases it can be as large as a GeV), which implies that \tilde{G} is the LSP. In particular, the gravitino is a potential dark matter candidate (for a recent review and guide to the literature, see Ref. 17). The couplings of the helicity $\pm\frac{1}{2}$ components of \tilde{G} to the particles of the MSSM (which approximate those of the goldstino, cf. Section I.2.3) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The concept of a hidden sector is more general than supersymmetry. *Hidden valley* models [65] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the Standard Model. The impact of a hidden valley on supersymmetric phenomenology at colliders can be profound if the LSP lies in the valley sector [66]. Standard supersymmetric particle search strategies will need to be reconsidered if such a scenario is realized in nature.

I.2.5. *Supersymmetry and extra dimensions:*

Approaches to supersymmetry breaking have also been developed in the context of theories in which the number of space dimensions is greater than three. In particular, a number of supersymmetry-breaking mechanisms have been proposed that are inherently extra-dimensional [67]. The size of the extra dimensions can be significantly larger than M_P^{-1} ; in some cases on the order of $(\text{TeV})^{-1}$ or even larger [68,69]. For example, in one approach, the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks supersymmetry lives on a second-separated brane. Two examples of this approach are anomaly-mediated supersymmetry breaking of Ref. 70, and gaugino-mediated supersymmetry breaking of Ref. 71; in both cases supersymmetry breaking is transmitted through fields that live in the bulk (the higher-dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated

supersymmetry breaking (*e.g.*, a hidden and visible sector and messengers).

Alternatively, one can consider a higher-dimensional theory that is compactified to four spacetime dimensions. In this approach, supersymmetry is broken by boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [72]. The phenomenology of such models can be strikingly different from that of the usual MSSM [73]. All these extra-dimensional ideas clearly deserve further investigation, although they will not be discussed further here.

I.2.6. *Split-supersymmetry:* If supersymmetry is not connected with the origin of the electroweak scale, string theory suggests that supersymmetry still plays a significant role in Planck-scale physics. However, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of *split-supersymmetry* [74], in which supersymmetric scalar partners of the quarks and leptons are significantly heavier (perhaps by many orders of magnitude) than 1 TeV, whereas the fermionic partners of the gauge and Higgs bosons have masses on the order of 1 TeV or below (presumably protected by some chiral symmetry). With the exception of a single light neutral scalar whose properties are indistinguishable from those of the Standard Model Higgs boson, all other Higgs bosons are also taken to be very heavy.

The supersymmetry breaking required to produce such a scenario would destabilize the gauge hierarchy. In particular, split-supersymmetry cannot provide a natural explanation for the existence of the light Standard-Model-like Higgs boson, whose mass lies orders below the mass scale of the heavy scalars. Nevertheless, models of split-supersymmetry can account for the dark matter (which is assumed to be the LSP) and gauge coupling unification. Thus, there is some motivation for pursuing the phenomenology of such approaches [75]. One notable difference from the usual MSSM phenomenology is the existence of a long-lived gluino [76].

I.3. *Parameters of the MSSM:* The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the tree-level MSSM parameters can be found in Ref. 77. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

I.3.1. *The supersymmetric-conserving parameters:*

The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings: g_s , g , and g' , corresponding to the Standard Model gauge group $SU(3) \times SU(2) \times U(1)$ respectively; (ii) a supersymmetry-conserving higgsino mass parameter μ ; and (iii) Higgs-fermion Yukawa coupling constants: λ_u , λ_d , and λ_e (corresponding to the coupling of one generation of left- and right-handed quarks and leptons, and their superpartners

Searches Particle Listings

Supersymmetric Particle Searches

to the Higgs bosons and higgsinos). Because there is no right-handed neutrino (and its superpartner) in the MSSM as defined here, one cannot introduce a Yukawa coupling λ_ν .

I.3.2. The supersymmetric-breaking parameters:

The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses M_3 , M_2 , and M_1 associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) five scalar squared-mass parameters for the squarks and sleptons, M_Q^2 , M_U^2 , M_D^2 , M_L^2 , and M_E^2 [corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of $(u, d)_L$, u_L^c , d_L^c , $(\nu, e^-)_L$, and e_L^c , where the superscript c indicates a charge-conjugated fermion and flavor indices are suppressed]; and (iii) Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with coefficients $\lambda_u A_U$, $\lambda_d A_D$, and $\lambda_e A_E$ (which define the so-called “ A -parameters”). It is traditional to factor out the Yukawa couplings in the definition of the A -parameters (originally motivated by a simple class of gravity-mediated supersymmetry-breaking models [2,4]). If the A -parameters defined in this way are parametrically of the same order (or smaller) as compared to other supersymmetry-breaking mass parameters, then only the A -parameters of the third generation will be phenomenologically relevant.

Finally, we add: (iv) three scalar squared-mass parameters—two of which (m_1^2 and m_2^2) contribute to the diagonal Higgs squared-masses, given by $m_1^2 + |\mu|^2$ and $m_2^2 + |\mu|^2$, and a third which contributes to the off-diagonal Higgs squared-mass term, $m_{12}^2 \equiv B\mu$ (which defines the “ B -parameter”). The breaking of the electroweak symmetry SU(2)×U(1) to U(1)_{EM} is only possible after introducing the supersymmetry-breaking Higgs squared-mass parameters. Minimizing the resulting Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_d and v_u (also called v_1 and v_2 , respectively, in the literature), and one physical Higgs mass. Here, v_d [v_u] is the vacuum expectation value of the neutral component of the Higgs field H_d [H_u] that couples exclusively to down-type (up-type) quarks and leptons. Note that $v_d^2 + v_u^2 = 4m_W^2/g^2 \simeq (246 \text{ GeV})^2$ is fixed by the W mass and the gauge coupling, whereas the ratio

$$\tan\beta = v_u/v_d \quad (1)$$

is a free parameter of the model. By convention, the Higgs field phases are chosen such that $0 \leq \beta \leq \pi/2$.

Note that supersymmetry-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-supersymmetry-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with a gauge-singlet superfield. The latter is not present in the MSSM; hence as noted in Ref. 12, these so-called non-standard soft-supersymmetry-breaking terms are benign. However, the

coefficients of these terms (which have dimensions of mass) are expected to be significantly suppressed compared to the TeV-scale in a fundamental theory of supersymmetry-breaking. Consequently, we follow the usual approach and omit these terms from further consideration.

I.3.3. MSSM-124: The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, M_Q^2 , M_U^2 , M_D^2 , M_L^2 , and M_E^2 are hermitian 3×3 matrices, and A_U , A_D , and A_E are complex 3×3 matrices. In addition, M_1 , M_2 , M_3 , B , and μ are, in general, complex. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings, λ_f ($f = u, d$, and e), are complex 3×3 matrices that are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f / \sqrt{2}$, where $v_e \equiv v_d$ [with v_u and v_d as defined above Eq. (1)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. 78 shows that the MSSM possesses 124 independent parameters. Of these, 18 parameters correspond to Standard Model parameters (including the QCD vacuum angle θ_{QCD}), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CP -violating phases in the gaugino/higgsino sector, 21 squark and slepton masses, 36 real mixing angles to define the squark and slepton mass eigenstates, and 40 CP -violating phases that can appear in squark and slepton interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [79].

I.4. The supersymmetric-particle spectrum: Consider the sector of supersymmetric particles (*sparticles*) in the MSSM. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending “ino” at the end of the corresponding Standard Model particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass $M_{\tilde{g}} = |M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix. As a result, the physical states of definite mass are model-dependent linear combinations of the charged and neutral gauginos and higgsinos, called *charginos* and *neutralinos*, respectively. Like the gluino, the neutralinos are also Majorana fermions, which provide for some distinctive phenomenological signatures [80,81]. The supersymmetric partners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. 82. The MSSM Feynman rules also are

implicitly contained in a number of Feynman diagram and amplitude generation software packages (see *e.g.*, Refs. 83–85).

I.4.1. The charginos and neutralinos: The mixing of the charged gauginos (\widetilde{W}^\pm) and charged higgsinos (H_u^\pm and H_d^\pm) is described (at tree-level) by a 2×2 complex mass matrix [86–88]:

$$M_C \equiv \begin{pmatrix} M_2 & \frac{1}{\sqrt{2}}g v_u \\ \frac{1}{\sqrt{2}}g v_d & \mu \end{pmatrix}. \quad (2)$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [89,90] of the complex matrix M_C :

$$U^* M_C V^{-1} = \text{diag}(M_{\widetilde{\chi}_1^\pm}, M_{\widetilde{\chi}_2^\pm}), \quad (3)$$

where U and V are unitary matrices, and the right-hand side of Eq. (3) is the diagonal matrix of (non-negative) chargino masses. The physical chargino states are denoted by $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^\pm$. These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of U and V [86–88]. The chargino masses correspond to the *singular values* [89] of M_C , *i.e.*, the positive square roots of the eigenvalues of $M_C^\dagger M_C$:

$$M_{\widetilde{\chi}_1^\pm, \widetilde{\chi}_2^\pm}^2 = \frac{1}{2} \left\{ |\mu|^2 + |M_2|^2 + 2m_W^2 \mp \left[(|\mu|^2 + |M_2|^2 + 2m_W^2)^2 - 4|\mu|^2|M_2|^2 - 4m_W^4 \sin^2 2\beta + 8m_W^2 \sin 2\beta \text{Re}(\mu M_2) \right]^{1/2} \right\}, \quad (4)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^\pm} \leq M_{\widetilde{\chi}_2^\pm}$. It is convenient to choose a convention where $\tan\beta$ and M_2 are real and positive. Note that the relative phase of M_2 and μ is meaningful. (If CP -violating effects are neglected, then μ can be chosen real but may be either positive or negative.) The sign of μ is convention-dependent; the reader is warned that both sign conventions appear in the literature. The sign convention for μ in Eq. (2) is used by the LEP collaborations [27] in their plots of exclusion contours in the M_2 vs. μ plane derived from the non-observation of $e^+e^- \rightarrow \widetilde{\chi}_1^+ \widetilde{\chi}_1^-$.

The mixing of the neutral gauginos (\widetilde{B} and \widetilde{W}^0) and neutral higgsinos (\widetilde{H}_d^0 and \widetilde{H}_u^0) is described (at tree-level) by a 4×4 complex symmetric mass matrix [86,87,91,92]:

$$M_N \equiv \begin{pmatrix} M_1 & 0 & -\frac{1}{2}g'v_d & \frac{1}{2}g'v_u \\ 0 & M_2 & \frac{1}{2}g v_d & -\frac{1}{2}g v_u \\ -\frac{1}{2}g'v_d & \frac{1}{2}g v_d & 0 & -\mu \\ \frac{1}{2}g'v_u & -\frac{1}{2}g v_u & -\mu & 0 \end{pmatrix}. \quad (5)$$

To determine the physical neutralino states and their masses, one must perform a Takagi-diagonalization [89,90,93,94] of the complex symmetric matrix M_N :

$$W^T M_N W = \text{diag}(M_{\widetilde{\chi}_1^0}, M_{\widetilde{\chi}_2^0}, M_{\widetilde{\chi}_3^0}, M_{\widetilde{\chi}_4^0}), \quad (6)$$

where W is a unitary matrix and the right-hand side of Eq. (6) is the diagonal matrix of (non-negative) neutralino masses. The physical neutralino states are denoted by $\widetilde{\chi}_i^0$ ($i = 1, \dots, 4$), where

the states are ordered such that $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$. The $\widetilde{\chi}_i^0$ are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of W (in Ref. 86, $W = N^{-1}$). The neutralino masses correspond to the singular values of M_N (*i.e.*, the positive square roots of the eigenvalues of $M_N^\dagger M_N$). Exact formulae for these masses can be found in Refs. [91] and [95]. A numerical algorithm for determining the mixing matrix W has been given by Ref. 96.

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if M_1 and M_2 are small compared to m_Z and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure *photino*, $\widetilde{\gamma}$, the supersymmetric partner of the photon. If M_1 and m_Z are small compared to M_2 and $|\mu|$, then the lightest neutralino would be nearly a pure *bin*o, \widetilde{B} , the supersymmetric partner of the weak hypercharge gauge boson. If M_2 and m_Z are small compared to M_1 and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure *win*os, \widetilde{W}^\pm , and \widetilde{W}_3^0 , the supersymmetric partners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to M_1 and M_2 , then the lightest neutralino would be nearly a pure *higgsino*. Each of the above cases leads to a strikingly different phenomenology.

I.4.2. The squarks, sleptons and sneutrinos: For a given fermion f , there are two supersymmetric partners, \widetilde{f}_L and \widetilde{f}_R , which are scalar partners of the corresponding left- and right-handed fermion. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, in general, \widetilde{f}_L and \widetilde{f}_R are not mass eigenstates, since there is \widetilde{f}_L - \widetilde{f}_R mixing. For three generations of squarks, one must in general diagonalize 6×6 matrices corresponding to the basis $(\widetilde{q}_{iL}, \widetilde{q}_{iR})$, where $i = 1, 2, 3$ are the generation labels. For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and is treated in Ref. 97.) Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [98]

$$M_F^2 = \begin{pmatrix} M_Q^2 + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M_R^2 + m_q^2 + R_q \end{pmatrix}, \quad (7)$$

where

$$X_q \equiv A_q - \mu^* (\cot\beta)^{2T_{3q}}, \quad (8)$$

and $T_{3q} = \frac{1}{2} [-\frac{1}{2}]$ for $q = t$ [b]. The diagonal squared masses are governed by soft-supersymmetry-breaking squared masses M_Q^2 and $M_R^2 \equiv M_D^2$ [M_U^2] for $q = t$ [b], the corresponding quark masses m_t [m_b], and electroweak correction terms:

$$L_q \equiv (T_{3q} - e_q \sin^2 \theta_W) m_Z^2 \cos 2\beta, \quad R_q \equiv e_q \sin^2 \theta_W m_Z^2 \cos 2\beta, \quad (9)$$

where $e_q = \frac{2}{3} [-\frac{1}{3}]$ for $q = t$ [b]. The off-diagonal squared squark masses are proportional to the corresponding quark masses and depend on $\tan\beta$ [Eq. (1)], the soft-supersymmetry-breaking A -parameters and the higgsino mass parameter μ . The signs of the A and μ parameters are convention-dependent;

Searches Particle Listings

Supersymmetric Particle Searches

other choices appear frequently in the literature. Due to the appearance of the *quark* mass in the off-diagonal element of the squark squared-mass matrix, one expects the \tilde{q}_L - \tilde{q}_R mixing to be small, with the possible exception of the third generation, where mixing can be enhanced by factors of m_t and $m_b \tan \beta$.

In the case of third generation \tilde{q}_L - \tilde{q}_R mixing, the mass eigenstates (usually denoted by \tilde{q}_1 and \tilde{q}_2 , with $m_{\tilde{q}_1} < m_{\tilde{q}_2}$) are determined by diagonalizing the 2×2 matrix M_F^2 given by Eq. (7). The corresponding squared masses and mixing angle are given by [98]:

$$m_{\tilde{q}_{1,2}}^2 = \frac{1}{2} \left[\text{Tr} M_F^2 \mp \sqrt{(\text{Tr} M_F^2)^2 - 4 \det M_F^2} \right],$$

$$\sin 2\theta_{\tilde{q}} = \frac{2m_q |X_q|}{m_{\tilde{q}_2}^2 - m_{\tilde{q}_1}^2}. \quad (10)$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions: $q \rightarrow \tau$ with $T_{3\tau} = -\frac{1}{2}$ and $e_\tau = -1$, and the replacement of the supersymmetry-breaking parameters: $M_Q^2 \rightarrow M_L^2$, $M_D^2 \rightarrow M_E^2$, and $A_q \rightarrow A_\tau$. For the neutral sleptons, $\tilde{\nu}_R$ does not exist in the MSSM, so $\tilde{\nu}_L$ is a mass eigenstate.

In the case of three generations, the supersymmetry-breaking scalar-squared masses [M_Q^2 , M_U^2 , M_D^2 , M_L^2 , and M_E^2] and the A -parameters that parameterize the Higgs couplings to up- and down-type squarks and charged sleptons (henceforth denoted by A_U , A_D , and A_E , respectively) are now 3×3 matrices as noted in Section I.3. The diagonalization of the 6×6 squark mass matrices yields \tilde{f}_{iL} - \tilde{f}_{jR} mixing (for $i \neq j$). In practice, since the \tilde{f}_L - \tilde{f}_R mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. 97 for examples in which the mixing between the second and third generations is relevant).

Radiative loop corrections will modify all tree-level results for masses quoted in this section. These corrections must be included in any precision study of supersymmetric phenomenology [99]. Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The supersymmetric parameter analysis (SPA) project proposed a set of conventions [100] based on a consistent set of conventions and input parameters. This work employs a consistent dimensional reduction scheme for the regularization of higher-order loop corrections in supersymmetric theories recently advocated in Ref. 101. More recently, the Supersymmetry Les Houches Accord (SLHA) [102] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators. Ultimately, these efforts will facilitate

the reconstruction of the fundamental supersymmetric theory (and its breaking mechanism) from high-precision studies of supersymmetric phenomena at future colliders.

I.5. The Higgs sector of the MSSM: Next, consider the MSSM Higgs sector [22,23,103]. Despite the large number of potential CP -violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs sector is automatically CP -conserving. That is, unphysical phases can be absorbed into the definition of the Higgs fields such that $\tan \beta$ is a real parameter (conventionally chosen to be positive). Consequently, the physical neutral Higgs scalars are CP eigenstates. The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair (H^\pm), two CP -even neutral Higgs bosons (denoted by h^0 and H^0 where $m_h < m_H$), and one CP -odd neutral Higgs boson (A^0).

I.5.1 The Tree-level MSSM Higgs sector: The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were specified above Eq. (1)] and quartic interaction terms governed by dimensionless couplings. The quartic interaction terms are manifestly supersymmetric at tree level (although these are modified by supersymmetry-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called “ F -terms”), and (ii) interaction terms related by supersymmetry to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called “ D -terms”). In the MSSM, F -term contributions to the quartic couplings are absent (although such terms may be present in extensions of the MSSM, *e.g.*, models with Higgs singlets). As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings. Due to the resulting constraint on the form of the two-Higgs-doublet scalar potential, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan \beta$ [defined in Eq. (1)] and one Higgs mass usually taken to be m_A . From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle α (which measures the component of the original $Y = \pm 1$ Higgs doublet states in the physical CP -even neutral scalars), and the Higgs boson self-couplings.

I.5.2 The radiatively-corrected MSSM Higgs sector: When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [104]. For example, the tree-level MSSM-124 prediction for the upper bound of the lightest CP -even Higgs mass, $m_h \leq m_Z |\cos 2\beta| \leq m_Z$ [22,23], can be substantially modified when radiative corrections are included. The qualitative behavior of these radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries and the two off-diagonal entries of the top-squark squared-mass matrix [Eq. (7)] are small in comparison to the average of the two top-squark squared masses,

$M_S^2 \equiv \frac{1}{2}(M_{t_1}^2 + M_{t_2}^2)$. In this case (assuming $m_A > m_Z$), the predicted upper bound for m_h (which reaches its maximum at large $\tan \beta$) is approximately given by

$$m_h^2 \lesssim m_Z^2 + \frac{3g^2 m_t^4}{8\pi^2 m_W^2} \left[\ln(M_S^2/m_t^2) + \frac{X_t^2}{M_S^2} \left(1 - \frac{X_t^2}{12M_S^2} \right) \right], \quad (11)$$

where $X_t \equiv A_t - \mu \cot \beta$ is the top-squark mixing factor [see Eq. (7)]. A more complete treatment of the radiative corrections [105] shows that Eq. (11) somewhat overestimates the true upper bound of m_h . These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield $m_h \lesssim 135$ GeV (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [105]. This Higgs-mass upper bound can be relaxed somewhat in non-minimal extensions of the MSSM, as noted in Section I.9.

In addition, one-loop radiative corrections can introduce CP -violating effects in the Higgs sector, which depend on some of the CP -violating phases among the MSSM-124 parameters [106]. Although these effects are more model-dependent, they can have a non-trivial impact on the Higgs searches at future colliders. A summary of the current MSSM Higgs mass limits can be found in Ref. 44.

I.6. Restricting the MSSM parameter freedom: In Sections I.4 and I.5, we surveyed the parameters that comprise the MSSM-124. However, in its most general form, the MSSM-124 is not a phenomenologically-viable theory over most of its parameter space. This conclusion follows from the observation that a generic point in the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers L_e , L_μ , and L_τ ; (ii) unsuppressed flavor-changing neutral currents (FCNC's); and (iii) new sources of CP violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of CP violation [107]. In particular, some combinations of the complex phases of the gaugino-mass parameters, the A parameters, and μ must be less than on the order of 10^{-2} – 10^{-3} (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [108–110]. The non-observation of FCNC's [29,30] places additional strong constraints on the off-diagonal matrix elements of the squark and slepton soft-supersymmetry-breaking squared masses and A -parameters (see Section I.3.3). As a result of the phenomenological deficiencies listed above, almost the entire MSSM-124 parameter space is ruled out! This theory is viable only at very special “exceptional” regions of the full parameter space.

The MSSM-124 is also theoretically incomplete as it provides no explanation for the origin of the supersymmetry-breaking parameters (and in particular, why these parameters should conform to the exceptional points of the parameter space mentioned above). Moreover, there is no understanding of the choice of parameters that leads to the breaking of the electroweak symmetry. What is needed ultimately is a fundamental theory of supersymmetry breaking (depending on far

fewer than 124 parameters), which would provide a rationale for a set of soft-supersymmetry-breaking terms that would be consistent with all phenomenological constraints.

I.6.1. Bottom-up approach for constraining the MSSM parameters: In the absence of a fundamental theory of supersymmetry breaking, there are two general approaches for reducing the parameter freedom of MSSM-124. In the low-energy approach, an attempt is made to elucidate the nature of the exceptional points in the MSSM-124 parameter space that are phenomenologically viable. Consider two possible scenarios (under the assumption that squark and slepton masses are not significantly larger than the scale of electroweak symmetry breaking). First, one can assume that M_Q^2 , M_U^2 , M_D^2 , M_L^2 , M_E^2 , and A_U , A_D , A_E are generation-independent (horizontal universality [8,78,111]). Alternatively, one can simply require that all the aforementioned matrices are flavor diagonal in a basis where the quark and lepton mass matrices are diagonal (flavor alignment [112]). In either case, L_e , L_μ , and L_τ are separately conserved, while tree-level FCNC's are automatically absent. In both cases, the number of free parameters characterizing the MSSM is substantially less than 124, although there is no obvious fundamental theoretical basis for either scenario. It has been argued that flavor alignment scenarios are disfavored [113] in light of the recent observation of D^0 – \bar{D}^0 mixing [114]. Thus, if squarks are discovered with masses below about 1–2 TeV, then one would expect the first two generations of squarks to be highly degenerate in mass.

I.6.2. Top-down approach for constraining the MSSM parameters: In the high-energy approach, one imposes a particular structure on the soft-supersymmetry-breaking terms at a common high-energy scale M_X (typically chosen to be the Planck scale, M_P , or the grand unification scale, M_{GUT}). Using the renormalization group equations, one can then derive the low-energy MSSM parameters relevant for collider physics. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory. Examples of this scenario are provided by models of gravity-mediated and gauge-mediated supersymmetry breaking (see Section I.7). One bonus of such an approach is that one of the diagonal Higgs squared-mass parameters is typically driven negative by renormalization group evolution [115]. Thus, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

One prediction of the high-energy approach that arises in many grand unified supergravity models and gauge-mediated supersymmetry-breaking models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale M_X :

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}. \quad (12)$$

Searches Particle Listings

Supersymmetric Particle Searches

Consequently, the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5M_2, \quad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2. \quad (13)$$

In this case, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ , and $\tan\beta$. If in addition $|\mu| \gg M_1 \gtrsim m_Z$, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders.

Although Eqs. (12) and (13) are often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters, M_i , to be independent parameters to be determined by experiment. For example, although LEP data yields a lower bound of 46 GeV on the mass of the lightest neutralino [28], an exactly massless neutralino *cannot* be ruled out today in a model-independent analysis [116].

Certain subsets of squark and slepton mass parameters are also unified in some top-down approaches. However, in contrast to the analysis of the gaugino masses, the renormalization group evolution of the scalar masses may depend strongly on the unknown fundamental supersymmetry-breaking dynamics [117]. Such effects have generally been ignored (or assumed to be negligible) in the prediction of low-energy scalar masses.

Finally, we remark that in certain top-down approaches the unification of gaugino masses and scalar masses can be accidental. In particular, the energy scale where unification takes place is not directly related to any physical scale. This phenomenon has been called *mirage unification* and can occur in certain theories of fundamental supersymmetry-breaking [118].

I.6.3. Anomaly-mediated supersymmetry-breaking:

In some supergravity models, tree-level masses for the gauginos are absent. The gaugino mass parameters arise at one-loop and do not satisfy Eq. (13). In this case, one finds a model-independent contribution to the gaugino mass whose origin can be traced to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [70]. This approach is called *anomaly-mediated* supersymmetry breaking (AMSB). Eq. (13) is then replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}, \quad (14)$$

where $m_{3/2}$ is the gravitino mass (assumed to be on the order of 1 TeV), and b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups: $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (14) yields $M_1 \simeq 2.8M_2$ and $M_3 \simeq -8.3M_2$, which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos, $\widetilde{W}^\pm, \widetilde{W}^0$ (c.f. Table 1), over most of the MSSM parameter space. (For example, if $|\mu| \gg m_Z$, then Eq. (14) implies that $M_{\widetilde{\chi}_1^\pm} \simeq M_{\widetilde{\chi}_1^0} \simeq M_2$ [119].) The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (13), and is explored in detail in Ref. 120. Under certain theoretical assumptions on

the structure of the Kähler potential (the so-called sequestered form introduced in Ref. 70), anomaly-mediated supersymmetry breaking also generates (approximate) flavor-diagonal squark and slepton mass matrices. However, this yields negative squared-mass contributions for the sleptons in the MSSM. It may be possible to cure this fatal flaw in approaches beyond the minimal supersymmetric model [121]. Alternatively, one may conclude that anomaly-mediation is not the sole source of supersymmetry-breaking in the slepton sector.

I.7. The constrained MSSMs: mSUGRA, GMSB, and SGUTs:

In this Section, we examine a number of top-down theoretical frameworks that constrain the parameters of the general MSSM and yield predictions for the low-energy supersymmetric particle spectrum as a function of their input parameters. In particular, the structure of the soft-supersymmetry-breaking parameters must be consistent with the absence of significant FCNC's mediated by virtual supersymmetric particle exchange.

Of course, any of the theoretical assumptions described in this Section could be wrong and must eventually be tested experimentally. In practice, one anticipates that the measurements of low-energy supersymmetric parameters may eventually provide sufficient information to determine the organizing principle governing supersymmetry breaking and yield significant constraints on the values of the fundamental (high-energy) supersymmetric parameters. In particular, a number of sophisticated techniques have been recently developed for analyzing experimental data to test the viability of the particular supersymmetric framework and for measuring the fundamental model parameters and their uncertainties [122].

I.7.1. The minimal supergravity model: In the *minimal* supergravity (mSUGRA) framework [2–4], a form of the Kähler potential is employed that yields minimal kinetic energy terms for the MSSM fields [123]. As a result, the soft-supersymmetry-breaking parameters at the high-energy scale M_X take a particularly simple form in which the scalar squared masses and the A -parameters are flavor-diagonal and universal [57]:

$$\begin{aligned} M_Q^2(M_X) &= M_U^2(M_X) = M_D^2(M_X) = m_0^2 \mathbf{1}, \\ M_L^2(M_X) &= M_E^2(M_X) = m_0^2 \mathbf{1}, \\ m_1^2(M_X) &= m_2^2(M_X) = m_0^2, \\ A_U(M_X) &= A_D(M_X) = A_E(M_X) = A_0 \mathbf{1}, \end{aligned} \quad (15)$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one must use the *low-energy* values for M_Q^2 , M_U^2 , and M_D^2 in Eq. (7). Through the renormalization group running with boundary conditions specified in Eqs. (13) and (15), one can show that the low-energy values of M_Q^2 , M_U^2 , and M_D^2 depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic

expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. 124.

In the mSUGRA approach, the MSSM-124 parameter freedom has been significantly reduced. Typical mSUGRA models give low-energy values for the scalar mass parameters that satisfy $M_{\tilde{L}} \lesssim M_{\tilde{E}} < M_{\tilde{Q}} \approx M_{\tilde{U}} \approx M_{\tilde{D}}$, with the squark mass parameters somewhere between a factor of 1–3 larger than the slepton mass parameters (*e.g.*, see Ref. 124). More precisely, the low-energy values of the squark mass parameters of the first two generations are roughly degenerate, while $M_{\tilde{Q}_3}$ and $M_{\tilde{U}_3}$ are typically reduced by a factor of 1–3 from the values of the first- and second-generation squark mass parameters, because of renormalization effects due to the heavy top-quark mass.

As a result, one typically finds that four flavors of squarks (with two squark eigenstates per flavor) and \tilde{b}_R are nearly mass-degenerate. The \tilde{b}_L mass and the diagonal \tilde{t}_L and \tilde{t}_R masses are reduced compared to the common squark mass of the first two generations. In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. Finally, third-generation squark masses and tau-slepton masses are sensitive to the strength of the respective \tilde{f}_L – \tilde{f}_R mixing, as discussed below Eq. (7). If $\tan\beta \gg 1$, then the pattern of third-generation squark masses is somewhat altered, as discussed in Ref. 125.

In mSUGRA models, the LSP is typically the lightest neutralino, $\tilde{\chi}_1^0$, which is dominated by its bino component. In particular, one can reject those mSUGRA parameter regimes in which the LSP is a chargino or the $\tilde{\tau}_1$ (the lightest scalar superpartner of the τ -lepton). In general, if one imposes the constraints of supersymmetric particle searches and those of cosmology (say, by requiring the LSP to be a suitable dark matter candidate), one obtains significant restrictions to the mSUGRA parameter space [42,126].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model parameters (excluding the Higgs mass), one must specify m_0 , $m_{1/2}$, A_0 , the Planck-scale values for μ and B -parameters (denoted by μ_0 and B_0), and the gravitino mass $m_{3/2}$. Without additional model assumptions, $m_{3/2}$ is independent of the parameters that govern the mass spectrum of the superpartners of the Standard Model [57]. In principle, A_0 , B_0 , μ_0 , and $m_{3/2}$ can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real. In the early literature, additional conditions were obtained by assuming a simplifying form for the hidden sector that provides the fundamental source of supersymmetry breaking. Two additional relations emerged among the mSUGRA parameters [123]: $B_0 = A_0 - m_0$ and $m_{3/2} = m_0$. Although these relations characterize a theory that was called minimal supergravity when first proposed, it is now more common to omit these extra constraints in defining the mSUGRA model. To accommodate this prevailing convention, we propose that the more constrained

Figure 1: Mass spectrum of supersymmetric particles and Higgs bosons for the mSUGRA reference point SPS 1a'. The masses of the first and second generation squarks, sleptons, and sneutrinos are denoted collectively by \tilde{q} , $\tilde{\ell}$ and $\tilde{\nu}_\ell$, respectively. Taken from Ref. 100. Color version at end of book.

mSUGRA models, in which additional parameter relations are imposed, shall be designated as *more* minimal supergravity (mmSUGRA) models. Detailed studies of the phenomenology of various mmSUGRA models have been presented in Ref. 127.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ [the sign of μ_0 , denoted $\text{sgn}(\mu_0)$ below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0, A_0, m_{1/2}, \tan\beta, \text{ and } \text{sgn}(\mu_0), \quad (16)$$

in addition to the 18 parameters of the Standard Model. However, the mSUGRA approach is probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [128]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In order to facilitate studies of supersymmetric phenomenology at colliders, it has been a valuable exercise to compile a set of benchmark supersymmetric parameters, from which supersymmetric spectra and couplings can be derived [129]. A compilation of benchmark mSUGRA points consistent with present data from particle physics and cosmology can be found in Ref. 130. One particular well-studied benchmark point, the so-called SPS 1a' reference point [100] (this is a slight modification of the SPS 1a point of Ref. 129, which incorporates the latest constraints from collider data and cosmology) has been

Searches Particle Listings

Supersymmetric Particle Searches

especially useful in experimental studies of supersymmetric phenomena at future colliders. In Fig. 1, the supersymmetric particle spectrum for the SPS 1a' reference point is exhibited. However, it is important to keep in mind that even within the mSUGRA framework, the resulting supersymmetric theory and its attendant phenomenology can be quite different from the SPS 1a' reference point.

I.7.2. Gauge-mediated supersymmetry breaking: In contrast to models of gravity-mediated supersymmetry breaking, the universality of the fundamental soft-supersymmetry-breaking squark and slepton squared-mass parameters is guaranteed in gauge-mediated supersymmetry breaking because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [62,63]. In the minimal gauge-mediated supersymmetry-breaking (GMSB) approach, there is one effective mass scale, Λ , that determines all low-energy scalar and gaugino mass parameters through loop effects (while the resulting A parameters are suppressed). In order that the resulting superpartner masses be on the order of 1 TeV or less, one must have $\Lambda \sim 100$ TeV. The origin of the μ and B -parameters is quite model-dependent, and lies somewhat outside the ansatz of gauge-mediated supersymmetry breaking. The simplest models of this type are even more restrictive than mSUGRA, with two fewer degrees of freedom. Benchmark reference points for GMSB models have been proposed in Ref. 129 to facilitate collider studies.

The minimal GMSB is not a fully realized model. The sector of supersymmetry-breaking dynamics can be very complex, and no complete model of gauge-mediated supersymmetry yet exists that is both simple and compelling. However, advances in the theory of dynamical supersymmetry breaking (which exploit the existence of metastable supersymmetry-breaking vacua in broad classes of models [131]) have generated new ideas and opportunities for model building. As a result, simpler models of successful gauge mediation of supersymmetry breaking have been achieved with the potential for overcoming a number of long-standing theoretical challenges [132]. In addition, model-independent techniques that encompass all known gauge mediation models have been recently formulated [133]. These methods are well-suited for a comprehensive analysis [134] of the phenomenological profile of gauge-mediated supersymmetry breaking.

It was noted in Section I.2 that the gravitino is the LSP in GMSB models. Thus, in such models, the next-to-lightest supersymmetric particle (NLSP) plays a crucial role in the phenomenology of supersymmetric particle production and decay. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\tilde{\chi}_1^0$ and $\tilde{\tau}_R^\pm$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$, $\tilde{\chi}_1^0 \rightarrow Z\tilde{G}$, or $\tilde{\tau}_R^\pm \rightarrow \tau^\pm\tilde{G}$), with lifetimes and branching ratios that depend on the model parameters.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [63,135]. For example, a long-lived $\tilde{\chi}_1^0$ -NLSP

that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the $\tilde{\chi}_1^0$ -LSP). On the other hand, if $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, in the case of a $\tilde{\tau}_R^\pm$ -NLSP, the $\tilde{\tau}_R^\pm$ would either be long-lived or would decay inside the detector into a τ -lepton plus missing energy.

I.7.3. Supersymmetric grand unification: Finally, grand unification [136] can impose additional constraints on the MSSM parameters. As emphasized in Section I.1, it is striking that the $SU(3)\times SU(2)\times U(1)$ gauge couplings unify in models of supersymmetric grand unified theories (SGUTs) [8,74,137,138] with (some of) the supersymmetry-breaking parameters on the order of 1 TeV or below. Gauge coupling unification, which takes place at an energy scale on the order of 10^{16} GeV, is quite robust [139].

Given the low-energy values of the electroweak couplings $g(m_Z)$ and $g'(m_Z)$, one can predict $\alpha_s(m_Z)$ by using the MSSM renormalization group equations to extrapolate to higher energies, and by imposing the unification condition on the three gauge couplings at some high-energy scale, M_X . This procedure, which fixes M_X , can be successful (*i.e.*, three running couplings will meet at a single point) only for a unique value of $\alpha_s(m_Z)$. The extrapolation depends somewhat on the low-energy supersymmetric spectrum (so-called low-energy “threshold effects”), and on the SGUT spectrum (high-energy threshold effects), which can somewhat alter the evolution of couplings. A comparison of data with the expectations of SGUTs shows that the measured value of $\alpha_s(m_Z)$ is in good agreement with the predictions of supersymmetric grand unification for a reasonable choice of supersymmetric threshold corrections [140].

Additional SGUT predictions arise through the unification of the Higgs-fermion Yukawa couplings (λ_f). There is some evidence that $\lambda_b = \lambda_\tau$ is consistent with observed low-energy data [141], and an intriguing possibility that $\lambda_b = \lambda_\tau = \lambda_t$ may be phenomenologically viable [125,142] in the parameter regime where $\tan\beta \simeq m_t/m_b$.

I.8. Massive neutrinos in low-energy supersymmetry:

In the minimal Standard Model and its supersymmetric extension, there are no right-handed neutrinos, and Majorana mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing [143,144], any viable model of fundamental particles must provide a mechanism for generating neutrino masses. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [145]. Although one can devise models for generating massive Dirac neutrinos [146], the most common approaches for incorporating neutrino masses are based on L -violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of L -violating supersymmetric models will now be considered.

I.8.1. The supersymmetric seesaw: In this approach, one starts with an extended version of the Standard Model, which incorporates new structure that yields nonzero neutrino masses. Following the procedures of Sections I.2 and I.3, one then formulates a supersymmetric version of this extended Standard Model. For example, neutrino masses can be incorporated into the Standard Model by introducing $SU(3) \times SU(2) \times U(1)$ singlet right-handed neutrinos (ν_R) and super-heavy Majorana masses (typically on the order of a grand unified mass) for the ν_R . In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and the ν_R . The Higgs vacuum expectation value then induces an off-diagonal ν_L - ν_R masses on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified as the light neutrino states observed in nature. This is the seesaw mechanism [147]. The supersymmetric generalization of the seesaw model of neutrino masses is now easily constructed [148,149].

In the seesaw-extended Standard Model, lepton number is broken due to the presence of $\Delta L = 2$ terms in the Lagrangian (which include the Majorana mass terms for the light and superheavy neutrinos). Consequently, the seesaw-extended MSSM conserves R-parity. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino-antisneutrino mixing phenomena [149,150].

I.8.2. R-parity-violating supersymmetry: A second approach to incorporating massive neutrinos in supersymmetric models is to retain the minimal particle content of the MSSM but remove the assumption of R-parity invariance [151]. The most general R-parity-violating (RPV) theory involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors. Each new interaction term violates either B or L conservation. For example, consider new scalar-fermion Yukawa couplings derived from the following interactions:

$$(\lambda_L)_{pmn} \hat{L}_p \hat{L}_m \hat{E}_n^c + (\lambda'_L)_{pmn} \hat{L}_p \hat{Q}_m \hat{D}_n^c + (\lambda_B)_{pmn} \hat{U}_p^c \hat{D}_m^c \hat{D}_n^c, \quad (17)$$

where p , m , and n are generation indices, and gauge group indices are suppressed. In the notation above, \hat{Q} , \hat{U}^c , \hat{D}^c , \hat{L} , and \hat{E}^c respectively represent $(u, d)_L$, u_L^c , d_L^c , $(\nu, e^-)_L$, and e_L^c and the corresponding superpartners. The Yukawa interactions are obtained from Eq. (17) by taking all possible combinations involving two fermions and one scalar superpartner. Note that the term in Eq. (17) proportional to λ_B violates B , while the other two terms violate L . Even if all the terms of Eq. (17) are absent, there is one more possible supersymmetric source of R-parity violation. In the notation of Eq. (17), one can add a term of the form $(\mu_L)_p \hat{H}_u \hat{L}_p$, where \hat{H}_u represents the $Y = 1$ Higgs doublet and its higgsino superpartner. This term is the RPV generalization of the supersymmetry-conserving Higgs mass parameter μ of the MSSM, in which the $Y = -1$ Higgs/higgsino super-multiplet \hat{H}_d is replaced by the slepton/lepton super-multiplet \hat{L}_p . The RPV-parameters $(\mu_L)_p$ also violate L .

Phenomenological constraints derived from data on various low-energy B - and L -violating processes can be used to establish limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [151,152]. If more than one coefficient is simultaneously non-zero, then the limits are, in general, more complicated [153]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B or L invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which B is conserved, but L is violated. It is possible to enforce baryon number conservation, while allowing for lepton-number-violating interactions by imposing a discrete \mathbf{Z}_3 baryon *triality* symmetry on the low-energy theory [154], in place of the standard \mathbf{Z}_2 R-parity. Since the distinction between the Higgs and matter super-multiplets is lost in RPV models, R-parity violation permits the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos, leading to more complicated mass matrices and mass eigenstates than in the MSSM.

The supersymmetric phenomenology of the RPV models exhibits features that are quite distinct from that of the MSSM [151]. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving supersymmetry [151].

In RPV models with lepton number violation (these include low-energy supersymmetry models with baryon triality mentioned above), both $\Delta L = 1$ and $\Delta L = 2$ phenomena are allowed, leading to neutrino masses and mixing [155], neutrinoless double-beta decay [156], sneutrino-antisneutrino mixing [157], s -channel resonant production of sneutrinos in e^+e^- collisions [158] and charged sleptons in $p\bar{p}$ and pp collisions [159]. For example, Ref. 160 demonstrates how one can fit both the solar and atmospheric neutrino data in an RPV model where μ_L provides the dominant source of R-parity violation.

I.9. Extensions beyond the MSSM: Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the μ parameter of the MSSM. Although μ is a supersymmetric-*preserving* parameter, it must be of order the supersymmetry-breaking scale to yield a consistent supersymmetric phenomenology. In the MSSM, one must devise a theoretical mechanism to guarantee that the

Searches Particle Listings

Supersymmetric Particle Searches

magnitude of μ is not larger than the TeV-scale (*e.g.*, in gravity-mediated supersymmetry, the Giudice-Masiero mechanism of Ref. 161 is the most cited explanation).

In extensions of the MSSM, new compelling solutions to the so-called μ -problem are possible. For example, one can replace μ by the vacuum expectation value of a new $SU(3) \times SU(2) \times U(1)$ singlet scalar field. In such a model, the Higgs sector of the MSSM is enlarged (and the corresponding fermionic higgsino superpartner is added). This is the so-called NMSSM (here, NM stands for non-minimal) [162]. There are some advantages to extending the model further by adding an additional $U(1)$ broken gauge symmetry [163] (which yields the USSM [94]).

Non-minimal extensions of the MSSM involving additional matter and/or Higgs super-multiplets can also yield a less restrictive bound on the mass of the lightest Higgs boson (as compared to the bound quoted in Section I.5.2). For example, MSSM-extended models consistent with gauge coupling unification can be constructed in which the upper limit on the lightest Higgs boson mass can be as high as 200–300 GeV [164] (a similar relaxation of the Higgs mass bound occurs in split supersymmetry [165] and extra-dimensional scenarios [166]).

Other MSSM extensions considered in the literature include an enlarged electroweak gauge group beyond $SU(2) \times U(1)$ [167]; and/or the addition of new, possibly exotic, matter super-multiplets (*e.g.*, new $U(1)$ gauge groups and a vector-like color triplet with electric charge $\frac{1}{3}e$ that appear as low-energy remnants in E_6 grand unification models [168]). A possible theoretical motivation for such new structures arises from the study of phenomenologically viable string theory ground states [169].

SUPERSYMMETRY, PART II (EXPERIMENT)

Updated August, 2009 by J.-F. Grivaz (LAL - Orsay).

II.1. Introduction: Low-energy supersymmetry (SUSY) is probably the most extensively studied among the theories beyond the Standard Model (SM). Reasons are its success in solving some of the deficiencies of the SM, such as the stabilization of the Higgs boson mass or gauge coupling unification, while not being in contradiction with the precision electroweak measurements. If unbroken, SUSY would predict the existence of partners of the SM particles, differing by half a unit of spin, but otherwise sharing the same properties. Since no such particles have been observed with the same mass as their SM counterpart, SUSY is a broken symmetry. With an appropriate

choice of SUSY-breaking terms, denoted “soft,” and with superpartner masses at the TeV scale, the good properties of SUSY, such as those mentioned above, however, remain preserved.

SUSY and SM particles are distinguished by a multiplicative quantum number, R -parity, with $R = (-1)^{3(B-L)+2S}$ where B and L are the baryon and lepton numbers, and S is the spin. Therefore, SM particles have $R = 1$ while SUSY particles have $R = -1$. If R -parity is violated, the exchange of SUSY particles may lead to an unacceptably fast proton decay. It is therefore commonly assumed that R -parity is conserved. As a consequence, SUSY particles are produced in pairs, and a SUSY particle decays (possibly via a cascade) into SM particles accompanied by the lightest SUSY particle (LSP) which is stable. Cosmological constraints require that the LSP be neutral and colorless.

The first part of this review, by H.E. Haber, provides details of the theoretical aspects of supersymmetry, of the various SUSY-breaking schemes, and of the structure of the minimal supersymmetric extension of the Standard Model (MSSM), as well as an extensive set of references. The same notations and terminology are used in the following.

As will unfortunately appear in this review, no evidence for SUSY particle production has been found up to now. The search results are therefore presented in terms of production cross-section upper limits or of mass lower limits. In the following, all such limits are given at the 95% confidence level.

II.2. SUSY models: In the MSSM, every degree of freedom of the SM is balanced by a new one differing by half-a-unit of spin. There are, for instance, two scalar-quark weak eigenstates \tilde{q}_L and \tilde{q}_R , associated with the left and right chirality states of a given quark flavor. Two Higgs doublets are, however, needed, in contrast to the minimal Standard Model, in order to give masses to both up-type and down-type quarks, with vacuum expectation values v_2 and v_1 , the ratio of which is denoted $\tan\beta$. The SUSY partner weak eigenstates of the W^\pm and charged Higgs bosons mix to form the two chargino mass eigenstates $\tilde{\chi}_i^\pm$ ($i = 1, 2$). Similarly, there are four neutralinos $\tilde{\chi}_i^0$ ($i = 1, 4$) associated to the B , W^0 , and neutral Higgs bosons. Full details are given in H.E. Haber’s review.

The main phenomenological features of SUSY models arise from the choice of mechanism for SUSY-breaking mediation yielding the structure of the soft SUSY-breaking terms. There are more than one hundred such terms in the MSSM (masses, trilinear couplings, phases), and simplifying assumptions are necessary to bring this number to a more manageable level. Requiring no additional source of flavor-mixing and CP -violation than those present in the Cabibbo-Kobayashi-Maskawa matrix of the SM leaves only the gaugino mass terms M_1 , M_2 , and M_3 associated with the three-gauge groups of the SM, mass terms for the various slepton and squark fields, *e.g.*, $m_{\tilde{t}_R}$, and trilinear Higgs-squark-squark, and Higgs-slepton-slepton couplings such as A_t . The model is then fully specified with the addition of $\tan\beta$, of the supersymmetric Higgs-mixing-mass term μ , and of the mass of the CP -odd Higgs boson m_A .

Searches Particle Listings

Supersymmetric Particle Searches

By far the most widely studied models involve mediation by gravitational forces. In these supergravity models, the gravitino plays essentially no rôle in the phenomenology, unless it is the LSP. This possibility, which has not been addressed by experimental searches at colliders up to now except in terms of future prospects, is not considered in this review. In the minimal model of supergravity (mSUGRA), the number of free parameters is reduced to five: a universal gaugino mass $m_{1/2}$, a universal scalar mass m_0 , and a universal trilinear coupling A_0 , all defined at the scale of grand unification (GUT), $\tan\beta$, and the sign of μ . The low-energy parameters are obtained using the renormalization group equations (RGEs), which in particular fix the absolute value of μ through the requirement of electroweak symmetry-breaking at the appropriate scale. In most of the mSUGRA parameter space, the LSP, required to be neutral and colorless, turns out to be the lightest neutralino, $\tilde{\chi}_1^0$. For appropriate mSUGRA parameter choices and imposing R -parity conservation, this neutralino LSP has the right properties to form the dark matter of the universe. A slightly less constrained model has also been used, primarily at LEP, where μ and m_A are kept free. In such an approach, the mass parameters in the Higgs sector are not related to the universal sfermion mass m_0 , where “sfermion” stands for squark and slepton.

In contrast, the LSP is a very light gravitino \tilde{G} in models with gauge mediated SUSY-breaking (GMSB). The phenomenology depends on the nature of the next-to-lightest SUSY particle (NLSP), typically the lightest neutralino or the lightest stau, and on its lifetime. Another mediation mechanism which has been considered is via the super-conformal anomaly (AMSB, for anomaly mediation SUSY-breaking). In such models, the LSP is a wino \tilde{W}^0 , with a small mass splitting with the lightest chargino, so that the lifetime of that chargino may become phenomenologically relevant, possibly long enough for the chargino to behave like a stable charged particle. More recently, a model called “split SUSY,” which does not aim at solving the hierarchy problem, sets all scalar quark and lepton masses at a very high scale, such as the GUT scale, while keeping the gauginos at the TeV scale. As a result, the gluino, whose decay is mediated by squark exchange, becomes long-lived, which leads to unusual signatures.

II.3. Search strategies: Indirect constraints on SUSY particles can be obtained from cosmological considerations, primarily from the relic dark-matter density [1], from measurements of, or limits on, rare decays, mostly of B mesons [2], from the anomalous magnetic moment of the muon [3], or from precision electroweak observables [4]. These topics are not within the scope of this review. The most significant direct constraints on SUSY particles have been obtained at LEP and at the Tevatron. The large e^+e^- collider, LEP, was in operation at CERN from 1989 to 2000, first at and near the mass of the Z boson, 91.2 GeV, and progressively up to a center-of-mass energy of 209 GeV. Four detectors, ALEPH, DELPHI, L3, and OPAL, each collected a total of about 1 fb^{-1} of data. The Tevatron is

a $p\bar{p}$ collider located at Fermilab. After a first run at a center-of-mass energy of 1.8 TeV, which ended in 1996, and during which the CDF and $D\bar{O}$ detectors collected about 110 pb^{-1} of data each, both the accelerator complex and the detectors were substantially upgraded for Run II, which began in 2001. The center-of-mass energy was raised to 1.96 TeV, and the instantaneous luminosity reached the level of $3.5 \cdot 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$ in the winter of 2009. By June 2009, over 6 fb^{-1} had been accumulated by each experiment.

The “canonical” SUSY scenario is an mSUGRA-inspired MSSM with R -parity conservation and a neutralino LSP. Since such an LSP is stable and weakly interacting, pair production of SUSY particles will lead to missing energy and momentum carried away by the LSPs resulting from the produced SUSY-particle decays. In scenarios other than the canonical one, the expected SUSY signatures may exhibit some additional, or even different features. In GMSB with a neutralino NLSP, for instance, photons are expected in addition to the missing energy carried away by the gravitino LSPs, arising from $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ decays. But in GMSB again, an stau NLSP might have a lifetime long enough to appear stable in the detector, and therefore not to give rise to missing energy. If R -parity is not conserved, the LSP will decay into SM particles; increased lepton or jet multiplicities are hence expected, but missing energy will arise only from possible final state neutrinos.

In e^+e^- collisions, the missing energy can be directly inferred as $\sqrt{s}-E$, from the center-of-mass energy \sqrt{s} , and from the total energy E of the visible final state products. Similarly, the missing momentum is the opposite of the total momentum of those products. The situation is different in $p\bar{p}$ collisions where the center-of-mass energy of the colliding partons is not known. Only its probability density can be determined, by making use of universal parton distribution functions (PDFs) obtained from fits to a large set of experimental data, most prominently the proton structure functions measured at HERA. Since most of the beam remnants escape undetected in the beam pipe, only conservation of momentum in the plane transverse to the beam direction can be used, and canonical SUSY signals will be searched for in events exhibiting large missing *transverse* energy \cancel{E}_T .

All SUSY particles, except for the gluino, are produced in a democratic way in e^+e^- collisions via electroweak interactions. The search is therefore naturally directed toward the lightest ones, typically the NLSP, and the results are interpreted in a fairly model-independent way. Further specifying the model, various search results can be combined to obtain constraints on the model parameters. In $p\bar{p}$ collisions, the most copiously produced SUSY particles are expected to be the colored ones, namely squarks and gluinos. The pattern of lighter SUSY particles, however, plays a rôle in the interpretation of the search results, as it has an impact on the squark and gluino decay chains. A model, typically mSUGRA, is therefore needed to translate the search results into constraints on physically relevant quantities such as SUSY-particle masses. As will be

discussed later, the searches for squarks and gluinos in the canonical scenario suffer from large backgrounds, which renders competitive the searches for electroweak gauginos, in spite of lower-production cross sections, for parameter configurations such that multileptonic final states arising from the gaugino decays are enhanced. Searches in scenarios other than the canonical one call for specific strategies relying, for instance, on the observation of additional photons or stable particles.

II.4. Searches at LEP in the canonical scenario: At LEP, the production of SUSY particles via electroweak interactions is only suppressed, compared to similar SM processes, by the phase space reduction near the kinematic limit. This suppression is stronger for scalars (sleptons and squarks) than for charginos. In general, for a given process, only data collected at the highest LEP energies are relevant for the ultimate mass limits obtained, but it may happen for some specific processes that the cross section is strongly reduced by mixing effects, *e.g.*, for neutralinos with a small higgsino component, in which case the large integrated luminosity collected at lower energies provides additional sensitivity.

Sleptons: The simplest case is that of smuon pair production, which proceeds only via s -channel Z/γ^* exchange. In models with slepton and gaugino mass unification, the $\tilde{\mu}_R$ is expected to be lighter than the $\tilde{\mu}_L$. The search results are therefore interpreted under this assumption, which is conservative since the $\tilde{\mu}_R$ coupling to the Z is smaller than that of the $\tilde{\mu}_L$. Only one parameter is necessary to calculate the production cross section at the tree level, the smuon mass $m_{\tilde{\mu}_R}$. If the $\tilde{\mu}_R$ is the NLSP, its only decay mode is $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$, and its pair production therefore leads to a distinct final state consisting of two acoplanar muons with missing energy. (“Acoplanar” means that the difference in azimuth between the two muons is smaller than 180° , *i.e.*, the two muons are not back-to-back when projected onto a plane perpendicular to the beam axis.) The only significant background comes from $e^+e^- \rightarrow W^+W^- \rightarrow \mu^+\nu\mu^-\bar{\nu}$, which is well under control. The selection efficiency is very high, except when the $\tilde{\mu}_R-\tilde{\chi}_1^0$ mass difference is small, in which case the muons carry little momentum. A second parameter, the LSP mass $m_{\tilde{\chi}_1^0}$ is therefore needed to interpret the search results, as shown in Fig. 1 for the combination of the four LEP experiments [5]. In models with gaugino mass unification, it is expected that the second lightest neutralino $\tilde{\chi}_2^0$ will have a mass roughly twice that of the LSP, in which case the $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_2^0$ decay can compete with the direct decay into $\mu\tilde{\chi}_1^0$ for small $\tilde{\chi}_1^0$ masses. The impact of this effective efficiency reduction at low $\tilde{\chi}_1^0$ mass values can be seen in Fig. 1, for $\mu = -200$ GeV and $\tan\beta = 1.5$. Altogether, smuon masses below 95 to 99 GeV, depending on the $\tilde{\chi}_1^0$ mass, are excluded as long as the $\tilde{\mu}_R-\tilde{\chi}_1^0$ mass difference is larger than 5 GeV.

Figure 1: Region in the $(m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0})$ plane excluded by the searches for smuons at LEP. Color version at end of book.

The case of staus is similar, except for the fact that the final taus further decay, and that the ultimate decay products are softer than the muons in the smuon case. The selection efficiency is therefore lower. An additional complication comes from the L - R mixing, which is expected to be non-negligible for large values of $\tan\beta$, and can reduce the coupling of the lightest stau to the Z . In the worst case where the stau does not couple to the Z , stau masses smaller than 86 to 95 GeV are excluded, depending on $m_{\tilde{\chi}_1^0}$, as long as the stau- $\tilde{\chi}_1^0$ mass difference is larger than 7 GeV [5].

For selectrons as for smuons, L - R mixing is expected to be negligible. But pair production receives an additional contribution from t -channel neutralino exchange, which tends to increase the production cross section. For $\mu = -200$ GeV and $\tan\beta = 1.5$, the \tilde{e}_R mass lower limit is 100 GeV for $m_{\tilde{\chi}_1^0} < 85$ GeV [5]. Furthermore, the t -channel exchange allows for associated $\tilde{e}_L\tilde{e}_R$ production. Assuming slepton and gaugino mass unification at the GUT scale, the \tilde{e}_L and \tilde{e}_R masses are related, with the former heavier by a few GeV. Associated production gives the viable signal of a single energetic electron in the case where the $\tilde{e}_R-\tilde{\chi}_1^0$ mass difference is too small to observe \tilde{e}_R pair production. This allows a lower limit of 73 GeV to be set on $m_{\tilde{e}_R}$, independent of the $\tilde{\chi}_1^0$ mass [6].

Indirect limits on the sneutrino mass can be derived from the slepton mass limits if slepton and gaugino mass unification is assumed. More generally, a $\tilde{\nu}$ LSP or NLSP mass limit of 45 GeV can be deduced from the measurement of the invisible Z width [7], for three mass degenerate sneutrinos.

Charginos and neutralinos: The masses and field content in the chargino sector depend on only three parameters: M_2 ,

Searches Particle Listings

Supersymmetric Particle Searches

μ and $\tan\beta$. The masses and field content in the neutralino sector depend on those same parameters, and, in addition, on M_1 . The latter is, however, related to M_2 assuming gaugino mass unification: $M_1 = (5/3)\tan^2\theta_W M_2 \sim 0.5M_2$. This assumption is made for the results presented below, unless explicitly specified. Traditionally, three regions are distinguished: “gaugino” if $M_2 \ll |\mu|$, “higgsino” if $|\mu| \ll M_2$, and mixed if M_2 and $|\mu|$ have similar values. In the gaugino region, the lighter chargino and second lightest neutralino masses are close to M_2 , the mass of the lightest neutralino is close to M_1 , while the heavier chargino and neutralinos all have masses close to $|\mu|$; this is the typical configuration encountered in mSUGRA. In the higgsino region, the lighter chargino and two lightest neutralino masses are close to $|\mu|$, so that the mass-splitting between the lightest chargino and neutralino tends to be small. In the following, “chargino” will stand for “lighter chargino.”

Chargino pair production proceeds via s -channel Z/γ^* and t -channel $\tilde{\nu}_e$ exchanges, with destructive interference. For chargino masses accessible at LEP energies, the decays are mediated by virtual W ($\tilde{\chi}^\pm \rightarrow W^{*\pm}\tilde{\chi}_1^0 \rightarrow f\bar{f}'\tilde{\chi}_1^0$) and sfermion ($\tilde{\chi}^\pm \rightarrow \tilde{f}^*\tilde{f}' \rightarrow f\bar{f}'\tilde{\chi}_1^0$) exchange. Two-body decays such as $\tilde{\chi}^\pm \rightarrow \ell^\pm\tilde{\nu}$ are occasionally kinematically allowed, in which case they are dominant. Similarly, neutralino pair or associated production proceeds via s -channel Z and t -channel \tilde{e} exchange, and $\tilde{\chi}_2^0$ decays are mediated by virtual Z and sfermion exchange. Here also, two-body decays such as $\tilde{\chi}_2^0 \rightarrow \nu\tilde{\nu}$ may have to be considered.

First, the case of heavy sfermions is addressed. Only s -channel exchange contributes to gaugino production, and the decays proceed via gauge boson exchange. For chargino pair production, the final states are therefore the same as those arising from W pairs, but for the addition of two LSPs. Selections have been designed for all-hadronic ($q\bar{q}'q\bar{q}'\tilde{\chi}_1^0\tilde{\chi}_1^0$), mixed ($q\bar{q}'\ell\nu\tilde{\chi}_1^0\tilde{\chi}_1^0$), and fully leptonic ($\ell\nu\ell\nu\tilde{\chi}_1^0\tilde{\chi}_1^0$) topologies. No excess over SM backgrounds, of which the largest comes from W -pair production, was observed. A scan over M_2 , μ , and $\tan\beta$ provided a robust chargino mass lower limit of 103 GeV for sneutrino masses larger than 200 GeV [8], except for very large values of M_2 ($\gtrsim 1$ TeV), in the so-called “deep higgsino” region, where the $\tilde{\chi}^\pm - \tilde{\chi}_1^0$ mass splitting is very small.

This limit is degraded for lower sneutrino masses for two reasons. First, the production cross section is reduced by the negative interference between the s - and t -channel exchanges. Second, two-body decays open up, which may reduce the selection efficiency. This is the case in particular in the so-called “corridor” where $m_{\tilde{\chi}^\pm} - m_{\tilde{\nu}}$ is smaller than a few GeV, so that the lepton from the $\tilde{\chi}^\pm \rightarrow \ell\tilde{\nu}$ decay is hardly visible. Neutralino-associated production ($e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_2^0$), for which the interference tends to be positive, can be used to mitigate those effects, and searches for acoplanar jets or leptons from $\tilde{\chi}_2^0 \rightarrow f\bar{f}\tilde{\chi}_1^0$ were devised, which did not reveal any excess over SM backgrounds. Chargino and neutralino production and decays now depend, however, on the detailed sfermion spectrum. To interpret the search results, squark and slepton

mass unification is therefore also assumed, so that the relevant phenomenology can be described with the addition of the single m_0 parameter. At this point, the results of neutralino searches can be combined with those for charginos into exclusion domains in the (M_2, μ) plane for selected values of $\tan\beta$ and m_0 .

The searches for neutralinos, however, lose their sensitivity when the two-body decay $\tilde{\chi}_2^0 \rightarrow \nu\tilde{\nu}$ opens up, which leads to an invisible final state. Slepton mass lower limits can provide useful constraints in that configuration. The reason is that the slepton and gaugino masses are related by the RGEs as $m_{\tilde{\ell}_R}^2 \simeq m_0^2 + 0.22M_2^2 - \sin^2\theta_W m_Z^2 \cos 2\beta$. For given values of $\tan\beta$ and m_0 , a lower limit on $m_{\tilde{\ell}_R}$ can therefore be translated into a lower limit on M_2 . In the end, the chargino-mass lower limit obtained in the simple case of heavy sfermions is only moderately degraded.

As indicated above, the chargino searches lose their sensitivity in the deep-higgsino region, because of too small a $\tilde{\chi}^\pm - \tilde{\chi}_1^0$ mass difference. In the most extreme case, the chargino becomes long-lived. Dedicated searches for charged massive stable particles were designed, which take advantage of the higher ionization of such particles. In less extreme cases, the soft final state products resemble those resulting from “two-photon” interactions. In such interactions, the beam electrons radiate quasi-real photons whose collision produces a low-mass system, while the incoming electrons escape undetected in the beam pipe. Chargino pair production can however be disentangled from that background when “tagged” by an energetic photon from initial state radiation ($e^+e^- \rightarrow \gamma\tilde{\chi}^+\tilde{\chi}^-$).

These various techniques allowed charginos with masses smaller than 92 GeV to be excluded in the canonical scenario with gaugino and sfermion mass unification [9].

The lightest neutralino: If the gaugino mass unification assumption is not made, there is no general mass limit from e^+e^- collisions for the lightest neutralino. A very light photino-like neutralino decouples from the Z , so that it cannot be pair produced via s -channel Z exchange, and production via t -channel selectron exchange can be rendered negligible for sufficiently heavy selectrons. The $e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_1^0\gamma$ channel provides a detectable final state that could be used in principle to infer constraints on the $\tilde{\chi}_1^0$ mass and couplings. However, it turns out that there is no sensitivity because of the overwhelming background from $e^+e^- \rightarrow \nu\bar{\nu}\gamma$.

With the assumption of gaugino mass unification, on the other hand, indirect mass limits can be derived, mostly from chargino pair production. In the case of heavy sfermions, the limit is 52 GeV at large $\tan\beta$, somewhat lower otherwise. If sfermions are allowed to be light, sfermion mass unification is used, and the limit at large $\tan\beta$ becomes 47 GeV. It is set by slepton searches in the corridor.

Higgs boson searches at LEP provide additional constraints at low $\tan\beta$. The analysis is rather involved, but can be summarized (and simplified) as follows. The mass of the lightest Higgs boson in the MSSM receives radiative corrections due to

the splitting between the top and stop masses. The stop mass depends on m_0 and M_3 , the latter being related by unification to M_2 . For given values of m_0 and $\tan\beta$, the mass lower limit on the Higgs boson translates into a lower limit on M_3 , hence on M_2 . These constraints are most effective at low m_0 and $\tan\beta$, where those from chargino searches are weakest.

The combination of chargino, slepton and Higgs boson searches provides the lower limit on $m_{\tilde{\chi}_1^0}$ as a function of $\tan\beta$ displayed in Fig. 2 [10]. The “absolute” lower limit is 47 GeV, obtained at large $\tan\beta$. In the more constrained mSUGRA scenario, where in particular μ is no longer a free parameter, a slightly tighter limit of 50 GeV is derived [11].

Figure 2: Lower mass limit for the lightest neutralino as a function of $\tan\beta$, inferred in the conventional scenario (with $M_1 \sim 0.5M_2$) from searches at LEP for charginos, sleptons, and neutral Higgs bosons.

Squarks: As will be seen later, the mass reach for squarks at the Tevatron extends well beyond the masses accessible at LEP. There are, however, configurations for which the Tevatron searches are not efficient, and for which useful information is still provided by LEP. This is particularly relevant in the stop sector because the lighter of the two mass eigenstates (hereafter simply denoted “stop” or \tilde{t}) may be substantially less massive than all other squarks. One reason is that, if squark masses are unified at the GUT scale, $m_{\tilde{t}_R}$ is driven at the electroweak scale to lower values than the other squark mass terms by the large top Yukawa coupling. Another reason is that the off-diagonal terms of the stop squared-mass matrix, which are proportional to m_t , are much larger than for the other squark species and enlarge the mass splitting.

At LEP energies, given the chargino mass limit which effectively forbids $\tilde{t} \rightarrow b\tilde{\chi}^+$, and as long as $m_{\tilde{t}} < m_W + m_b + m_{\tilde{\chi}_1^0}$, the main stop decay mode is expected to be $\tilde{t} \rightarrow c\tilde{\chi}_1^0$, which proceeds via flavor-changing loops. The stop lifetime may therefore be

long enough to compete with the hadronization time, a feature which has been included in the simulation programs. The final state arising from stop pair production followed by $\tilde{t} \rightarrow c\tilde{\chi}_1^0$ is a pair of acoplanar jets with missing energy. The mass limit obtained depends slightly on the amount of L - R mixing. In the worst case where the stop does not couple to the Z , stop masses from 96 to 99 GeV, depending on the $\tilde{\chi}_1^0$ mass, are excluded as long as $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} - m_c > 5$ GeV [12]. Dedicated searches were performed in addition to cope with smaller mass differences. In particular, the creation of long-lived R -hadrons in the stop hadronization process was taken into account, as well as the specific interactions of those R -hadrons in the detector material. (R -hadrons are color-neutral exotic bound states, *e.g.*, formed from a squark and an antiquark.) In the end, a mass lower limit of 63 GeV was set for the top squark, irrespective of $m_{\tilde{t}} - m_{\tilde{\chi}_1^0}$ [13].

It has been pointed out that, for specific choices of parameters, the four-body decay mode $\tilde{t} \rightarrow bff'\tilde{\chi}_1^0$ could compete with $\tilde{t} \rightarrow c\tilde{\chi}_1^0$ [14]. A set of selections was designed to address this possibility, and the 63 GeV mass limit was found to hold, independent of the proportions of four-body and two-body decay modes [13]. Finally, if sneutrinos are sufficiently light for the $\tilde{t} \rightarrow b\tilde{\nu}$ three-body decay mode to be kinematically allowed, in which case it will be dominant, a stop mass lower limit of 96 GeV was obtained for sneutrino masses smaller than 86 GeV [12].

The lightest sbottom mass eigenstate, \tilde{b} , could also be light for large values of $\tan\beta$, which enhance the off-diagonal terms of the sbottom squared-mass matrix. The situation is simpler than for the stop, because the $\tilde{b} \rightarrow b\tilde{\chi}_1^0$ tree-level decay mode is expected to be dominant. Searches for acoplanar b -flavored jets were performed, leading to mass lower limits of about 95 GeV for a vanishing coupling of the sbottom to the Z [12].

II.5. Searches at LEP in non-canonical scenarios:

SUSY scenarios beyond the canonical one were also extensively studied at LEP.

GMSB: The phenomenology of GMSB, with an ultra-light gravitino LSP, depends essentially on the nature of the NLSP and on its lifetime.

In the case of a neutralino NLSP, the $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ decay mode is expected to be dominant in the mass range accessible at LEP. The production of a pair of $\tilde{\chi}_1^0$ with short lifetime would therefore lead to acoplanar photons with missing energy. No excess was observed above the background from $e^+e^- \rightarrow (Z^*) \rightarrow \nu\bar{\nu}\gamma\gamma$ [15]. In typical GMSB models, the neutralino NLSP is bino-like. Pair production is thus mediated by t -channel selectron exchange. An exclusion domain in the $(m_{\tilde{e}_R}, m_{\tilde{\chi}_1^0})$ plane was therefore derived. The highest $\tilde{\chi}_1^0$ mass excluded is 102 GeV for light selectrons, and the interpretation of an anomalous $ee\gamma\gamma + \cancel{E}_T$ event observed by CDF in Run I of the Tevatron [16] in terms of pair production of selectrons with $\tilde{e} \rightarrow e\tilde{\chi}_1^0 \rightarrow e\gamma\tilde{G}$ is excluded. For non-prompt decays, searches for photons which do not point back to the primary vertex were

Searches Particle Listings

Supersymmetric Particle Searches

performed, while long neutralino lifetimes lead to a phenomenology similar to that of the canonical scenario. Combinations of the results of these and a number of other searches in various topologies expected within a minimal GMSB framework were performed, leading to an absolute neutralino NLSP mass limit of 54 GeV [17].

The other generic NLSP candidate in GMSB is a scalar tau, for some parameter configurations almost mass-degenerate with \tilde{e}_R and $\tilde{\mu}_R$. A stau NLSP decays according to $\tilde{\tau} \rightarrow \tau \tilde{G}$. For prompt decays, this is similar to a stau NLSP with a light $\tilde{\chi}_1^0$ in the canonical scenario. For long lifetimes, the stau will appear as a highly ionizing charged particle, for which searches have been designed as discussed for charginos in the deep-higgsino region. For intermediate lifetimes, dedicated selections for in-flight decays along charged particle tracks were devised. A combination of all these searches excluded a stau NLSP with mass below 87 GeV, irrespective of its lifetime [18].

AMSB: With a wino LSP, the mass difference between the chargino and the LSP is expected to be small, leading to topologies identical to those encountered in the deep higgsino region of the canonical scenario. The chargino mass lower limit of 92 GeV [9] also holds in the AMSB framework for large sfermion masses.

A gluino LSP: The possibility that the LSP be a light gluino has also been considered. Gluinos cannot be produced directly by e^+e^- annihilation, but they could be produced by gluon splitting, for instance in $e^+e^- \rightarrow Z \rightarrow q\bar{q}g^* \rightarrow q\bar{q}\tilde{g}\tilde{g}$, or in the decays of pair-produced squarks. Such gluinos would then hadronize into long-lived R -hadrons. Dedicated searches were performed [19], leading to the exclusion of a gluino LSP with mass smaller than 27 GeV.

R -parity violation: If R -parity is allowed to be violated, new terms appear in the superpotential that do not conserve the lepton or baryon number: $\lambda_{ijk}\hat{L}_i\hat{L}_j\hat{E}_k^c$, $\lambda'_{ijk}\hat{L}_i\hat{Q}_j\hat{D}_k^c$, $\lambda''_{ijk}\hat{U}_i^c\hat{D}_j^c\hat{D}_k^c$, where \hat{L} and \hat{Q} are lepton- and quark-doublet superfields, \hat{E}^c , \hat{D}^c and \hat{U}^c are lepton and quark singlet superfields, and i, j , and k are generation indices. These terms induce new couplings such that the LSP can decay to SM particles. For instance, a neutralino LSP could decay according to $\tilde{\chi}_1^0 \rightarrow e\mu\nu$ via a λ type coupling. With a λ'' coupling, a $\tilde{\chi}_1^0$ decay would lead to three hadronic jets. Since the simultaneous presence of different coupling types is strongly constrained, for instance by the lower limit on the proton lifetime, the assumption was made that only one of the R -parity-violating couplings is non-vanishing. It was also assumed that this coupling is sufficiently large for the R -parity-violating decays to take place close to the e^+e^- collision point ($< \sim 1$ cm) so that lifetime issues can be ignored.

Even with these simplifying assumptions, the number of possible final states arising from SUSY particle pair production is considerable. Nevertheless, all were considered at LEP, ranging from four leptons with missing energy for a λ coupling and $\tilde{\chi}_1^0$ pair production, now a process leaving a visible signature, to ten jets for a λ'' coupling and chargino pair production with

$\tilde{\chi}^\pm \rightarrow q\bar{q}\tilde{\chi}_1^0$. In the end, limits at least as constraining as in the canonical scenario were obtained [20].

Single production of a SUSY particle may also take place when R -parity is violated, with a production cross section now depending on the value of the λ coupling involved. The possibility of single, possibly resonant sneutrino production was investigated [21], and, in the absence of any signal, sneutrino mass lower limits extending almost to the full center-of-mass energy were established for sufficiently large values of the coupling.

II.6. Searches at HERA: The HERA $e^\pm p$ collider at DESY terminated its operation at the end of June 2007, after having delivered an integrated luminosity of ~ 0.5 fb $^{-1}$ at a center-of-mass energy of 320 GeV to each of the H1 and ZEUS experiments. Since ep collisions do not involve annihilation processes, only R -parity-violating resonant production of squarks could be investigated with good sensitivity. The production proceeds via a λ'_{j1} or λ'_{11k} coupling, with a cross section depending on the value of the R -parity-violating coupling involved. The produced squark can decay either directly with R -parity violation, or indirectly via a cascade leading to the LSP which in turn decays to SM particles (two jets and a neutrino or a charged lepton). Selections for these various topologies were combined to lead, within some mild model assumptions, to squark mass lower limits as high as 275 GeV for a λ' coupling of electromagnetic strength, *i.e.*, equal to 0.3 [22]. These results should be improved once the full HERA integrated luminosity is analyzed.

II.7. Searches at the Tevatron: Because of the much higher center-of-mass energy, the mass reach of the Tevatron for SUSY particles is expected to largely exceed the one achieved at LEP. In $p\bar{p}$ collisions, however, the effective parton-parton center-of-mass energy $\sqrt{\hat{s}}$ is only a fraction $\sqrt{x_1x_2}$ of the total center-of-mass energy \sqrt{s} , where x_1 and x_2 are the fractions of the p and \bar{p} momenta carried by the colliding partons. Because of the rapid decrease of the PDFs as a function of x , probing high $\sqrt{\hat{s}}$ values implies accumulating correspondingly large integrated luminosities.

Compared to the situation at LEP, the searches for SUSY in $p\bar{p}$ collisions are further complicated by the huge disparity between the cross sections of the processes of interest, currently of order 0.1 pb, and those of the SM backgrounds, *e.g.*, ~ 80 mb for the total inelastic cross section. Even for final states involving leptons, one has to cope with the $W \rightarrow \ell\nu$ and $Z \rightarrow \ell\ell$ backgrounds, with cross sections as large as ~ 2.6 nb and ~ 240 pb, respectively, per lepton flavor.

In the following, all results presented were obtained during Run II of the Tevatron collider, as they supersede those from Run I due to the higher center-of-mass energy and to integrated luminosities recorded already a factor fifty larger.

Squarks and gluinos: Colored SUSY particles are expected to be the most copiously produced in $p\bar{p}$ collisions. If $m_{\tilde{q}} \ll m_{\tilde{g}}$, $\tilde{q}\tilde{q}$ and, to a lesser extent, $\tilde{q}\tilde{q}$ pair productions are the dominant processes, and the search is performed in the $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ decay

channel, which leads to a final state consisting of a pair of acoplanar jets. If $m_{\tilde{g}} \ll m_{\tilde{q}}$, gluino pair production dominates, and the decay channel considered is $\tilde{g} \rightarrow \tilde{q}^* \tilde{q} \rightarrow q \bar{q} \tilde{\chi}_1^0$, leading to a four-jet final state with \cancel{E}_T . Finally, if squark and gluino masses are similar, three-jet final states are expected to arise from $\tilde{q} \tilde{g}$ associated production. Soft jets from initial and final state radiation may increase these jet multiplicities. Cascade decays such as $\tilde{q} \rightarrow \tilde{\chi}^\pm q' \rightarrow \ell \nu q' \tilde{\chi}_1^0$, however, complicate the picture, and a specific model has to be used to assess their impact: both CDF and DØ revert to the mSUGRA framework to interpret their search results, in which case the ten SUSY partners of the five light quark flavors can be considered mass-degenerate for practical purposes.

Backgrounds to squark and gluino production arise from two types of sources: those with real \cancel{E}_T , such as $(W \rightarrow \ell \nu) + \text{jets}$, and those with fake \cancel{E}_T from jet-energy mismeasurements in standard multijet events produced by strong interaction. In the following, these backgrounds are denoted SM and QCD, respectively. Selection criteria were designed for each of the three relative mass configurations listed above, with at least two, at least three, and at least four energetic jets, and with large \cancel{E}_T . Backgrounds of the SM type are largely suppressed by vetoes on isolated leptons, except for $(Z \rightarrow \nu \nu) + \text{jets}$, which is irreducible, and the remaining contribution is determined from Monte Carlo simulations. In the QCD background, the distribution of missing transverse energy from jet mismeasurements peaks strongly at low values but, because of the huge multijet production cross section, significant contributions remain even at large \cancel{E}_T . A substantial reduction is obtained, however, by requiring that the \cancel{E}_T direction point away from the jets. While CDF estimates the remaining contribution from Monte Carlo simulations calibrated on control samples, DØ applies tighter selection criteria so that the QCD background is brought to a negligible level.

In the end, no excess was observed above expected backgrounds in the various selections, which translates into excluded domains in the $(m_{\tilde{g}}, m_{\tilde{q}})$ plane. Taking into account the large theoretical uncertainties on the signal production cross sections arising from the choice of PDFs, and of renormalization and factorization scales, lower limits of 379 and 308 GeV were published by DØ [23] for the squark and gluino masses, respectively, based on an integrated luminosity of 2.1 fb^{-1} . Along the $m_{\tilde{g}} = m_{\tilde{q}}$ line, the limit is 390 GeV. These results, derived for $\tan \beta = 3$, $A_0 = 0$, and $\mu < 0$, are valid for a large class of parameter sets at low $\tan \beta$. Similar results were obtained by the CDF collaboration, based on an integrated luminosity of 2.0 fb^{-1} [24], as shown in Fig. 3. Within the mSUGRA framework, these limits can be compared with those from slepton and chargino searches in e^+e^- collisions, as shown for CDF in Fig. 3 and for DØ in Fig. 4. The domain in the parameter space excluded at LEP is extended for simultaneously low values of m_0 and $m_{1/2}$.

Figure 3: Region in the $(m_{\tilde{g}}, m_{\tilde{q}})$ plane excluded by CDF Run II and by earlier experiments. Color version at end of book.

Figure 4: Region in the $(m_0, m_{1/2})$ plane excluded by the search for squarks and gluinos by DØ and by the searches for sleptons and charginos by the LEP experiments. The band at the edge of the excluded region represents the uncertainty associated with the scale and PDF choice, with the red curve corresponding to the nominal choice.

For larger values of $\tan \beta$, mass hierarchies such as $m_{\tilde{q}_L} > m_{\tilde{e}} \sim m_{\tilde{\mu}} > m_{\tilde{\chi}^\pm} > m_{\tilde{\tau}}$ are not uncommon, for which squark pair production leads to final states involving jets, τ s, and \cancel{E}_T . A dedicated search for these topologies was performed by DØ [25], which provides additional sensitivity for squark searches at larger values of $\tan \beta$.

Stop and sbottom: As explained earlier, a stop mass eigenstate could be much lighter than the other squarks. Dedicated searches were therefore performed by both CDF [26] and DØ [27] for stop pair production followed by $\tilde{t} \rightarrow c \tilde{\chi}_1^0$ decays. The final

Searches Particle Listings

Supersymmetric Particle Searches

state is a pair of acoplanar charm jets with \cancel{E}_T . Compared to the previous case of generic squarks, the cross section is much smaller because only one squark specie is produced. The mass range probed is, therefore, accordingly smaller. Consequently, the jets are softer and there is less \cancel{E}_T . A lifetime-based heavy-flavor tagging is used in the selection to mitigate the corresponding loss of sensitivity. The CDF analysis, based on an integrated luminosity of 2.6 fb^{-1} , excludes $m_{\tilde{t}} < 180 \text{ GeV}$ for $m_{\tilde{\chi}_1^0} = 95 \text{ GeV}$, as shown in Fig. 5. These stop searches at the Tevatron lose their sensitivity when the $\tilde{t}-\tilde{\chi}_1^0$ mass difference becomes smaller than $\sim 40 \text{ GeV}$, because of the \cancel{E}_T requirement applied to reduce the otherwise overwhelming QCD background, so that the LEP constraints remain relevant, although restricted to $m_{\tilde{t}} < 100 \text{ GeV}$.

Figure 5: Region in the $(m_{\tilde{t}}, m_{\tilde{\chi}_1^0})$ plane excluded by CDF and by earlier experiments.

Similar searches were performed for sbottom pair production [28,29], with $\tilde{b} \rightarrow b\tilde{\chi}_1^0$. The sensitivity extends to higher masses than in the stop case because heavy-flavor tagging is more efficient for b than for c jets. The lower \tilde{b} mass limit set by DØ reaches 240 GeV for $m_{\tilde{\chi}_1^0} < 80 \text{ GeV}$, based on an integrated luminosity of 4.0 fb^{-1} . The CDF collaboration investigated the configuration where gluinos are lighter than all squark species except for the sbottom, thus decaying according to $\tilde{g} \rightarrow b\tilde{b}$, followed by $\tilde{b} \rightarrow b\tilde{\chi}_1^0$. The final state consists of four b jets with \cancel{E}_T . Gluino and sbottom mass lower limits reaching 350 and 325 GeV , respectively, were obtained for $m_{\tilde{\chi}_1^0} = 60 \text{ GeV}$, based on an integrated luminosity of 2.5 fb^{-1} [30].

Searches for stop pair production followed by $\tilde{t} \rightarrow b\ell\tilde{\nu}$ decays were also performed by CDF [31] and DØ [32], based on up to 3.1 fb^{-1} , to address the parameter configurations leading to light sneutrinos. Final states with two leptons, b jets and \cancel{E}_T were investigated. The largest stop mass excluded is 200 GeV for sneutrino masses up to 110 GeV [32]. The CDF collaboration also considered the possibility of a $\tilde{t} \rightarrow b\tilde{\chi}^+$ decay,

analyzing the same final-state topology, and derived limits in the $(m_{\tilde{t}}, m_{\tilde{\chi}_1^0})$ plane for various chargino masses and various branching fractions for the $\tilde{\chi}^+ \rightarrow \ell\nu\tilde{\chi}_1^0$ decay [33].

Finally, the possibility of a stop stable on the scale of the time needed to escape the detector was considered by the CDF collaboration [34]. The resulting R -hadron would behave as a slow-moving muon, and can be discriminated from the real muon background by comparing its momentum and its velocity, using a time-of-flight measurement. A mass lower limit of 250 GeV was obtained, based on an integrated luminosity of 1 fb^{-1} .

Charginos and neutralinos: Associated chargino-neutralino production, $p\bar{p} \rightarrow \tilde{\chi}^\pm\tilde{\chi}_2^0$, proceeds via s -channel W and t -channel squark exchange, with destructive interference. This process could provide a distinct trilepton+ \cancel{E}_T signal at the Tevatron if the branching ratios for leptonic decays ($\tilde{\chi}^\pm \rightarrow \ell^\pm\nu\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0 \rightarrow \ell^+\ell^-\tilde{\chi}_1^0$) are sufficiently large. Since these decays are mediated by virtual vector boson or sfermion exchange, this condition will be satisfied if sleptons are sufficiently light. The search is nevertheless challenging because the final-state leptons carry little energy, and the production cross section is only a fraction of a picobarn.

In order to reduce the impact of lepton identification inefficiencies, and also to retain some sensitivity for final states involving τ s, only two leptons were required to be positively identified as electrons or muons, while for the third lepton only an isolated charged-track requirement was imposed. Series of analysis criteria involving requirements on the lepton and third-track isolation, on the amount of \cancel{E}_T , and on the absence of energetic jets were applied. The ultimate background arises from associated WZ production.

No significant excess over SM background expectation was observed by DØ [35] or CDF [36], based on 2.3 fb^{-1} and 3.2 fb^{-1} , respectively. These results were interpreted within the mSUGRA framework, with $\tan\beta = 3$, $A_0 = 0$, and $\mu > 0$, as shown in Fig. 6. The domain excluded at LEP is substantially extended. As an example, a chargino mass limit of 164 GeV is obtained for $m_0 = 60 \text{ GeV}$ [36]. The dependence of the exclusion range on $\tan\beta$ is discussed in [35]: for a chargino mass of 130 GeV , the exclusion holds for $\tan\beta \lesssim 10$. The gap in the exclusion domain visible in Fig. 6 is due to configurations where the $\tilde{\chi}_2^0 - \tilde{\ell}$ mass difference is very small, so that one of the final-state leptons cannot be detected. Searches for same sign lepton pairs can, however, be used in this configuration, as was shown in earlier DØ analyses [37]. The CDF collaboration also considered the same sign dilepton signature [38].

R -parity violation: A whole new phenomenology opens up if R -parity is not assumed to be conserved. The searches can be divided into two classes.

First, R -parity-conserving pair production of SUSY particles has been considered, with R -parity violation appearing only in the LSP decay at the end of the decay chains. The case of gaugino pair production, with a lepton-number-violating

Figure 6: Regions in the $(m_0, m_{1/2})$ plane excluded by the $D\bar{O}$ search for trileptons and by the LEP experiments. Color version at end of book.

coupling of the λ type in the neutralino LSP decay, has been extensively studied. Four charged leptons are expected in the final state, with flavors depending on the generation indices in the λ_{ijk} coupling, and there is also some \cancel{E}_T from the two neutrinos. Searches have been performed by CDF [39] and $D\bar{O}$ [40] in the cases of λ_{121} and λ_{122} couplings, and by $D\bar{O}$ in the case of a λ_{133} coupling for which τ s appear in the final state. The chargino mass lower limits obtained by $D\bar{O}$ in the mSUGRA framework with $m_0 = 1$ TeV, $\tan\beta = 5$, and $\mu > 0$ are 231, 229, and 166 GeV for the λ_{121} , λ_{122} , and λ_{133} couplings, respectively, based on 360 pb^{-1} .

The CDF collaboration also searched for stop pair production, with $\tilde{t} \rightarrow b\tau$ decays mediated by a λ'_{333} coupling [41]. No such signal was observed in the topology where one τ decays into an electron or a muon and the other into hadrons, and a stop mass lower limit of 151 GeV was derived, based on 322 pb^{-1} .

The $D\bar{O}$ collaboration investigated the case of pair production of a neutralino LSP with a mass of a few GeV, followed by $\tilde{\chi}_1^0 \rightarrow \mu^+ \mu^- \nu$ decays via a λ_{i22} coupling [42]. The values of the coupling considered were such that the $\tilde{\chi}_1^0$ is long-lived, and the search was therefore directed toward dimuon vertices displaced from the main-interaction vertex. This search was motivated by anomalous dimuon events observed by the NuTeV collaboration in a neutrino experiment [43]. With no signal observed by $D\bar{O}$, such an explanation for those events has been ruled out.

Second, resonant slepton production could occur via a λ'_{i11} R -parity-violating coupling. The case of a λ'_{211} coupling was considered by $D\bar{O}$ [44], with R -parity-conserving decays of the resonantly produced slepton ($\tilde{\mu} \rightarrow \tilde{\chi}_i^0 \mu$ and $\tilde{\nu}_\mu \rightarrow \tilde{\chi}^\pm \mu$). The violation of R -parity is again manifest in the decay of the neutralino LSP into a muon or a neutrino + two jets. No excess

over background was observed, and an exclusion domain was placed in the $(m_{\tilde{\mu}}, \lambda'_{211})$ plane, the production cross section now depending on the value of λ'_{211} . For $\lambda'_{211} = 0.1$, a smuon mass lower limit of 363 GeV is obtained in mSUGRA with $\tan\beta = 5$, $A_0 = 0$ and $\mu < 0$, based on 380 pb^{-1} .

Resonant sneutrino production was also investigated in the case where the sneutrino decays via a λ type coupling, hence different from the coupling involved in the production. The decay channels considered were ee , $\mu\mu$, $\tau\tau$ and $e\mu$. Sneutrino mass limits were derived, dependent on the product of the λ' and λ couplings considered [45].

Other non-canonical scenarios: As discussed earlier, a neutralino or stau NLSP is expected in GMSB. SUSY-particle pair production, with cascade decays to a $\tilde{\chi}_1^0$ NLSP followed by $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$, has been investigated by both CDF [46] and $D\bar{O}$ [47] through inclusive searches for diphoton final states with large \cancel{E}_T . Backgrounds from photon misidentification or from fake \cancel{E}_T were determined from data, and no significant excess of events was observed. The results were interpreted in a benchmark GMSB model known as the ‘‘Snowmass slope SPS 8’’ [48]. (This model has one parameter, the effective SUSY-breaking scale Λ , with $N_5 = 1$ messenger, a messenger mass of 2Λ , $\tan\beta = 15$ and $\mu > 0$.) The CDF analysis, based on 2.6 fb^{-1} , sets a neutralino NLSP mass limit of 149 GeV.

The additional possibility of non-prompt $\tilde{\chi}_1^0$ decays was considered by CDF, taking advantage of the timing information provided by their calorimeter [49]. No signal of delayed photons was observed in 570 pb^{-1} , and an excluded domain in the $(m_{\tilde{\chi}_1^0}, \tau_{\tilde{\chi}_1^0})$ plane was derived, where $\tau_{\tilde{\chi}_1^0}$ is the $\tilde{\chi}_1^0$ lifetime, extending out to 101 GeV for $\tau_{\tilde{\chi}_1^0} = 5 \text{ ns}$.

The case of a long-lived stau NLSP was also investigated. Pair production would resemble a pair of slow-moving muons. The timing information of their muon system was used by $D\bar{O}$, and no excess of such anomalously slow muons was observed in 1.1 fb^{-1} [50]. However, the sensitivity of the search is not yet sufficient to set a stau mass lower limit. Long-lived charginos as in AMSB would lead to the same signature. The larger production cross section allowed a lower limit of 206 GeV to be set on the mass of such long-lived gaugino-like charginos.

Within the recently proposed model of split SUSY, gluinos are expected to acquire a substantial lifetime. After hadronization into a R -hadron, such a long-lived gluino produced in a $p\bar{p}$ collision could come to rest in a calorimeter, and decay during a later bunch crossing than that during which it was produced [51]. The main decay mode is expected to be $\tilde{g} \rightarrow g\tilde{\chi}_1^0$, with some competition from $\tilde{g} \rightarrow q\bar{q}\tilde{\chi}_1^0$. Such a late gluino decay would appear as a jet not pointing toward the detector center in an otherwise empty event. Such a possibility was considered by the $D\bar{O}$ collaboration. The main backgrounds, coming from showering cosmic muons and from muons belonging to the beam halo, were estimated from data, and no excess of such a topology was observed. Based on an integrated luminosity of 410 pb^{-1} , limits were set on the mass of such a gluino,

Searches Particle Listings

Supersymmetric Particle Searches

with some dependence on the lifetime, the decay-branching ratio, the $\tilde{\chi}_1^0$ mass, and the probability for a neutral R -hadron to convert into a charged one in the calorimeter [52]. For instance, for a lifetime smaller than three hours, a neutralino mass of 50 GeV, a conversion cross section of 3 mb, and a 100% branching ratio into $g\tilde{\chi}_1^0$, a mass limit of 270 GeV was obtained.

II.8. Conclusion: The masses of SUSY particles other than the gluino and the LSP have been constrained at LEP to be larger than ~ 100 GeV, essentially independent of any specific model. Within the MSSM with unification of gaugino and sfermion masses, an indirect lower limit of 47 GeV has been set by the LEP experiments for the mass of a neutralino LSP. The mass reach at the Tevatron is much larger than at LEP, but the results need to be interpreted in the context of specific models. Based on an integrated luminosity of 2 fb^{-1} , the current squark and gluino mass lower limits are 379 and 308 GeV, respectively, within the mSUGRA framework at low $\tan\beta$, and chargino masses up to 170 GeV are excluded for favorable choices of slepton masses. More than 6 fb^{-1} have already been accumulated at the Tevatron by spring 2009, and it is expected that the LHC will begin operation at a center-of-mass energy of 7 TeV in the winter 2009 – 2010, which will open a whole new window for SUSY searches.

SUPERSYMMETRIC MODEL ASSUMPTIONS

The exclusion of particle masses within a mass range (m_1, m_2) will be denoted with the notation “none m_1 – m_2 ” in the VALUE column of the following Listings.

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that R -parity (R) is conserved. Unless otherwise indicated, the results also assume that:

- 1) The $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP)
- 2) $m_{\tilde{f}_L} = m_{\tilde{f}_R}$, where $\tilde{f}_{L,R}$ refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R -parity violation (\tilde{R}) are characterized by a superpotential of the form: $\lambda_{ijk} L_i L_j e_k^c + \lambda'_{ijk} L_i Q_j d_k^c + \lambda''_{ijk} u_i^c d_j^c d_k^c$, where i, j, k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\tilde{E}$, $LQ\tilde{D}$, and $U\tilde{D}\tilde{D}$. Mass limits in the presence of \tilde{R} will often refer to “direct” and “indirect” decays. Direct refers to \tilde{R} decays of the particle in consideration. Indirect refers to cases where \tilde{R} appears in the decays of the LSP.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino (\tilde{G}) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and $m_{\tilde{G}}$ is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lightest supersymmetric particle (NLSP), and are assumed to decay to their even- R partner plus \tilde{G} . If the lifetime is short enough for the decay to take place within the detector, \tilde{G} is assumed to be undetected and to give rise to missing energy (\cancel{E}) or missing transverse energy (\cancel{E}_T) signatures.

When needed, specific assumptions on the eigenstate content of $\tilde{\chi}^0$ and $\tilde{\chi}^\pm$ states are indicated, using the notation $\tilde{\gamma}$ (photino), \tilde{H} (higgsino), \tilde{W} (wino), and \tilde{Z} (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

$\tilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

$\tilde{\chi}_1^0$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\tilde{\chi}_2^0, \tilde{\chi}_3^0, \tilde{\chi}_4^0$ section below.

We have divided the $\tilde{\chi}_1^0$ listings below into five sections:

- 1) Accelerator limits for stable $\tilde{\chi}_1^0$,
- 2) Bounds on $\tilde{\chi}_1^0$ from dark matter searches,
- 3) Bounds on $\tilde{\chi}_1^0$ elastic cross sections from dark matter searches,
- 4) Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology, and
- 5) Bounds on unstable $\tilde{\chi}_1^0$.

Accelerator limits for stable $\tilde{\chi}_1^0$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}_i^0 \tilde{\chi}_j^0$ ($i \geq 1, j \geq 2$), $\tilde{\chi}_1^+ \tilde{\chi}_1^-$, and (in the case of hadronic collisions) $\tilde{\chi}_1^+ \tilde{\chi}_2^0$ pairs. The mass limits on $\tilde{\chi}_1^0$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ . In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from e^+e^- collisions up to $\sqrt{s}=184$ GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

1 ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 < 5000$ GeV, $-1000 < \mu < 1000$ GeV and $\tan\beta$ from 1 to 40. This limit supersedes ABBIENDI 00H.

2 HEISTER 04 data collected up to 209 GeV. Updates earlier analysis of selections from HEISTER 02E, includes a new analysis of charginos and neutralinos decaying into stau and uses results on charginos with initial state radiation from HEISTER 02J. The limit is based on the direct search for charginos and neutralinos, the constraints from the slepton search and the Higgs mass limits from HEISTER 02 using a top mass of 175 GeV, interpreted in a framework with universal gaugino and sfermion masses. Assuming the mixing in the stau sector to be negligible, the limit improves to 43.1 GeV. Under the assumption of MSUGRA with unification of the Higgs and sfermion masses, the limit improves to 50 GeV, and reaches 53 GeV for $A_0 = 0$. These limits include and update the results of BARATE 01.

3 ABDALLAH 03M uses data from $\sqrt{s} = 192$ –208 GeV. A limit on the mass of $\tilde{\chi}_1^0$ is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of $\tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_1^0 \tilde{\chi}_3^0$, as well as $\tilde{\chi}_2^0 \tilde{\chi}_3^0$ and $\tilde{\chi}_2^0 \tilde{\chi}_4^0$ giving rise to cascade decays, and $\tilde{\chi}_1^0 \tilde{\chi}_2^0$ and $\tilde{\chi}_1^0 \tilde{\chi}_3^0$, followed by the decay $\tilde{\chi}_2^0 \rightarrow \tilde{\tau}\tau$. The results hold for the parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. The limit is obtained for $\tan\beta = 1$ and large m_0 , where $\tilde{\chi}_2^0 \tilde{\chi}_3^0$ and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the M_h^{max} scenario with $m_t = 174.3$ GeV. These limits update the results of ABREU 00.

4 ABDALLAH 03M uses data from $\sqrt{s} = 192$ –208 GeV. An indirect limit on the mass of $\tilde{\chi}_1^0$ is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states), for charginos (for all Δm_\pm) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming $m_t = 174.3$ GeV are included. The limit is obtained for $\tan\beta \geq 5$ when stau mixing leads to mass degeneracy between $\tilde{\tau}_1$ and $\tilde{\chi}_1^0$ and the limit is based on $\tilde{\chi}_2^0$ production followed by its decay to $\tilde{\tau}_1\tau$. In the pathological scenario where m_0 and $|\mu|$ are large, so that the $\tilde{\chi}_2^0$ production cross section is negligible, and where there is mixing in the stau sector but not in stop nor

Searches Particle Listings

Supersymmetric Particle Searches

sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs 40–42 for the dependence of the limit on $\tan\beta$ and $m_{\tilde{\nu}}$. These limits update the results of ABREU 00w.

- 5 ACCIARRI 00d data collected at $\sqrt{s}=189$ GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $m_0 \leq 500$ GeV, $|\mu| \leq 2$ TeV. The minimum mass limit is reached for $\tan\beta=1$ and large m_0 . The results of slepton searches from ACCIARRI 99w are used to help set constraints in the region of small m_0 . The limit improves to 48 GeV for $m_0 \gtrsim 200$ GeV and $\tan\beta \gtrsim 10$. See their Figs. 6–8 for the $\tan\beta$ and m_0 dependence of the limits. Updates ACCIARRI 98f.
- 6 DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists a model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless $\tilde{\chi}_1^0$ is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_2 , μ and the slepton and squark masses.
- 7 ABBOTT 98c searches for trilepton final states ($\ell=e,\mu$). See footnote to ABBOTT 98c in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 51$ GeV.
- 8 ABE 98j searches for trilepton final states ($\ell=e,\mu$). See footnote to ABE 98j in the Chargino Section for details on the assumptions. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, $\tan\beta=2$, and $\mu=-600$ GeV.

Bounds on $\tilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2 - \mu$ parameter plane assuming that $\tilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments or by the absence of a signal in underground neutrino detectors. The latter signal is expected if $\tilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν 's.

- 1 ABBASI 09 is based on data collected during 104.3 effective days with the IceCube 22-string detector. They looked for interactions of ν_μ 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 25–5000 GeV.
- 2 ACHTERBERG 06 is based on data collected during 421.9 effective days with the AMANDA detector. They looked for interactions of ν_μ 's from the centre of the Earth over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into $W^+ W^-$ and $b\bar{b}$ at the centre of the Earth for MSSM parameters compatible with the relic dark matter density, see their Fig. 7.
- 3 ACKERMANN 06 is based on data collected during 143.7 days with the AMANDA-II detector. They looked for interactions of ν_μ 's from the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into $W^+ W^-$ in the Sun for SUSY model parameters compatible with the relic dark matter density, see their Fig. 3.
- 4 DEBOER 06 interpret an excess of diffuse Galactic gamma rays observed with the EGRET satellite as originating from π^0 decays from the annihilation of neutralinos into quark jets. They analyze the corresponding parameter space in a supergravity inspired MSSM model with radiative electroweak symmetry breaking, see their Fig. 3 for the preferred region in the $(m_0, m_{1/2})$ plane of a scenario with large $\tan\beta$.
- 5 AMBROSIO 99 and DESAI 04 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the Sun and the Earth.
- 6 LOSECCO 95 reanalyzed the IMB data and places lower limit on $m_{\tilde{\chi}_1^0}$ of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector.
- 7 MORI 93 excludes some region in $M_2 - \mu$ parameter space depending on $\tan\beta$ and lightest scalar Higgs mass for neutralino dark matter $m_{\tilde{\chi}_1^0} > m_{H^\pm}$, using limits on ongoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.
- 8 BOTTINO 92 excludes some region $M_2 - \mu$ parameter space assuming that the lightest neutralino is the dark matter, using ongoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.
- 9 BOTTINO 91 excluded a region in $M_2 - \mu$ plane using ongoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.
- 10 GELMINI 91 exclude a region in $M_2 - \mu$ plane using dark matter searches.
- 11 KAMIONKOWSKI 91 excludes a region in the $M_2 - \mu$ plane using IMB limit on ongoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming

that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim 50$ GeV. See Fig. 8 in the paper.

- 12 MORI 91b exclude a part of the region in the $M_2 - \mu$ plane with $m_{\tilde{\chi}_1^0} \lesssim 80$ GeV using a limit on ongoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim 80$ GeV.
- 13 OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

$\tilde{\chi}_1^0 - p$ elastic cross section

Experimental results on the $\tilde{\chi}_1^0 - p$ elastic cross section are evaluated at $m_{\tilde{\chi}_1^0} = 100$ GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form $\bar{\chi}\gamma^\mu\mu\gamma^5\chi\bar{q}\gamma_\mu\gamma^5q$) and spin-independent interactions ($\bar{\chi}\chi\bar{q}q$). For calculational details see GRIEST 88b, ELLIS 88d, BARBIERI 89c, DREES 93b, ARNOWITZ 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Physics," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

Spin-dependent interactions

- 1 The strongest limit is 0.16 pb and occurs at $m_\chi = 24$ GeV. The strongest limit for the scattering on neutrons is 2.6 pb, also at $m_\chi = 24$ GeV.
- 2 The strongest upper limit is 0.76 pb and occurs at $m_\chi \simeq 55$ GeV. The strongest limit on the neutron spin-dependent cross section is 0.01 pb, also at $m_\chi \simeq 55$ GeV (the same limit is achieved for $m_\chi = 100$ GeV).
- 3 The strongest limit is 0.6 pb and occurs at $m_\chi = 30$ GeV. The limit for scattering on neutrons is 0.01 pb at $m_\chi = 100$ GeV, and the strongest limit is 0.0045 pb at $m_\chi = 30$ GeV.
- 4 Limit applies to neutron elastic cross section.
- 5 The strongest upper limit is 0.25 pb and occurs at $m_\chi \simeq 40$ GeV.
- 6 The strongest upper limit is 14 pb and occurs at $m_\chi \simeq 65$ GeV. The limit on the neutron spin-dependent cross section is 0.08 pb at $m_\chi = 100$ GeV and the strongest limit for scattering on neutrons is 0.07 pb at $m_\chi = 65$ GeV.
- 7 The limit on the neutron spin-dependent cross section is 6 pb at $m_\chi = 100$ GeV.
- 8 The strongest upper limit is 4 pb and occurs at $m_\chi \simeq 60$ GeV. The limit on the neutron spin-dependent elastic cross section is 0.07 pb. This latter limit is improved in AHMED 09, where a limit of 0.02 pb is obtained at $m_\chi = 100$ GeV. The strongest limit in AHMED 09 is 0.018 pb and occurs at $m_\chi = 60$ GeV.
- 9 The strongest upper limit is 1.2 pb and occurs at $m_\chi \simeq 40$ GeV. The limit on the neutron spin-dependent cross section is 35 pb.
- 10 The strongest upper limit is 0.35 pb and occurs at $m_\chi \simeq 60$ GeV.
- 11 The strongest upper limit is 1.2 pb and occurs $m_\chi \simeq 30$ GeV.
- 12 The strongest upper limit is 1.2 pb and occurs $m_\chi \simeq 40$ GeV.
- 13 ELLIS 04 calculates the χp elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses. In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-4} , see ELLIS 03e.
- 14 The strongest upper limit is 10 pb and occurs at $m_\chi \simeq 30$ GeV.
- 15 The strongest upper limit is 0.75 pb and occurs at $m_\chi \simeq 70$ GeV.

- 16 The strongest upper limit is 30 pb and occurs at $m_\chi \approx 20$ GeV.
- 17 The strongest upper limit is 8 pb and occurs at $m_\chi \approx 30$ GeV.
- 18 ELLIS 01c calculates the χ - p elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. In models with nonuniversal Higgs masses, the upper limit to the cross section is 6×10^{-4} .
- 19 The strongest upper limit is 3 pb and occurs at $m_\chi \approx 60$ GeV. The limits are for inelastic scattering $\chi^0 + 129\text{Xe} \rightarrow \chi^0 + 129\text{Xe}^*$ (39.58 keV).
- 20 The strongest upper limit is 9 pb and occurs at $m_\chi \approx 30$ GeV.
- 21 The strongest upper limit is 4.4 pb and occurs at $m_\chi \approx 60$ GeV.
- 22 The strongest upper limit is about 35 pb and occurs at $m_\chi \approx 15$ GeV.

- 1 AHMED 09 updates the results of AKERIB 06A. The strongest limit is 4.6×10^{-8} pb and occurs at $m_\chi = 60$ GeV.
- 2 The strongest upper limit is 4.8×10^{-7} pb and occurs at $m_\chi = 50$ GeV.
- 3 BUCHMUELLER 09 makes predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 4 The strongest upper limit is 8.1×10^{-8} pb and occurs at $m_\chi = 60$ GeV.
- 5 The strongest upper limit is 5.1×10^{-8} pb and occurs at $m_\chi \approx 30$ GeV. The values quoted here are based on the analysis performed in ANGLE 08 with the update from SORENSEN 09.
- 6 The strongest upper limit is 6.6×10^{-7} pb and occurs at $m_\chi \approx 65$ GeV.
- 7 The strongest upper limit is 1.9×10^{-7} pb and occurs at $m_\chi \approx 65$ GeV. Supersedes LEE 06.
- 8 AKERIB 06A updates the results of AKERIB 05. The strongest upper limit is 1.6×10^{-7} pb and occurs at $m_\chi \approx 60$ GeV.
- 9 The strongest upper limit is 8×10^{-6} pb and occurs at $m_\chi \approx 70$ GeV.
- 10 AKERIB 05 is incompatible with the DAMA most likely value. The strongest upper limit is 4×10^{-7} pb and occurs at $m_\chi \approx 60$ GeV.
- 11 The strongest upper limit is also close to 1.0×10^{-6} pb and occurs at $m_\chi \approx 70$ GeV. BENOIT 06 claim that the discrimination power of ZEPLIN-I measurement (ALNER 05A) is not reliable enough to obtain a limit better than 1×10^{-3} pb. However, SMITH 06 do not agree with the criticisms of BENOIT 06.
- 12 The strongest upper limit is also close to 1.4×10^{-6} pb and occurs at $m_\chi \approx 70$ GeV.

- 13 AKERIB 04 is incompatible with BERNABEI 00 most likely value, under the assumption of standard WIMP-halo interactions. The strongest upper limit is 4×10^{-7} pb and occurs at $m_\chi \approx 60$ GeV.
- 14 KIM 02 and ELLIS 04 calculate the χ - p elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses.
- 15 In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-6} (2×10^{-11} when constraint from the BNL $g-2$ experiment are included), see ELLIS 03e. ELLIS 05 display the sensitivity of the elastic scattering cross section to the π -Nucleon Σ term.
- 16 PIERCE 04A calculates the χ - p elastic scattering cross section in the framework of models with very heavy scalar masses. See Fig. 2 of the paper.
- 17 The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 80$ GeV.
- 18 Under the assumption of standard WIMP-halo interactions, Akerib 03 is incompatible with BERNABEI 00 most likely value at the 99.98% CL. See Fig. 4.
- 19 BAER 03A calculates the χ - p elastic scattering cross section in several models including the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 20 The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \approx 30$ GeV.
- 21 ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is 3×10^{-6} pb and occurs at $m_\chi \approx 30$ GeV.
- 22 BENOIT 02 excludes the central result of DAMA at the 99.8% CL.
- 23 The strongest upper limit is 2×10^{-5} pb and occurs at $m_\chi \approx 40$ GeV.
- 24 The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \approx 46$ GeV.
- 25 The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 32$ GeV
- 26 BOTTINO 01 calculates the χ - p elastic scattering cross section in the framework of the following supersymmetric models: $N=1$ supergravity with the radiative breaking of the electroweak gauge symmetry, $N=1$ supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.
- 27 Calculates the χ - p elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 28 ELLIS 01c calculates the χ - p elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range 2×10^{-8} - 1.5×10^{-7} at $\tan\beta=50$. In models with nonuniversal Higgs masses, the upper limit to the cross section is 4×10^{-7} .
- 29 ACCOMANDO 00 calculate the χ - p elastic scattering cross section in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models with nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to $< 9 \times 10^{-8}$ ($\tan\beta < 55$).
- 30 BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4σ and are consistent, for a particular model framework quoted there, with $m_{\chi^0}=44^{+12}_{-9}$ GeV and a spin-independent X^0 -proton cross section of $(5.4 \pm 1.0) \times 10^{-6}$ pb. See also BERNABEI 01 and BERNABEI 00c.
- 31 FENG 00 calculate the χ - p elastic scattering cross section in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At $\tan\beta=50$, the range is 8×10^{-8} - 4×10^{-7} .
- 32 BERNABEI 99 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 99.6%CL and are consistent, for the particular model framework considered there, with $m_{\chi^0}=59^{+17}_{-14}$ GeV and spin-independent X^0 -proton cross section of $(7.0^{+0.4}_{-1.2}) \times 10^{-6}$ pb (1 σ errors).
- 33 BERNABEI 98 search for annual modulation of the WIMP signal. The data are consistent, for the particular model framework considered there, with $m_{\chi^0}=59^{+36}_{-19}$ GeV and spin-independent X^0 -proton cross section of $(1.0^{+0.1}_{-0.4}) \times 10^{-5}$ pb (1 σ errors).

Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

- 1 ELLIS 00 updates ELLIS 98. Uses LEP e^+e^- data at $\sqrt{s}=202$ and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on $\tan\beta$ improve to > 2.7 ($\mu > 0$), > 2.2 ($\mu < 0$) when scalar mass universality is assumed and > 1.9 (both signs of μ) when Higgs mass universality is relaxed.
- 2 BUCHMUELLER 09 places constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.
- 3 BUCHMUELLER 08 places constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.
- 4 Places constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.
- 5 ELLIS 07 places constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality below the GUT scale.
- 6 HOOPER 03, BOTTINO 03 (see also BOTTINO 03A and BOTTINO 04), and BELANGER 04 do not assume gaugino or scalar mass unification.
- 7 Limit assumes a pseudo scalar mass < 200 GeV. For larger pseudo scalar masses, $m_\chi > 18(29)$ GeV for $\tan\beta = 50(10)$. Bounds from WMAP, $(g-2)_\mu, b \rightarrow s\gamma$, LEP.
- 8 ELLIS 04b places constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters. See also ELLIS 03d.
- 9 PIERCE 04A places constraints on the SUSY parameter space in the framework of models with very heavy scalar masses.
- 10 BAER 03, CHATTOPADHYAY 03, ELLIS 03c and LAHANAS 03 place constraints on the SUSY parameter space in the framework of $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark matter density.
- 11 BOEHM 00b and ELLIS 03 place constraints on the SUSY parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of $\chi-\tilde{\tau}$ co-annihilations.
- 12 DJOUADI 01, ROSZKOWSKI 01, and BAER 02 place constraints on the SUSY parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 13 ELLIS 02 places constraints on the soft supersymmetry breaking masses in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 14 LAHANAS 02 places constraints on the SUSY parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.
- 15 BARGER 01c use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 16 ELLIS 01b places constraints on the SUSY parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large $\tan\beta$.
- 17 FENG 00 explores cosmologically allowed regions of MSSM parameter space with multi-TeV masses.
- 18 LAHANAS 00 use the new cosmological data which favor a cosmological constant and its implications on the relic density to constrain the parameter space in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 19 ELLIS 98b assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of $\chi - \tilde{\tau}_R$ coannihilations.
- 20 EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.
- 21 Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking.
- 22 Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV for $m_t = 174$ GeV.
- 23 DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal $N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

- 24 FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the MSSM.
- 25 MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.
- 26 LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.
- 27 MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.
- 28 GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.
- 29 NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to narrow cosmologically allowed parameter space.
- 30 Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 350$ GeV for $m_t \leq 200$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde{H}} \lesssim 1$ TeV for $m_t \leq 200$ GeV.
- 31 ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region.
- 32 Mass of the bino (=LSP) is limited to $m_{\tilde{B}} \lesssim 550$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\tilde{H}} \lesssim 3.2$ TeV.
- 33 KRAUSS 83 finds $m_{\tilde{\gamma}} \leq 30$ eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\tilde{\gamma}} = 4-20$ MeV exists if $m_{\text{gravitino}} < 40$ TeV. See figure 2.

Unstable $\tilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\tilde{G}}$ is assumed to be negligible relative to all other masses. In the following, \tilde{G} is assumed to be undetected and to give rise to a missing energy (\cancel{E}) signature.

- 1 AALTONEN 10 searched in 2.6 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for diphoton events with large E_T . They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying into $\tilde{\chi}_1^0$ which itself decays in GMSB to $\gamma\tilde{G}$. There is no excess of events beyond expectation. An upper limit on the cross section is calculated in the GMSB model as a function of the $\tilde{\chi}_1^0$ mass and lifetime, see their Fig. 2. A limit is derived on the $\tilde{\chi}_1^0$ mass of 149 GeV for $\tau_{\tilde{\chi}_1^0} \ll 1$ ns, which improves the results of previous searches.
- 2 AALTONEN 08U searched in 570 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events that contain a time-delayed photon, at least one jet, and large E_T . The time-of-arrival is measured for each electromagnetic tower with a resolution of 0.50 ns. The number of observed events in the signal region is consistent with the background estimation. An upper limit on the cross section is derived as a function of the $\tilde{\chi}_1^0$ mass and lifetime, shown in their Fig. 24. The comparison with the NLO cross section for GMSB yields an exclusion of the $\tilde{\chi}_1^0$ mass as a function of its lifetime, see Fig. 25. See ABULENCIA 07P for a previous analysis of the same data set.

- ³ ABAZOV 08F looked in 1.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for diphoton events with large \cancel{E}_T . They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\tilde{\chi}_1^0 \rightarrow \gamma \tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 91.5 \text{ TeV}$. Supersedes the results of ABAZOV 05A.
- ⁴ ABAZOV 08x searched in 1.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for an excess of events with electron pairs. Their vertex, reconstructed from the directions measured in the segmented electromagnetic calorimeter, is required to be away from the primary interaction point. Such delayed decays might be expected for a Higgsino-like $\tilde{\chi}_1^0$ in GMSB. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted as a function of the lifetime for several ranges of dielectron invariant masses, see their Fig. 3.
- ⁵ ABULENCIA 07H searched in 346 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with at least three leptons (e or μ) from the decay of $\tilde{\chi}_1^0$ via $L\tilde{L}\tilde{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.
- ⁶ ABAZOV 06d looked in 360 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with three leptons originating from the pair production of charginos and neutralinos, followed by \tilde{R} decays mediated by $L\tilde{L}\tilde{E}$ couplings. One coupling is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $e\ell\ell$, $\mu\mu\ell$ nor $e\ell\tau$ ($\ell = e, \mu$) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their Table III and Fig. 4.
- ⁷ ABAZOV 06p looked in 380 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with at least 2 opposite sign isolated muons which might arise from the decays of neutralinos into $\mu\mu\nu$ via \tilde{R} couplings $L\tilde{L}\tilde{E}$. No events are observed in the decay region defined by a radius between 5 and 20 cm, in agreement with the SM expectation. Limits are set on the cross-section times branching ratio as a function of lifetime, shown in their Fig. 3. This limit excludes the SUSY interpretation of the NuTeV excess of dimuon events reported in ADAMS 01.
- ⁸ ABBIENDI 06b use 600 pb^{-1} of data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$. They look for events with diphotons + \cancel{E} final states originating from prompt decays of pair-produced neutralinos in a GMSB scenario with $\tilde{\chi}_1^0$ NLSP. Limits on the cross-section are computed as a function of $m(\tilde{\chi}_1^0)$, see their Fig. 14. The limit on the $\tilde{\chi}_1^0$ mass is for a pure Bino state assuming a prompt decay, with lifetimes up to 10^{-9} s. Supersedes the results of ABBIENDI 04n.
- ⁹ ABDALLAH 05B use data from $\sqrt{s} = 180\text{--}209 \text{ GeV}$. They look for events with single photons + \cancel{E} final states. Limits are computed in the plane $(m(\tilde{G}), m(\tilde{\chi}_1^0))$, shown in their Fig. 9b for a pure Bino state in the GMSB framework and in Fig. 9c for a no-scale supergravity model. Supersedes the results of ABREU 00z.
- ¹⁰ ABDALLAH 05B use data from $\sqrt{s} = 130\text{--}209 \text{ GeV}$. They look for events with diphotons + \cancel{E} final states and single photons not pointing to the vertex, expected in GMSB when the $\tilde{\chi}_1^0$ is the NLSP. Limits are computed in the plane $(m(\tilde{G}), m(\tilde{\chi}_1^0))$, see their Fig. 10. The lower limit is derived on the $\tilde{\chi}_1^0$ mass for a pure Bino state assuming a prompt decay and $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 2 m_{\tilde{\chi}_1^0}$. It improves to 100 GeV for $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 1.1 m_{\tilde{\chi}_1^0}$ and the limit in the plane $(m(\tilde{\chi}_1^0), m(\tilde{e}_R))$ is shown in Fig. 10b. For long-lived neutralinos, cross-section limits are displayed in their Fig. 11. Supersedes the results of ABREU 00z.
- ¹¹ ACOSTA 05E looked in 202 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for diphoton events with large \cancel{E}_T . They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\gamma \tilde{G}$. No events are selected at large \cancel{E}_T compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 69 \text{ TeV}$. Supersedes the results of ABE 99i.
- ¹² AKTAS 05 data collected at 319 GeV with 64.3 pb^{-1} of e^+p and 13.5 pb^{-1} of e^-p . They look for \tilde{R} resonant $\tilde{\chi}_1^0$ production via t -channel exchange of a \tilde{e} , followed by prompt GMSB decay of the $\tilde{\chi}_1^0$ to $\gamma \tilde{G}$. Upper limits at 95% on the cross section are derived, see their Figure 4, and compared to two example scenarios. In Figure 5, they display 95% exclusion limits in the plane of $M(\tilde{\chi}_1^0)$ versus $M(\tilde{e}_L) - M(\tilde{\chi}_1^0)$ for the two scenarios and several values of the χ' Yukawa coupling.
- ¹³ ABBIENDI 04n use data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$, setting limits on $\sigma(e^+e^- \rightarrow XX) \times B^2(X \rightarrow Y\gamma)$, with Y invisible (see their Fig. 4). Limits on $\tilde{\chi}_1^0$ masses for a specific model are given. Supersedes the results of ABBIENDI, G 00d.
- ¹⁴ ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192\text{--}208 \text{ GeV}$. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50 \text{ TeV}$, $0 < m_0 < 1000 \text{ GeV}$, $1.5 < \tan\beta < 35$, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t = 174.3 \text{ GeV}$ (see Table 2 for other m_t values).
- ¹⁵ The limit improves to 73 GeV for $\mu < 0$.
- ¹⁶ ABDALLAH 04M use data from $\sqrt{s} = 192\text{--}208 \text{ GeV}$ to derive limits on sparticle masses under the assumption of \tilde{R} with $L\tilde{L}\tilde{E}$ or $\tilde{U}\tilde{D}\tilde{D}$ couplings. The results are valid in the ranges $90 < m_0 < 500 \text{ GeV}$, $0.7 < \tan\beta < 30$, $-200 < \mu < 200 \text{ GeV}$, $0 < M_2 < 400 \text{ GeV}$. Supersedes the result of ABREU 01d and ABREU 00u.
- ¹⁷ The limit improves to 39.5 GeV for $L\tilde{L}\tilde{E}$ couplings.
- ¹⁸ ACHARD 04E use data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$. They look for events with single photons + \cancel{E} final states. Limits are computed in the plane $(m(\tilde{G}), m(\tilde{\chi}_1^0))$, shown in their Fig. 8c for a no-scale supergravity model, excluding, e.g., Gravitino masses below 10^{-5} eV for neutralino masses below 172 GeV. Supersedes the results of ACCIARRI 99r.
- ¹⁹ ACHARD 04E use data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$. They look for events with diphotons + \cancel{E} final states. Limits are computed in the plane $(m(\tilde{\chi}_1^0), m(\tilde{e}_R))$, see their Fig. 8d. The limit on the $\tilde{\chi}_1^0$ mass is for a pure Bino state assuming a prompt decay, with $m_{\tilde{e}_L} = 1.1 m_{\tilde{\chi}_1^0}$ and $m_{\tilde{e}_R} = 2.5 m_{\tilde{\chi}_1^0}$. Supersedes the results of ACCIARRI 99r.
- ²⁰ ABDALLAH 03D use data from $\sqrt{s} = 161\text{--}208 \text{ GeV}$. They look for 4-tau + \cancel{E} final states, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP, and 4-lepton + \cancel{E} final states, expected in the co-NLSP scenario, and assuming a short-lived $\tilde{\chi}_1^0$ ($m(\tilde{G}) < 1 \text{ eV}$). Limits are computed in the plane $(m(\tilde{\tau}_1), m(\tilde{\chi}_1^0))$ from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production from the same paper to cover prompt decays and for the case of $\tilde{\chi}_1^0$ NLSP from ABREU 00z. The limit above is reached for a single generation of messengers and when the $\tilde{\tau}_1$ is the NLSP. Stronger limits are obtained when more messenger generations are assumed or when the other sleptons are co-NLSP, see their Fig. 10. Supersedes the results of ABREU 01g.
- ²¹ HEISTER 03c use the data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$ to search for $\gamma \cancel{E}_T$ final states with non-pointing photons and $\gamma \gamma \cancel{E}_T$ events. Interpreted in the framework of Minimal GMSB, a lower bound on the $\tilde{\chi}_1^0$ mass is obtained as function of its lifetime. For a laboratory lifetime of less than 3 ns, the limit at 95% CL is 98.8 GeV. For other lifetimes, see their Fig. 5. These results are interpreted in a more general GMSB framework in HEISTER 02r.
- ²² HEISTER 03c use the data from $\sqrt{s} = 189\text{--}209 \text{ GeV}$ to search for $\gamma \cancel{E}_T$ final states. They obtained an upper bound on the cross section for the process $e^+e^- \rightarrow \tilde{G} \tilde{\chi}_1^0$, followed by the prompt decay $\tilde{\chi}_1^0 \rightarrow \gamma \tilde{G}$, shown in their Fig. 4. These results supersede BARATE 98h.
- ²³ ACHARD 02 searches for the production of sparticles in the case of \tilde{R} prompt decays with $L\tilde{L}\tilde{E}$ or $\tilde{U}\tilde{D}\tilde{D}$ couplings at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. The search is performed for direct and indirect decays, assuming one coupling at a time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $\tilde{U}\tilde{D}\tilde{D}$ couplings and increases to 40.2 GeV for $L\tilde{L}\tilde{E}$ couplings. For L3 limits from $L\tilde{Q}\tilde{D}$ couplings, see ACCIARRI 01.
- ²⁴ HEISTER 02r search for signals of GMSB in the 189–209 GeV data. For the $\tilde{\chi}_1^0$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\cancel{E}$ or a single γ not pointing to the interaction vertex. For the $\tilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\cancel{E}$ or $4\ell\cancel{E}$ (from $\tilde{\chi}_1^0 \tilde{\chi}_1^0$ production), including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limits are valid whichever is the NLSP. The absolute mass bound on the $\tilde{\chi}_1^0$ for any lifetime includes indirect limits from the chargino search, and from the slepton search HEISTER 02e performed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. Limits on the universal SUSY mass scale Λ are also derived in the paper. Supersedes the results from BARATE 00c.
- ²⁵ ABBIENDI 01 looked for final states with $\gamma\gamma\cancel{E}$, $\ell\ell\cancel{E}$, with possibly additional activity and four leptons + \cancel{E} to search for prompt decays of $\tilde{\chi}_1^0$ or $\tilde{\ell}_1$ in GMSB. They derive limits in the plane $(m_{\tilde{\chi}_1^0}, m_{\tilde{\tau}_1})$, see Fig. 6, allowing either the $\tilde{\chi}_1^0$ or a $\tilde{\ell}_1$ to be the NLSP. Two scenarios are considered: $\tan\beta=2$ with the 3 sleptons degenerate in mass and $\tan\beta=20$ where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}=189 \text{ GeV}$.
- ²⁶ ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from \tilde{R} prompt decays with $L\tilde{L}\tilde{E}$, $L\tilde{Q}\tilde{D}$, or $\tilde{U}\tilde{D}\tilde{D}$ couplings at $\sqrt{s}=189 \text{ GeV}$. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99i.
- ²⁷ ADAMS 01 looked for neutral particles with mass $> 2.2 \text{ GeV}$, produced by 900 GeV protons incident on a Beryllium oxide target and decaying through weak interactions into $\mu\mu$, μe , or $\mu\pi$ final states in the decay channel of the NuTeV detector (E815) at Fermilab. The number of observed events is $3\mu\mu$, $0\mu e$, and $0\mu\pi$ with an expected background of 0.069 ± 0.010 , 0.13 ± 0.02 , and 0.14 ± 0.02 , respectively. The $\mu\mu$ events are consistent with the \tilde{R} decay of a neutralino with mass around 5 GeV. However, they share several aspects with ν -interaction backgrounds. An upper limit on the differential production cross section of neutralinos in pp interactions as function of the decay length is given in Fig. 3.
- ²⁸ ABBIENDI 99t searches for the production of neutralinos in the case of R -parity violation with $L\tilde{L}\tilde{E}$, $L\tilde{Q}\tilde{D}$, or $\tilde{U}\tilde{D}\tilde{D}$ couplings using data from $\sqrt{s}=183 \text{ GeV}$. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at a time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\tilde{U}\tilde{D}\tilde{D}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the neutralino mass are obtained for non-zero $L\tilde{L}\tilde{E}$ couplings $> 10^{-5}$. The limit disappears for $\tan\beta < 1.2$ and it improves to 50 GeV for $\tan\beta > 20$.
- ²⁹ BARATE 99e looked for the decay of gauginos via R -violating couplings $L\tilde{Q}\tilde{D}$. The bound is significantly reduced for smaller values of m_0 . Data collected at $\sqrt{s}=130\text{--}172 \text{ GeV}$.
- ³⁰ ABREU 98 uses data at $\sqrt{s}=161$ and 172 GeV. Upper bounds on $\gamma\gamma\cancel{E}$ cross section are obtained. Similar limits on $\gamma\cancel{E}$ are also given, relevant for $e^+e^- \rightarrow \tilde{\chi}_1^0 \tilde{G}$ production.
- ³¹ BARATE 98s looked for the decay of gauginos via R -violating coupling $L\tilde{L}\tilde{E}$. The bound improves to 25 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at $\sqrt{s}=130\text{--}172 \text{ GeV}$.
- ³² ELLIS 97 re-analyzed the LEP 2 ($\sqrt{s}=161 \text{ GeV}$) limits of $\sigma(\gamma\gamma + E_{\text{miss}}) < 0.2 \text{ pb}$ to exclude $m_{\tilde{\chi}_1^0} < 63 \text{ GeV}$ if $m_{\tilde{e}_L} = m_{\tilde{e}_R} < 150 \text{ GeV}$ and $\tilde{\chi}_1^0$ decays to $\gamma \tilde{G}$ inside detector.
- ³³ CABIBBO 81 consider $\tilde{\gamma} \rightarrow \gamma$ goldstino. Photino must be either light enough ($< 30 \text{ eV}$) to satisfy cosmology bound, or heavy enough ($> 0.3 \text{ MeV}$) to have disappeared at early universe.

$\tilde{\chi}_2^0, \tilde{\chi}_3^0, \tilde{\chi}_4^0$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}_2^0, \tilde{\chi}_3^0$, and $\tilde{\chi}_4^0$. $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay

Searches Particle Listings

Supersymmetric Particle Searches

modes, on the masses of decay products ($\tilde{e}, \tilde{\gamma}, \tilde{q}, \tilde{g}$), and on the \tilde{e} mass exchanged in $e^+e^- \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\tilde{\chi}_0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g. the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino (\tilde{Z}), or pure neutral higgsino (\tilde{H}^0), the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. $\Delta m = m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$.

¹ ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 < 5000$ GeV, $-1000 < \mu < 1000$ GeV and $\tan\beta$ from 1 to 40. This limit supersedes ABBIENDI 00H.

² ABREU 00W combines data collected at $\sqrt{s}=189$ GeV with results from lower energies. The mass limit is obtained by constraining the MSSM parameter space with gaugino and stfermion mass universality at the GUT scale, using the results of negative direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states) from ABREU 01, for charginos from ABREU 00J and ABREU 00T (for all Δm_{\pm}), and for charged sleptons from ABREU 01B. The results hold for the full parameter space defined by all values of M_2 and $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP.

³ ABULENCIA 07N searched in 1 fb^{-1} of $\rho\bar{\rho}$ collisions at $\sqrt{s} = 1.96$ TeV for events with two same sign leptons (e or μ) from the decay of $\tilde{\chi}_1^\pm \tilde{\chi}_2^0 X$ and large \cancel{E}_T . A slight excess of 13 events is observed over a SM background expectation of 7.8 ± 1.1 . However, the kinematic distributions do not show any anomalous deviation from expectations in any particular region of parameter space.

⁴ ABDALLAH 05B use data from $\sqrt{s} = 130\text{--}209$ GeV, looking for events with diphotons + \cancel{E} . Limits on the cross-section are computed in the plane $(m(\tilde{\chi}_2^0), m(\tilde{\chi}_1^0))$, see Fig. 12. Supersedes the results of ABREU 00Z.

⁵ ACHARD 04E use data from $\sqrt{s} = 189\text{--}209$ GeV, looking for events with diphotons + \cancel{E} . Limits are computed in the plane $(m(\tilde{\chi}_2^0), m(\tilde{e}_R))$, for $\Delta m > 10$ GeV, see Fig. 7. Supersedes the results of ACCIARRI 99R.

⁶ ACHARD 02 searches for the production of sparticles in the case of \tilde{R} prompt decays with $LL\bar{E}$ or UDD couplings at $\sqrt{s}=189\text{--}208$ GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\tilde{\chi}_2^0$ holds for UDD couplings and increases to 84.0 GeV for $LL\bar{E}$ couplings. The same $\tilde{\chi}_3^0$ limit holds for both $LL\bar{E}$ and UDD couplings. For L3 limits from $LQ\bar{D}$ couplings, see ACCIARRI 01.

⁷ ABREU 01B used data from $\sqrt{s}=189$ GeV to search for the production of $\tilde{\chi}_i^0 \tilde{\chi}_j^0$. They looked for di-jet and di-lepton pairs with \cancel{E} for events from $\tilde{\chi}_i^0 \tilde{\chi}_j^0$ with the decay $\tilde{\chi}_j^0 \rightarrow f\bar{f} \tilde{\chi}_1^0$; multi-jet and multi-lepton pairs with or without additional photons to cover the cascade decays $\tilde{\chi}_j^0 \rightarrow f\bar{f} \tilde{\chi}_2^0$, followed by $\tilde{\chi}_j^0 \rightarrow \tilde{f}\tilde{f} \tilde{\chi}_1^0$ or $\tilde{\chi}_j^0 \rightarrow \gamma \tilde{\chi}_1^0$; multi-tau final states from $\tilde{\chi}_j^0 \rightarrow \tilde{\tau}\tau$ with $\tilde{\tau} \rightarrow \tau \tilde{\chi}_1^0$. See Figs. 9 and 10 for limits on the (μ, M_2) plane for $\tan\beta=1.0$ and different values of m_0 .

⁸ ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from \tilde{R} prompt decays with $LL\bar{E}, LQ\bar{D}$, or UDD couplings at $\sqrt{s}=189$ GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

⁹ ABREU 00u searches for the production of charginos and neutralinos in the case of R -parity violation with $LL\bar{E}$ couplings, using data from $\sqrt{s}=189$ GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and $\tan\beta$.

¹⁰ ABBIENDI 99F looked for $\gamma\tilde{E}$ final states at $\sqrt{s}=183$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_1^0$ followed by the prompt decay $\tilde{\chi}_2^0 \rightarrow \gamma \tilde{\chi}_1^0$ of 0.075–0.80 pb in the region $m_{\tilde{\chi}_2^0} + m_{\tilde{\chi}_1^0} > m_Z, m_{\tilde{\chi}_2^0} = 91\text{--}183$ GeV, and $\Delta m > 5$ GeV. See Fig. 7 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

¹¹ ABBIENDI 99F looked for $\gamma\gamma\tilde{E}$ final states at $\sqrt{s}=183$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \rightarrow \gamma \tilde{\chi}_1^0$ of 0.08–0.37 pb for $m_{\tilde{\chi}_2^0} = 45\text{--}81.5$ GeV, and $\Delta m > 5$ GeV. See Fig. 11 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

¹² ABBOTT 98c searches for trilepton final states ($\ell=e, \mu$). See footnote to ABBOTT 98c in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 103$ GeV.

¹³ ABE 98J searches for trilepton final states ($\ell=e, \mu$). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result for $m_{\tilde{\chi}_2^0}$ corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}, \tan\beta=2$, and $\mu=-600$ GeV.

¹⁴ ACCIARRI 98F is obtained from direct searches in the $e^+e^- \rightarrow \tilde{\chi}_{1,2}^0 \tilde{\chi}_2^0$ production channels, and indirectly from $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ searches within the MSSM. See footnote to ACCIARRI 98F in the Chargino Section for further details on the assumptions. Data taken at $\sqrt{s} = 130\text{--}172$ GeV.

¹⁵ ACCIARRI 98V looked for $\gamma(\gamma)\tilde{E}$ final states at $\sqrt{s}=183$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_{1,2}^0$ followed by the prompt decay $\tilde{\chi}_2^0 \rightarrow \gamma \tilde{\chi}_1^0$. See Figs. 4a and 6a for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

¹⁶ BARATE 98H looked for $\gamma\gamma\tilde{E}$ final states at $\sqrt{s} = 161, 172$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \rightarrow \gamma \tilde{\chi}_1^0$ of 0.4–0.8 pb for $m_{\tilde{\chi}_2^0} = 10\text{--}80$ GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R} = 100$ GeV. See Fig. 6 and 7 for explicit limits in the $(\tilde{\chi}_2^0, \tilde{\chi}_1^0)$ plane and in the $(\tilde{\chi}_2^0, \tilde{e}_R)$ plane.

¹⁷ BARATE 98J looked for $\gamma\gamma\tilde{E}$ final states at $\sqrt{s} = 161\text{--}183$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \rightarrow \gamma \tilde{\chi}_1^0$ of 0.08–0.24 pb for $m_{\tilde{\chi}_2^0} < 91$ GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R} = 100$ GeV.

¹⁸ ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on $\sigma(\tilde{\chi}_1^\pm \tilde{\chi}_2^0) \times \text{B}(\tilde{\chi}_1^\pm \rightarrow \ell\nu_{\tilde{\chi}_1^0}) \times \text{B}(\tilde{\chi}_2^0 \rightarrow \ell^+ \ell^- \tilde{\chi}_1^0)$ as a function of $m_{\tilde{\chi}_1^0}$. Limits range from 3.1 pb ($m_{\tilde{\chi}_1^0} = 45$ GeV) to 0.6 pb ($m_{\tilde{\chi}_1^0} = 100$ GeV).

¹⁹ ABE 96K looked for trilepton events from chargino-neutralino production. They obtained lower bounds on $m_{\tilde{\chi}_2^0}$ as a function of μ . The lower bounds are in the 45–50 GeV range for gaugino-dominant $\tilde{\chi}_2^0$ with negative μ , if $\tan\beta < 10$. See paper for more details of the assumptions.

$\tilde{\chi}_1^\pm, \tilde{\chi}_2^0$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of w -inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino ($\tilde{\chi}_1^\pm$) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and stfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_1^\pm \tilde{\chi}_1^\mp$ and (in the case of hadronic collisions) $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$ pairs, including the effects of cascade decays. The mass limits on $\tilde{\chi}_1^\pm$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ . For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\tilde{\chi}_1^\pm} \lesssim \sqrt{s}/2$. The still unpublished combination of the results of the four LEP collaborations from the 2000 run of LEP 2 at \sqrt{s} up to $\simeq 209$ GeV yields a lower mass limit of 103.5 GeV valid for general MSSM models. The limits become however weaker in certain regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen

when: (i) the mass differences $\Delta m_{\pm} = m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\chi}_1^0}$ or $\Delta m_{\nu} = m_{\tilde{\chi}_1^{\pm}} - m_{\tilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\tilde{\chi}_1^{\pm}$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

1 ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 \leq 5000$ GeV, $-1000 < \mu < 1000$ GeV and $\tan\beta$ from 1 to 40. This limit supersedes ABBIENDI 00h.

2 ABBIENDI 03H used e^+e^- data at $\sqrt{s} = 188\text{--}209$ GeV to search for chargino pair production in the case of small Δm_{\pm} . They select events with an energetic photon, large E and little hadronic or leptonic activity. The bound applies to higgsino-like charginos with zero lifetime and a 100% branching ratio $\tilde{\chi}_1^{\pm} \rightarrow \tilde{\chi}_1^0 W^*$. The mass limit for gaugino-like charginos, in case of non-universal gaugino masses, is of 92 GeV for $m_{\tilde{\nu}} = 1000$ GeV and is lowered to 74 GeV for $m_{\tilde{\nu}} \geq 100$ GeV. Limits in the plane $(m_{\tilde{\chi}_1^{\pm}}, \Delta m_{\pm})$ are shown in Fig. 7. Exclusion regions are also derived for the AMSB scenario in the $(m_{3/2}, \tan\beta)$ plane, see their Fig. 9.

3 ABDALLAH 03M searches for the production of charginos using data from $\sqrt{s} = 192$ to 208 GeV to investigate topologies with multiple leptons, jets plus leptons, multi-jets, or isolated photons. The first limit holds for $\tan\beta \geq 1$ and is obtained at $\Delta m_{\pm} = 3$ GeV in the higgsino region. For $\Delta m_{\pm} \geq 10$ (5) GeV and large m_0 , the limit improves to 102.7 (101.7) GeV. For the region of small Δm_{\pm} , all data from $\sqrt{s} = 130$ to 208 GeV are used to investigate final states with heavy stable charged particles, decay vertices inside the detector and soft topologies with a photon from initial state radiation. The second limit is obtained in the higgsino region, assuming gaugino mass universality at the GUT scale and $1 < \tan\beta < 50$. For the case of non-universality of gaugino masses, the parameter space is scanned in the domain $1 < \tan\beta < 50$ and, for $\Delta m_{\pm} < 3$ GeV, for

values of M_1, M_2 and μ such that $M_2 \leq 2M_1 \leq 10M_2$ and $|\mu| \geq M_2$. The third limit is obtained in the gaugino region. See Fig. 36 for the dependence of the low Δm_{\pm} limits on Δm_{\pm} . These limits include and update the results of ABREU 00j and ABREU 00t.

4 ABDALLAH 03M uses data from $\sqrt{s} = 192\text{--}208$ GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays), for charginos and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming $m_t = 174.3$ GeV are included. The quoted limit applies if there is no mixing in the third family or when $m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0} > 6$ GeV. If mixing is included the limit degrades to 90 GeV. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00w.

5 HEISTER 02j search for chargino production with small Δm_{\pm} in final states with a hard isolated initial state radiation photon and few low-momentum particles, using 189–208 GeV data. This search is sensitive in the intermediate Δm_{\pm} region. Combined with searches for E topologies and for stable charged particles, the above bound is obtained for m_0 larger than few hundred GeV, $1 < \tan\beta < 300$ and holds for any chargino field contents. For light scalars, the general limit reduces to the one from the Z^0 , but under the assumption of gaugino and sfermion mass unification the above bound is recovered. See Figs. 4–6 for the more general dependence of the limits on Δm_{\pm} . Updates BARATE 98x.

6 ACCIARRI 00d data collected at $\sqrt{s}=189$ GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 2$ TeV $m_0 \leq 500$ GeV. The results of slepton searches from ACCIARRI 99w are used to help set constraints in the region of small m_0 . See their Figs. 5 for the $\tan\beta$ and M_2 dependence on the limits. See the text for the impact of a large $B(\tilde{\chi}^{\pm} \rightarrow \tau\tilde{\nu}_{\tau})$ on the result. The region of small Δm_{\pm} is excluded by the analysis of ACCIARRI 00k. Updates ACCIARRI 98f.

7 ACCIARRI 00k searches for the production of charginos with small Δm_{\pm} using data from $\sqrt{s}=189$ GeV. They investigate soft final states with a photon from initial state radiation. The results are combined with the limits on prompt decays from ACCIARRI 00d and from heavy stable charged particles from ACCIARRI 99L (see Heavy Charged Lepton Searches). The production and decay branching ratios are evaluated within the MSSM, assuming heavy sfermions. The parameter space is scanned in the domain $1 < \tan\beta < 50$, $0.3 < M_1/M_2 < 50$, and $0 < |\mu| < 2$ TeV. The limit is obtained in the higgsino region and improves to 78.6 GeV for gaugino-like charginos. The limit is unchanged for light scalar quarks. For light $\tilde{\tau}$ or $\tilde{\nu}_{\tau}$, the limit is unchanged in the gaugino-like region and is lowered by 0.8 GeV in the higgsino-like case. For light $\tilde{\mu}$ or $\tilde{\nu}_{\mu}$, the limit is unchanged in the higgsino-like region and is lowered by 0.9 GeV in the gaugino-like region. No direct mass limits are obtained for light \tilde{e} or $\tilde{\nu}_e$.

8 AALTONEN 09g searched in 976 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons ($\mu\mu\mu$ or $\mu\mu e$) with a low, 5 GeV, p_T threshold, and large E_T from the decay of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The results are combined with the analysis of AALTONEN 07j to set a limit on the $\tilde{\chi}_1^{\pm}$ mass for a mSUGRA scenario with no slepton mixing.

9 ABAZOV 09t searched in 2.3 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons (e, μ or hadronically decaying τ) from the decay of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$ and large E_T . No evidence for a signal is observed. The data are used to constrain the cross section times branching ratio as a function of the $\tilde{\chi}_1^{\pm}$ mass under the assumption that $m_{\tilde{\chi}_1^{\pm}} = m_{\tilde{\chi}_2^0} = 2 m_{\tilde{\chi}_1^0}$, $\tan\beta = 3$, $\mu > 0$ and that the sleptons are heavier than the $\tilde{\chi}_1^{\pm}$, see their Fig. 8. A chargino lighter than 138 GeV is excluded in the “3l-max” scenario. Exclusion regions in the $(m_0, m_{1/2})$ plane are shown in their Fig. 9 for a mSUGRA scenario with $\tan\beta = 3$, $A_0 = 0$ and $\mu > 0$. The $\tan\beta$ dependence of this exclusion is illustrated in Fig. 10. Supersedes the results of ABAZOV 05u.

10 AALTONEN 08ae searched in 2.0 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons (e, μ or a charged isolated track from τ) from the decay of $p\bar{p} \rightarrow \tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$ and large E_T . The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\tilde{\chi}_1^{\pm}$ mass. Exclusion regions in the $(m_0, m_{1/2})$ plane are shown in their

Fig. 2 for a mSUGRA scenario. When the $\tilde{\chi}_1^{\pm}$ is nearly mass degenerate with the $\tilde{\tau}_1$ the leptons are too soft and no limit is obtained. For the case $m_0 = 60$ GeV a lower limit of 145 GeV on the chargino mass is obtained in this mSUGRA scenario.

11 AALTONEN 08l searched in 0.7 to 1.0 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with one high- p_T electron or muon and two additional leptons (e or μ) from the decay of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\tilde{\chi}_1^{\pm}$ mass. The results are compared to three MSSM scenarios. An exclusion on chargino and neutralino production is only obtained in a scenario of no mixing between sleptons, yielding nearly equal branching ratios to all three lepton flavors. It amounts to $m_{\tilde{\chi}_1^{\pm}} > 151$ GeV, while the analysis is not sensitive to chargino masses below about 110 GeV. The analyses have been combined with the analyses of AALTONEN 07j and ABULENCIA 07n. The observed limits for the combination are less stringent than the one obtained for the high- p_T analysis due to slight excesses in the other channels.

12 ABAZOV 08f looked in 1.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for diphoton events with large E_T . They may originate from the production of $\tilde{\chi}^{\pm}$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in $\text{GMSB} \rightarrow \tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 91.5$ TeV. Supersedes the results of ABAZOV 05a.

13 AALTONEN 07j searched in 0.7 to 1.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with either two same sign leptons (e or μ) or trileptons from the decay of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$ and large E_T . The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\tilde{\chi}_1^{\pm}$ mass. The results, shown in their Fig. 2, are compared to several MSSM scenarios. The strongest exclusion is in the case of no mixing between sleptons, yielding

Searches Particle Listings

Supersymmetric Particle Searches

- nearly equal branching ratios to all three lepton flavors, and amounting to $m_{\tilde{\chi}_1^\pm} > 129$ GeV. This analysis includes the same sign dilepton analysis of ABULENCIA 07N.
- 14 ABULENCIA 07H searched in 346 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with at least three leptons (e or μ) from the decay of $\tilde{\chi}_1^0$ via $LL\bar{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.
- 15 ABULENCIA 07N searched in 1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with two same sign leptons (e or μ) from the decay of $\tilde{\chi}_1^\pm \tilde{\chi}_1^0 X$ and large $E_{T\cancel{e}}$. A slight excess of 13 events is observed over a SM background expectation of 7.8 ± 1.1 . However, the kinematic distributions do not show any anomalous deviation from expectations in any particular region of parameter space.
- 16 ABAZOV 06d looked in 360 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with three leptons originating from the pair production of charginos and neutralinos, followed by R decays mediated by $LL\bar{E}$ couplings. One coupling is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $e\bar{e}l, \mu\bar{\mu}l$ nor $e\bar{e}\tau$ ($l = e, \mu$) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their Table III and Fig. 4.
- 17 ABAZOV 05a looked in 263 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for diphoton events with large $E_{T\cancel{e}}$. They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_1^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$. No significant excess was found at large $E_{T\cancel{e}}$ compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 79.6 \text{ TeV}$. Very similar results are obtained for different choices of parameters, see their Table 2. Supersedes the results of ABBOTT 98.
- 18 ACOSTA 05e looked in 202 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for diphoton events with large $E_{T\cancel{e}}$. They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_1^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$. No events are selected at large $E_{T\cancel{e}}$ compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 69 \text{ TeV}$. Supersedes the results of ABE 99i.
- 19 ABDALLAH 04h use data from LEP 1 and $\sqrt{s} = 192\text{--}208 \text{ GeV}$. They re-use results or re-analyze the data from ABDALLAH 03m to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50 \text{ TeV}$, $0 < m_0 < 1000 \text{ GeV}$, $1.5 < \tan\beta < 35$, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV . The limit is for $m_{\tilde{t}} = 174.3 \text{ GeV}$ (see Table 2 for other $m_{\tilde{t}}$ values).
- 20 The limit improves to 73 GeV for $\mu < 0$.
- 21 ABDALLAH 04m use data from $\sqrt{s} = 192\text{--}208 \text{ GeV}$ to derive limits on sparticle masses under the assumption of R with $LL\bar{E}$ or UDD couplings. The results are valid in the ranges $90 < m_0 < 500 \text{ GeV}$, $0.7 < \tan\beta < 30$, $-200 < \mu < 200 \text{ GeV}$, $0 < M_2 < 400 \text{ GeV}$. Supersedes the result of ABREU 01d and ABREU 00u.
- 22 The limit improves to 103 GeV for $LL\bar{E}$ couplings.
- 23 ABDALLAH 03d use data from $\sqrt{s} = 183\text{--}208 \text{ GeV}$. They look for final states with two acoplanar leptons, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP and assuming a short-lived $\tilde{\chi}_1^\pm$. Limits are obtained in the plane $(m(\tilde{\tau}), m(\tilde{\chi}_1^\pm))$ for different domains of $m(\tilde{G})$, after combining these results with the search for slepton pair production from the same paper. The limit above is valid if the $\tilde{\tau}_1$ is the NLSP for all values of $m(\tilde{G})$ provided $m(\tilde{\chi}_1^\pm) - m(\tilde{\tau}_1) \geq 0.3 \text{ GeV}$. For larger $m(\tilde{G}) > 100 \text{ eV}$ the limit improves to 102 GeV , see their Fig. 11. In the co-NLSP scenario, the limits are 96 and 102 GeV for all $m(\tilde{G})$ and $m(\tilde{G}) > 100 \text{ eV}$, respectively. Supersedes the results of ABREU 01g.
- 24 HEISTER 03g searches for the production of charginos prompt decays. In the case of R prompt decays with $LL\bar{E}$, $LQ\bar{D}$ or UDD couplings at $\sqrt{s} = 189\text{--}209 \text{ GeV}$. The search is performed for indirect decays, assuming one coupling at a time to be non-zero. The limit holds for $\tan\beta = 1.41$. Excluded regions in the (μ, M_2) plane are shown in their Fig. 3.
- 25 ACHARD 02 searches for the production of sparticles in the case of R prompt decays with $LL\bar{E}$ or UDD couplings at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\tilde{\chi}_1^\pm$ holds for UDD couplings and increases to 103.0 GeV for $LL\bar{E}$ couplings. For L3 limits from $LQ\bar{D}$ couplings, see ACCIARRI 01.
- 26 GHODBANE 02 reanalyzes DELPHI data at $\sqrt{s} = 189 \text{ GeV}$ in the presence of complex phases for the MSSM parameters.
- 27 ABREU 01c looked for τ pairs with E at $\sqrt{s} = 183\text{--}189 \text{ GeV}$ to search for the associated production of charginos, followed by the decay $\tilde{\chi}^\pm \rightarrow \tau J$, J being an invisible massless particle. See Fig. 6 for the regions excluded in the (μ, M_2) plane.
- 28 ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with $LL\bar{E}$, $LQ\bar{D}$, or UDD couplings at $\sqrt{s} = 189 \text{ GeV}$. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or \tilde{l} as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99i.
- 29 BARATE 01b searches for the production of charginos in the case of R prompt decays with $LL\bar{E}$, $LQ\bar{D}$, or UDD couplings at $\sqrt{s} = 189\text{--}202 \text{ GeV}$. The search is performed for indirect decays, assuming one coupling at a time to be non-zero. Updates BARATE 00h.
- 30 ABREU 00v use data from $\sqrt{s} = 183\text{--}189 \text{ GeV}$. They look for final states with two acoplanar leptons, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP and assuming a short-lived $\tilde{\chi}_1^\pm$. Limits are obtained in the plane $(m(\tilde{\tau}), m(\tilde{\chi}_1^\pm))$ for different domains of $m(\tilde{G})$, after combining these results with the search for slepton pair production in the SUGRA
- framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. The limit above is valid for all values of $m_{\tilde{G}}$.
- 31 CHO 00b studied constraints on the MSSM spectrum from precision EW observables. Global fits favour charginos with masses at the lower bounds allowed by direct searches. Allowing for variations of the squark and slepton masses does not improve the fits.
- 32 ABBIENDI 99t searches for the production of neutralinos in the case of R -parity violation with $LL\bar{E}$, $LQ\bar{D}$, or UDD couplings using data from $\sqrt{s} = 183 \text{ GeV}$. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the UDD couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the chargino mass are obtained for non-zero $LL\bar{E}$ couplings $> 10^{-5}$ and assuming decays via a W^* .
- 33 MALTONI 99b studied the effect of light chargino-neutralino to the electroweak precision data with a particular focus on the case where they are nearly degenerate ($\Delta m_{\pm} \sim 1 \text{ GeV}$) which is difficult to exclude from direct collider searches. The quoted limit is for higgsino-like case while the bound improves to 56 GeV for wino-like case. The values of the limits presented here are obtained in an update to MALTONI 99b, as described in MALTONI 00.
- 34 ABE 98t searches for trilepton final states ($l = e, \mu$). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by $1.1 < \tan\beta < 8$, $-1000 < \mu(\text{GeV}) < -200$, and $m_{\tilde{g}}/m_{\tilde{g}} = 1\text{--}2$. In this region $m_{\tilde{\chi}_1^\pm} \sim m_{\tilde{\chi}_2^0}$ and $m_{\tilde{\chi}_1^\pm} \sim 2m_{\tilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\bar{p} \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_2^0) \times \text{B}(3\ell)$. Limits range from 0.8 pb ($m_{\tilde{\chi}_1^\pm} = 50 \text{ GeV}$) to 0.23 pb ($m_{\tilde{\chi}_1^\pm} = 100 \text{ GeV}$) at 95%CL. The gaugino mass unification hypothesis and the assumed mass relation between squarks and gluinos define the value of the leptonic branching ratios. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{g}} > m_{\tilde{g}}$, $\tan\beta = 2$, and $\mu = -600 \text{ GeV}$. Mass limits for different values of $\tan\beta$ and μ are given in Fig. 2.
- 35 ACKERSTAFF 98k looked for dilepton+ $E_{T\cancel{e}}$ final states at $\sqrt{s} = 130\text{--}172 \text{ GeV}$. Limits on $\sigma(e^+e^- \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_1^0) \times \text{B}^2(\ell)$, with $\text{B}(\ell) = \text{B}(\chi^+ \rightarrow \ell^+ \nu_\ell \chi_1^0)$ ($\text{B}(\ell) = \text{B}(\chi^+ \rightarrow \ell^+ \tilde{\nu}_\ell)$), are given in Fig. 16 (Fig. 17).
- 36 ACKERSTAFF 98l limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The dependence on the trilinear-coupling parameter A is studied, and found negligible. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97h) and for all values of m_0 where the condition $\Delta m_{\tilde{\nu}} > 2.0 \text{ GeV}$ is satisfied. $\Delta m_{\tilde{\nu}} > 10 \text{ GeV}$ if $\tilde{\chi}^\pm \rightarrow \ell \tilde{\nu}_\ell$. The limit improves to 84.5 GeV for $m_0 = 1 \text{ TeV}$. Data taken at $\sqrt{s} = 130\text{--}172 \text{ GeV}$.
- 37 ACKERSTAFF 98v excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\tilde{\chi}_1^\pm, \tilde{\chi}_2^0 \rightarrow q\bar{q}\tilde{g}$ from total hadronic cross sections at $\sqrt{s} = 130\text{--}172 \text{ GeV}$. See paper for the case of nonuniversal gaugino mass.
- 38 CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large $\tan\beta$.
- 39 KALINOWSKI 97 studies the constraints on the chargino-neutralino parameter space from limits on $\Gamma(W \rightarrow \tilde{\chi}_1^\pm \tilde{\chi}_1^0)$ achievable at LEP2. This is relevant when $\tilde{\chi}_1^\pm$ is "invisible", i.e., if $\tilde{\chi}_1^\pm$ dominantly decays into $\tilde{\nu}_\ell \ell^\pm$ with little energy for the lepton. Small otherwise allowed regions could be excluded.
- 40 ABE 96k looked for trilepton events from chargino-neutralino production. The bound on $m_{\tilde{\chi}_1^\pm}$ can reach up to 47 GeV for specific choices of parameters. The limits on the combined production cross section times 3-lepton branching ratios range between 1.4 and 0.4 pb , for $45 < m_{\tilde{\chi}_1^\pm}(\text{GeV}) < 100$. See the paper for more details on the parameter dependence of the results.

Long-lived $\tilde{\chi}^\pm$ (Chargino) MASS LIMITS

Limits on charginos which leave the detector before decaying.

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT

> 28.2	95	ADACHI	90C TOPZ	

1 ABAZOV 09M searched in 1.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with direct production of a pair of charged massive stable particles identified by their TOF. The number of the observed events is consistent with the predicted background. The data are used to constrain the production cross section as a function of the $\tilde{\chi}_1^\pm$ mass, see their Fig. 2. The quoted limit improves to 206 GeV for gaugino-like charginos.

2 ABBIENDI 03L used e^+e^- data at $\sqrt{s} = 130\text{--}209 \text{ GeV}$ to select events with two high momentum tracks with anomalous dE/dx . The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than 10^{-6} s . Supersedes the results from ACKERSTAFF 98p.

3 ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from $\sqrt{s} = 130$ to 189 GeV . These limits include and update the results of ABREU 98p.

4 BARATE 97k uses e^+e^- data collected at $\sqrt{s} = 130\text{--}172 \text{ GeV}$. Limit valid for $\tan\beta = \sqrt{2}$ and $m_{\tilde{\nu}_\tau} > 100 \text{ GeV}$. The limit improves to 86 GeV for $m_{\tilde{\nu}_\tau} > 250 \text{ GeV}$.

$\tilde{\nu}$ (Sneutrino) MASS LIMIT

The limits may depend on the number, $M(\tilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\tilde{\nu}_L$ (not $\tilde{\nu}_R$) is assumed to exist. It is possible that $\tilde{\nu}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the fit of the final results obtained by the LEP Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{\text{inv.}} < 2.0$ MeV, LEP-SLC 06): $m_{\tilde{\nu}} > 43.7$ GeV ($N(\tilde{\nu})=1$) and $m_{\tilde{\nu}} > 44.7$ GeV ($N(\tilde{\nu})=3$).

1 ABDALLAH 03M uses data from $\sqrt{s} = 192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

2 HEISTER 02N derives a bound on $m_{\tilde{\nu}_e}$ by exploiting the mass relation between the $\tilde{\nu}_e$ and \tilde{e} , based on the assumption of universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 and the search described in the e section. In the MSUGRA framework with radiative electroweak symmetry breaking, the limit improves to $m_{\tilde{\nu}_e} > 130$ GeV, assuming a trilinear coupling $A_0=0$ at the GUT scale. See Figs. 5 and 7 for the dependence of the limits on $\tan\beta$.

3 ADRIANI 93M limit from $\Delta\Gamma(Z)(\text{invisible}) < 16.2$ MeV.

4 DECAMP 92 limit is from $\Gamma(\text{invisible})/\Gamma(\ell\ell) = 5.91 \pm 0.15$ ($N_\nu = 2.97 \pm 0.07$).

5 ALEXANDER 91F limit is for one species of $\tilde{\nu}$ and is derived from $\Gamma(\text{invisible, new})/\Gamma(\ell\ell) < 0.38$.

6 AALTONEN 09V searched in 2.3 fb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with an oppositely charged pair originating from the R production of a sneutrino decaying to dimuons. A limit is derived on the cross section times branching ratio, B , of $\tilde{\nu} \rightarrow \mu\mu$ for several values of the coupling λ' , see their Fig. 3. For $\lambda'^2 B = 0.01$, the range 100 GeV $\leq m_{\tilde{\nu}} \leq 810$ GeV is excluded.

7 ABAZOV 08Q searched in 1.04 fb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with R where a sneutrino is produced by $LQ\bar{D}$ couplings and decays via $L\bar{L}\bar{E}$ couplings, focusing on $\tilde{\nu}_\tau$, hence on the λ'_{311} and λ_{312} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and displayed in their Fig. 2. Exclusion regions are determined for the $\tilde{\nu}_\tau$ mass as a function of both couplings, see their Fig. 3. As an indication, for $\tilde{\nu}_\tau$ masses of 100 GeV and $\lambda_{312} = 0.01$, values of $\lambda'_{311} \geq 1.6 \times 10^{-3}$ are excluded at the 95% C.L.

8 SCHAEEL 07A searches for the s - or t -channel exchange of sneutrinos in the case of R with $L\bar{L}\bar{E}$ couplings by studying di-lepton production at $\sqrt{s} = 189$ –209 GeV. Limits are obtained on the couplings as a function of the $\tilde{\nu}$ mass, see their Figs. 22–24. The results of this analysis are combined with BARATE 00I.

9 ABAZOV 06I looked in 380 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 2 muons and 2 jets for s -channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via R couplings $LQ\bar{D}$. The data are in agreement with the SM expectation. They set limits on resonant slepton production and derive exclusion contours on λ'_{211} in the mass plane of $\tilde{\ell}$ versus $\tilde{\chi}_1^0$ assuming a MSUGRA model with $\tan\beta = 5$, $\mu < 0$ and $A_0 = 0$, see their Fig. 3. For $\lambda'_{211} \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABAZOV 02H.

10 ABDALLAH 06C searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+ \ell^- (\gamma)$ final states ($\ell = e, \mu, \tau$) from 675 pb $^{-1}$ of $e^+ e^-$ data at $\sqrt{s} = 130$ –207 GeV. Limits are set on the s - and t -channel exchange of sneutrinos in the presence of R with $\lambda L\bar{L}\bar{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the $(\lambda, m_{\tilde{\nu}})$ plane are given in Fig. 16. These limits include and update the results of ABREU 00S.

11 ABULENCIA 06M searched in 344 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with R where a sneutrino is produced by $LQ\bar{D}$ couplings and decays via $L\bar{L}\bar{E}$ couplings, focusing on $\tilde{\nu}_\tau$, hence on the λ'_{311} and λ_{312} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and exclusion regions determined for the $\tilde{\nu}_\tau$ mass as a function of both couplings, see their Fig. 3. As an indication, $\tilde{\nu}_\tau$ masses are excluded up to 300 GeV for $\lambda'_{311} \geq 0.01$ and $\lambda_{312} \geq 0.02$.

12 ABULENCIA 05A looked in ~ 200 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for dimuon and dielectron events. They may originate from the R production of a sneutrino decaying to dileptons. No significant excess rate was found compared to the background expectation. A limit is derived on the cross section times branching ratio, B , of $\tilde{\nu} \rightarrow e e, \mu\mu$ of 25 fb at high mass, see their Figure 2. Sneutrino masses are excluded at 95% CL below 680, 620, 460 GeV ($e e$ channel) and 665, 590, 450 GeV ($\mu\mu$ channel) for a λ' coupling and branching ratio such that $\lambda'^2 B = 0.01, 0.005, 0.001$, respectively.

13 ACOSTA 05R looked in 195 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for ditau events with one identified hadronic tau decay and one other tau decay. They may originate from the R production of a sneutrino decaying to $\tau\tau$. No significant excess rate was found compared to the background expectation, dominated by Drell-Yan. A limit is derived on the cross section times branching ratio, B , of $\tilde{\nu} \rightarrow \tau\tau$, see their Figure 3. Sneutrino masses below 377 GeV are excluded at 95% CL for a λ' coupling to $d\bar{d}$ and branching ratio such that $\lambda'^2 B = 0.01$.

14 ABBIENDI 04F use data from $\sqrt{s} = 189$ –209 GeV. They derive limits on sparticle masses under the assumption of R with $L\bar{L}\bar{E}$ or $LQ\bar{D}$ couplings. The results are valid for $\tan\beta = 1.5$, $\mu = -200$ GeV, and a BR for the decay given by CMSSM, assuming no sensitivity to other decays. Limits are quoted for $m_{\tilde{\chi}_1^0} = 60$ GeV and degrade for low-mass $\tilde{\chi}_1^0$. For $\tilde{\nu}_e$ the direct (indirect) limits with $L\bar{L}\bar{E}$ couplings are 89 (95) GeV and with $LQ\bar{D}$ they are 89 (88) GeV. For $\tilde{\nu}_{\mu,\tau}$ the direct (indirect) limits with $L\bar{L}\bar{E}$ couplings are 79 (81) GeV and with $LQ\bar{D}$ they are 74 (no limit) GeV. Supersedes the results of ABBIENDI 00I.

15 ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192$ –208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan\beta < 35$, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t = 174.3$ GeV (see Table 2 for other m_t values).

16 The limit improves to 114 GeV for $\mu < 0$.

17 ABDALLAH 04M use data from $\sqrt{s} = 189$ –208 GeV. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays the limit on $\tilde{\nu}_e$ decreases to 96 GeV if the constraint from the neutralino is not used and for direct decays it remains 96 GeV. For indirect decays the limit on $\tilde{\nu}_\mu$ decreases to 82 GeV if the constraint from the neutralino is not used and to 83 GeV for direct decays. For indirect decays the limit on $\tilde{\nu}_\tau$ decreases to 82 GeV if the constraint from the neutralino is not used and improves to 91 GeV for direct decays. Supersedes the results of ABREU 00U.

18 ABDALLAH 03F looked for events of the type $e^+ e^- \rightarrow \tilde{\nu} \rightarrow \tilde{\chi}_1^0 \nu, \tilde{\chi}_1^\pm \ell\bar{\ell}'$ followed by R decays of the $\tilde{\chi}_1^0$ via λ_{1j1} ($j = 2, 3$) couplings in the data at $\sqrt{s} = 183$ –208 GeV. From a scan over the SUGRA parameters, they derive upper limits on the λ_{1j1} couplings as a function of the sneutrino mass, see their Figs. 5–8.

19 ACOSTA 03E search for $e\mu, e\tau$ and $\mu\tau$ final states, and sets limits on the product of production cross-section and decay branching ratio for a $\tilde{\nu}$ in RPV models (see Fig. 3).

20 HEISTER 03G searches for the production of sneutrinos in the case of R prompt decays with $L\bar{L}\bar{E}, LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s} = 189$ –209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect $\tilde{\nu}$ decays via $U\bar{D}\bar{D}$ couplings and $\Delta m > 10$ GeV. Stronger limits are reached for $(\tilde{\nu}_e, \tilde{\nu}_{\mu,\tau})$ for $L\bar{L}\bar{E}$ direct (100,90) GeV or indirect (98,89) GeV and for $LQ\bar{D}$ direct (–79) GeV or indirect (91,78) GeV couplings. For $L\bar{L}\bar{E}$ indirect decays, use is made of the bound $m(\tilde{\chi}_1^0) > 23$ GeV from BARATE 98S. Supersedes the results from BARATE 01B.

21 ABAZOV 02H looked in 94 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV for events with at least 2 muons and 2 jets for s -channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via R couplings $LQ\bar{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the $(m_0, m_{1/2})$ plane, examples being shown in Fig. 2.

22 ACHARD 02 searches for the associated production of sneutrinos in the case of R prompt decays with $L\bar{L}\bar{E}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s} = 189$ –208 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays via $L\bar{L}\bar{E}$ couplings. Stronger limits are reached for $(\tilde{\nu}_e, \tilde{\nu}_{\mu,\tau})$ for $L\bar{L}\bar{E}$ indirect (99,78) GeV and for $U\bar{D}\bar{D}$ direct or indirect (99,70) GeV decays. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $U\bar{D}\bar{D}$ couplings and increases to 152.7 GeV for $L\bar{L}\bar{E}$ couplings.

Searches Particle Listings

Supersymmetric Particle Searches

- ²³ HEISTER 02F searched for single sneutrino production via $e\gamma \rightarrow \bar{\nu}_j \ell_k$ mediated by R $LL\bar{E}$ couplings, decaying directly or indirectly via a $\tilde{\chi}_1^0$ and assuming a single coupling to be nonzero at a time. Final states with three leptons and possible \cancel{E}_T due to neutrinos were selected in the 189–209 GeV data. Limits on the couplings λ_{1jk} as function of the sneutrino mass are shown in Figs. 10–14. The couplings λ_{232} and λ_{233} are not accessible and λ_{121} and λ_{131} are measured with better accuracy in sneutrino resonant production. For all tested couplings, except λ_{133} , the limits are significantly improved compared to the low-energy limits.
- ²⁴ ABBIENDI 00R studied the effect of s - and t -channel τ or μ sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}=130$ –189 GeV, via the R -parity violating coupling $\lambda_{1j1}L_1L_1e_j^c$ ($i=2$ or 3). The limits quoted here hold for $\lambda_{1j1} > 0.13$, and supersede the results of ABBIENDI 99. See Fig. 11 for limits on $m_{\tilde{\nu}_\tau}$ versus coupling.
- ²⁵ ABBIENDI 00R studied the effect of s -channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at $\sqrt{s}=130$ –189 GeV, in presence of the R -parity violating couplings $\lambda_{1j3}L_1L_3e_j^c$ ($i=1$ and 2), with $\lambda_{131}=\lambda_{232}$. The limits quoted here hold for $\lambda_{131} > 0.09$, and supersede the results of ABBIENDI 99. See Fig. 12 for limits on $m_{\tilde{\nu}_\tau}$ versus coupling.
- ²⁶ ABREU 00s searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+\ell^-(\gamma)$ final states ($\ell=e,\mu,\tau$) from e^+e^- collisions at $\sqrt{s}=130$ –189 GeV. Limits are set on the s - and t -channel exchange of sneutrinos in the presence of R with $\lambda LL\bar{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the $(\lambda, m_{\tilde{\nu}_\tau})$ plane are given in Fig. 5. These limits include and update the results of ABREU 99a.
- ²⁷ ACCIARRI 00P use the dilepton total cross sections and asymmetries at $\sqrt{s}=m_Z$ and $\sqrt{s}=130$ –189 GeV data to set limits on the effect of R $LL\bar{E}$ couplings giving rise to μ or τ sneutrino exchange. See their Fig. 5 for limits on the sneutrino mass versus couplings.
- ²⁸ BARATE 00I studied the effect of s -channel and t -channel τ or μ sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}=130$ –183 GeV, via the R -parity violating coupling $\lambda_{1j1}L_1L_1e_j^c$ ($i=2$ or 3). The limits quoted here hold for $\lambda_{1j1} > 0.1$. See their Fig. 15 for limits as a function of the coupling.
- ²⁹ BARATE 00I studied the effect of s -channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at $\sqrt{s}=130$ –183 GeV, in presence of the R -parity violating coupling $\lambda_{1j3}L_1L_3e_j^c$ ($i=1$ and 2). The limits quoted here hold for $\sqrt{|\lambda_{131}\lambda_{232}|} > 0.2$. See their Fig. 16 for limits as a function of the coupling.
- ³⁰ ABBIENDI 99 studied the effect of t -channel electron sneutrino exchange in $e^+e^- \rightarrow \tau^+\tau^-$ at $\sqrt{s}=130$ –183 GeV, in presence of the R -parity violating couplings $\lambda_{131}L_1L_3e_1^c$. The limits quoted here hold for $\lambda_{131} > 0.6$.
- ³¹ ACCIARRI 97U studied the effect of the s -channel tau-sneutrino exchange in $e^+e^- \rightarrow e^+e^-$ at $\sqrt{s}=m_Z$ and $\sqrt{s}=130$ –172 GeV, via the R -parity violating coupling $\lambda_{131}L_1L_1e_1^c$. The limits quoted here hold for $\lambda_{131} > 0.05$. Similar limits were studied in $e^+e^- \rightarrow \mu^+\mu^-$ together with $\lambda_{232}L_2L_3e_2^c$ coupling.
- ³² CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large $\tan\beta$.
- ³³ BUSKULIC 95E looked for $Z \rightarrow \bar{\nu}\nu$, where $\bar{\nu} \rightarrow \nu\chi_1^0$ and χ_1^0 decays via R -parity violating interactions into two leptons and a neutrino.
- ³⁴ BECK 94 limit can be inferred from limit on Dirac neutrino using $\sigma(\bar{\nu}) = 4\sigma(\nu)$. Also private communication with H.V. Klapdor-Kleingrothaus.
- ³⁵ FALK 94 puts an upper bound on $m_{\tilde{\nu}_\tau}$ when $\bar{\nu}$ is LSP by requiring its relic density does not overclose the Universe.
- ³⁶ SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86.

CHARGED SLEPTONS

This section contains limits on charged scalar leptons ($\tilde{\ell}$, with $\ell=e,\mu,\tau$). Studies of width and decays of the Z boson (use is made here of $\Delta\Gamma_{\text{inv}} < 2.0$ MeV, LEP 00) conclusively rule out $m_{\tilde{\ell}_R} < 40$ GeV (41 GeV for $\tilde{\ell}_L$), independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\tilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting $\Delta m = m_{\tilde{\ell}_L} - m_{\tilde{\chi}_1^0}$. The mass and composition of $\tilde{\chi}_1^0$ may affect the slepton production rate in e^+e^- collisions through t -channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\tilde{\ell}_1 = \tilde{\ell}_R \sin\theta_\ell + \tilde{\ell}_L \cos\theta_\ell$. It is generally assumed that only $\tilde{\tau}$ may have significant mixing. The coupling to the Z vanishes for $\theta_\ell=0.82$. In the high-energy limit of e^+e^- collisions the interference between γ and Z exchange leads to a minimal cross section for $\theta_\ell=0.91$, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\tilde{\ell}_R}$ are quoted, it is understood that limits on $m_{\tilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\tilde{\chi}_1^0$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\tilde{\ell}^+\tilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of e^+e^- collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos (\tilde{G}), $m_{\tilde{G}}$ is assumed to be negligible relative to all other masses.

¹ ABBIENDI 04 search for $\tilde{e}_R \tilde{e}_R$ production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit at $\tan\beta=35$. This limit supersedes ABBIENDI 00G.

² ACHARD 04 search for $\tilde{e}_R \tilde{e}_L$ and $\tilde{e}_R \tilde{e}_R$ production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99w.

³ ABDALLAH 03M looked for acoplanar dielectron + \cancel{E} final states at $\sqrt{s}=189$ –208 GeV. The limit assumes $\mu=-200$ GeV and $\tan\beta=1.5$ in the calculation of the production cross section and $B(\tilde{e} \rightarrow e\tilde{\chi}_1^0)$. See Fig. 15 for limits in the $(m_{\tilde{e}_R}, m_{\tilde{\chi}_1^0})$ plane. These limits include and update the results of ABREU 01.

⁴ ABDALLAH 03M uses data from $\sqrt{s}=192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the LUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00w.

⁵ HEISTER 02E looked for acoplanar dielectron + \cancel{E}_T final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $\mu < -200$ GeV and $\tan\beta=2$ for the production cross section and $B(\tilde{e} \rightarrow e\tilde{\chi}_1^0)=1$. See their Fig. 4 for the dependence of the limit on Δm . These limits include and update the results of BARATE 01.

⁶ HEISTER 02N search for $\tilde{e}_R \tilde{e}_L$ and $\tilde{e}_R \tilde{e}_R$ production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 50$ and $-10 \leq \mu \leq 10$ TeV. The region of small $|\mu|$, where cascade decays are important, is covered by a search for $\tilde{\chi}_1^0 \tilde{\chi}_3^0$ in final states with leptons and possibly photons. Limits on $m_{\tilde{e}_L}$ are derived by exploiting the mass relation between the \tilde{e}_L and \tilde{e}_R , based on universal m_0 and $m_{1/2}$. When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to $m_{\tilde{e}_R} > 77(75)$ GeV and $m_{\tilde{e}_L} > 115(115)$ GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to $m_{\tilde{e}_R} > 95$ GeV and $m_{\tilde{e}_L} > 152$ GeV, assuming a trilinear coupling $A_0=0$ at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on $\tan\beta$.

⁷ ABBIENDI 04F use data from $\sqrt{s}=189$ –209 GeV. They derive limits on sparticle masses under the assumption of R with $LL\bar{E}$ or $LQ\bar{D}$ couplings. The results are valid for $\tan\beta=1.5$, $\mu=-200$ GeV, with, in addition, $\Delta m \geq 5$ GeV for indirect decays via $LQ\bar{D}$. The limit quoted applies to direct decays via $LL\bar{E}$ or $LQ\bar{D}$ couplings. For indirect decays, the limits on the \tilde{e}_R mass are respectively 99 and 92 GeV for $LL\bar{E}$ and $LQ\bar{D}$ couplings and $m_{\tilde{\chi}_1^0}=10$ GeV and degrade slightly for larger $\tilde{\chi}_1^0$ mass. Supersedes the results of ABBIENDI 00.

⁸ ABDALLAH 04M use data from $\sqrt{s}=192$ –208 GeV to derive limits on sparticle masses under the assumption of R with $LL\bar{E}$ or $U\bar{D}\bar{D}$ couplings. The results are valid for $\mu=-200$ GeV, $\tan\beta=1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $U\bar{D}\bar{D}$ decays using the neutralino constraint of 39.5 GeV for $LL\bar{E}$ and of 38.0 GeV for $U\bar{D}\bar{D}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\bar{E}$ the limit improves to 95 GeV if the constraint from the neutralino is used and to 94 GeV if it is not used. For indirect decays via $U\bar{D}\bar{D}$ couplings it remains unchanged when the neutralino constraint is not used. Supersedes the result of ABREU 00u.

⁹ HEISTER 03G searches for the production of selectrons in the case of R prompt decays with $LL\bar{E}$, $LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s}=189$ –209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $LQ\bar{D}$ couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\bar{E}$ direct ($m_{\tilde{e}_R} > 96$ GeV) and indirect decays ($m_{\tilde{e}_R} > 96$ GeV for $m(\tilde{\chi}_1^0) > 23$ GeV from BARATE 98s) and for $U\bar{D}\bar{D}$ indirect decays ($m_{\tilde{e}_R} > 94$ GeV with $\Delta m > 10$ GeV). Supersedes the results from BARATE 01b.

¹⁰ ACHARD 02 searches for the production of selectrons in the case of R prompt decays with $LL\bar{E}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s}=189$ –208 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays via $LL\bar{E}$ couplings. Stronger limits are reached for $LL\bar{E}$ indirect (79 GeV) and for $U\bar{D}\bar{D}$ direct or indirect (96 GeV) decays.

- ¹¹ BARATE 01 looked for acoplanar dielectron + \cancel{E}_T final states at 189 to 202 GeV. The limit assumes $\mu = -200$ GeV and $\tan\beta = 2$ for the production cross section and 100% branching ratio for $\tilde{e} \rightarrow e\tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm . These limits include and update the results of BARATE 99q.
- ¹² ABBIENDI 00j looked for acoplanar dielectron + \cancel{E}_T final states at $\sqrt{s} = 161$ –183 GeV. The limit assumes $\mu < -100$ GeV and $\tan\beta = 1.5$ for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}_1^0$. See their Fig. 12 for the dependence of the limit on Δm and $\tan\beta$.
- ¹³ ABREU 00u studies decays induced by R -parity violating $LL\tilde{E}$ couplings, using data from $\sqrt{s} = 189$ GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits assume a neutralino mass limit of 30 GeV, also derived in ABREU 00u. Updates ABREU 00i.
- ¹⁴ ABREU 00v use data from $\sqrt{s} = 130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as a function of $m_{\tilde{G}}$, from a scan of the GMSB parameter space, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.
- ¹⁵ BARATE 00g combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the schannel. Data collected at $\sqrt{s} = 189$ GeV.
- ¹⁶ ACCIARRI 99i establish indirect limits on $m_{\tilde{e}_R}$ from the regions excluded in the M_2 versus m_0 plane by their chargino and neutralino searches at $\sqrt{s} = 130$ –183 GeV. The situations where the $\tilde{\chi}_1^0$ is the LSP (indirect decays) and where a \tilde{e} is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct decays with $U\tilde{D}\tilde{D}$ couplings; $LL\tilde{E}$ couplings or indirect decays lead to a stronger limit.
- ¹⁷ ACCIARRI 98f looked for acoplanar dielectron + \cancel{E}_T final states at $\sqrt{s} = 130$ –172 GeV. The limit assumes $\mu = -200$ GeV, and zero efficiency for decays other than $\tilde{e}_R \rightarrow e\tilde{\chi}_1^0$. See their Fig. 6 for the dependence of the limit on Δm .
- ¹⁸ BARATE 98k looked for $e^+e^-\gamma\gamma + \cancel{E}$ final states at $\sqrt{s} = 161$ –184 GeV. The limit assumes $\mu = -200$ GeV and $\tan\beta = 2$ for the evaluation of the production cross section. See Fig. 4 for limits on the $(m_{\tilde{e}_R}, m_{\tilde{\chi}_1^0})$ plane and for the effect of cascade decays.
- ¹⁹ BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into $(e\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. See paper for dependences in $m(\tilde{q})$, $m(\tilde{\chi}_1^0)$.
- ²⁰ AID 96c used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via neutralino exchange with decays into $(e\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. See the paper for dependences on $m_{\tilde{q}}$, $m_{\tilde{\chi}_1^0}$.

¹ ABBIENDI 04 search for $\tilde{\mu}_R \tilde{\mu}_R$ production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the

limit at $\tan\beta = 35$. Under the assumption of 100% branching ratio for $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}_1^0$, the limit improves to 94.0 GeV for $\Delta m > 4$ GeV. See Fig. 11 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ at several values of the branching ratio. This limit supersedes ABBIENDI 00g.

² ACHARD 04 search for $\tilde{\mu}_R \tilde{\mu}_R$ production in acoplanar di-muon final states in the 192–209 GeV data. Limits on $m_{\tilde{\mu}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99w.

³ ABDALLAH 03M looked for acoplanar dimuon + \cancel{E} final states at $\sqrt{s} = 189$ –208 GeV. The limit assumes $B(\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0) = 100\%$. See Fig. 16 for limits on the $(m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0})$ plane. These limits include and update the results of ABREU 01.

⁴ ABDALLAH 03M uses data from $\sqrt{s} = 192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00w.

⁵ HEISTER 02E looked for acoplanar dimuon + \cancel{E}_T final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $B(\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0) = 1$. See their Fig. 4

for the dependence of the limit on Δm . These limits include and update the results of BARATE 01.

⁶ ABAZOV 06i looked in 380 pb⁻¹ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via \tilde{R} couplings $LQ\tilde{D}$. The data are in agreement with the SM expectation. They set limits on resonant slepton production and derive exclusion contours on λ_{211}' in the mass plane of \tilde{e} versus $\tilde{\chi}_1^0$ assuming a MSUGRA model with $\tan\beta = 5$, $\mu < 0$ and $A_0 = 0$, see their Fig. 3. For $\lambda_{211}' \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABÁZOV 02h.

⁷ ABBIENDI 04F use data from $\sqrt{s} = 189$ –209 GeV. They derive limits on sparticle masses under the assumption of \tilde{R} with $LL\tilde{E}$ or $LQ\tilde{D}$ couplings. The results are valid for $\tan\beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\tilde{D}$. The limit quoted applies to direct decays with $LL\tilde{E}$ couplings and improves to 75 GeV for $LQ\tilde{D}$ couplings. The limits on the $\tilde{\mu}_R$ mass for indirect decays are respectively 94 and 87 GeV for $LL\tilde{E}$ and $LQ\tilde{D}$ couplings and $m_{\tilde{\chi}_1^0} = 10$ GeV. Supersedes the results of ABBIENDI 00.

⁸ ABDALLAH 04M use data from $\sqrt{s} = 192$ –208 GeV to derive limits on sparticle masses under the assumption of \tilde{R} with $LL\tilde{E}$ or $U\tilde{D}\tilde{D}$ couplings. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV for the given decay. The limit quoted is for indirect $U\tilde{D}\tilde{D}$ decays using the neutralino constraint of 39.5 GeV for $LL\tilde{E}$ and of 38.0 GeV for $U\tilde{D}\tilde{D}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\tilde{E}$ the limit improves to 90 GeV if the constraint from the neutralino is used and remains at 87 GeV if it is not used. For indirect decays via $U\tilde{D}\tilde{D}$ couplings it degrades to 85 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 00u.

⁹ HEISTER 03G searches for the production of smuons in the case of \tilde{R} prompt decays with $LL\tilde{E}$, $LQ\tilde{D}$ or $U\tilde{D}\tilde{D}$ couplings at $\sqrt{s} = 189$ –209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by \tilde{R} $LQ\tilde{D}$ couplings and improves to 90 GeV for indirect decays (for $\Delta m > 10$ GeV). Limits are also given for $LL\tilde{E}$ direct ($m_{\tilde{\mu}_R} > 87$ GeV) and indirect decays ($m_{\tilde{\mu}_R} > 96$ GeV for $m(\tilde{\chi}_1^0) > 23$ GeV from BARATE 98s) and for $U\tilde{D}\tilde{D}$ indirect decays ($m_{\tilde{\mu}_R} > 85$ GeV for $\Delta m > 10$ GeV). Supersedes the results from BARATE 01b.

¹⁰ ABÁZOV 02H looked in 94 pb⁻¹ of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via \tilde{R} couplings $LQ\tilde{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the $(m_0, m_{1/2})$ plane, examples being shown in Fig. 2.

¹¹ ACHARD 02 searches for the production of smuons in the case of \tilde{R} prompt decays with $LL\tilde{E}$ or $U\tilde{D}\tilde{D}$ couplings at $\sqrt{s} = 189$ –208 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be nonzero. The limit holds for direct decays via $LL\tilde{E}$ couplings. Stronger limits are reached for $LL\tilde{E}$ indirect (87 GeV) and for $U\tilde{D}\tilde{D}$ direct or indirect (86 GeV) decays.

¹² BARATE 01 looked for acoplanar dimuon + \cancel{E}_T final states at 189 to 202 GeV. The limit assumes 100% branching ratio for $\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm . These limits include and update the results of BARATE 99q.

¹³ ABBIENDI 00j looked for acoplanar dimuon + \cancel{E}_T final states at $\sqrt{s} = 161$ –183 GeV. The limit assumes $B(\tilde{\mu} \rightarrow \mu\tilde{\chi}_1^0) = 1$. Using decay branching ratios derived from the MSSM, a lower limit of 65 GeV is obtained for $\mu < -100$ GeV and $\tan\beta = 1.5$. See their Figs. 10 and 13 for the dependence of the limit on the branching ratio and on Δm .

¹⁴ ABREU 00v use data from $\sqrt{s} = 130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

¹⁵ BARATE 98k looked for $\mu^+\mu^-\gamma\gamma + \cancel{E}$ final states at $\sqrt{s} = 161$ –184 GeV. See Fig. 4 for limits on the $(m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0})$ plane and for the effect of cascade decays.

¹ ABBIENDI 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$ and for the limit

at $\tan\beta = 35$. Under the assumption of 100% branching ratio for $\tilde{\tau}_R \rightarrow \tau\tilde{\chi}_1^0$, the limit improves to 89.8 GeV for $\Delta m > 8$ GeV. See Fig. 12 for the dependence of the limits on

Searches Particle Listings

Supersymmetric Particle Searches

- $m_{\tilde{\chi}_1^0}$ at several values of the branching ratio and for their dependence on $\theta_{\tilde{\tau}}$. This limit supersedes ABBIENDI 00g.
- ² ACHARD 04 search for $\tilde{\tau}\tilde{\tau}$ production in acoplanar di-tau final states in the 192–209 GeV data. Limits on $m_{\tilde{\tau}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$.
- ³ ABDALLAH 03M looked for acoplanar ditau + \cancel{E} final states at $\sqrt{s} = 130$ –208 GeV. A dedicated search was made for low mass $\tilde{\tau}$ s decoupling from the Z^0 . The limit assumes $B(\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0) = 100\%$. See Fig. 20 for limits on the $(m_{\tilde{\tau}_R}, m_{\tilde{\chi}_1^0})$ plane and as function of the $\tilde{\chi}_1^0$ mass and of the branching ratio. The limit in the low-mass region improves to 29.6 and 31.1 GeV for $\tilde{\tau}_R$ and $\tilde{\tau}_L$, respectively, at $\Delta m > m_{\tilde{\tau}}$. The limit in the high-mass region improves to 84.7 GeV for $\tilde{\tau}_R$ and $\Delta m > 15$ GeV. These limits include and update the results of ABREU 01.
- ⁴ HEISTER 02E looked for acoplanar ditau + \cancel{E}_T final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $B(\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0) = 1$. See their Fig. 4 for the dependence of the limit on Δm . These limits include and update the results of BARATE 01.
- ⁵ ABBIENDI 06B use 600 pb⁻¹ of data from $\sqrt{s} = 189$ –209 GeV. They look for events from pair-produced staus in a GMSB scenario with $\tilde{\tau}$ NLSP including prompt $\tilde{\tau}$ decays to ditau + \cancel{E} final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of $m(\tilde{\tau})$ and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space.
- ⁶ ABBIENDI 04F use data from $\sqrt{s} = 189$ –209 GeV. They derive limits on sparticle masses under the assumption of \tilde{R} with $LL\tilde{E}$ or $LQ\tilde{D}$ couplings. The results are valid for $\tan\beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\tilde{D}$. The limit quoted applies to direct decays with $LL\tilde{E}$ couplings and improves to 75 GeV for $LQ\tilde{D}$ couplings. The limit on the $\tilde{\tau}_R$ mass for indirect decays is 92 GeV for $LL\tilde{E}$ couplings at $m_{\tilde{\chi}_1^0} = 10$ GeV and no exclusion is obtained for $LQ\tilde{D}$ couplings. Supersedes the results of ABBIENDI 00.
- ⁷ ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192$ –208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan\beta < 35$, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_{\tilde{t}} = 174.3$ GeV (see Table 2 for other $m_{\tilde{t}}$ values).
- ⁸ The limit improves to 75 GeV for $\mu < 0$.
- ⁹ ABDALLAH 04M use data from $\sqrt{s} = 192$ –208 GeV to derive limits on sparticle masses under the assumption of \tilde{R} with $LL\tilde{E}$ couplings. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays via $LL\tilde{E}$ the limit decreases to 86 GeV if the constraint from the neutralino is not used. Supersedes the result of ABREU 00u.
- ¹⁰ ABDALLAH 03D use data from $\sqrt{s} = 130$ –208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of $m(\tilde{G})$, after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays. The above limit is reached for the stau decaying promptly, $m(\tilde{G}) < 6$ eV, and is computed for stau mixing yielding the minimal cross section. Stronger limits are obtained for longer lifetimes. See their Fig. 9. Supersedes the results of ABREU 01g.
- ¹¹ HEISTER 03g searches for the production of stau in the case of \tilde{R} prompt decays with $LL\tilde{E}$, $LQ\tilde{D}$ or UDD couplings at $\sqrt{s} = 189$ –209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by \tilde{R} UDD couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\tilde{E}$ direct ($m_{\tilde{\tau}_R} > 87$ GeV) and indirect decays ($m_{\tilde{\tau}_R} > 95$ GeV for $m(\tilde{\chi}_1^0) > 23$ GeV from BARATE 98s) and for $LQ\tilde{D}$ indirect decays ($m_{\tilde{\tau}_R} > 76$ GeV). Supersedes the results from BARATE 01b.
- ¹² ACHARD 02 searches for the production of staus in the case of \tilde{R} prompt decays with $LL\tilde{E}$ or UDD couplings at $\sqrt{s} = 189$ –208 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays via $LL\tilde{E}$ couplings. Stronger limits are reached for $LL\tilde{E}$ indirect (86 GeV) and for UDD direct or indirect (75 GeV) decays.
- ¹³ HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\tilde{\chi}_1^0$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\cancel{E}$ or a single γ not pointing to the interaction vertex. For the $\tilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\cancel{E}$, including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limit remains valid whichever is the NLSP. The absolute mass bound on the $\tilde{\chi}_1^0$ for any lifetime includes indirect limits from the slepton search HEISTER 02E performed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. In the co-NLSP scenario, limits $m_{\tilde{\tau}_R} > 83$ GeV (neglecting t -channel exchange) and $m_{\tilde{\mu}_R} > 88$ GeV are obtained independent of the lifetime. Supersedes the results from BARATE 00g.
- ¹⁴ BARATE 01 looked for acoplanar ditau + \cancel{E}_T final states at 189 to 202 GeV. A slight excess (with 1.2% probability) of events is observed relative to the expected SM background. The limit assumes 100% branching ratio for $\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm . These limits include and update the results of BARATE 99a.
- ¹⁵ ABBIENDI 00j looked for acoplanar ditau + \cancel{E}_T final states at $\sqrt{s} = 161$ –183 GeV. The limit assumes $B(\tilde{\tau} \rightarrow \tau\tilde{\chi}_1^0) = 1$. Using decay branching ratios derived from the MSSM, a lower limit of 60 GeV at $\Delta m > 9$ GeV is obtained for $\mu < -100$ GeV and $\tan\beta = 1.5$. See their Figs. 11 and 14 for the dependence of the limit on the branching ratio and on Δm .
- ¹⁶ ABREU 00v use data from $\sqrt{s} = 130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. The above limit assumes the degeneracy of stau and smuon. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

- ¹⁷ ABREU 00v use data from $\sqrt{s} = 130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. The above limit is reached for the stau mixing yielding the minimal cross section and decaying promptly. Stronger limits are obtained for longer lifetimes or for $\tilde{\tau}_R$; see their Fig. 11. For $10 \leq m_{\tilde{G}} \leq 310$ eV, the whole range $2 \leq m_{\tilde{\tau}_1} \leq 80$ GeV is excluded. Supersedes the results of ABREU 99c and ABREU 99f.
- ¹⁸ BARATE 98k looked for $\tau^+\tau^-\gamma\gamma + \cancel{E}$ final states at $\sqrt{s} = 161$ –184 GeV. See Fig. 4 for limits on the $(m_{\tilde{\tau}_R}, m_{\tilde{\chi}_1^0})$ plane and for the effect of cascade decays.

Degenerate Charged Sleptons

Unless stated otherwise in the comment lines or in the footnotes, the following limits assume 3 families of degenerate charged sleptons.

- ¹ BARATE 01 looked for acoplanar dilepton + \cancel{E}_T and single electron (for $\tilde{\ell}_R \tilde{\ell}_L$) final states at 189 to 202 GeV. The limit assumes $\mu = -200$ GeV and $\tan\beta = 2$ for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{\ell} \rightarrow \ell \tilde{\chi}_1^0$. The slepton masses are determined from the GUT relations without stau mixing. See their Fig. 1 for the dependence of the limit on Δm .
- ² ABBIENDI 06B use 600 pb⁻¹ of data from $\sqrt{s} = 189$ –209 GeV. They look for events from pair-produced staus in a GMSB scenario with $\tilde{\ell}$ co-NLSP including prompt $\tilde{\ell}$ decays to dileptons + \cancel{E} final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of $m(\tilde{\ell})$ and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space. The highest mass limit is reached for $\tilde{\mu}_R$, from which the quoted mass limit is derived by subtracting $m_{\tilde{\tau}}$.
- ³ ABDALLAH 03D use data from $\sqrt{s} = 130$ –208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of $m(\tilde{G})$, after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays. The above limit is reached for prompt decays and assumes the degeneracy of the sleptons. For limits at different $m(\tilde{G})$, see their Fig. 9. Supersedes the results of ABREU 01g.
- ⁴ ACHARD 02 searches for the production of sparticles in the case of \tilde{R} prompt decays with $LL\tilde{E}$ or UDD couplings at $\sqrt{s} = 189$ –208 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale and no mixing in the slepton sector, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $LL\tilde{E}$ couplings and increases to 88.7 GeV for UDD couplings. For L3 limits from $LQ\tilde{D}$ couplings, see ACCIARRI 01.
- ⁵ ABBIENDI 01 looked for final states with $\gamma\gamma\cancel{E}$, $\ell\ell\cancel{E}$, with possibly additional activity and four leptons + \cancel{E} to search for prompt decays of $\tilde{\chi}_1^0$ or $\tilde{\ell}_1$ in GMSB. They derive limits in the plane $(m_{\tilde{\chi}_1^0}, m_{\tilde{\tau}_1})$, see Fig. 6, allowing either the $\tilde{\chi}_1^0$ or a $\tilde{\ell}_1$ to be the NLSP. Two scenarios are considered: $\tan\beta=2$ with the 3 sleptons degenerate in mass and $\tan\beta=20$ where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s} = 189$ GeV. For $\tan\beta=20$, the obtained limits are $m_{\tilde{\tau}_1} > 69$ GeV and $m_{\tilde{\mu}_1, \tilde{\nu}_1} > 88$ GeV.
- ⁶ ABREU 01 looked for acoplanar dilepton + diphoton + \cancel{E} final states from $\tilde{\ell}$ cascade decays at $\sqrt{s} = 130$ –189 GeV. See Fig. 9 for limits on the (μ, M_2) plane for $m_{\tilde{\ell}} = 80$ GeV, $\tan\beta = 1.0$, and assuming degeneracy of $\tilde{\mu}$ and \tilde{e} .
- ⁷ ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from \tilde{R} prompt decays with $LL\tilde{E}$, $LQ\tilde{D}$, or UDD couplings at $\sqrt{s} = 189$ GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be non-zero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99i.
- ⁸ ABREU 00v use data from $\sqrt{s} = 130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.
- ⁹ The above limit assumes the degeneracy of stau and smuon.

Long-lived $\tilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. Selection limits from e^+e^- collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

Searches Particle Listings Supersymmetric Particle Searches

- ¹ ABBIENDI 03L used e^+e^- data at $\sqrt{s}=130\text{--}209$ GeV to select events with two high momentum tracks with anomalous dE/dx . The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for $\tilde{\mu}_L$ and $\tilde{\tau}_L$. The bounds are valid for colorless spin 0 particles with lifetimes longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.
- ² ABREU 00Q searches for the production of pairs of heavy, charged stable particles in e^+e^- annihilation at $\sqrt{s}=130\text{--}189$ GeV. The upper bound improves to 88 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. These limits include and update the results of ABREU 98P.
- ³ ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at $\sqrt{s}=130\text{--}183$ GeV. The upper bound improves to 82.2 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$.
- ⁴ The BARATE 98K mass limit improves to 82 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. Data collected at $\sqrt{s}=161\text{--}184$ GeV.

\tilde{q} (Squark) MASS LIMIT

For $m_{\tilde{q}} > 60\text{--}70$ GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from e^+e^- collisions depend on the mixing angle of the lightest mass eigenstate $\tilde{q}_1 = q_R \sin\theta_q + \tilde{q}_L \cos\theta_q$. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ decays if $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}_1^0} \gtrsim 5$ GeV. For smaller values of Δm , current constraints on the invisible width of the Z ($\Delta\Gamma_{\text{inv}} < 2.0$ MeV, LEP 00) exclude $m_{\tilde{u}_{L,R}} < 44$ GeV, $m_{\tilde{d}_R} < 33$ GeV, $m_{\tilde{d}_L} < 44$ GeV and, assuming all squarks degenerate, $m_{\tilde{q}} < 45$ GeV.

Limits made obsolete by the most recent analyses of e^+e^- , $p\bar{p}$, and ep collisions can be found in previous Editions of this Review.

- ¹ AALTONEN 09s searched in 2 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 jets and E_T . No evidence for a signal is observed. A limit is derived for a MSUGRA scenario in the $m_{\tilde{q}}$ versus $m_{\tilde{g}}$ plane, see their Fig. 2. For $m_{\tilde{g}} < 340$ GeV the bound increases to 400 GeV.
- ² ABAZOV 08G looked in 2.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with acoplanar jets or multijets with large E_T . No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific MSUGRA parameter values, see Figure 3. Similar results would be obtained for a large class of parameter sets. Supersedes the results of ABAZOV 06c.
- ³ ACHARD 04 search for the production of $\tilde{q}\tilde{q}$ of the first two generations in acoplanar di-jet final states in the 192–209 GeV data. Degeneracy of the squark masses is assumed either for both left and right squarks or for right squarks only, as well as $B(\tilde{q} \rightarrow q\tilde{\chi}_1^0) = 1$. See Fig. 7 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99v.
- ⁴ ABBOTT 01D looked in $\sim 108 \text{ pb}^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with e, μ, μ , or $e\mu$ accompanied by at least 2 jets and E_T . Excluded regions are obtained in the MSUGRA framework from a scan over the parameters $0 < m_0 < 300$ GeV, $10 < m_{1/2} < 110$ GeV, and $1.2 < \tan\beta < 10$.
- ⁵ BARATE 01 looked for acoplanar dijets + E_T final states at 189 to 202 GeV. The limit assumes $B(\tilde{q} \rightarrow q\tilde{\chi}_1^0) = 1$, with $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}_1^0}$. It applies to $\tan\beta=4$, $\mu=-400$ GeV. See their Fig. 2 for the exclusion in the $(m_{\tilde{q}}, m_{\tilde{g}})$ plane. These limits include and update the results of BARATE 99q.
- ⁶ ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing E_T . The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for fixed $\tan\beta=4.0$, $\mu=-400$ GeV, and $m_{H^\pm}=500$ GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario.
- ⁷ ABAZOV 09s looked in 0.96 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 jets, a tau decaying hadronically and E_T from the production $\tilde{q}_L\tilde{q}_R$, with the taus originating from the decay of a $\tilde{\chi}_2^0$ or $\tilde{\chi}_1^\pm$. The results were combined with ABAZOV 08G which searched for events with jets and E_T without requiring tau. No evidence for an excess over the SM expectation is observed. The excluded region is shown for an mSUGRA model in a plane of $m_{1/2}$ versus m_0 in the “tau corridor,” see their Figs. 5 and 6. The largest excluded squark mass in the corridor is 340 GeV for the tau analysis only and 410 GeV for the combined analysis.
- ⁸ SCHAEEL 07A studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating couplings $LQ\bar{D}$ at $\sqrt{s}=189\text{--}209$ GeV. The limit here refers to the case $j=1, 2$ and holds for λ'_{1jk} of electromagnetic strength. The results of this analysis are combined with BARATE 00i.
- ⁹ CHEKANOV 05A search for lepton flavor violating processes $e^\pm p \rightarrow \ell X$, where $\ell = \mu$ or τ with high p_T , in 130 pb^{-1} at 300 and 318 GeV. Such final states may originate from LQD couplings with simultaneously non-zero λ'_{1jk} and λ'_{ijk} ($i=2$ or 3). The quoted mass bounds hold for a u -type squark, assume a λ' of electromagnetic strength and contributions from only direct squark decays. For d -type squarks the bounds are strengthened to 278 and 275 GeV for the μ and τ final states, respectively. Supersedes the results of CHEKANOV 02.
- ¹⁰ AKTAS 04D looked in 77.8 pb^{-1} of $e^\pm p$ collisions at $\sqrt{s}=319$ GeV for resonant production of \tilde{q} by R-parity violating $LQ\bar{D}$ couplings assuming that one of the λ' couplings dominates over all others. They consider final states with or without leptons and/or jets and/or p_T resulting from direct and indirect decays. They combine the channels to derive limits on λ'_{1j1} and λ'_{11k} as a function of the squark mass, see their Figs. 8 and 9, from a scan over the parameters $70 < M_2 < 350$ GeV, $-300 < \mu < 300$ GeV,

Searches Particle Listings

Supersymmetric Particle Searches

- $\tan\beta = 6$, for a fixed mass of 90 GeV for degenerate sleptons and an LSP mass > 30 GeV. The quoted limits refer to $\lambda' = 0.3$, with $U=u,c,t$ and $D=d,s,b$. Supersedes the results of ADLOFF 01b.
- 11 ADLOFF 03 looked for the s-channel production of squarks via R $LQ\bar{D}$ couplings in 117.2 pb^{-1} of e^+p data at $\sqrt{s} = 301$ and 319 GeV and of e^-p data at $\sqrt{s} = 319$ GeV. The comparison of the data with the SM differential cross section allows limits to be set on couplings for processes mediated through contact interactions. They obtain lower bounds on the value of $m_{\tilde{q}}/\lambda'$ of 710 GeV for the process $e^+\bar{\nu} \rightarrow \tilde{d}^k$ (and charge conjugate), mediated by λ'_{11k} , and of 430 GeV for the process $e^+d \rightarrow \tilde{u}^j$ (and charge conjugate), mediated by λ'_{1j1} .
- 12 CHEKANOV 03B used 131.5 pb^{-1} of e^+p and e^-p data taken at 300 and 318 GeV to look for narrow resonances in the e or ν final states. Such final states may originate from $LQ\bar{D}$ couplings with non-zero λ'_{1j1} (leading to \tilde{u}_j) or λ'_{11k} (leading to \tilde{d}_k). See their Fig. 8 and explanations in the text for limits. The quoted mass bound assumes that only direct squark decays contribute.
- 13 HEISTER 03c searches for the production of squarks in the case of R prompt decays with $\overline{UD\bar{D}}$ direct couplings at $\sqrt{s} = 189\text{--}209$ GeV.
- 14 ABAZOV 02F looked in 77.5 pb^{-1} of $p\bar{p}$ collisions at 1.8 TeV for events with $\geq 2\mu + \geq 4$ jets, originating from associated production of squarks followed by an indirect R decay (of the $\tilde{\chi}_1^0$) via $LQ\bar{D}$ couplings of the type λ'_{2jk} where $j=1,2$ and $k=1,2,3$. Bounds are obtained in the MSUGRA scenario by a scan in the range $0 \leq M_0 \leq 400$ GeV, $60 \leq m_{1/2} \leq 120$ GeV for fixed values $A_0=0$, $\mu < 0$, and $\tan\beta=2$ or 6 . The bounds are weaker for $\tan\beta=6$. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for $\tan\beta=2$ and 6 , respectively.
- 15 ABAZOV 02g search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV, using events with one electron, ≥ 4 jets, and large \cancel{E}_T . The results are compared to a MSUGRA scenario with $\mu < 0$, $A_0=0$, and $\tan\beta=3$ and allow to exclude a region of the $(m_0, m_{1/2})$ shown in Fig. 11.
- 16 ABBIENDI 02 looked for events with an electron or neutrino and a jet in e^+e^- at 189 GeV. Squarks (or leptoquarks) could originate from a $LQ\bar{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Figs. 8–9, assuming that only direct squark decays contribute.
- 17 ABBIENDI 02b looked for events with an electron or neutrino and a jet in e^+e^- at 189–209 GeV. Squarks (or leptoquarks) could originate from a $LQ\bar{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute. The quoted limits are read off from Fig. 4. Supersedes the results of ABBIENDI 02.
- 18 ACHARD 02 searches for the production of squarks in the case of R prompt decays with $\overline{UD\bar{D}}$ couplings at $\sqrt{s}=189\text{--}208$ GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for indirect decays. Stronger limits are reached for (\bar{u}_R, \bar{d}_R) direct (80,56) GeV and (\bar{u}_L, \bar{d}_L) direct or indirect (87,86) GeV decays.
- 19 CHEKANOV 02 search for lepton flavor violating processes $e^+p \rightarrow \ell X$, where $\ell = \mu$ or τ with high p_T , in 47.7 pb^{-1} of e^+p collisions at 300 GeV. Such final states may originate from $LQ\bar{D}$ couplings with simultaneously nonzero λ'_{1jk} and λ'_{ijk} ($i=2$ or 3). The quoted mass bound assumes that only direct squark decays contribute.
- 20 BARATE 01B searches for the production of squarks in the case of R prompt decays with \overline{LLE} indirect or $\overline{UD\bar{D}}$ direct couplings at $\sqrt{s}=189\text{--}202$ GeV. The limit holds for direct decays mediated by R $\overline{UD\bar{D}}$ couplings. Limits are also given for \overline{LLE} indirect decays ($m_{\tilde{u}_R} > 90$ GeV and $m_{\tilde{d}_R} > 89$ GeV). Supersedes the results from BARATE 00b.
- 21 BREITWEG 01 searches for squark production in 47.7 pb^{-1} of e^+p collisions, mediated by R couplings $LQ\bar{D}$ and leading to final states with $\tilde{\nu}$ and ≥ 1 jet, complementing the e^+X final states of BREITWEG 00e. Limits are derived on $\lambda'\sqrt{\beta}$, where β is the branching fraction of the squarks into e^+q , as function of the squark mass, see their Fig. 15. The quoted mass limit assumes that only direct squark decays contribute.
- 22 ABBOTT 00c searched in $\sim 94 \text{ pb}^{-1}$ of $p\bar{p}$ collisions for events with $\mu\mu$ +jets, originating from associated production of leptoquarks. The results can be interpreted as limits on production of squarks followed by direct R decay via $\lambda'_{2jk}L_2Q_jd_k^c$ couplings. Bounds are obtained on the cross section for branching ratios of 1 and 1/2, see their Fig. 4. The former yields the limit on the \tilde{u}_L . The latter is combined with the bound of ABBOTT 99i from the $\mu\nu$ +jets channel and of ABBOTT 98E and ABBOTT 98j from the $\nu\nu$ +jets channel to yield the limit on \tilde{d}_R .
- 23 ACCIARRI 00P studied the effect on hadronic cross sections of t -channel down-type squark exchange via R -parity violating coupling $\lambda'_{1jk}L_1Q_jd_k^c$. The limit here refers to the case $j=1,2$, and holds for $\lambda'_{1jk}=0.3$. Data collected at $\sqrt{s}=130\text{--}189$ GeV, superseding the results of ACCIARRI 98j.
- 24 AFFOLDER 00k searched in $\sim 88 \text{ pb}^{-1}$ of $p\bar{p}$ collisions for events with 2–3 jets, at least one being b -tagged, large \cancel{E}_T and no high p_T leptons. Such $\nu\nu$ + b jets events would originate from associated production of squarks followed by direct R decay via $\lambda'_{1j3}L_1Q_jd_3^c$ couplings. Bounds are obtained on the production cross section assuming zero branching ratio to charged leptons.
- 25 BARATE 00i studied the effect on hadronic cross sections and charge asymmetries of t -channel down-type squark exchange via R -parity violating coupling $\lambda'_{1jk}L_1Q_jd_k^c$. The limit here refers to the case $j=1,2$, and holds for $\lambda'_{1jk}=0.3$. A 50 GeV limit is found for up-type squarks with $k=3$. Data collected at $\sqrt{s}=130\text{--}183$ GeV.
- 26 BREITWEG 00e searches for squark exchange in e^+p collisions, mediated by R couplings $LQ\bar{D}$ and leading to final states with an identified e^+ and ≥ 1 jet. The limit applies to up-type squarks of all generations, and assumes $B(\tilde{q} \rightarrow qe)=1$.
- 27 ABBOTT 99 searched for $\gamma\cancel{E}_T + \geq 2$ jet final states, and set limits on $\sigma(p\bar{p} \rightarrow \tilde{q}+X) \cdot B(\tilde{q} \rightarrow \gamma\cancel{E}_T X)$. The quoted limits correspond to $m_{\tilde{g}} \geq m_{\tilde{q}}$, with $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 \gamma)=1$ and $B(\tilde{\chi}_1^0 \rightarrow \tilde{G}\gamma)=1$, respectively. They improve to 31.0 GeV (360 GeV in the case of $\tilde{q}\tilde{G}$ decay) for $m_{\tilde{g}}=m_{\tilde{q}}$.
- 28 ABBOTT 99k uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via R $LQ\bar{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the $(m_0, m_{1/2})$ plane under the assumption that $A_0=0$, $\mu < 0$, $\tan\beta=2$ and any one of the couplings $\lambda'_{1jk} > 10^{-3}$ ($j=1,2$ and $k=1,2,3$) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0 , but the limit deteriorates rapidly with increasing $\tan\beta$ or $\mu > 0$.
- 29 ABBOTT 99l consider events with three or more jets and large \cancel{E}_T . Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses. See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\tilde{q}}$ and $m_{\tilde{g}}$.
- 30 ABE 99m looked in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with like sign dielectrons and two or more jets from the sequential decays $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \rightarrow e q\bar{q}'$, assuming R coupling $L_1Q_jD_k^c$, with $j=2,3$ and $k=1,2,3$. They assume five degenerate squark flavors, $B(\tilde{q} \rightarrow q\tilde{\chi}_1^0)=1$, $B(\tilde{\chi}_1^0 \rightarrow e q\bar{q}')=0.25$ for both e^+ and e^- , and $m_{\tilde{g}} \geq 200$ GeV. The limit is obtained for $m_{\tilde{\chi}_1^0} \geq m_{\tilde{q}}/2$ and improves for heavier gluinos or heavier $\tilde{\chi}_1^0$.
- 31 ABREU 99c looked for events with an electron or neutrino and a jet in e^+e^- at 183 GeV. Squarks (or leptoquarks) could originate from a $LQ\bar{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute.
- 32 ABBOTT 98E searched in $\sim 115 \text{ pb}^{-1}$ of $p\bar{p}$ collisions for events with $e\nu$ +jets, originating from associated production of squarks followed by direct R decay via $\lambda'_{1jk}L_1Q_jd_k^c$ couplings. Bounds are obtained by combining these results with the previous bound of ABBOTT 97B from the ee +jets channel and with a reinterpretation of ABACHI 96b $\nu\nu$ +jets channel.
- 33 ABE 98s looked in $\sim 110 \text{ pb}^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with $\mu\mu$ +jets originating from associated production of squarks followed by direct R decay via $\lambda'_{2jk}L_2Q_jd_k^c$ couplings. Bounds are obtained on the production cross section times the square of the branching ratio, see Fig. 2. Mass limits result from the comparison with theoretical cross sections and branching ratio equal to 1 for \tilde{u}_L and 1/2 for \tilde{d}_R .
- 34 ACKERSTAFF 98v and ACCIARRI 98j studied the interference of t -channel squark (\tilde{d}_R) exchange via R -parity violating $\lambda'_{1jk}L_1Q_jd_k^c$ coupling in $e^+e^- \rightarrow q\bar{q}$. The limit is for $\lambda'_{1jk}=0.3$. See paper for related limits on \tilde{u}_L exchange. Data collected at $\sqrt{s}=130\text{--}172$ GeV.
- 35 BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}q$ via gaugino-like neutralino exchange with decays into $(e\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. See paper for dependences in $m_{\tilde{e}}$, $m_{\tilde{\chi}_1^0}$.
- 36 DATTA 97 argues that the squark mass bound by ABACHI 95c can be weakened by 10–20 GeV if one relaxes the assumption of the universal scalar mass at the GUT-scale so that the $\tilde{\chi}_1^{\pm}, \tilde{\chi}_2^0$ in the squark cascade decays have dominant and invisible decays to $\tilde{\nu}$.
- 37 DERRICK 97 looked for lepton-number violating final states via R -parity violating couplings $\lambda'_{ijk}L_iQ_jd_k$. When $\lambda'_{11k}\lambda'_{ijk} \neq 0$, the process $e u \rightarrow \tilde{d}_k^* \rightarrow \ell_j u_j$ is possible. When $\lambda'_{1j1}\lambda'_{ijk} \neq 0$, the process $e\bar{\nu} \rightarrow \tilde{u}_j^* \rightarrow \ell_j \bar{d}_k$ is possible. 100% branching fraction $\tilde{q} \rightarrow \ell j$ is assumed. The limit quoted here corresponds to $\tilde{t} \rightarrow \tau q$ decay, with $\lambda'=0.3$. For different channels, limits are slightly better. See Table 6 in their paper.
- 38 HEWETT 97 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{q} \rightarrow q\tilde{g}$) from ALITTI 93 quoted in “Limits for Excited q (q^*) from Single Production,” ABE 96 in “SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$,” and unpublished CDF, $D\bar{0}$ bounds. The bound applies to the gluino mass of 5 GeV, and improves for lighter gluino. The analysis has gluinos in parton distribution function.
- 39 TEREKHOV 97 improved the analysis of TEREKHOV 96 by including di-jet angular distributions in the analysis.
- 40 AID 96c used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}q$ via neutralino exchange with decays into $(e\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. See the paper for dependences on $m_{\tilde{e}}$, $m_{\tilde{\chi}_1^0}$.
- 41 TEREKHOV 96 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{u} \rightarrow u\tilde{g}$) from ABE 95N quoted in “MASS LIMITS for g_A (axigluon).” The bound applies only to the case with a light gluino.
- 42 ABACHI 95c assume five degenerate squark flavors with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$, $\mu = -250$ GeV, and $m_{H^\pm}=500$ GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for $m_{\text{gluino}} > 547$ GeV.
- 43 ABE 95t looked for a cascade decay of five degenerate squarks into $\tilde{\chi}_1^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, $\tan\beta = 1.5$, and heavy gluinos, the range $50 < m_{\tilde{q}} \text{ (GeV)} < 110$ is excluded at 90% CL. See the paper for details.
- 44 ABE 92l assume five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. ABE 92l includes the effect of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, $\tan\beta = 2$. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\tilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if $B(\tilde{q} \rightarrow q\tilde{\gamma}) = 1$. Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}_1^0} \approx m_{\tilde{g}}/6$. This last relation implies that as $m_{\tilde{g}}$ increases, the mass of $\tilde{\chi}_1^0$ will eventually exceed $m_{\tilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\tilde{g}} > 410$ GeV, $m_{H^\pm}=500$ GeV.

See key on page 405

Supersymmetric Particle Searches

- ⁴⁵ ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R -parity violating models. The 100% decay $\tilde{q} \rightarrow q\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\tilde{\nu}$ or $\ell\ell\tilde{\nu}$ is assumed.
- ⁴⁶ NOJRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

Long-lived \tilde{q} (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L \cos\theta_q + \tilde{q}_R \sin\theta_q$.

The coupling to the Z^0 boson vanishes for up-type squarks when $\theta_u=0.98$, and for down type squarks when $\theta_d=1.17$.

- ¹ AALTONEN 09Z searched in 1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with direct production of a pair of charged massive stable particles identified by their TOF. No excess of events is observed over the expected background. The data are used to set a bound on the production cross section, and the result is compared with the pair production cross section of stable stops as a function of the \tilde{t} mass, see their Fig. 2.
- ² HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for hadronizing stable squarks. Combining their results on searches for charged and neutral R -hadrons with JANOT 03, a lower limit of 15.7 GeV on the mass is obtained. Combining this further with the results of searches for tracks with anomalous ionization in data from 183 to 208 GeV yields the quoted bounds.
- ³ ABREU 98P assumes that 40% of the squarks will hadronise into a charged hadron, and 60% into a neutral hadron which deposits most of its energy in hadron calorimeter. Data collected at $\sqrt{s}=130\text{--}183 \text{ GeV}$.

\tilde{b} (Sbottom) MASS LIMIT

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1 = \tilde{b}_L \cos\theta_b + \tilde{b}_R \sin\theta_b$. Coupling to the Z vanishes for $\theta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region $\lesssim 40 \text{ GeV}$ is available in the literature at this time from e^+e^- collisions. In the Listings below, we use $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0}$.

		23 ABBOTT 99F	D0	$\tilde{b} \rightarrow b\tilde{\chi}_1^0$, $m_{\tilde{\chi}_1^0} < 20 \text{ GeV}$

- ¹ AALTONEN 07E searched in 295 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for multijet events with large E_T . They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom versus $\tilde{\chi}_1^0$, see their Fig. 5.
- ² ABAZOV 06R looked in 310 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with 2 or 3 jets and large E_T with at least 1 b -tagged jet and a veto against isolated leptons.

No excess is observed relative to the SM background expectations. Limits are set on the sbottom pair production cross-section under the assumption that the only decay mode is into $b\tilde{\chi}_1^0$. Exclusion contours are derived in the plane of sbottom versus neutralino masses, shown in their Fig. 2. The observed limit is more constraining than the expected one due to a lack of events corresponding to large sbottom masses. Supersedes the results of ABBOTT 99F.

- ³ ABULENCIA 06i searched in 156 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for multijet events with large E_T . They request at least 2 b -tagged jets and no isolated leptons. They investigate the production of gluinos decaying into $\tilde{b}_1 b$ followed by $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$. Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and gluinos, see their Fig. 3.
- ⁴ ACHARD 04 search for the production of $b\tilde{b}$ in acoplanar b -tagged di-jet final states in the 192–209 GeV data. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99v.
- ⁵ JANOT 04 reanalyzes $e^+e^- \rightarrow$ hadrons total cross section data with $\sqrt{s} = 20\text{--}209 \text{ GeV}$ from PEP, PETRA, TRISTAN, SLC, and LEP and constrains the mass of \tilde{b}_1 assuming it decays quickly to hadrons.
- ⁶ ABDALLAH 03M looked for \tilde{b} pair production in events with acoplanar jets and E at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. The limit improves to 87 (98) GeV for all θ_b ($\theta_b = 0$) for $\Delta m > 10 \text{ GeV}$. See Fig. 24 and Table 11 for other choices of Δm . These limits include and update the results of ABREU, P 00D.
- ⁷ ABBIENDI 02H search for events with two acoplanar jets and p_T in the 161–209 GeV data. The limit assumes 100% branching ratio and uses the exclusion at large Δm from CDF (AFFOLDER 00D). For $\theta_b=0$, the bound improves to $> 96.9 \text{ GeV}$. See Fig. 4 and Table 6 for the more general dependence on the limits on Δm . These results supersede ABBIENDI 99M.
- ⁸ HEISTER 02K search for bottom squarks in final states with acoplanar jets with b tagging, using 183–209 GeV data. The mass bound uses the CDF results from AFFOLDER 00D. See Fig. 5 for the more general dependence of the limits on Δm . Updates BARATE 01.
- ⁹ SAVINOV 01 use data taken at $\sqrt{s}=10.52 \text{ GeV}$, below the $B\bar{B}$ threshold. They look for events with a pair of leptons with opposite charge and a fully reconstructed hadronic D or D^* decay. These could originate from production of a light-sbottom hadron followed by $\tilde{B} \rightarrow D^{(*)} \ell^- \tilde{\nu}$, in case the $\tilde{\nu}$ is the LSP, or $\tilde{B} \rightarrow D^{(*)} \pi \ell^-$, in case of R . The mass range $3.5 \leq M(\tilde{B}) \leq 4.5 \text{ GeV}$ was explored, assuming 100% branching ratio for either of the decays. In the $\tilde{\nu}$ LSP scenario, the limit holds only for $M(\tilde{\nu})$ less than about 1 GeV and for the D^* decays it is reduced to the range 3.9–4.5 GeV. For the R decay, the whole range is excluded.
- ¹⁰ AFFOLDER 00D search for final states with 2 or 3 jets and E_T , one jet with a b tag. See their Fig. 3 for the mass exclusion in the $m_{\tilde{t}}, m_{\tilde{\chi}_1^0}$ plane.
- ¹¹ AALTONEN 09R searched in 2.5 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with at least 2 b -tagged jets and E_T , originating from the decay $\tilde{g} \rightarrow b\tilde{b}$ followed by $\tilde{b} \rightarrow b\tilde{\chi}_1^0$. Both decays are assumed to have 100% branching ratio. No significant deviation from the SM prediction is observed. An upper limit on the gluino pair production cross section is calculated as a function of the gluino mass, see their Fig. 2. A limit is derived in the $m_{\tilde{g}}$ versus $m_{\tilde{g}}$ plane which improves the results of previous searches, see their Fig. 3.
- ¹² ABDALLAH 04M use data from $\sqrt{s} = 192\text{--}208 \text{ GeV}$ to derive limits on sparticle masses under the assumption of R with $U\bar{D}\bar{D}$ couplings. The results are valid for $\mu = -200 \text{ GeV}$, $\tan\beta = 1.5$, $\Delta m > 5 \text{ GeV}$ and assuming a BR of 1 for the given decay. The limit quoted is for indirect $U\bar{D}\bar{D}$ decays using the neutralino constraint of 38.0 GeV, also derived in ABDALLAH 04M, and assumes no mixing. For indirect decays it remains at 78 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 01b.
- ¹³ ABDALLAH 03C looked for events of the type $q\bar{q}R^\pm R^\pm$, $q\bar{q}R^\pm R^0$, or $q\bar{q}R^0 R^0$ in e^+e^- interactions at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. The R^\pm bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\tilde{b}), m(\tilde{g}))$ plane for $m(\tilde{g}) > 2 \text{ GeV}$ are obtained for several values of the probability for the gluino to fragment into R^\pm or R^0 , as shown in their Fig. 19. The limit improves to 94 GeV for $\theta_b=0$.
- ¹⁴ BERGER 03 studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region coming from radiative decays of $T(\text{nS})$ into sbottomonium. The constraints apply only if \tilde{b}_1 lives long enough to permit formation of the sbottomonium bound state. A small region of mass in the $m_{\tilde{b}_1} - m_{\tilde{g}}$ plane survives current experimental constraints from CLEO.
- ¹⁵ HEISTER 03G searches for the production of \tilde{b} pairs in the case of R prompt decays with $L\bar{L}E$, $LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s} = 189\text{--}209 \text{ GeV}$. The limit holds for indirect decays mediated by R $U\bar{D}\bar{D}$ couplings. It improves to 90 GeV for indirect decays mediated by R $L\bar{L}E$ couplings and to 80 GeV for indirect decays mediated by R $LQ\bar{D}$ couplings. Supersedes the results from BARATE 01b.
- ¹⁶ HEISTER 03H use their results on bounds on stable squarks, on stable gluinos and on squarks decaying to a stable gluino from the same paper to derive a mass limit on \tilde{b} , see their Fig. 13. The limit for a long-lived \tilde{b}_1 is 92 GeV.
- ¹⁷ ACHARD 02 searches for the production of squarks in the case of R prompt decays with $U\bar{D}\bar{D}$ couplings at $\sqrt{s}=189\text{--}208 \text{ GeV}$. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for indirect decays and reaches 55 GeV for direct decays.
- ¹⁸ BAEK 02 studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. It is noted that CP -violating couplings in the MSSM parameters relax the strong constraints otherwise derived from CP conservation.
- ¹⁹ BECHER 02 studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region coming from radiative B meson decays, and sets limits on the off-diagonal flavor-changing couplings $q\bar{b}\tilde{g}$ ($q=d,s$).
- ²⁰ CHEUNG 02b studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.
- ²¹ CHO 02 studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. Strong constraints are obtained for CP -conserving MSSM couplings.

Searches Particle Listings

Supersymmetric Particle Searches

²²BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m \sim 12\text{--}16$ GeV) with subsequent 2-body decay into a light sbottom ($m \sim 2\text{--}5.5$ GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R -parity- and B -violating interaction, or be long-lived. Constraints on the mass spectrum are derived from the measurements of time-averaged $B^0\text{--}\bar{B}^0$ mixing.

²³ABBOTT 99F looked for events with two jets, with or without an associated muon from b decay, and \cancel{E}_T . See Fig. 2 for the dependence of the limit on $m_{\tilde{\chi}_1^0}$. No limit for $m_{\tilde{\chi}_1^0} > 47$ GeV.

$\tilde{\tau}$ (Stop) MASS LIMIT

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\tilde{\tau}_1 = \tilde{\tau}_L \cos\theta_t + \tilde{\tau}_R \sin\theta_t$. The coupling to the Z vanishes when $\theta_t = 0.98$. In the Listings below, we use $\Delta m \equiv m_{\tilde{\tau}_1} - m_{\tilde{\chi}_1^0}$ or $\Delta m \equiv m_{\tilde{\tau}_1} - m_{\tilde{\nu}}$, depending on relevant decay mode. See also bounds in "q (Squark)

MASS LIMIT." Limits made obsolete by the most recent analyses of e^+e^- and $p\bar{p}$ collisions can be found in previous Editions of this Review.

¹ABAZOV 09o looked in 1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with two electrons or one electron and one muon and \cancel{E}_T originating from associated production $\tilde{\tau}\tilde{\tau}$, followed by the three-body decays $\tilde{\tau} \rightarrow b\ell\bar{\nu}$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{\nu}}$ versus $m_{\tilde{\tau}}$, see their Fig. 3. The largest excluded $\tilde{\tau}$ mass is 175 GeV for a $\tilde{\nu}$ mass of 45 GeV, and the largest excluded $\tilde{\nu}$ mass is 96 GeV for a $\tilde{\tau}$ mass of 140 GeV. Supersedes the results of ABAZOV 08 and ABAZOV 02c.

²ABAZOV 08z looked in 995 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with exactly 2 jets, at least one being tagged as heavy quark, and \cancel{E}_T , originating from stop pair production. Branching ratios are assumed to be 100% for $\tilde{\tau}_1 \rightarrow c\tilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{\tau}}$ versus $m_{\tilde{\chi}_1^0}$, see their Fig. 5. No limit can be obtained for $m_{\tilde{\chi}_1^0} > 70$ GeV. Supersedes the results of ABAZOV 07b.

³ABAZOV 04 looked at 108.3 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV for events with $e^+\mu^+\cancel{E}_T$ as signature for the 3- and 4-body decays of stop into $b\ell\nu\tilde{\chi}_1^0$ final states. For the $b\ell\nu$ channel they use the results from ABAZOV 02c. No significant excess is observed compared to the Standard Model expectation and limits are derived on the mass of $\tilde{\tau}_1$ for the 3- and 4-body decays in the $(m_{\tilde{\tau}}, m_{\tilde{\chi}_1^0})$ plane, see their Figure 4.

⁴ACHARD 04 search in the 192–209 GeV data for the production of $\tilde{\tau}\tilde{\tau}$ in acoplanar dijet final states and, in case of $b\ell\nu$ ($b\tau\nu$) final states, two leptons (taus). The limits for $\theta_t = 0$ improve to 95, 96 and 93 GeV, respectively. All limits assume 100% branching ratio for the respective decay modes. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. These limits supersede ACCIARRI 99v.

⁵ABDALLAH 03M looked for $\tilde{\tau}$ pair production in events with acoplanar jets and $\cancel{E} \approx \sqrt{s} = 189\text{--}208$ GeV. See Fig. 23 and Table 11 for other choices of Δm . These limits include and update the results of ABREU 00d.

⁶ACOSTA 03c searched in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV for pair production of $\tilde{\tau}$ followed by the decay $\tilde{\tau} \rightarrow b\ell\bar{\nu}$. They looked for events with two isolated leptons (e or μ), at least one jet and \cancel{E}_T . The excluded mass range is reduced for larger $m_{\tilde{\nu}}$, and no limit is set for $m_{\tilde{\nu}} > 88.4$ GeV (see Fig. 2).

⁷ABBIENDI 02h looked for events with two acoplanar jets, \cancel{p}_T , and, in the case of $b\ell\bar{\nu}$ final states, two leptons, in the 161–209 GeV data. The bound for $c\tilde{\chi}_1^0$ applies to the region where $\Delta m < m_{W+m_b}$, else the decay $\tilde{\tau}_1 \rightarrow b\tilde{\chi}_1^0 W^+$ becomes dominant. The limit for $b\ell\bar{\nu}$ assumes equal branching ratios for the three lepton flavors and for $b\tau\bar{\nu}$ 100% for this channel. For $\theta_t = 0$, the bounds improve to > 97.6 GeV ($c\tilde{\chi}_1^0$), > 96.0 GeV ($b\ell\bar{\nu}$), and > 95.5 GeV ($b\tau\bar{\nu}$). See Figs. 5–6 and Table 5 for the more general dependence of the limits on Δm . These results supersede ABBIENDI 99M.

⁸HEISTER 02k search for top squarks in final states with jets (with/without b tagging or leptons) or long-lived hadrons, using 183–209 GeV data. The absolute mass bound is obtained by varying the branching ratio of $\tilde{\tau} \rightarrow c\tilde{\chi}_1^0$ and the lepton fraction in $\tilde{\tau} \rightarrow b\tilde{\chi}_1^0 \ell\bar{\nu}$ decays. The mass bound for $\tilde{\tau} \rightarrow c\tilde{\chi}_1^0$ uses the CDF results from AFFOLDER 00d and for $\tilde{\tau} \rightarrow b\ell\bar{\nu}$ the DØ results from ABAZOV 02c. See Figs. 2–5 for the more general dependence of the limits on Δm . Updates BARATE 01 and BARATE 00p.

⁹ABAZOV 09n looked in 0.9 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with ≥ 3 jets, at least one being b -tagged, one electron or muon and \cancel{E}_T originating from associated production $\tilde{\tau}\tilde{\tau}$, with one $\tilde{\tau}$ decaying leptonically, the other hadronically. The branching ratios for $\tilde{\tau}_1 \rightarrow b\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^\pm \rightarrow \tilde{\chi}_1^0 W^\pm$ are assumed to be 100%. The separation from the dominant $t\bar{t}$ background is based on a multivariate likelihood discriminant analysis. The tested mass range is $130\text{ GeV} \leq m_{\tilde{\tau}_1} \leq 190\text{ GeV}$, $90\text{ GeV} \leq m_{\tilde{\chi}_1^\pm} \leq 150\text{ GeV}$ and $m_{\tilde{\chi}_1^0} = 50$ GeV fixed. The excluded cross section is a factor 2–13 larger than the theoretical expectation in the considered MSSM scenarios, see their Fig. 3.

¹⁰AALTONEN 08z searched in 322 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for dijet events with a lepton (e or μ) and a hadronic τ decay produced via R -parity violating couplings $LQ\bar{D}$. No heavy flavour-tagged jets are requested. No significant excess was found compared to the background expectation. Upper limits on the cross-section times the square of the branching ratio $B(\tilde{\tau}_1 \rightarrow b\tau)$ are extracted, and a limit is derived on the stop mass assuming $B(\tilde{\tau}_1 \rightarrow b\tau) = 1$, see their Fig. 2. Supersedes the results of ACOSTA 04b.

¹¹ABAZOV 08l looked at approximately 400 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with $b\bar{b}\ell\ell'\cancel{E}_T$ with $\ell\ell' = e^\pm\mu^\mp$ or $\ell\ell' = \mu^\pm\mu^\mp$, originating from associated production $\tilde{\tau}\tilde{\tau}$. Branching ratios are assumed to be 100% for both $\tilde{\chi}_1^\pm \rightarrow \ell\nu$ and $\tilde{\nu} \rightarrow \nu\tilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{\nu}}$ versus $m_{\tilde{\tau}}$, see their Fig. 3.

¹²AALTONEN 07e searched in 295 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for multijet events with large \cancel{E}_T . They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\tilde{\tau}_1 \rightarrow c\tilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of stop versus $\tilde{\chi}_1^0$, see their Fig. 4.

¹³ABAZOV 07b looked in 360 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with a pair of acoplanar heavy-flavor jets with \cancel{E}_T . No excess is observed relative to the SM background expectations. Limits are set on the production of $\tilde{\tau}_1$ under the assumption that the only decay mode is into $c\tilde{\chi}_1^0$, see their Fig. 4 for the limit in the $(m_{\tilde{\tau}_1}, m_{\tilde{\chi}_1^0})$ plane. No limit can be obtained for $m_{\tilde{\chi}_1^0} > 54$ GeV. Supersedes the results of ABAZOV 04b.

¹⁴CHEKANOV 07 search for the $LQ\bar{D}$ R -parity violating process $e^+p \rightarrow \tilde{\tau}_1$ in 65 pb^{-1} at 318 GeV. Final states may originate from $LQ\bar{D}$ couplings $\tilde{\tau} \rightarrow e^+d$ and from the R -parity conserving decay $\tilde{\tau} \rightarrow \tilde{\chi}^+b$, giving rise to $e + \text{jet}$, $e + \text{multi-jet}$, and $\nu + \text{multi-jet}$. The excluded region in an MSSM scenario is presented for λ_{131} as a function

- of the stop mass in Fig. 6. Other excluded regions in a more restricted mSUGRA model are shown in Fig. 7 and 8.
- 15 ABBIENDI 04F use data from $\sqrt{s} = 189\text{--}209$ GeV. They derive limits on the stop mass under the assumption of R with $LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings. The limit quoted applies to direct decays with $U\bar{D}\bar{D}$ couplings when the stop decouples from the Z^0 and improves to 88 GeV for $\theta_t = 0$. For $LQ\bar{D}$ couplings, the limit improves to 98 (100) GeV for λ'_{13k} or λ'_{23k} couplings and all θ_t ($\theta_t = 0$). For λ'_{33k} couplings it is 96 (98) GeV for all θ_t ($\theta_t = 0$). Supersedes the results of ABBIENDI 00.
- 16 ABDALLAH 04M use data from $\sqrt{s} = 192\text{--}208$ GeV to derive limits on sparticle masses under the assumption of R with LLE or $U\bar{D}\bar{D}$ couplings. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for decoupling of the stop from the Z^0 and indirect $U\bar{D}\bar{D}$ decays using the neutralino constraint of 39.5 GeV for LLE and of 38.0 GeV for $U\bar{D}\bar{D}$ couplings, also derived in ABDALLAH 04M. For no mixing (decoupling) and indirect decays via LLE the limit improves to 92 (87) GeV if the constraint from the neutralino is used and to 88 (81) GeV if it is not used. For indirect decays via $U\bar{D}\bar{D}$ couplings it improves to 87 GeV for no mixing and using the constraint from the neutralino, whereas it becomes 81 GeV (67) GeV for no mixing (decoupling) if the neutralino constraint is not used. Supersedes the result of ABREU 01d.
- 17 AKTAS 04B looked in 106 pb^{-1} of $e^\pm p$ collisions at $\sqrt{s} = 319$ GeV and 301 GeV for resonant production of \tilde{t}_1 by R -parity violating $LQ\bar{D}$ couplings with λ'_{131} , others being zero. They consider the decays $\tilde{t}_1 \rightarrow e^+ d$ and $\tilde{t}_1 \rightarrow W\bar{b}$ followed by $\bar{b} \rightarrow \bar{c} d$ and assume gauginos too heavy to participate in the decays. They combine the channels $j e \cancel{p}_T$, $j \mu \cancel{p}_T$, $j j \cancel{p}_T$ to derive limits in the plane $(m_{\tilde{t}_1}, \lambda'_{131})$, see their Fig. 5.
- 18 DAS 04 reanalyzes AFFOLDER 00G data and obtains constraints on $m_{\tilde{t}_1}$ as a function of $B(\tilde{t} \rightarrow b\ell\nu\chi^0) \times B(\tilde{t} \rightarrow b\bar{q}'\chi^0)$, $B(\tilde{t} \rightarrow c\chi^0)$ and m_{χ^0} . Bound weakens for larger $B(\tilde{t} \rightarrow c\chi^0)$ and m_{χ^0} .
- 19 ABDALLAH 03c looked for events of the type $q\bar{q}R^\pm R^\pm$, $q\bar{q}R^\pm R^0$ or $q\bar{q}R^0 R^0$ in e^+e^- interactions at $\sqrt{s} = 189\text{--}208$ GeV. The R^\pm bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\tilde{t}), m(\tilde{g}))$ plane for $m(\tilde{g}) > 2$ GeV are obtained for several values of the probability for the gluino to fragment into R^\pm or R^0 , as shown in their Fig. 18. The limit improves to 90 GeV for $\theta_t = 0$.
- 20 Theoretical analysis of $e^+e^- + 2$ jet final states from the RPV decay of $\tilde{t}\tilde{t}^*$ pairs produced in $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV. 95%CL limits of 220 (165) GeV are derived for $B(\tilde{t} \rightarrow e q)=1$ (0.5).
- 21 HEISTER 03G searches for the production of \tilde{t} pairs in the case of R prompt decays with LLE , $LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s} = 189\text{--}209$ GeV. The limit holds for indirect decays mediated by R $U\bar{D}\bar{D}$ couplings. It improves to 91 GeV for indirect decays mediated by R LLE couplings, to 97 GeV for direct (assuming $B(\tilde{t}_L \rightarrow q\tau) = 100\%$) and to 85 GeV for indirect decays mediated by R $LQ\bar{D}$ couplings. Supersedes the results from BARATE 01b.
- 22 HEISTER 03H use e^+e^- data from 183–208 GeV to look for the production of stop decaying into a c quark and a stable gluino hadronizing into charged or neutral R -hadrons. Combining these results with bounds on stable squarks and on a stable gluino LSP from the same paper yields the quoted limit. See their Fig. 13 for the dependence of the mass limit on the gluino mass and on θ_t .
- 23 ABAZOV 02c looked in 108.3pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with $e\mu\cancel{E}_T$, originating from associated production $\tilde{t}\tilde{t}$. Branching ratios are assumed to be 100%. The bound for the $b\ell\nu$ decay weakens for large $\tilde{\nu}$ mass (see Fig. 3), and no limit is set when $m_{\tilde{\nu}} > 85$ GeV. See Fig. 4 for the limits in case of decays to a real $\tilde{\chi}_1^\pm$, followed by $\tilde{\chi}_1^\pm \rightarrow \ell\tilde{\nu}$, as a function of $m_{\tilde{\chi}_1^\pm}$.
- 24 ACHARD 02 searches for the production of squarks in the case of R prompt decays with $U\bar{D}\bar{D}$ couplings at $\sqrt{s}=189\text{--}208$ GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for both direct and indirect decays.
- 25 AFFOLDER 01B searches for decays of the top quark into stop and LSP, in $t\bar{t}$ events. Limits on the stop mass as a function of the LSP mass and of the decay branching ratio are shown in Fig. 3. They exclude branching ratios in excess of 45% for SLP masses up to 40 GeV.
- 26 ABREU 00i searches for the production of stop in the case of R -parity violation with LLE couplings, for which only indirect decays are allowed. They investigate topologies with jets plus leptons in data from $\sqrt{s}=183$ GeV. The lower bound on the stop mass assumes a neutralino mass limit of 27 GeV, also derived in ABREU 00i.
- 27 AFFOLDER 00D search for final states with 2 or 3 jets and \cancel{E}_T , one jet with a c tag. See their Fig. 2 for the mass exclusion in the $(m_{\tilde{t}_1}, m_{\tilde{\chi}_1^0})$ plane. The maximum excluded $m_{\tilde{t}_1}$ value is 119 GeV, for $m_{\tilde{\chi}_1^0} = 40$ GeV.
- 28 AFFOLDER 00G searches for $\tilde{t}_1\tilde{t}_1^*$ production, with $\tilde{t}_1 \rightarrow b\ell\nu$, leading to topologies with ≥ 1 isolated lepton (e or μ), \cancel{E}_T , and ≥ 2 jets with ≥ 1 tagged as b quark by a secondary vertex. See Fig. 4 for the excluded mass range as a function of $m_{\tilde{\nu}}$. Cross-section limits for $\tilde{t}_1\tilde{t}_1^*$, with $\tilde{t}_1 \rightarrow b\chi_1^\pm$ ($\chi_1^\pm \rightarrow \ell^\pm\nu\chi_1^0$), are given in Fig. 2.
- 29 ABE 99M looked in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with like sign dileptons and two or more jets from the sequential decays $\tilde{q} \rightarrow q\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0 \rightarrow e q\bar{q}'$, assuming R coupling $L_1 Q_j D_k^c$, with $j=2,3$ and $k=1,2,3$. They assume $B(\tilde{t}_1 \rightarrow c\chi_1^0)=1$, $B(\tilde{\chi}_1^0 \rightarrow e q\bar{q}')=0.25$ for both e^+ and e^- , and $m_{\tilde{\chi}_1^0} \geq m_{\tilde{t}_1}/2$. The limit improves for heavier $\tilde{\chi}_1^0$.
- 30 AID 96 considers photoproduction of $\tilde{t}\tilde{t}$ pairs, with 100% R -parity violating decays of \tilde{t} to $e q$, with $q=d, s$, or b quarks.
- 31 AID 96 considers production and decay of \tilde{t} via the R -parity violating coupling $\lambda' L_1 Q_3 \bar{q}_1^c$.
- 32 CHO 96 studied the consistency among the $B^0\text{--}\bar{B}^0$ mixing, ϵ in $K^0\text{--}\bar{K}^0$ mixing, and the measurements of V_{cb} , V_{ub}/V_{cb} . For the range $25.5\text{ GeV} < m_{\tilde{t}_1} < m_Z/2$ left by

AKERS 94k for $\theta_t = 0.98$, and within the allowed range in $M_2\text{--}\mu$ parameter space from chargino, neutralino searches by ACCIARRI 95E, they found the scalar top contribution to $B^0\text{--}\bar{B}^0$ mixing and ϵ to be too large if $\tan\beta < 2$. For more on their assumptions, see the paper and their reference 10.

33 BUSKULIC 95E looked for $Z \rightarrow \tilde{t}\tilde{t}$, where $\tilde{t} \rightarrow c\chi_1^0$ and χ_1^0 decays via R -parity violating interactions into two leptons and a neutrino.

34 SHIRAI 94 bound assumes the cross section without the s -channel Z -exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume $m_C=1.5$ GeV.

Heavy \tilde{g} (Gluino) MASS LIMIT

For $m_{\tilde{g}} > 60\text{--}70$ GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included. Limits made obsolete by the most recent analyses of $p\bar{p}$ collisions can be found in previous Editions of this Review.

1 AALTONEN 09S searched in 2 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 2 jets and \cancel{E}_T . No evidence for a signal is observed. A limit is derived for a mSUGRA scenario in the $m_{\tilde{q}}$ versus $m_{\tilde{g}}$ plane, see their Fig. 2.

2 ABAZOV 08G looked in 2.1 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with acoplanar jets or multijets with large \cancel{E}_T . No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific mSUGRA parameter values, see Figure 3. Similar results would be obtained for a large class of parameter sets. Supersedes the results of ABAZOV 06c.

3 ABULENCIA 06i searched in 156 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for multijet events with large \cancel{E}_T . They request at least 2 b -tagged jets and no isolated leptons. They investigate the production of gluinos decaying into $\tilde{b}_1 b$ followed by $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$. Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and gluinos, see their Fig. 3.

9 ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8 \text{ TeV}$, using events with one electron, ≥ 4 jets, and large \cancel{E}_T . The results are compared to a MSUGRA scenario with $\mu < 0$, $A_0=0$, and $\tan\beta=3$ and allow to exclude a region of the $(m_0, m_{1/2})$ shown in Fig. 11.	> 3.8 > 3.2 none 0.6-2.2	90	27 ARNOLD 87 EMUL $\pi^- (350 \text{ GeV})$. $\sigma \simeq A^1$ 28 ARNOLD 87 EMUL $\pi^- (350 \text{ GeV})$. $\sigma \simeq A^{0.72}$ 29 TUNTS 87 CUSB $\gamma(1S) \rightarrow \gamma + \text{gluonium}$
10 CHEUNG 02B studies the constraints on a \tilde{b}_1 with mass in the 2.2-5.5 GeV region and a gluino in the mass range 12-16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.	none 1-4.5 none 1-4 none 3-5 none	90	29 ALBRECHT 86C ARG $1 \times 10^{-11} \lesssim \tau \lesssim 1 \times 10^{-9} \text{ s}$ 30 BADIER 86 BDMP $1 \times 10^{-10} < \tau < 1 \times 10^{-7} \text{ s}$ 31 BARNETT 86 RVUE $p\bar{p} \rightarrow \text{gluino gluino gluon}$ 32 VOLOSHIN 86 RVUE If (quasi) stable; $\tilde{g}uud$
11 BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m \sim 12-16 \text{ GeV}$) with subsequent 2-body decay into a light sbottom ($m \sim 2-5.5 \text{ GeV}$) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R -parity- and B -violating interaction, or be long-lived.	none 0.5-2 none 0.5-4 none 0.5-3	95	33 COOPER... 85B BDMP For $m_{\tilde{q}}=300 \text{ GeV}$ 33 COOPER... 85B BDMP For $m_{\tilde{q}} < 65 \text{ GeV}$ 33 COOPER... 85B BDMP For $m_{\tilde{q}}=150 \text{ GeV}$
12 ABBOTT 99 searched for $\gamma\cancel{E}_T + \geq 2$ jet final states, and set limits on $\sigma(p\bar{p} \rightarrow \tilde{g} + X) \cdot \text{B}(\tilde{g} \rightarrow \gamma\tilde{g}\tilde{X})$. The quoted limits correspond to $m_{\tilde{g}} \geq m_{\tilde{g}}$, with $\text{B}(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0\gamma)=1$ and $\text{B}(\tilde{\chi}_1^0 \rightarrow \tilde{G}\gamma)=1$, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}=m_{\tilde{q}}$.	none 2-4 none 1-2.5 none 0.5-4.1	90	34 DAWSON 85 RVUE $\tau > 10^{-7} \text{ s}$ 34 DAWSON 85 RVUE For $m_{\tilde{q}}=100 \text{ GeV}$ 35 FARRAR 85 RVUE FNAL beam dump 36 GOLDMAN 85 RVUE Gluonium 37 HABER 85 RVUE 38 BALL 84 CALO 39 BRICK 84 RVUE 40 FARRAR 84 RVUE
13 ABBOTT 99k uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via $R LQ\bar{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the $(m_0, m_{1/2})$ plane under the assumption that $A_0=0$, $\mu < 0$, $\tan\beta=2$ and any one of the couplings $\lambda'_{jk} > 10^{-3}$ ($j=1,2$ and $k=1,2,3$) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0 , but the limit deteriorates rapidly with increasing $\tan\beta$ or $\mu > 0$.	> 2 >2-3 >1.5-2	95	41 BERGSMA 83C RVUE For $m_{\tilde{q}} < 100 \text{ GeV}$ 42 CHANOWITZ 83 RVUE $\tilde{g}u\bar{d}, \tilde{g}uud$ 43 KANE 82 RVUE Beam dump FARRAR 78 RVUE R-hadron
14 ABACHI 95c assume five degenerate squark flavors with $m_{\tilde{q}} = m_{\tilde{q}}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$, $\mu = -250 \text{ GeV}$, and $m_{H^+} = 500 \text{ GeV}$, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.			1 ABAZOV 07L looked in approximately 410 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ for events with a long-lived gluino from split supersymmetry, decaying after stopping in the detector into $\tilde{g}\tilde{\chi}_1^0$ with lifetimes from $30 \mu\text{s}$ to 100 h . The signal signature is a largely empty event with a single large transverse energy deposit in the calorimeter. The main background is due to cosmic muons interacting in the calorimeter. The data agree with the estimated background and allow the authors to estimate a limit on the rate of an out-of-time monojet signal of a given energy. Assuming the branching ratios $\tilde{g} \rightarrow \tilde{g}\tilde{\chi}_1^0$ to be 100% the results can be translated to limits on the gluino cross section versus the gluino mass for fixed $\tilde{\chi}_1^0$ mass. After comparing to the expected gluino cross sections, the excluded region of gluino masses can be obtained, see examples in their Fig. 3.
15 ABE 95T looked for a cascade decay of gluino into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40 \text{ GeV}$, $\tan\beta = 1.5$, and heavy squarks, the range $50 < m_{\tilde{g}} < 140 \text{ GeV}$ is excluded at 90% CL. See the paper for details.			2 BERGER 05 include the light gluino in proton PDF and perform global analysis of hadronic data. Effects on the running of α_s also included. Strong dependency on $\alpha_s(m_Z)$. Bound quoted for $\alpha_s(m_Z) = 0.118$.
16 HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks $N=6.3 \pm 1.1$ is obtained, which is compared to that with a light gluino, $N=8$.			3 ABDALLAH 03c looked for events of the type $q\bar{q}R^{\pm}R^{\pm}$, $q\bar{q}R^{\pm}R^0$ or $q\bar{q}R^0R^0$ in e^+e^- interactions at 91.2 GeV collected in 1994. The R^{\pm} bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. The upper value of the excluded range depends on the probability for the gluino to fragment into R^{\pm} or R^0 , see their Fig. 17. It improves to 23 GeV for 100% fragmentation to R^{\pm} .
17 ABE 92L bounds are based on similar assumptions as ABACHI 95c. Not sensitive to $m_{\text{gluino}} < 40 \text{ GeV}$ (but other experiments rule out that region).			4 ABDALLAH 03c used e^+e^- data at and around the Z^0 peak, above the Z^0 up to $\sqrt{s} = 202 \text{ GeV}$ and events from radiative return to cover the low energy region. They perform a direct measurement of the QCD beta-function from the means of fully inclusive event observables. Compared to the energy range, gluinos below 5 GeV can be considered massless and are firmly excluded by the measurement.
18 ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R -parity violating models. The 100% decay $\tilde{g} \rightarrow q\bar{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $lq\bar{d}$ or $l\ell\bar{e}$ is assumed.			5 HEISTER 03 use e^+e^- data from 1994 and 1995 at and around the Z^0 peak to measure the 4-jet rate and angular correlations. The comparison with QCD NLO calculations allow $\alpha_s(M_Z)$ and the color factor ratios to be extracted and the results are in agreement with the expectations from QCD. The inclusion of a massless gluino in the beta functions yields $T_R / C_F = 0.15 \pm 0.06 \pm 0.06$ (expectation is $T_R / C_F = 3/8$), excluding a massless gluino at more than 95% CL. As no NLO calculations are available for massive gluinos, the earlier LO results from BARATE 97L for massive gluinos remain valid.
19 NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.			6 HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for stable gluinos hadronizing into charged or neutral R-hadrons with arbitrary branching ratios. Combining these results with bounds on the Z^0 hadronic width from electroweak measurements (JANOT 03) to cover the low mass region the quoted lower limit on the mass of a long-lived gluino is obtained.
20 The limits of ALBAJAR 87D are from $p\bar{p} \rightarrow \tilde{g}\tilde{g}\tilde{X}$ ($\tilde{g} \rightarrow q\bar{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20 \text{ GeV}$ and $\tau(\tilde{g}) < 10^{-10} \text{ s}$.			
21 The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.			

Long-lived/light \tilde{g} (Gluino) MASS LIMIT

Limits on light gluinos ($m_{\tilde{g}} < 5 \text{ GeV}$), or gluinos which leave the detector before decaying.

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
•••	•••	•••	•••	•••

••• We do not use the following data for averages, fits, limits, etc. •••

- 7 JANOT 03 excludes a light gluino from the upper limit on an additional contribution to the Z hadronic width. At higher confidence levels, $m_{\tilde{g}} > 5.3(4.2)$ GeV at $3\sigma(5\sigma)$ level.
- 8 MAFI 00 reanalyzed CDF data assuming a stable heavy gluino as the LSP, with model for R-hadron-nucleon scattering. Gluino masses between 35 GeV and 115 GeV are excluded based on the CDF Run I data. Combined with the analysis of BAER 99, this allows a LSP gluino mass between 25 and 35 GeV if the probability of fragmentation into charged R-hadron $P > 1/2$. The cosmological exclusion of such a gluino LSP are assumed to be avoided as in BAER 99. Gluino could be NLSP with $\tau_{\tilde{g}} \sim 100$ yrs, and decay to gluon gravitino.
- 9 ALAVI-HARATI 99E looked for R^0 bound states, yielding $\pi^+\pi^-$ or π^0 in the final state. The experiment is sensitive to values of $\Delta m = m_{R^0} - m_{\tilde{\gamma}}$ larger than 280 MeV and 140 MeV for the two decay modes, respectively, and to R^0 mass and lifetime in the ranges 0.8–5 GeV and 10^{-10} – 10^{-3} s. The limits obtained depend on $B(R^0 \rightarrow \pi^+\pi^- \text{photon})$ and $B(R^0 \rightarrow \pi^0 \text{photon})$ on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_L^0)$. See Figures in the paper for the excluded R^0 production rates as a function of Δm , R^0 mass and lifetime. Using the production rates expected from perturbative QCD, and assuming dominance of the above decay channels over the suitable phase space, R^0 masses in the range 0.8–5 GeV are excluded at 90%CL for a large fraction of the sensitive lifetime region. ALAVI-HARATI 99E updates and supersedes the results of ADA MS 97b.
- 10 BAER 99 set constraints on the existence of stable \tilde{g} hadrons, in the mass range $m_{\tilde{g}} > 3$ GeV. They argue that strong-interaction effects in the low-energy annihilation rates could leave small enough relic densities to evade cosmological constraints up to $m_{\tilde{g}} < 10$ TeV. They consider $\text{jet} + \cancel{E}_T$ as well as heavy-ionizing charged-particle signatures from production of stable \tilde{g} hadrons at LEP and Tevatron, developing modes for the energy loss of \tilde{g} hadrons inside the detectors. Results are obtained as a function of the fragmentation probability P of the \tilde{g} into a charged hadron. For $P < 1/2$, and for various energy-loss models, OPAL and CDF data exclude gluinos in the $3 < m_{\tilde{g}}(\text{GeV}) < 130$ mass range. For $P > 1/2$, gluinos are excluded in the mass ranges $3 < m_{\tilde{g}}(\text{GeV}) < 23$ and $50 < m_{\tilde{g}}(\text{GeV}) < 200$.
- 11 FANTI 99 looked for R^0 bound states yielding high $P_T \eta \rightarrow 3\pi^0$ decays. The experiment is sensitive to a region of R^0 mass and lifetime in the ranges of 1–5 GeV and 10^{-10} – 10^{-3} s. The limits obtained depend on $B(R^0 \rightarrow \eta\gamma)$, on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_L^0)$. See Fig. 6–7 for the excluded production rates as a function of R^0 mass and lifetime.
- 12 ACKERSTAFF 98v excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\tilde{\chi}_1^\pm, \tilde{\chi}_2^0 \rightarrow q\tilde{q}\tilde{g}$ from total hadronic cross sections at $\sqrt{s}=130$ –172 GeV. See paper for the case of nonuniversal gaugino mass.
- 13 ADA MS 97b looked for $\rho^0 \rightarrow \pi^+\pi^-$ as a signature of $R^0=(\tilde{g}\tilde{g})$ bound states. The experiment is sensitive to an R^0 mass range of 1.2–4.5 GeV and to a lifetime range of 10^{-10} – 10^{-3} sec. Precise limits depend on the assumed value of $m_{R^0}/m_{\tilde{\gamma}}$. See Fig. 7 for the excluded mass and lifetime region.
- 14 ALBUQUERQUE 97 looked for weakly decaying baryon-like states which contain a light gluino, following the suggestions in FARRAR 96. See their Table 1 for limits on the production fraction. These limits exclude gluino masses in the range 100–600 MeV for the predicted lifetimes (FARRAR 96) and production rates, which are assumed to be comparable to those of strange or charmed baryons.
- 15 BARATE 97L studied the QCD color factors from four-jet angular correlations and the differential two-jet rate in Z decay. Limit obtained from the determination of $n_f = 4.24 \pm 0.29 \pm 1.15$, assuming $T_F/C_F=3/8$ and $C_A/C_F=9/4$.
- 16 CSIKOR 97 combined the α_s from $\sigma(e^+e^- \rightarrow \text{hadron})$, τ decay, and jet analysis in Z decay. They exclude a light gluino below 5 GeV at more than 99.7%CL.
- 17 DEGOUVEA 97 reanalyzed AKERS 95A data on Z decay into four jets to place constraints on a light stable gluino. The mass limit corresponds to the pole mass of 2.8 GeV. The analysis, however, is limited to the leading-order QCD calculation.
- 18 FARRAR 96 studied the possible $R^0=(\tilde{g}\tilde{g})$ component in Fermilab E799 experiment and used its bound $B(K_L^0 \rightarrow \pi^0\nu\bar{\nu}) \leq 5.8 \times 10^{-5}$ to place constraints on the combination of R^0 production cross section and its lifetime.
- 19 AKERS 95R looked for Z decay into $q\tilde{q}\tilde{g}\tilde{g}$, by searching for charged particles with dE/dx consistent with \tilde{g} fragmentation into a state $(\tilde{g}q\tilde{q})^\pm$ with lifetime $\tau > 10^{-7}$ sec. The fragmentation probability into a charged state is assumed to be 25%.
- 20 CLAVELLI 95 updates the analysis of CLAVELLI 93, based on a comparison of the hadronic widths of charmonium and bottomonium S-wave states. The analysis includes a parametrization of relativistic corrections. Claims that the presence of a light gluino improves agreement with the data by slowing down the running of α_s .
- 21 CAKIR 94 reanalyzed TUTS 87 and later unpublished data from CUSB to exclude pseudo-scalar gluinoonium $\eta_{\tilde{g}}(\tilde{g}\tilde{g})$ of mass below 7 GeV. It was argued, however, that the perturbative QCD calculation of the branching fraction $\Upsilon \rightarrow \eta_{\tilde{g}}\gamma$ is unreliable for $m_{\eta_{\tilde{g}}} < 3$ GeV. The gluino mass is defined by $m_{\tilde{g}}=(m_{\eta_{\tilde{g}}})/2$. The limit holds for any gluino lifetime.
- 22 LOPEZ 93c uses combined restraint from the radiative symmetry breaking scenario within the minimal supergravity model, and the LEP bounds on the (M_2, μ) plane. Claims that the light gluino window is strongly disfavored.
- 23 CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between α_s at LEP and at quarkonia (Υ), since a light gluino slows the running of the QCD coupling.
- 24 ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of α_s between 5 GeV and m_Z . The significance is less than 2 s.d.
- 25 ANTONIADIS 91 interpret the search for missing energy events in 450 GeV/c pN collisions, AKESSON 91, in terms of light gluinos.
- 26 NAKAMURA 89 searched for a long-lived ($\tau \gtrsim 10^{-7}$ s) charge-(± 2) particle with mass $\lesssim 1.6$ GeV in proton-Pt interactions at 12 GeV and found that the yield is less than 10^{-8} times that of the pion. This excludes $R\Delta^{++}$ (a $\tilde{g}uuu$ state) lighter than 1.6 GeV.
- 27 The limits assume $m_{\tilde{q}} = 100$ GeV. See their figure 3 for limits vs. $m_{\tilde{q}}$.
- 28 The gluino mass is defined by half the bound $\tilde{g}\tilde{g}$ mass. If zero gluino mass gives a $\tilde{g}\tilde{g}$ of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.
- 29 ALBRECHT 86c search for secondary decay vertices from $\chi_{b1}(1P) \rightarrow \tilde{g}\tilde{g}\tilde{g}$ where \tilde{g} 's make long-lived hadrons. See their figure 4 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ and $m_{\tilde{g}} - m_{\tilde{q}}$ plane. The lower $m_{\tilde{g}}$ region below ~ 2 GeV may be sensitive to fragmentation effects. Remark that the \tilde{g} -hadron mass is expected to be ~ 1 GeV (glueball mass) in the zero \tilde{g} mass limit.
- 30 BADIER 86 looked for secondary decay vertices from long-lived \tilde{g} -hadrons produced at 300 GeV π^- beam dump. The quoted bound assumes \tilde{g} -hadron nucleon total cross section of $10\mu\text{b}$. See their figure 7 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ plane for several assumed total cross-section values.
- 31 BARNETT 86 rule out light gluinos ($m = 3$ –5 GeV) by calculating the monojet rate from gluino gluino events (and from gluino gluon events) and by using UA1 data from $p\bar{p}$ collisions at CERN.
- 32 VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron $\tilde{g}uud$. Quasi-stable ($\tau > 1 \times 10^{-7}$ s) light gluino of $m_{\tilde{g}} < 3$ GeV is also ruled out by nonobservation of the stable charged particles, $\tilde{g}uud$, in high energy hadron collisions.
- 33 COOPER-SARKAR 85B is BEBC beam-dump. Gluinos decaying in dump would yield $\tilde{\gamma}$'s in the detector giving neutral-current-like interactions. For $m_{\tilde{q}} > 330$ GeV, no limit is set.
- 34 DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam dump experiment.
- 35 FARRAR 85 points out that BALL 84 analysis applies only if the \tilde{g} 's decay before interacting, i.e. $m_{\tilde{q}} < 80m_{\tilde{g}}^{1.5}$. FARRAR 85 finds $m_{\tilde{g}} < 0.5$ not excluded for $m_{\tilde{q}} = 30$ –1000 GeV and $m_{\tilde{g}} < 1.0$ not excluded for $m_{\tilde{q}} = 100$ –500 GeV by BALL 84 experiment.
- 36 GOLDMAN 85 use nonobservation of a pseudoscalar $\tilde{g}\tilde{g}$ bound state in radiative ψ decay.
- 37 HABER 85 is based on survey of all previous searches sensitive to low mass \tilde{g} 's. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersymmetric particle.
- 38 BALL 84 is FNAL beam dump experiment. Observed no interactions of $\tilde{\gamma}$ in the calorimeter, where $\tilde{\gamma}$'s are expected to come from pair-produced \tilde{g} 's. Search for long-lived $\tilde{\gamma}$ interacting in calorimeter 56m from target. Limit is for $m_{\tilde{q}} = 40$ GeV and production cross section proportional to $A^{0.72}$. BALL 84 find no \tilde{g} allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on $m_{\tilde{q}}$ and A. See also KANE 82.
- 39 BRICK 84 reanalyzed FNAL 147 GeV HBC data for $R\Delta(1232)^{++}$ with $\tau > 10^{-9}$ s and $p_{\text{lab}} > 2$ GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in $p\bar{p}$, $\pi^+\pi^-$, K^+p collisions respectively. $R\Delta^{++}$ is defined as being \tilde{g} and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.
- 40 FARRAR 84 argues that $m_{\tilde{g}} < 100$ MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than $\tilde{\gamma}$'s or if $m_{\tilde{q}} > 100$ GeV.
- 41 BERGSMAN 83c is reanalysis of CERN-SPS beam-dump data. See their figure 1.
- 42 CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if $m_{\tilde{g}} < 1$ GeV. This is important since tracks from decay of neutral s-hadron cannot be reconstructed to primary vertex because of missed $\tilde{\gamma}$. Charged s-hadron leaves track from vertex.
- 43 KANE 82 inferred above \tilde{g} mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if \tilde{g} decays inside detector.

LIGHT \tilde{G} (Gravitino) MASS LIMITS FROM COLLIDER EXPERIMENTS

The following are bounds on light ($\ll 1$ eV) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy (\cancel{E}) signature.

- 1 ABDALLAH 05B use data from $\sqrt{s} = 180$ –208 GeV. They look for events with a single photon + \cancel{E} final states from which a cross section limit of $\sigma < 0.18$ pb at 208 GeV is obtained, allowing a limit on the mass to be set. Supersedes the results of ABREU 00Z.
- 2 ACHARD 04E use data from $\sqrt{s} = 189$ –209 GeV. They look for events with a single photon + \cancel{E} final states from which a limit on the Gravitino mass is set corresponding to $\sqrt{F} > 238$ GeV. Supersedes the results of ACCIARRI 99R.
- 3 HEISTER 03C use the data from $\sqrt{s} = 189$ –209 GeV to search for $\gamma\cancel{E}_T$ final states.
- 4 ACOSTA 02H looked in 87 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with a high- E_T photon and \cancel{E}_T . They compared the data with a GMSB model where the final state could arise from $q\tilde{q} \rightarrow \tilde{G}\tilde{G}\gamma$. Since the cross section for this process scales as $1/|F|^4$, a limit at 95% CL is derived on $|F|^{1/2} > 221$ GeV. A model independent limit for the above topology is also given in the paper.
- 5 ABBIENDI,G 00D searches for $\gamma\cancel{E}$ final states from $\sqrt{s}=189$ GeV.
- 6 ABREU 00Z, ACCIARRI 99R search for $\gamma\cancel{E}$ final states using data from $\sqrt{s}=189$ GeV.
- 7 AFFOLDER 00I searches for final states with an energetic jet (from quark or gluon) and large \cancel{E}_T from undetected gravitinos.

9	ABACHI 97	D0	$\gamma\gamma X$
10	BARBER 84B	RVUE	
11	HOFFMAN 83	CNTR	$\pi p \rightarrow n(e^+e^-)$

- LOVE 08A searched for decays of $Y(n)$ with $n = 1, 2, 3$ into $\mu\tau$ in 1.1, 1.3, 1.4 fb^{-1} , respectively, in the CLEO III detector at CESR. The signature is a muon with $\approx 97\%$ of the beam energy and an electron from the decay of τ . No evidence for lepton flavour violation is found and 95% CL limits on the branching ratio are estimated to be 6.0, 14.4 and 20.3×10^{-6} for $n = 1, 2, 3$, respectively.
- ABULENCIA 06P searched in 305 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with $\ell\gamma\bar{E}_T$ and $\ell\ell\gamma$ ($\ell = e, \mu$). No significant excess was found compared to the background expectation. No events are found such as the $ee\gamma\bar{E}_T$ event observed in ABE 99i.
- ACOSTA 04E looked in 107 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV for events with two same sign leptons without selection of other objects nor \bar{E}_T . No significant excess is observed compared to the Standard Model expectation and constraints are derived on the parameter space of MSUGRA models, see Figure 4.
- Looked for the scalar partner of a goldstino in decays $K^- \rightarrow \pi^- \pi^0 P$ from a 25 GeV K^- beam produced at the IHEP 70 GeV proton synchrotron. The goldstino is assumed to be sufficiently long-lived to be invisible. A 90% CL upper limit on the decay branching ratio is set at $\sim 9.0 \times 10^{-6}$ for a goldstino mass range from 0 to 200 MeV, excluding the interval near $m(\pi^0)$, where the limit is $\sim 3.5 \times 10^{-5}$.
- AFFOLDER 02D looked in 85 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with a high- E_T photon, and a b -tagged jet with or without \bar{E}_T . They compared the data with models where the final state could arise from cascade decays of gluinos and/or squarks into $\bar{\chi}^\pm$ and $\bar{\chi}_2^0$ or direct associated production of $\bar{\chi}_2^0 \bar{\chi}_2^\pm$, followed by $\bar{\chi}_2^0 \rightarrow \gamma\bar{\chi}_1^0$ or a GMSB model where $\bar{\chi}_1^0 \rightarrow \gamma G$. It is concluded that the experimental sensitivity is insufficient to detect the associated production or the GMSB model, but some sensitivity may exist to the cascade decays. A model independent limit for the above topology is also given in the paper.
- AFFOLDER 01H searches for $p\bar{p} \rightarrow \gamma\gamma X$ events, where the di-photon system originates from goldstino production, in 100 pb^{-1} of data. Upper limits on the cross section times branching ratio are shown as a function of the di-photon mass > 70 GeV in Fig. 5. Excluded regions are derived in the plane of the goldstino mass versus the supersymmetry breaking scale for two representative sets of parameter values, as shown in Figs. 6 and 7.
- ABBOTT 00G searches for trilepton final states ($\ell = e, \mu$) with \bar{E}_T from the indirect decay of gauginos via LLE couplings. Efficiencies are computed for all possible production and decay modes of SUSY particles in the framework of the Minimal Supergravity scenario. See Figs. 1-4 for excluded regions in the $m_{1/2}$ versus m_0 plane.
- ABREU,P 00C look for the CP -even (S) and CP -odd (P) scalar partners of the goldstino, expected to be produced in association with a photon. The S/P decay into two photons or into two gluons and both the tri-photon and the photon + two jets topologies are investigated. Upper limits on the production cross section are shown in Fig. 5 and the excluded regions in Fig. 6. Data collected at $\sqrt{s} = 189\text{--}202$ GeV.
- ABACHI 97 searched for $p\bar{p} \rightarrow \gamma\gamma \bar{E}_T + X$ as supersymmetry signature. It can be caused by selectron, sneutrino, or neutralino production with a radiative decay of their decay products. They placed limits on cross sections.
- BARBER 84B consider that $\bar{\mu}$ and \bar{e} may mix leading to $\mu \rightarrow e\bar{\gamma}\bar{\gamma}$. They discuss mass-mixing limits from decay dist. asym. in LBL-TRIUMF data and e^+ polarization in SIN data.
- HOFFMAN 83 set CL = 90% limit $d\sigma/dt B(e^+e^-) < 3.5 \times 10^{-32} \text{ cm}^2/\text{GeV}^2$ for spin-1 partner of Goldstone fermions with $140 < m < 160$ MeV decaying $\rightarrow e^+e^-$ pair.

DYNAMICAL ELECTROWEAK SYMMETRY BREAKING

Revised August 2009 by R.S. Chivukula (Michigan State University), M. Narain (Brown University), and J. Womersley (STFC, Rutherford Appleton Laboratory).

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a fermion bilinear. These theories may thereby avoid the introduction of fundamental scalar particles, of which we have no examples in nature. In this note, we review the status of experimental searches for the particles predicted in technicolor, topcolor, and related models. The limits from these searches are summarized in Table 1.

I. Technicolor

The earliest models [1,2] of dynamical electroweak symmetry breaking [3] include a new asymptotically free non-abelian gauge theory (“technicolor”) and additional massless fermions (“technifermions”) transforming under a vectorial representation of the gauge group) which feel this new force. The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral $SU(2) \times SU(2)$ symmetry in QCD is broken down to $SU(2)$ isospin by the formation of a quark condensate. If the quantum numbers of the technifermions are chosen

Table 1: Summary of the mass limits. Symbols are defined in the text.

Process	Excluded mass range	Decay channels Ref.
$p\bar{p} \rightarrow \rho_T \rightarrow W\pi_T$	$170 < m_{\rho_T} < 215$ GeV and $80 < m_{\pi_T} < 115$ GeV for $M_V = 500$ GeV	$\rho_T \rightarrow W\pi_T$ [19] $\pi_T^0 \rightarrow b\bar{b}$ $\pi_T^\pm \rightarrow b\bar{c}$
$p\bar{p} \rightarrow \omega_T \rightarrow \gamma\pi_T$	$140 < m_{\omega_T} < 290$ GeV for $m_{\pi_T} \approx m_{\omega_T}/3$ and $M_T = 100$ GeV	$\omega_T \rightarrow \gamma\pi_T$ [20] $\pi_T^0 \rightarrow b\bar{b}$ $\pi_T^\pm \rightarrow b\bar{c}$

$\rightarrow \pi_{LQ}\pi_{LQ}$	$m_{\rho_{T8}} < 600$ GeV	$\pi_{LQ} \rightarrow b\nu$ [28]
	$m_{\rho_{T8}} < 465$ GeV	$\pi_{LQ} \rightarrow \tau q$ [27]
$p\bar{p} \rightarrow g_t$	$0.3 < m_{g_t} < 0.6$ TeV for $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$	$g_t \rightarrow b\bar{b}$ [35]
$p\bar{p} \rightarrow Z'$	$m_{Z'} < 480$ GeV for $\Gamma = 0.012m_{Z'}$ $m_{Z'} < 780$ GeV for $\Gamma = 0.04m_{Z'}$	$Z' \rightarrow t\bar{t}$ [36]

correctly (*e.g.*, by choosing technifermions in the fundamental representation of an $SU(N)$ technicolor gauge group, with the left-handed technifermions being weak doublets and the right-handed ones weak singlets), this condensate can break the electroweak interactions down to electromagnetism.

The breaking of the global chiral symmetries implies the existence of Goldstone bosons, the “technipions” (π_T). Through the Higgs mechanism, three of the Goldstone bosons become the longitudinal components of the W and Z , and the weak gauge bosons acquire a mass proportional to the technipion decay constant (the analog of f_π in QCD). The quantum numbers and masses of any remaining technipions are model-dependent. There may be technipions which are colored (octets and triplets), as well as those carrying electroweak quantum numbers, and some color-singlet technipions are too light [4,3] unless additional sources of chiral-symmetry breaking are introduced. The next lightest technicolor resonances are expected to be the analogs of the vector mesons in QCD. The technivector mesons can also have color and electroweak quantum numbers and, for a theory with a small number of technifermions, are expected to have a mass in the TeV range [5].

While technicolor chiral-symmetry breaking can give mass to the W and Z particles, additional interactions must be introduced to produce the masses of the standard model

fermions. The most thoroughly studied mechanism for this invokes “extended technicolor” (ETC) gauge interactions [4,6]. In ETC, technicolor and flavor are embedded into a larger gauge group, which is broken at a sequence of mass scales down to the residual, exact technicolor gauge symmetry. The massive gauge bosons associated with this breaking mediate transitions between quarks/leptons and technifermions, giving rise to the couplings necessary to produce fermion masses. The ETC gauge bosons also mediate transitions among technifermions themselves, leading to interactions which can explicitly break unwanted chiral symmetries and raise the masses of any light technipions. The ETC interactions connecting technifermions to quarks/leptons also mediate technipion decays to ordinary fermion pairs. Since these interactions are responsible for fermion masses, one generally expects technipions to decay to the heaviest fermions kinematically allowed (though this need not hold in all models).

In addition to quark masses, ETC interactions must also give rise to quark mixing. One expects, therefore, that there are ETC interactions coupling quarks of the same charge from different generations. A stringent limit on these flavor-changing neutral current interactions comes from $K^0-\bar{K}^0$ mixing [4]. These force the scale of ETC breaking and the corresponding ETC gauge boson masses to be in the 100-1000 TeV range (at least insofar as ETC interactions of first two generations are concerned). To obtain quark and technipion masses that are large enough then requires an enhancement of the technifermion condensate over that expected naively by scaling from QCD. Such an enhancement can occur if the technicolor gauge coupling runs very slowly, or “walks” [7]. Some theories of walking technicolor incorporate many technifermions, implying that the technicolor scale and, in particular, the technivector mesons may be much lighter than 1 TeV [3,8]. It should also be noted that there is no reliable calculation of electroweak parameters in a walking technicolor theory, and the values of precisely measured electroweak quantities [9] cannot directly be used to constrain the models.† Recently, progress has been made in constructing a complete theory of fermion masses (including neutrino masses) in the context of extended technicolor [11].

In existing colliders, technivector mesons are dominantly produced when an off-shell standard model gauge boson “resonates” into a technivector meson with the same quantum numbers [12]. The technivector mesons may then decay, in analogy with $\rho \rightarrow \pi\pi$, to pairs of technipions. However, in walking technicolor the technipion masses may be increased to the point that the decay of a technirho to pairs of technipions is kinematically forbidden [8]. In this case the decay to a technipion and a longitudinally polarized weak boson (an “eaten” Goldstone boson) may be preferred, and the technivector meson

would be very narrow. Alternatively, the technivector may also decay, in analogy with the decay $\rho \rightarrow \pi\gamma$, to a technipion plus a photon, gluon, or transversely polarized weak gauge boson. Finally, in analogy with the decay $\rho \rightarrow e^+e^-$, the technivector meson may resonate back to an off-shell gluon or electroweak gauge boson, leading to a decay into a pair of leptons, quarks, or gluons.

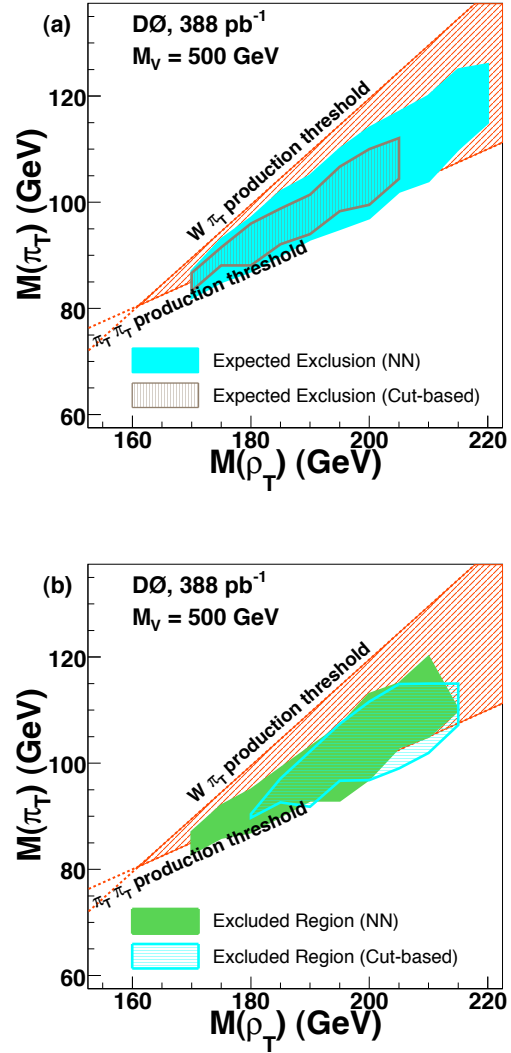

Figure 1: Search for a light technirho decaying to W^\pm and a π_T , and in which the π_T decays to two jets including at least one b quark [19]. Expected region of exclusion (a) and excluded region (b) at the 95% C.L. in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T \rightarrow W\pi_T \rightarrow e\nu b\bar{b}(\bar{c})$ production with $M_V = 500$ GeV. Kinematic thresholds from $W\pi_T$ and $\pi_T\pi_T$ are shown on the figures. Color version at end of book.

† Indeed, it is possible that the spectrum of these theories is quite different from QCD – perhaps even a parity-doubled spectrum including light composite scalar states [10].

When comparing the various results presented in this review, one should be aware that the more recent analyses [18,19,21,23] make use of newer calculations [13] of technihadron production and decay, as implemented in PYTHIA [14]

Searches Particle Listings

Technicolor

version 6.126 and higher [15]. The results obtained with older cross section calculations are not generally directly comparable, and have only been listed in Table 1 when newer results are not available.

If the dominant decay mode of the technirho is $W_L\pi_T$, promising signal channels [16] are $\rho_T^\pm \rightarrow W^\pm\pi_T^0$ and $\rho_T^0 \rightarrow W^\pm\pi_T^\mp$. If we assume that the technipions decay to $b\bar{b}$ (neutral) and $b\bar{c}$ (charged), then both channels yield a signal of $W(\ell\nu) + 2$ jets, with one or more heavy flavor tags. The CDF collaboration carried out a search in this final state [17] based on Run I data and using PYTHIA version 6.1 for the signal simulation. Using 1.9 fb^{-1} of data from Run II, CDF [18] has shown a preliminary update of this analysis. The DØ [19] collaboration published an analysis based on 388 pb^{-1} of data from Run II and PYTHIA 6.22. The searches are sensitive to $\sigma \cdot B \gtrsim 4 \text{ pb}$ and DØ finds mass combinations up to $m_{\rho_T} = 215 \text{ GeV}$, $m_{\pi_T} = 115 \text{ GeV}$ to be excluded for certain values of the model parameters. The expected sensitivity and the region excluded at 95% C.L. by the DØ analysis for $M_V = 500 \text{ GeV}$ is shown in Fig. 1. For $M_V = 100 \text{ GeV}$, only a small region around $M(\rho_T) = 190 \text{ GeV}$ and $M(\pi_T) = 95 \text{ GeV}$ can be excluded. For an integrated luminosity of 2 fb^{-1} , the 5σ discovery reach is expected to extend to $m_{\rho_T} = 210 \text{ GeV}$ and $m_{\pi_T} = 110 \text{ GeV}$, while the 95% exclusion sensitivity will extend to $m_{\rho_T} = 250 \text{ GeV}$ and $m_{\pi_T} = 145 \text{ GeV}$.

Figure 2: 95% CL exclusion region [20] for a light techniomuon decaying to γ and a π_T , and in which the π_T decays to two jets, including at least one b quark. (Inset: cross section limit for $m_{\pi_T} = 120 \text{ GeV}$.)

CDF also searched [20] in Run I for the process $\omega_T^0 \rightarrow \gamma\pi_T^0$, yielding a signal of a hard photon plus two jets, with one or more heavy flavor tags. The sensitivity to $\sigma \cdot B$ is of order 1 pb . The excluded region is shown in Fig. 2 and is roughly $140 < m_{\omega_T} < 290 \text{ GeV}$ at the 95% level, for $m_{\pi_T} \approx m_{\omega_T}/3$. The analysis assumes four technicolors, $Q_D = Q_U - 1 = \frac{1}{3}$ and $M_T = 100 \text{ GeV}/c^2$. Here Q_U and Q_D are the charges of the lightest technifermion doublet, and M_T is a dimensionful parameter, of order $100 \text{ GeV}/c^2$, which controls the rate of $\rho_T, \omega_T \rightarrow \gamma\pi_T$.

Figure 3: 95% CL cross-section limit [21] for a light techniomuon decaying to $\ell^+\ell^-$.

The DØ experiment has searched [21] for low-scale technicolor resonances ρ_T and ω_T decaying to dileptons, using an inclusive e^+e^- sample from Run I. In the search, the ρ_T and ω_T are assumed to be degenerate in mass. The absence of structure in the dilepton invariant mass distribution is then used to set limits. Masses $m_{\rho_T} = m_{\omega_T} \lesssim 200 \text{ GeV}$ are excluded, provided either $m_{\rho_T} < m_{\pi_T} + m_W$, or $M_T > 200 \text{ GeV}$ (as shown in Fig. 3). The CDF experiment also performed a similar search with 200 pb^{-1} of Run II data, and excluded equal $m_{\rho_T} = m_{\omega_T}$ masses below 280 GeV for $M_V = 500 \text{ GeV}$ and $m_{\rho_T} < m_{\pi_T} + m_W$ at 95% C.L. [22]. With 2 fb^{-1} of data, the sensitivity will extend to $m_{\rho_T} = m_{\omega_T} \approx 500 \text{ GeV}$.

DELPHI [23] has reported a search for technicolor production in 452 pb^{-1} of e^+e^- data taken between 192 and 208 GeV. The analysis combines searches for $e^+e^- \rightarrow \rho_T(\gamma)$ with $\rho_T \rightarrow W_L W_L$, $\rho_T \rightarrow \text{hadrons} (\pi_T\pi_T \text{ or } q\bar{q})$, $\rho_T \rightarrow \pi_T\gamma$, and $e^+e^- \rightarrow \rho_T^* \rightarrow W_L\pi_T$ or $\pi_T\pi_T$. Technirho masses in the range $90 < m_{\rho_T} < 206.7 \text{ GeV}$ are excluded, while technipion masses $m_{\pi_T} < 79.8 \text{ GeV}$ are ruled out independent of the parameters of the technicolor model.

Figure 4: 95% CL exclusion region [23] in the technirho-technipion mass plane obtained from searches by the DELPHI collaboration at LEP 2, for nine technifermion doublets. The dashed line shows the expected limit for the 4-jet analysis. Color version at end of book.

Figure 6: 95% CL exclusion region [28] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to $b\nu$. Color version at end of book.

Figure 5: 95% CL Cross-section limits [25] for a technirho decaying to two jets at the Tevatron.

Searches have also been carried out at the Tevatron for colored technihadron resonances [24,25]. CDF has used a search for structure in the dijet invariant mass spectrum to set

limits on a color-octet technirho ρ_{T8} produced by an off-shell gluon, and decaying to two real quarks or gluons. As shown in Fig. 5, masses $260 < m_{\rho_{T8}} < 480$ GeV are excluded; in Run II the limits will improve to cover the whole mass range up to about 0.8 TeV [26].

The CDF second- and third-generation leptoquark searches (see Refs. [27,28]) have also been interpreted in terms of the complementary ρ_{T8} decay mode: $p\bar{p} \rightarrow \rho_{T8} \rightarrow \pi_{LQ}\pi_{LQ}$. Here π_{LQ} denotes a color-triplet technipion carrying both color and lepton number, assumed to decay to $b\nu$ or $c\nu$ [28], or to a τ plus a quark [27]. The searches exclude technirho masses $m_{\rho_{T8}}$ less than 510 GeV ($\pi_{LQ} \rightarrow c\nu$), 600 GeV ($\pi_{LQ} \rightarrow b\nu$), and 465 GeV ($\pi_{LQ} \rightarrow \tau q$) for technipion masses up to $m_{\rho_{T8}}/2$. Figure 6 shows the $\pi_{LQ} \rightarrow b\nu$ exclusion region. (Leptoquark masses $m_{\pi_{LQ}}$ less than 123 GeV ($c\nu$), 148 GeV ($b\nu$), and 99 GeV (τq) are already ruled out by standard continuum-production leptoquark searches).

Recently, it has been demonstrated that there is substantial uncertainty in the theoretical estimate of the ρ_{T8} production cross section at the Tevatron and that the cross section may be as much as an order of magnitude lower than the naive vector meson dominance estimate [29]. To establish the range of allowed masses, these limits will need to be redone with a reduced theoretical cross section.

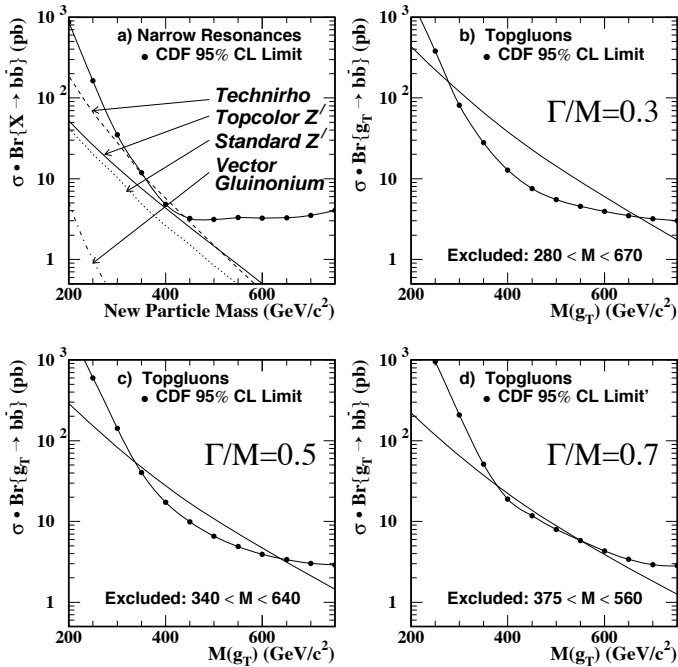

Figure 7: Tevatron limits [35] on new particles decaying to $b\bar{b}$: narrow resonances and topgluons for various widths.

Figure 8: Cross-section limits for a narrow resonance decaying to $t\bar{t}$ [36] and expected cross section for a leptophobic topcolor Z' boson.

Within the context of the model in reference [13], both the ATLAS and CMS experiments have carried out sensitivity studies for observing technihadron production in proton-proton collisions at the LHC. A study of the process ρ_T and ω_T decaying to $\mu^+\mu^-$ by the ATLAS experiment [30] shows that

with about 1.5 (4.5) fb^{-1} of integrated luminosity at $\sqrt{s} = 14$ TeV, a 5σ discovery reach is possible for masses below 700 GeV (1 TeV). The CMS experiment has examined the sensitivity to ρ_T and its axial-vector partner, a_T production at $\sqrt{s} = 10$ TeV using the $\rho_T/a_T \rightarrow WZ \rightarrow ll\nu$ final state [31]. They conclude that it is possible to exclude masses up to 300 GeV with 450 pb^{-1} of data. For a 5σ discovery about 1 fb^{-1} or more of luminosity is needed. The discovery potential is expected to be enhanced when the LHC operates at the design energy of $\sqrt{s} = 14$ TeV.

II. Top Condensate, Higgsless, and Related Models

The top quark is much heavier than other fermions and must be more strongly coupled to the symmetry-breaking sector. It is natural to consider whether some or all of electroweak-symmetry breaking is due to a condensate of top quarks [3,32]. Top quark condensation alone, without additional fermions, seems to produce a top quark mass larger [33] than observed experimentally, and is therefore not favored. Topcolor-assisted technicolor [34] combines technicolor and top condensation. In addition to technicolor, which provides the bulk of electroweak symmetry breaking, top condensation and the top quark mass arise predominantly from “topcolor,” a new QCD-like interaction which couples strongly to the third generation of quarks. An additional, strong, U(1) interaction (giving rise to a topcolor Z') precludes the formation of a b -quark condensate.

CDF has searched [35] for the “topgluon,” a massive color-octet vector which couples preferentially to the third generation, in the mode $p\bar{p} \rightarrow g_t \rightarrow b\bar{b}$. The results are shown in Fig. 7. Topgluon masses from approximately 0.3 to 0.6 TeV are excluded at 95% confidence level, for topgluon widths in the range $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$. Results have also been reported by CDF [36] on a search for narrow resonances in the $t\bar{t}$ invariant mass distribution. The cross section limit is shown in Fig. 8 and excludes a leptophobic topcolor Z' with masses less than 480 (780) GeV/c^2 , for the case where its width $\Gamma = 0.012(0.04)m_{Z'}$. (DØ has carried out a similar search, with greater sensitivity [37], but has not derived comparable Z' mass limits.) A broad topgluon could also be detected in the same final state, though no results are yet available. In Run II, the Tevatron [26] should be sensitive to topgluon and topcolor Z' masses up to of order 1 TeV in $b\bar{b}$ and $t\bar{t}$ final states. A detailed theoretical analysis of $B-\bar{B}$ mixing and light quark mass generation in top-color-assisted technicolor shows that, at least in some models, the topgluon and Z' boson masses must be greater than about 5 TeV [38].

The top quark seesaw model of electroweak symmetry breaking [39] is a variant of the original top condensate idea which reconciles top condensation with a lighter top quark mass. Such a model can easily be consistent with precision electroweak tests, either because the spectrum includes a light composite Higgs [40], or because additional interactions allow for a heavier Higgs [41]. Such theories may arise naturally from gauge fields propagating in compact extra spatial dimensions [42].

See key on page 405

A variant of topcolor-assisted technicolor is flavor-universal, in which the topcolor $SU(3)$ gauge bosons, called colorons, couple equally to all quarks [43]. Flavor-universal versions of the seesaw model [44] incorporating a gauged flavor symmetry are also possible. In these models *all* left-handed quarks (and possibly leptons as well) participate in electroweak-symmetry-breaking condensates with separate (one for each flavor) right-handed weak singlets, and the different fermion masses arise by adjusting the parameters which control the mixing of each fermion with the corresponding condensate.

A prediction of these flavor-universal models is the existence of new heavy gauge bosons, coupling to color or flavor, at relatively low mass scales. The absence of an excess of high- E_T jets in $D\bar{O}$ data [45] has been used to constrain strongly coupled flavor-universal colorons (massive color-octet bosons coupling to all quarks). A mass limit of between 0.8 and 3.5 TeV is set [46] depending on the coloron-gluon mixing angle. Precision electroweak measurements constrain [47] the masses of these new gauge bosons to be greater than 1–3 TeV in a variety of models, for strong couplings.

A new class [48] of composite Higgs model [49], dubbed “Little Higgs Theory,” has been developed which gives rise to naturally light Higgs bosons without supersymmetry [50]. Inspired by discretized versions of higher-dimensional gauge theory [51], these models are based on the chiral symmetries of “theory space.” The models involve extended gauge groups and novel gauge symmetry-breaking patterns [52]. The new chiral symmetries prevent large corrections to the Higgs boson mass, and allow the scale (Λ) of the underlying strong dynamics giving rise to the composite particles to be as large as 10 TeV. These models typically require new gauge bosons and fermions, and possibly additional composite scalars beyond the Higgs, in the TeV mass range [53].

Finally, “Higgsless” models [54] provide electroweak symmetry breaking, including unitarization of the scattering of longitudinal W and Z bosons, without employing a scalar Higgs boson. The most extensively studied models [55] are based on a five-dimensional $SU(2) \times SU(2) \times U(1)$ gauge theory in a slice of Anti-deSitter space, and electroweak symmetry breaking is encoded in the boundary conditions of the gauge fields. Using the AdS/CFT correspondence [56], these theories may be viewed as “dual” descriptions of walking technicolor theories [7]. In addition to a massless photon and near-standard W and Z bosons, the spectrum includes an infinite tower of additional massive vector bosons (the higher Kaluza-Klein or KK excitations), whose exchange is responsible for unitarizing longitudinal W and Z boson scattering [57]. Using deconstruction, it has been shown [58] that a Higgsless model whose fermions are localized (*i.e.*, derive their electroweak properties from a single site on the deconstructed lattice) cannot simultaneously satisfy unitarity bounds and precision electroweak constraints.

It has recently been proposed [59] that the size of corrections to electroweak processes in Higgsless models may be reduced by

considering delocalized fermions, *i.e.*, considering the effect of the distribution of the wavefunctions of ordinary fermions in the fifth dimension (corresponding, in the deconstruction language, to allowing the fermions to derive their electroweak properties from several sites on the lattice). It has been shown [60] that, in an arbitrary Higgsless model, if the probability distribution of the delocalized fermions is related to the W wavefunction (a condition called “ideal” delocalization), then deviations in precision electroweak parameters are minimized. Phenomenological limits on delocalized Higgsless models may be derived [61] from limits on the deviation of the triple-gauge boson (WWZ) vertices from the standard model, and current constraints allow for the lightest KK resonances (which tend to be fermiophobic in the case of ideal fermion delocalization) to have masses of only a few hundred GeV. Such resonances would have to be studied using WW scattering [62].

An alternative approach to “Higgsless” models, dubbed “holographic technicolor” [63], incorporates a generalized extra-dimensional framework and allows for arbitrary couplings of the vector mesons to the light fermions, resulting in a wide variety of potential signatures at the LHC [64].

- 1 ABAZOV 07I search for the vector techni-resonances (ρ_T, ω_T) decaying into $W\pi_T$ with $W \rightarrow e\nu$ and $\pi_T \rightarrow b\bar{b}$ or $b\bar{c}$. See their Fig. 2 for the exclusion plot in the $M_{\pi_T} - M_{\rho_T}$ plane.
- 2 ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\bar{p}$ collisions. at $\sqrt{s} = 1.96$ TeV. The limit assumes Technicolor-scale mass parameters $M_V = M_A = 500$ GeV.
- 3 CHEKANOV 02B search for color octet techni- π P decaying into dijets in ep collisions. See their Fig. 5 for the limit on $\sigma(ep \rightarrow ePX) \cdot B(P \rightarrow 2j)$.
- 4 ABAZOV 01B searches for vector techni-resonances (ρ_T, ω_T) decaying to e^+e^- . The limit assumes $M_{\rho_T} = M_{\omega_T} < M_{\pi_T} + M_W$.
- 5 The limit is independent of the π_T mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the $M_{\rho_T} - M_{\pi_T}$ plane. ABDALLAH 01 limit on the techni- π mass is $M_{\pi_T} > 79.8$ GeV for $N_D = 2$, assuming its point-like coupling to gauge bosons.
- 6 AFFOLDER 00F search for ρ_T decaying into $W\pi_T$ or $\pi_T\pi_T$ with $W \rightarrow \ell\nu$ and $\pi_T \rightarrow \bar{b}b, \bar{b}c$. See Fig. 1 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_T} - M_{\pi_T}$ plane.
- 7 AFFOLDER 00k search for the ρ_{T8} decaying into $\pi_{LQ}\pi_{LQ}$ with $\pi_{LQ} \rightarrow b\nu$. For $\pi_{LQ} \rightarrow c\nu$, the limit is $M_{\rho_{T8}} > 510$ GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the $M_{\rho_{T8}} - M_{\pi_{LQ}}$ plane.
- 8 AFFOLDER 00L search for top-color Z'_{top} decaying into $\bar{t}t$. The quoted limit is for Z'_{top} with decay width $\Gamma = 0.012 M_{Z'}$. For $\Gamma = 0.04 M_{Z'}$, the limit becomes 780 GeV.
- 9 ABE 99f search for a new particle X decaying into $b\bar{b}$ in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.8$ TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\bar{p} \rightarrow X) \cdot B(X \rightarrow b\bar{b})$. ABE 99f also exclude top gluons of width $\Gamma = 0.3M$ in the mass interval $280 < M < 670$ GeV, of width $\Gamma = 0.5M$ in the mass interval $340 < M < 640$ GeV, and of width $\Gamma = 0.7M$ in the mass interval $375 < M < 560$ GeV.
- 10 ABE 99h search for the color-octet techni- ρ decaying into a pair of color-triplet technipions which subsequently decay into $\tau\tau$ -jet. See Fig. 6 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_{T8}} - M_{\pi_{LQ}}$ plane.
- 11 ABE 99n search for the techni- ω decaying into $\gamma\pi_T$. The technipion is assumed to decay $\pi_T \rightarrow b\bar{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\omega_T} - M_{\pi_T}$ plane.
- 12 ABE 97g search for a new particle X decaying into dijets in $p\bar{p}$ collisions at $E_{\text{cm}} = 1.8$ TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\bar{p} \rightarrow X) \cdot B(X \rightarrow 2j)$.

**Quark and Lepton Compositeness,
Searches for**

**SEARCHES FOR QUARK AND
LEPTON COMPOSITENESS**

Revised 2001 by K. Hagiwara (KEK), and K. Hikasa and M. Tanabashi (Tohoku University).

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ . The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2} \left[\eta_{LL} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L + \eta_{RR} \bar{\psi}_R \gamma_\mu \psi_R \bar{\psi}_R \gamma^\mu \psi_R + 2\eta_{LR} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_R \gamma^\mu \psi_R \right]. \quad (1)$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ . We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned} \Lambda &= \Lambda_{LL}^\pm \quad \text{for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, 0, 0), \\ \Lambda &= \Lambda_{RR}^\pm \quad \text{for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm 1, 0), \\ \Lambda &= \Lambda_{VV}^\pm \quad \text{for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \pm 1), \\ \Lambda &= \Lambda_{AA}^\pm \quad \text{for } (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1, \pm 1, \mp 1), \end{aligned} \quad (2)$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, *e.g.*, for $ee \rightarrow ee$) and/or by exchange of the binding quanta (when ever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for $g=2$ suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by $SU(2) \times U(1)$ quantum numbers. Typical examples are:

- Sequential type

$$\left(\begin{array}{c} \nu^* \\ \ell^* \end{array} \right)_L, \quad [\nu_R^*], \quad \ell_R^*.$$

ν_R^* is necessary unless ν^* has a Majorana mass.

Searches Particle Listings

Quark and Lepton Compositeness

2. Mirror type

$$[\nu_L^*], \quad \ell_L^*, \quad \begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_R.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_L, \quad \begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_R.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in ‘‘Standard Model of Electroweak Interactions’’):

	Sequential type	Mirror type	Homodoublet type
V^{ℓ^*}	$-\frac{1}{2} + 2 \sin^2 \theta_W$	$-\frac{1}{2} + 2 \sin^2 \theta_W$	$-1 + 2 \sin^2 \theta_W$
A^{ℓ^*}	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{\nu_D^*}$	$+\frac{1}{2}$	$+\frac{1}{2}$	+1
$A^{\nu_D^*}$	$+\frac{1}{2}$	$-\frac{1}{2}$	0
$V^{\nu_M^*}$	0	0	—
$A^{\nu_M^*}$	+1	-1	—

Here ν_D^* (ν_M^*) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned} \mathcal{L} = & \frac{\lambda_\gamma^{(f^*)}}{2m_{f^*}} \bar{f}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) f F_{\mu\nu} \\ & + \frac{\lambda_Z^{(f^*)}}{2m_{f^*}} \bar{f}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) f Z_{\mu\nu} \\ & + \frac{\lambda_W^{(\ell^*)}}{2m_{\ell^*}} g \bar{\ell}^* \sigma^{\mu\nu} \frac{1-\gamma_5}{2} \nu W_{\mu\nu} \\ & + \frac{\lambda_W^{(\nu^*)}}{2m_{\nu^*}} g \bar{\nu}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \ell W_{\mu\nu}^\dagger \\ & + \text{h.c.}, \end{aligned} \quad (3)$$

where $g = e/\sin \theta_W$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, etc. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0. \quad (4)$$

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1, 0)$ or $(0, 1)$ after rescaling λ .

These couplings in Eq. (3) can arise from $SU(2) \times U(1)$ -invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda} \bar{L}^* \sigma^{\mu\nu} (g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \frac{1-\gamma_5}{2} L + \text{h.c.}, \quad (5)$$

where L denotes the lepton doublet (ν, ℓ) , Λ is the compositeness scale, g, g' are $SU(2)$ and $U(1)_Y$ gauge couplings, and $W_{\mu\nu}^a$ and $B_{\mu\nu}$ are the field strengths for $SU(2)$ and $U(1)_Y$ gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of $(250 \text{ GeV})/\Lambda$ or m_{L^*}/Λ . In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2} \sin^2 \theta_W (\lambda_Z \cot \theta_W + \lambda_\gamma). \quad (6)$$

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned} \mathcal{L} = & \frac{1}{2\Lambda} \bar{Q}^* \sigma^{\mu\nu} (g_s f_s \frac{\lambda^a}{2} G_{\mu\nu}^a + g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \\ & \times \frac{1-\gamma_5}{2} Q + \text{h.c.}, \end{aligned} \quad (7)$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G_{\mu\nu}^a$ the gluon field strength.

It should be noted that the electromagnetic radiative decay of $\ell^*(\nu^*)$ is forbidden if $f = -f'$ ($f = f'$). These two possibilities ($f = f'$ and $f = -f'$) are investigated in many analyses of the LEP experiments above the Z pole.

Several different conventions are used by LEP experiments on Z pole to express the transition magnetic couplings. To facilitate comparison, we re-express these in terms of λ_Z and λ_γ using the following relations and taking $\sin^2 \theta_W = 0.23$. We assume chiral couplings, *i.e.*, $|c| = |d|$ in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2} \lambda_Z \quad (1990 \text{ papers}) \quad (8a)$$

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*} [\text{or } m_{\nu^*}]} \quad (\text{for } |c| = |d|) \quad (8b)$$

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin \theta_W \cos \theta_W}{\sqrt{\frac{1}{4} - \frac{2}{3} \sin^2 \theta_W + \frac{8}{9} \sin^4 \theta_W}} \lambda_Z = 1.11 \lambda_Z \quad (9)$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot \theta_W - \tan \theta_W} \lambda_Z = -1.10 \lambda_Z \quad (10)$$

4. L3 (neutrino)

$$f_{\nu}^{L3} = \sqrt{2}\lambda_Z \quad (11)$$

5. OPAL (charged lepton)

$$\frac{f^{\text{OPAL}}}{\Lambda} = -\frac{2}{\cot\theta_W - \tan\theta_W} \frac{\lambda_Z}{m_{\ell^*}} = -1.56 \frac{\lambda_Z}{m_{\ell^*}} \quad (12)$$

6. OPAL (quark)

$$\frac{f^{\text{OPAL}c}}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|) \quad (13)$$

7. DELPHI (charged lepton)

$$\lambda_{\gamma}^{\text{DELPHI}} = -\frac{1}{\sqrt{2}} \lambda_{\gamma} \quad (14)$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_{\ell} \left\{ \bar{\ell}_8^{\alpha} g_S F_{\mu\nu}^{\alpha} \sigma^{\mu\nu} (\eta_L \ell_L + \eta_R \ell_R) + h.c. \right\} \quad (15)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L \eta_R = 0$ as before.

¹³ ABDALLAH 09 and SCHAEEL 07A limits are from R_b , A_{FB}^b .

¹⁴ SCHAEEL 07A limits are from R_c , Q_{FB}^{depl} , and hadronic cross section measurements.

¹⁵ CHEUNG 01B is an update of BARGER 98E.

¹⁶ SCHAEEL 07A limit assumes quark flavor universality of the contact interactions.

¹⁷ ABULENCIA 06L limits are from $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

¹⁸ ABBIENDI 04G limits are from $e^+e^- \rightarrow q\bar{q}$ cross section at $\sqrt{s} = 130$ –207 GeV.

¹⁹ ADLOFF 03 limits are from the $d\sigma/dQ^2$ measurement of $e^\pm p \rightarrow e^\pm X$.

²⁰ ACHARD 02i limit is from the bound on the $e^+e^- \rightarrow t\bar{t}$ cross section. $\Lambda_{LL} = \Lambda_{LR} = \Lambda_{RR}$ and $m_t = 175$ GeV are assumed.

²¹ ABBIENDI 00R limits are from $e^+e^- \rightarrow q\bar{q}$ cross section at $\sqrt{s} = 130$ –189 GeV.

²² ACCIARRI 00P limit is from $e^+e^- \rightarrow q\bar{q}$ cross section at $\sqrt{s} = 130$ –189 GeV.

²³ ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+p \rightarrow e^+X$.

²⁴ BARATE 00i limits are from $e^+e^- \rightarrow q\bar{q}$ cross section and jet-charge asymmetry at 130–183 GeV.

²⁵ BARATE 00i limits are from R_b and jet-charge asymmetry at 130–183 GeV.

²⁶ BREITWEG 00B limits are from Q^2 spectrum measurement of e^+p collisions. See their Table 3 for the limits of various models.

²⁷ ABBIENDI 99 limits are from $e^+e^- \rightarrow q\bar{q}$ cross section at 130–136, 161–172, 183 GeV.

²⁸ ABBIENDI 99 limits are from R_b at 130–136, 161–172, 183 GeV.

²⁹ ABBOTT 99d limits are from e^+e^- mass distribution in $p\bar{p} \rightarrow e^+e^-X$ at $E_{cm} = 1.8$ TeV.

³⁰ ABREU 99A limits are from flavor-tagged $e^+e^- \rightarrow q\bar{q}$ cross section at 130–172 GeV.

³¹ ZARNECKI 99 use data from HERA, LEP, Tevatron, and various low-energy experiments.

³² ACCIARRI 98j limits are from $e^+e^- \rightarrow q\bar{q}$ cross section at $E_{cm} = 130$ –172 GeV.

³³ ACKERSTAFF 98v limits are from $e^+e^- \rightarrow q\bar{q}$ at $E_{cm} = 130$ –172 GeV.

³⁴ ACKERSTAFF 98v limits are from R_b measurements at $E_{cm} = 130$ –172 GeV.

³⁵ BARGER 98E use data from HERA, LEP, Tevatron, and various low-energy experiments.

> 6.5		39 DIAZCRUZ	94	RVUE $\Lambda_{LL}^-(\tau\nu_\tau\mu\nu_\mu)$
³⁷ JODIDIO 86 limit is from $\mu^+ \rightarrow \bar{\nu}_\mu e^+ \nu_e$. Chirality invariant interactions $L = (g^2/\Lambda^2)$ [$\eta_{LL}(\bar{\nu}_\mu L \gamma^\alpha \mu_L)(\bar{e} L \gamma^\alpha \nu_e L) + \eta_{LR}(\bar{\nu}_\mu L \gamma^\alpha \nu_e L)(\bar{e} R \gamma^\alpha \mu_R)$] with $g^2/4\pi = 1$ and $(\eta_{LL}, \eta_{LR}) = (0, \pm 1)$ are taken. No limits are given for Λ_{LL}^\pm with $(\eta_{LL}, \eta_{LR}) = (\pm 1, 0)$. For more general constraints with right-handed neutrinos and chirality nonconserving contact interactions, see their text.				
³⁸ DIAZCRUZ 94 limits are from $\Gamma(\tau \rightarrow e\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau e\nu_e) \ll \Lambda(\mu\nu_\mu e\nu_e)$.				
³⁹ DIAZCRUZ 94 limits are from $\Gamma(\tau \rightarrow \mu\nu\nu)$ and assume flavor-dependent contact interactions with $\Lambda(\tau\nu_\tau\mu\nu_\mu) \ll \Lambda(\mu\nu_\mu e\nu_e)$.				

SCALE LIMITS for Contact Interactions: $\Lambda(e\nu qq)$

VALUE (TeV)	CL%	DOCUMENT ID	TECN	
> 2.81	95	40 AFFOLDER	01i	CDF

⁴⁰ AFFOLDER 00i bound is for a scalar interaction $\bar{q}_R q_L \bar{\nu}_R \nu_L$.

SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$

Limits are for Λ_{LL}^\pm with color-singlet isoscalar exchanges among u_L 's and d_L 's only, unless otherwise noted. See EICHTEN 84 for details.

VALUE (TeV)	CL%	DOCUMENT ID	TECN	COMMENT
> 2.96	95	41 ABAZOV	09AE	D0 $p\bar{p} \rightarrow$ dijet, angl. Λ_{LL}^+

		45 BERTRAM	98	RVUE $p\bar{p} \rightarrow$ dijet mass

⁴¹ ABAZOV 09AE also obtain $\Lambda_{LL}^- > 2.96$ TeV.

⁴² The quoted limit for ABBOTT 00E is from H_T distribution in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. CTEQ4M PDF and $\mu = E_T^{\text{max}}$ are assumed. For limits with different assumptions, see their Tables 2 and 3. All quarks are assumed composite.

⁴³ The quoted limit is from inclusive dijet mass spectrum in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. ABBOTT 99C also obtain $\Lambda_{LL}^- > 2.4$ TeV. All quarks are assumed composite.

⁴⁴ ABBOTT 98G limit is from dijet angular distribution in $p\bar{p}$ collisions at $E_{cm} = 1.8$ TeV. All quarks are assumed composite.

⁴⁵ BERTRAM 98 obtain limit on the scale of color-octet axial-vector flavor-universal contact interactions: $\Lambda_{A8} > 2.1$ TeV. They also obtain a limit $\Lambda_{V8} > 2.4$ TeV on a color-octet flavor-universal vectorial contact interaction.

SCALE LIMITS for Contact Interactions: $\Lambda(\nu\nu qq)$

Limits are for Λ_{LL}^\pm only. For other cases, see each reference.

$\Lambda_{LL}^+(\text{TeV})$	$\Lambda_{LL}^-(\text{TeV})$	CL%	DOCUMENT ID	TECN	COMMENT
> 5.0	> 5.4	95	46 MCFARLAND	98	CCFR νN scattering

⁴⁶ MCFARLAND 98 assumed a flavor universal interaction. Neutrinos were mostly of muon type.

MASS LIMITS for Excited $e(e^*)$

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited $e(e^*)$ from Pair Production

These limits are obtained from $e^+e^- \rightarrow e^+e^*e^-$ and thus rely only on the (electroweak) charge of e^* . Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t -channel contribution from transition magnetic coupling is neglected. All limits assume a dominant $e^* \rightarrow e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

⁴⁷ From e^+e^- collisions at $\sqrt{s} = 183$ –209 GeV. $f = f'$ is assumed.

⁴⁸ From e^+e^- collisions at $\sqrt{s} = 189$ –209 GeV. $f = f'$ is assumed. ACHARD 03B also obtain limit for $f = -f'$: $m_{e^*} > 96.6$ GeV.

⁴⁹ From e^+e^- collisions at $\sqrt{s} = 192$ –202 GeV. $f = f'$ is assumed. ACCIARRI 01D also obtain limit for $f = -f'$: $m_{e^*} > 93.4$ GeV.

⁵⁰ From e^+e^- collisions at $\sqrt{s} = 161$ –183 GeV. $f = f'$ is assumed. ABBIENDI 00i also obtain limit for $f = -f'$ ($e^* \rightarrow \nu W$): $m_{e^*} > 86.0$ GeV.

⁵¹ From e^+e^- collisions at $\sqrt{s} = 189$ GeV. $f = f'$ is assumed. ACCIARRI 00E also obtain limit for $f = -f'$ ($e^* \rightarrow \nu W$): $m_{e^*} > 92.6$ GeV.

⁵² From e^+e^- collisions at $\sqrt{s} = 183$ GeV. $f = f'$ is assumed. ABREU 99o also obtain limit for $f = -f'$ ($e^* \rightarrow \nu W$): $m_{e^*} > 81.3$ GeV.

⁵³ From e^+e^- collisions at $\sqrt{s} = 170$ –172 GeV. ACKERSTAFF 98C also obtain limit from $e^* \rightarrow \nu W$ decay mode: $m_{e^*} > 81.3$ GeV.

See key on page 405

Searches Particle Listings Quark and Lepton Compositeness

⁵⁴ BARATE 98U obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.

⁵⁵ From e^+e^- collisions at $\sqrt{s}=161$ GeV.

⁵⁶ ABREU 97B also obtain limit from charged current decay mode $e^* \rightarrow \nu W$, $m_{e^*} > 70.9$ GeV.

⁵⁷ ABREU 97B also obtain limit from charged current decay mode $e^* \rightarrow \nu W$, $m_{e^*} > 44.6$ GeV.

Limits for Excited e (e^*) from Single Production

These limits are from $e^+e^- \rightarrow e^*e$, $W \rightarrow e^*\nu$, or $ep \rightarrow e^*X$ and depend on transition magnetic coupling between e and e^* . All limits assume $e^* \rightarrow e\gamma$ decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the $\lambda-m_{e^*}$ plane. See the original papers.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

⁵⁸ AARON 08A search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . The quoted limit assumes $f = f' = \Lambda/m_{e^*}$. See their Fig. 3 and Fig. 4 for the exclusion plots in the mass-coupling plane.

⁵⁹ ABAZOV 08H search for single e^* production in $p\bar{p}$ collisions with the decays $e^* \rightarrow e\gamma$. The e^* production is assumed to be described by an effective four-fermion interaction. See their Fig. 5 for the exclusion plot in the mass-coupling plane.

⁶⁰ ACOSTA 05B search for single e^* production in $p\bar{p}$ collisions with the decays $e^* \rightarrow e\gamma$. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

⁶¹ ACHARD 03B result is from e^+e^- collisions at $\sqrt{s} = 189$ –209 GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

⁶² ABBIENDI 02G result is from e^+e^- collisions at $\sqrt{s} = 183$ –209 GeV. $f = f' = \Lambda/m_{e^*}$ is assumed for e^* coupling. See their Fig. 4c for the exclusion limit in the mass-coupling plane.

⁶³ ADLOFF 02B search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 3 for the exclusion plot in the mass-coupling plane.

⁶⁴ CHEKANOV 02D search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 5a for the exclusion plot in the mass-coupling plane.

⁶⁵ ACCIARRI 01D result is from e^+e^- collisions at $\sqrt{s} = 192$ –202 GeV. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 4 for limits in the mass-coupling plane.

⁶⁶ ABBIENDI 00I result is from e^+e^- collisions at $\sqrt{s} = 161$ –183 GeV. See their Fig. 7 for limits in mass-coupling plane.

⁶⁷ ACCIARRI 00E result is from e^+e^- collisions at $\sqrt{s} = 189$ GeV. See their Fig. 3 for limits in mass-coupling plane.

⁶⁸ ADLOFF 00E search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 9 for the exclusion plot in the mass-coupling plane.

⁶⁹ ABREU 99O result is from e^+e^- collisions at $\sqrt{s} = 183$ GeV. See their Figs. 4 and 5 for the exclusion limit in the mass-coupling plane.

⁷⁰ ACCIARRI 98T search for single e^* production in quasi-real Compton scattering. The limit is for $|\lambda| > 1.0 \times 10^{-1}$ and non-chiral coupling of e^* . See their Fig. 7 for the exclusion plot in the mass-coupling plane.

⁷¹ ACKERSTAFF 98C from e^+e^- collisions at $\sqrt{s} = 170$ –172 GeV. See their Fig. 11 for the exclusion limit in the mass-coupling plane.

⁷² BARATE 98U is from e^+e^- collision at $\sqrt{s} = M_Z$. See their Fig. 12 for limits in mass-coupling plane

⁷³ From e^+e^- collisions at $\sqrt{s} = 161$ GeV.

⁷⁴ See Fig. 4a and Fig. 5a of ABREU 97B for the exclusion limit in the mass-coupling plane.

⁷⁵ See Fig. 2 and Fig. 3 of ACCIARRI 97G for the exclusion limit in the mass-coupling plane.

⁷⁶ ACKERSTAFF 97 result is from e^+e^- collisions at $\sqrt{s} = 161$ GeV. See their Fig. 3 for the exclusion limit in the mass-coupling plane.

⁷⁷ ADLOFF 97 search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . See their Fig. 4 for the rejection limits on the product of the production cross section and the branching ratio into a specific decay channel.

⁷⁸ BREITWEG 97C search for single e^* production in ep collisions with the decays $e^* \rightarrow e\gamma$, eZ , νW . $f = f' = 2\Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 9 for the exclusion plot in the mass-coupling plane.

Limits for Excited e (e^*) from $e^+e^- \rightarrow \gamma\gamma$

These limits are derived from indirect effects due to e^* exchange in the t channel and depend on transition magnetic coupling between e and e^* . All limits are for $\lambda_\gamma = 1$. All limits except ABE 89J and ACHARD 02D are for nonchiral coupling with $\eta_L = \eta_R = 1$. We choose the chiral coupling limit as the best limit and list it in the Summary Table.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

⁷⁹ ABDALLAH 04N also obtain a limit on the excited electron mass with e^* chiral coupling, $m_{e^*} > 295$ GeV at 95% CL.

⁸⁰ ACCIARRI 00G also obtain a limit on e^* with chiral coupling, $m_{e^*} > 213$ GeV.

⁸¹ BARATE 98U is from e^+e^- collision at $\sqrt{s} = M_Z$. See their Fig. 5 for limits in mass-coupling plane

Indirect Limits for Excited e (e^*)

These limits make use of loop effects involving e^* and are therefore subject to theoretical uncertainty.

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	⁸² DORENBOSCH 89	CHRM	$\bar{\nu}_\mu e \rightarrow \bar{\nu}_\mu e$ and $\nu_\mu e \rightarrow \nu_\mu e$
	⁸³ GRIFOLS 86	THEO	$\nu_\mu e \rightarrow \nu_\mu e$
	⁸⁴ RENARD 82	THEO	$g-2$ of electron

⁸² DORENBOSCH 89 obtain the limit $\lambda_\gamma^2 \Lambda_{\text{cut}}^2 / m_{e^*}^2 < 2.6$ (95% CL), where Λ_{cut} is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that $\Lambda_{\text{cut}} = 1$ TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*} / \Lambda_{\text{cut}}$ in composite models.

⁸³ GRIFOLS 86 uses $\nu_\mu e \rightarrow \nu_\mu e$ and $\bar{\nu}_\mu e \rightarrow \bar{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

⁸⁴ RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^* . See figures 2 and 3 of the paper.

MASS LIMITS FOR EXCITED μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \rightarrow \mu^+\mu^*$ and thus rely only on the (electroweak) charge of μ^* . Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume a dominant $\mu^* \rightarrow \mu\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

- 126 From e^+e^- collisions at $\sqrt{s} = 189\text{--}209$ GeV. $f = -f'$ is assumed. ACHARD 03b also obtain limit for $f = f'$: $m_{\nu_e^*} > 101.7$ GeV, $m_{\nu_\mu^*} > 101.8$ GeV, and $m_{\nu_\tau^*} > 92.9$ GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.
- 127 From e^+e^- collisions at $\sqrt{s} = 192\text{--}209$ GeV, ABBIENDI 04N obtain limit on $\sigma(e^+e^- \rightarrow \nu^*\nu^*) B^2(\nu^* \rightarrow \nu\gamma)$. See their Fig. 2. The limit ranges from 20 to 45fb for $m_{\nu^*} > 45$ GeV.
- 128 From e^+e^- collisions at $\sqrt{s} = 192\text{--}202$ GeV. $f = -f'$ is assumed. ACCIARRI 01d also obtain limit for $f = -f'$: $m_{\nu_e^*} > 99.1$ GeV, $m_{\nu_\mu^*} > 99.3$ GeV, $m_{\nu_\tau^*} > 90.5$ GeV.
- 129 From e^+e^- collisions at $\sqrt{s} = 161\text{--}183$ GeV. $f = -f'$ (photonic decay) is assumed. ABBIENDI 00i also obtain limit for $f = f'$ ($\nu^* \rightarrow \ell W$): $m_{\nu_e^*} > 91.1$ GeV, $m_{\nu_\mu^*} > 91.1$ GeV, $m_{\nu_\tau^*} > 83.1$ GeV.
- 130 From e^+e^- collisions at $\sqrt{s} = 189$ GeV. ABBIENDI,G 00d obtain limit on $\sigma(e^+e^- \rightarrow \nu^*\nu^*)B(\nu^* \rightarrow \nu\gamma)^2$. See their Fig. 14. The limit ranges from 50 to 80 fb for $\sqrt{s}/2 = 95$ GeV $> m_{\nu^*} > 45$ GeV.
- 131 From e^+e^- collisions at $\sqrt{s} = 189$ GeV. $f = -f'$ (photonic decay) is assumed. ACCIARRI 00E also obtain limit for $f = f'$ ($\nu^* \rightarrow \ell W$): $m_{\nu_e^*} > 93.9$ GeV, $m_{\nu_\mu^*} > 94.0$ GeV, $m_{\nu_\tau^*} > 91.5$ GeV.
- 132 From e^+e^- collisions at $\sqrt{s} = 130\text{--}183$ GeV, ABBIENDI 99F obtain limit on $\sigma(e^+e^- \rightarrow \nu^*\nu^*) B(\nu^* \rightarrow \nu\gamma)^2$. See their Fig. 13. The limit ranges from 0.094 to 0.14 pb for $\sqrt{s}/2 > m_{\nu^*} > 45$ GeV.
- 133 From e^+e^- collisions at $\sqrt{s} = 183$ GeV. $f = -f'$ is assumed. ABREU 99o also obtain limit for $f = f'$: $m_{\nu_e^*} > 87.3$ GeV, $m_{\nu_\mu^*} > 88.0$ GeV, $m_{\nu_\tau^*} > 81.0$ GeV.
- 134 From e^+e^- collisions at $\sqrt{s} = 170\text{--}172$ GeV. ACKERSTAFF 98c also obtain limit from charged decay modes: $m_{\nu_e^*} > 84.1$ GeV, $m_{\nu_\mu^*} > 83.9$ GeV, and $m_{\nu_\tau^*} > 79.4$ GeV.
- 135 BARATE 98u obtain limits on the form factor. See their Fig. 14 for limits in mass-form factor plane.
- 136 From e^+e^- collisions at $\sqrt{s} = 161$ GeV.
- 137 ABREU 97b also obtain limits from charged current decay modes, $m_{\nu^*} > 56.4$ GeV.
- 138 ABREU 97b also obtain limits from charged current decay modes, $m_{\nu^*} > 44.9$ GeV.
- 139 ACCIARRI 97G also obtain limits from charged current decay mode $\nu_e^* \rightarrow e W$, $m_{\nu^*} > 64.5$ GeV.

Limits for Excited ν (ν^*) from Single Production

These limits are from $e^+e^- \rightarrow \nu\nu^*$, $Z \rightarrow \nu\nu^*$, or $ep \rightarrow \nu^*X$ and depend on transition magnetic coupling between ν/e and ν^* . Assumptions about ν^* decay mode are given in footnotes.

| | | 171 | KIM | 90 | AMY $e_g: e^+ e^- \rightarrow g g; R$ |
- 168 ABE 89D look for pair production of unit-charged particles which leave the detector before decaying. In the above limit the color octet lepton is assumed to fragment into a unit-charged or neutral hadron with equal probability and to have long enough lifetime not to decay within the detector. The limit improves to 99 GeV if it always fragments into a unit-charged hadron.
- 169 ABT 93 search for e_g production via e -gluon fusion in ep collisions with $e_g \rightarrow eg$. See their Fig. 3 for exclusion plot in the $m_{e_g} - \Lambda$ plane for $m_{e_g} = 35\text{--}220$ GeV.
- 170 KIM 90 is at $E_{cm} = 50\text{--}60.8$ GeV. The same assumptions as in BARTEL 87B are used.
- 171 KIM 90 result $(m_{e_g} \Lambda_M)^{1/2} > 178.4$ GeV (95%CL, $\alpha_s = 0.16$ used) is subject to the same restriction as for BARTEL 85K.

MASS LIMITS for Color Octet Neutrinos (ν_g)

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
$\lambda \equiv m_{\nu_g} / \Lambda$				
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 3.8–29.8	95	173	KIM	90 AMY $\nu_g: e^+ e^- \rightarrow \text{acoplanar jets}$
none 9–21.9	95	174	BARTEL	87B JADE $\nu_g: e^+ e^- \rightarrow \text{acoplanar jets}$
172 BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_g \rightarrow \nu g$ is assumed.				
173 KIM 90 is at $E_{cm} = 50\text{--}60.8$ GeV. The same assumptions as in BARTEL 87B are used.				
174 BARTEL 87B is at $E_{cm} = 46.3\text{--}46.78$ GeV. The limit assumes the ν_g pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its $SU(2)_L \times U(1)_Y$ quantum numbers.				

MASS LIMITS for W_g (Color Octet W Boson)

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
175 ALBAJAR 89 give $\sigma(W_g \rightarrow W + \text{jet}) / \sigma(W) < 0.019$ (90% CL) for $m_{W_g} > 220$ GeV.	89 UA1	$p\bar{p} \rightarrow W_g X, W_g \rightarrow Wg$

Extra Dimensions

For explanation of terms used and discussion of significant model dependence of following limits, see the "Extra Dimensions" review. Footnotes describe originally quoted limit. n indicates the number of extra dimensions.

Limits not encoded here are summarized in the "Extra Dimensions" review.

EXTRA DIMENSIONS

Updated Sept. 2007 by G.F. Giudice (CERN) and J.D. Wells (MCTP/Michigan).

I Introduction

The idea of using extra spatial dimensions to unify different forces started in 1914 with Nordstöm, who proposed a 5-dimensional vector theory to simultaneously describe electromagnetism and a scalar version of gravity. After the invention of general relativity, in 1919 Kaluza noticed that the 5-dimensional generalization of Einstein theory can simultaneously describe gravitational and electromagnetic interactions. The role of gauge invariance and the physical meaning of the compactification of extra dimensions was elucidated by Klein. However, the Kaluza-Klein (KK) theory failed in its original purpose because of internal inconsistencies and was essentially abandoned until the advent of supergravity in the late 1970's. Higher-dimensional theories were reintroduced in physics to exploit the special properties that supergravity and superstring theories possess for particular values of spacetime dimensions. More recently it was realized [1,2] that extra dimensions with a fundamental scale of order TeV^{-1} could address the $M_W - M_{Pl}$ hierarchy problem and therefore have direct implications for collider experiments. Here we will review [3] the proposed scenarios with experimentally accessible extra dimensions.

II Gravity in Flat Extra Dimensions**II.1 Theoretical Setup**

Following Ref. 1, let us consider a D -dimensional spacetime with $D = 4 + \delta$, where δ is the number of extra spatial dimensions. The space is factorized into $R^4 \times M_\delta$ (meaning that the 4-dimensional part of the metric does not depend on extra-dimensional coordinates), where M_δ is a δ -dimensional compact space with finite volume V_δ . For concreteness, we will consider a δ -dimensional torus of radius R , for which $V_\delta = (2\pi R)^\delta$. Standard Model (SM) fields are assumed to be localized on a $(3 + 1)$ -dimensional subspace. This assumption can be realized in field theory, but it is most natural [4] in the setting of string theory, where gauge and matter fields can be confined to live on “branes” (for a review see Ref. 5). On the other hand, gravity, which according to general relativity is described by the spacetime geometry, extends to all D dimensions. The Einstein action takes the form

$$S_E = \frac{\bar{M}_D^{2+\delta}}{2} \int d^4x d^\delta y \sqrt{-\det g} \mathcal{R}(g), \quad (1)$$

where x and y describe ordinary and extra coordinates, respectively. The metric g , the scalar curvature \mathcal{R} , and the reduced Planck mass \bar{M}_D refer to the D -dimensional theory. The effective action for the 4-dimensional graviton is obtained by restricting the metric indices to 4 dimensions and by performing the integral in y . Because of the above-mentioned factorization hypothesis, the integral in y reduces to the volume V_δ , and therefore the 4-dimensional reduced Planck mass is given by

$$\bar{M}_{\text{Pl}}^2 = \bar{M}_D^{2+\delta} V_\delta = \bar{M}_D^{2+\delta} (2\pi R)^\delta, \quad (2)$$

where $\bar{M}_{\text{Pl}} = M_{\text{Pl}}/\sqrt{8\pi} = 2.4 \times 10^{18}$ GeV. The same formula can be obtained from Gauss’s law in extra dimensions [6]. Following ref. [7], we will consider $M_D = (2\pi)^\delta/(2+\delta)\bar{M}_D$ as the fundamental D -dimensional Planck mass.

The key assumption of Ref. 1 is that the hierarchy problem is solved because the truly fundamental scale of gravity M_D (and therefore the ultraviolet cut-off of field theory) lies around the TeV region. From Eq. (2) it follows that the correct value of \bar{M}_{Pl} can be obtained with a large value of RM_D . The inverse compactification radius is therefore given by

$$R^{-1} = M_D (M_D/\bar{M}_{\text{Pl}})^{2/\delta}, \quad (3)$$

which corresponds to 4×10^{-4} eV, 20 keV, 7 MeV for $M_D = 1$ TeV and $\delta = 2, 4, 6$, respectively. In this framework, gravity is weak because it is diluted in a large space ($R \gg M_D^{-1}$). Of course, a complete solution of the hierarchy problem would require a dynamical explanation for the radius stabilization at a large value.

A D -dimensional bosonic field can be expanded in Fourier modes in the extra coordinates

$$\phi(x, y) = \sum_{\vec{n}} \frac{\varphi^{(\vec{n})}(x)}{\sqrt{V_\delta}} \exp\left(i \frac{\vec{n} \cdot \vec{y}}{R}\right). \quad (4)$$

The sum is discrete because of the finite size of the compactified space. The fields $\varphi^{(\vec{n})}$ are called the n^{th} KK excitations (or modes) of ϕ , and correspond to particles propagating in 4 dimensions with masses $m_{(\vec{n})}^2 = |\vec{n}|^2/R^2 + m_0^2$, where m_0 is the mass of the zero mode. The D -dimensional graviton can then be recast as a tower of KK states with increasing mass. However, since R^{-1} in Eq. (3) is smaller than the typical energy resolution in collider experiments, the mass distribution of KK gravitons is practically continuous.

Although each KK graviton has a purely gravitational coupling suppressed by \bar{M}_{Pl}^{-1} , inclusive processes in which we sum over the large number of available gravitons have cross sections suppressed only by powers of M_D . Indeed, for scatterings with typical energy E , we expect $\sigma \sim E^\delta/M_D^{2+\delta}$, as evident from power-counting in D dimensions. Processes involving gravitons are therefore detectable in collider experiments if M_D is in the TeV region.

The astrophysical considerations described in Sec. II.6 set very stringent bounds on M_D for $\delta < 4$, in some cases even ruling out the possibility of observing any signal at the LHC. However, these bounds disappear if there are no KK gravitons lighter than about 100 MeV. Variations of the original model exist [8,9] in which the light KK gravitons receive small extra contributions to their masses, sufficient to evade the astrophysical bounds. Notice that collider experiments are nearly insensitive to such modifications of the infrared part of the KK graviton spectrum, since they mostly probe the heavy graviton modes. Therefore, in the context of these variations, it is important to test at colliders extra-dimensional gravity also for low values of δ , and even for $\delta = 1$ [9]. In addition to these direct experimental constraints, the proposal of gravity in flat extra dimensions has dramatic cosmological consequences and requires a rethinking of the thermal history of the universe for temperatures as low as the MeV scale.

II.2 Collider Signals in Linearized Gravity

By making a derivative expansion of Einstein gravity, one can construct an effective theory describing KK graviton interactions, which is valid for energies much smaller than M_D [7,10,11]. With the aid of this effective theory, it is possible to make predictions for graviton-emission processes at colliders. Since the produced gravitons interact with matter only with rates suppressed by inverse powers of \bar{M}_{Pl} , they will remain undetected leaving a “missing-energy” signature. Extra-dimensional gravitons have been searched for in the processes $e^+e^- \rightarrow \gamma + \cancel{E}$ and $e^+e^- \rightarrow Z + \cancel{E}$ at LEP, and $p\bar{p} \rightarrow \text{jet} + \cancel{E}_T$ and $p\bar{p} \rightarrow \gamma + \cancel{E}_T$ at the Tevatron. The combined LEP 95% CL limits are [12] $M_D > 1.60, 1.20, 0.94, 0.77, 0.66$ TeV for $\delta = 2, \dots, 6$ respectively. Experiments at the LHC will improve the sensitivity. However, the theoretical predictions for the graviton-emission rates should be applied with care to hadron machines. The effective theory results are valid only for center-of-mass energy of the parton collision much smaller than M_D .

Extra Dimensions

The effective theory under consideration also contains the full set of higher-dimensional operators, whose coefficients are, however, not calculable, because they depend on the ultraviolet properties of gravity. This is in contrast with graviton emission, which is a calculable process within the effective theory because it is linked to the infrared properties of gravity. The higher-dimensional operators are the analogue of the contact interactions described in ref. [13]. Of particular interest is the dimension-8 operator mediated by tree-level graviton exchange [7,11,14]

$$\mathcal{L}_{\text{int}} = \pm \frac{4\pi}{\Lambda_T^4} \mathcal{T}, \quad \mathcal{T} = \frac{1}{2} \left(T_{\mu\nu} T^{\mu\nu} - \frac{1}{\delta+2} T_\mu^\mu T_\nu^\nu \right), \quad (5)$$

where $T_{\mu\nu}$ is the energy momentum tensor. (There exist several alternate definitions in the literature for the cutoff in Eq. (5) including M_{TT} used in the Listings, where $M_{TT}^4 = (2/\pi)\Lambda_T^4$.) This operator gives anomalous contributions to many high-energy processes. The 95% CL limit from Bhabha scattering and diphoton production at LEP is [15] $\Lambda_T > 1.29$ (1.12) TeV for constructive (destructive) interference, corresponding to the \pm signs in Eq. (5). The analogous limit from Drell-Yan and diphotons at Tevatron is [16] $\Lambda_T > 1.43$ (1.27) TeV.

Graviton loops can be even more important than tree-level exchange, because they can generate operators of dimension lower than 8. For simple graviton loops, there is only one dimension-6 operator that can be generated (excluding Higgs fields in the external legs) [18,19],

$$\mathcal{L}_{\text{int}} = \pm \frac{4\pi}{\Lambda_T^2} \Upsilon, \quad \Upsilon = \frac{1}{2} \left(\sum_{f=q,\ell} \bar{f} \gamma_\mu \gamma_5 f \right)^2. \quad (6)$$

Here the sum extends over all quarks and leptons in the theory. The 95% CL combined LEP limit [20] from lepton-pair processes is $\Lambda_T > 17.2$ (15.1) TeV for constructive (destructive) interference, and $\Lambda_T > 15.3$ (11.5) TeV is obtained from $b\bar{b}$ production. Limits from graviton emission and effective operators cannot be compared in a model-independent way, unless one introduces some well-defined cutoff procedure (see, *e.g.*, Ref. 19).

II.3 The Transplanckian Regime

The use of linearized Einstein gravity, discussed in Sec. II.2, is valid for processes with typical center-of-mass energy $\sqrt{s} \ll M_D$. The physics at $\sqrt{s} \sim M_D$ can be described only with knowledge of the underlying quantum-gravity theory. Toy models have been used to mimic possible effects of string theory at colliders [21]. Once we access the transplanckian region $\sqrt{s} \gg M_D$, a semiclassical description of the scattering process becomes adequate. Indeed, in the transplanckian limit, the Schwarzschild radius for a colliding system with center-of-mass energy \sqrt{s} in $D = 4 + \delta$ dimensions,

$$R_S = \left[\frac{2^\delta \pi^{(\delta-3)/2}}{\delta+2} \Gamma\left(\frac{\delta+3}{2}\right) \frac{\sqrt{s}}{M_D^{\delta+2}} \right]^{1/(\delta+1)}, \quad (7)$$

is larger than the D -dimensional Planck length M_D^{-1} . Therefore, quantum-gravity effects are subleading with respect to classical gravitational effects (described by R_S).

If the impact parameter b of the process satisfies $b \gg R_S$, the transplanckian collision is determined by linear semiclassical gravitational scattering. The corresponding cross sections have been computed [22] in the eikonal approximation, valid in the limit of small deflection angle. The collider signal at the LHC is a dijet final state, with features characteristic of gravity in extra dimensions.

When $b < R_S$, we expect gravitational collapse and black-hole formation [23,24] (see Ref. 25 and references therein). The black-hole production cross section is estimated to be of order the geometric area $\sigma \sim \pi R_S^2$. This estimate has large uncertainties due, for instance, to the unknown amount of gravitational radiation emitted during collapse. Nevertheless, for M_D close to the weak scale, the black-hole production rate at the LHC is large. For example, the production cross section of 6 TeV black holes is about 10 pb, for $M_D = 1.5$ TeV. The produced black-hole emits thermal radiation with Hawking temperature $T_H = (\delta+1)/(4\pi R_S)$ until it reaches the Planck phase (where quantum-gravity effects become important). A black hole of initial mass M_{BH} completely evaporates with lifetime $\tau \sim M_{BH}^{(\delta+3)/(\delta+1)} / M_D^{2(\delta+2)/(\delta+1)}$, which typically is 10^{-26} – 10^{-27} s for $M_D = 1$ TeV. The black hole can be easily detected because it emits a significant fraction of visible (*i.e.*, non-gravitational) radiation, although the precise amount is not known in the general case of D dimensions. Computations exist [26] for the grey-body factors, which describe the distortion of the emitted radiation from pure black-body caused by the strong gravitational background field.

To trust the semiclassical approximation, the typical energy of the process has to be much larger than M_D . Given the present constraints on extra-dimensional gravity, it is clear that the maximum energy available at the LHC allows, at best, to only marginally access the transplanckian region. If gravitational scattering and black-hole production are observed at the LHC, it is likely that significant quantum-gravity (or string-theory) corrections will affect the semiclassical calculations or estimates. In the context of string theory, it is possible that the production of string-balls [27] dominates over black holes.

If M_D is around the TeV scale, transplanckian collisions would regularly occur in the interaction of high-energy cosmic rays with the earth's atmosphere and could be observed in present and future cosmic ray experiments [28,29].

II.4 Graviscalars

After compactification, the D -dimensional graviton contains KK towers of spin-2 gravitational states (as discussed above), of spin-1 “graviphoton” states, and of spin-0 “graviscalar” states. In most processes, the graviphotons and graviscalars are much less important than their spin-2 counterparts. A single graviscalar tower is coupled to SM fields through the trace of the energy momentum tensor. The resulting coupling is, however, very weak for SM particles with small masses.

Perhaps the most accessible probe of the graviscalars would be through their allowed mixing with the Higgs boson [30] in the induced curvature-Higgs term of the 4-dimensional action. This can be recast as a contribution to the decay width of the SM Higgs boson into an invisible channel. Although the invisible branching fraction is a free parameter of the theory, it is more likely to be important when the SM Higgs boson width is particularly narrow ($m_H \lesssim 140$ GeV). The collider phenomenology of invisibly decaying Higgs bosons investigated in the literature is applicable here (see Ref. 31 and references therein).

II.5 Tests of the Gravitational Force Law

The theoretical developments in gravity with large extra dimensions have further stimulated interest in experiments looking for possible deviations from the gravitational inverse-square law (for a review, see Ref. 32). Such deviations are usually parametrized by a modified Newtonian potential of the form

$$V(r) = -G_N \frac{m_1 m_2}{r} [1 + \alpha \exp(-r/\lambda)]. \quad (8)$$

The experimental limits on the parameters α and λ are summarized in Fig. 1, taken from Ref. 33.

Figure 1: Experimental limits on α and λ of Eq. (8), which parametrize deviations from Newton’s law. From Ref. 33.

For gravity with δ extra dimensions, in the case of toroidal compactifications, the parameter α is given by $\alpha = 8 \delta/3$ and λ is the Compton wavelength of the first graviton Kaluza-Klein mode, equal to the radius R . From the results shown in Fig. 1, one finds $R < 37$ (44) μm at 95% CL for $\delta = 2$ (1) which, using Eq. (3), becomes $M_D > 3.6$ TeV for $\delta = 2$. This bound is weaker than the astrophysical bounds discussed in Sec. II.6, which actually exclude the occurrence of any visible signal in planned tests of Newton’s law. However, in the context of higher-dimensional theories, other particles like light gauge bosons, moduli or radions could mediate detectable modifications of Newton’s law, without running up against the astrophysical limits.

II.6 Astrophysical Bounds

Because of the existence of the light and weakly-coupled KK gravitons, gravity in extra dimensions is strongly constrained by several astrophysical considerations (see Ref. [34] and references therein). The requirement that KK gravitons do not carry away more than half of the energy emitted by the supernova SN1987A gives the bounds [35] $M_D > 14$ (1.6) TeV for $\delta = 2$ (3). KK gravitons produced by all supernovae in the universe lead to a diffuse γ ray background generated by graviton decays into photons. Measurements by the EGRET satellite imply [36] $M_D > 38$ (4.1) TeV for $\delta = 2$ (3). Most of the KK gravitons emitted by supernova remnants and neutron stars are gravitationally trapped. The gravitons forming this halo occasionally decay, emitting photons. Limits on γ rays from neutron-star sources imply [34] $M_D > 200$ (16) TeV for $\delta = 2$ (3). The decay products of the gravitons forming the halo can hit the surface of the neutron star, providing a heat source. The low measured luminosities of some pulsars imply [34] $M_D > 750$ (35) TeV for $\delta = 2$ (3). These bounds are valid only if the graviton KK mass spectrum below about 100 MeV is not modified by distortions of the compactification space (see Sec. II.1).

III Gravity in Warped Extra Dimensions

III.1 Theoretical Setup

In the proposal of Ref. 2, the M_W - M_{Pl} hierarchy is explained using an extra-dimensional analogy of the classical gravitational redshift in curved space, as we illustrate below. The setup consists of a 5-dimensional space in which the fifth dimension is compactified on S^1/Z_2 , *i.e.*, a circle projected into a segment by identifying points of the circle opposite with respect to a given diameter. Each end-point of the segment (the “fixed-points” of the orbifold projection) is the location of a 3-dimensional brane. The two branes have equal but opposite tensions. We will refer to the negative-tension brane as the infrared (IR) brane, where SM fields are assumed to be localized, and the positive-tension brane as the ultraviolet (UV) brane. The bulk cosmological constant is fine-tuned such that the effective cosmological constant in the 3-dimensional space exactly cancels.

The solution of the Einstein equation in vacuum gives the metric corresponding to the line element

$$ds^2 = \exp(-2k|y|) \eta_{\mu\nu} dx^\mu dx^\nu - dy^2. \quad (9)$$

Here y is the 5th coordinate, with the UV and IR branes located at $y = 0$ and $y = \pi R$, respectively; R is the compactification radius and k is the AdS curvature. The 4-dimensional metric in Eq. (9) is modified with respect to the flat Minkowski metric $\eta_{\mu\nu}$ by the factor $\exp(-2k|y|)$. This shows that the 5-dimensional space is not factorized, meaning that the 4-dimensional metric depends on the extra-dimensional coordinate y . This feature is key to the desired effect.

As is known from general relativity, the energy of a particle travelling through a gravitational field is redshifted by

Searches Particle Listings

Extra Dimensions

an amount proportional to $|g_{00}|^{-1/2}$, where g_{00} is the time-component of the metric. Analogously, energies (or masses) viewed on the IR brane ($y = \pi R$) are red-shifted with respect to their values at the UV brane ($y = 0$) by an amount equal to the warp factor $\exp(-\pi kR)$, as shown by Eq. (9):

$$m_{IR} = m_{UV} \exp(-\pi kR). \quad (10)$$

A mass $m_{UV} \sim \mathcal{O}(\overline{M}_{\text{Pl}})$ on the UV brane corresponds to a mass on the IR brane with a value $m_{IR} \sim \mathcal{O}(M_{\text{W}})$, if $R \simeq 12k^{-1}$. A radius moderately larger than the fundamental scale k is therefore sufficient to reproduce the large hierarchy between the Planck and Fermi scales. A simple and elegant mechanism to stabilize the radius exists [38], by adding a scalar particle with a bulk mass and different potential terms on the two branes.

The effective theory describing the interaction of the KK modes of the graviton is characterized by two mass parameters, which we take to be m_1 and Λ_π . Both are a warp-factor smaller than the UV scale, and therefore they are naturally of order the weak scale. The parameter m_1 is the mass of the first KK graviton mode, from which the mass m_n of the generic n^{th} mode is determined,

$$m_n = \frac{x_n}{x_1} m_1. \quad (11)$$

Here x_n is the n^{th} root of the Bessel function J_1 ($x_1 = 3.83$, $x_2 = 7.02$ and, for large n , $x_n = (n + 1/4)\pi$). The parameter Λ_π determines the strength of the coupling of the KK gravitons $h_{\mu\nu}^{(n)}$ with the energy momentum tensor $T_{\mu\nu}$,

$$\mathcal{L} = -\frac{T^{\mu\nu}}{\overline{M}_{\text{Pl}}} h_{\mu\nu}^{(0)} - \frac{T^{\mu\nu}}{\Lambda_\pi} \sum_{n=1}^{\infty} h_{\mu\nu}^{(n)}. \quad (12)$$

In the approach discussed in Sec. II.1, \overline{M}_{Pl} appears to us much larger than the weak scale because gravity is diluted in a large space. In the approach described in this section, the explanation lies instead in the non-trivial configuration of the gravitational field: the zero-mode graviton wavefunction is peaked around the UV brane and it has an exponentially small overlap with the IR brane where we live. The extra dimensions discussed in Sec. II.1 are large and “nearly flat;” the graviton excitations are very weakly coupled and have a mass gap that is negligibly small in collider experiments. Here, instead, the gravitons have a mass gap of \sim TeV size and become strongly-coupled at the weak scale.

III.2 Collider Signals

The KK excitations of the graviton, possibly being of order the TeV scale, are subject to experimental discovery at high-energy colliders. As discussed above, KK graviton production cross-sections and decay widths are set by the first KK mass m_1 and the graviton-matter interaction scale Λ_π . Some studies use m_1 and k as the independent parameters, and so it is helpful to keep in mind that the relationships between all of these parameters are

$$\frac{m_n}{\Lambda_\pi} = \frac{kx_n}{\overline{M}_{\text{Pl}}}, \quad \Lambda_\pi = \overline{M}_{\text{Pl}} \exp(-\pi kR), \quad (13)$$

where again x_n are the zeros of the J_1 Bessel function. Resonant and on-shell production of the n^{th} KK gravitons leads to characteristic peaks in the dilepton and diphoton invariant-mass spectra and it is probed at colliders for $\sqrt{s} \geq m_n$. Current limits from dimuon, dielectron, and diphoton channels at CDF and DØ give the 95% CL limits $\Lambda_\pi > 4.3(2.6)$ TeV for $m_1 = 500(700)$ GeV [16,17].

Contact interactions arising from integrating out heavy KK modes of the graviton generate the dimension-8 operator \mathcal{T} , analogous to the one in Eq. (5) in the flat extra dimensions case. Although searches for effects of these non-renormalizable operators cannot confirm directly the existence of a heavy spin-2 state, they nevertheless provide a good probe of the model [39,40].

Searches for direct production of KK excitations of the graviton and contact interactions induced by gravity in compact extra-dimensional warped space will continue at the LHC. With the large increase in energy, one expects prime regions of the parameter space up to $m_n, \Lambda_\pi \sim 10$ TeV [39] to be probed.

If SM states are in the AdS bulk, KK graviton phenomenology becomes much more model dependent. Present limits and future collider probes of the masses and interaction strengths of the KK gravitons to matter fields are significantly reduced [41] in some circumstances, and each specific model of SM fields in the AdS bulk should be analyzed on a case-by-case basis.

For warped metrics, black-hole production is analogous to the case discussed in Sec. II.3, as long the radius of the black hole is smaller than the AdS radius $1/k$, when the space is effectively flat. For heavier black holes, the production cross section is expected to grow with energy only as $\log^2 E$, saturating the Froissart bound [37].

III.3 The Radion

The size of the warped extra-dimensional space is controlled by the value of the radion, a scalar field corresponding to an overall dilatation of the extra coordinates. Stabilizing the radion is required for a viable theory, and known stabilization mechanisms often imply that the radion is less massive than the KK excitations of the graviton [38], thus making it perhaps the lightest beyond-the-SM particle in this scenario.

The coupling of the radion r to matter is $\mathcal{L} = -rT/\Lambda_\varphi$, where T is the trace of the energy momentum tensor and $\Lambda_\varphi = \sqrt{24}\Lambda_\pi$ is expected to be near the weak scale. The relative couplings of r to the SM fields are similar to, but not exactly the same as, those of the Higgs boson. The partial widths are generally smaller by a factor of v/Λ_φ compared to SM Higgs decay widths, where $v = 246$ GeV is the vacuum expectation value of the SM Higgs doublet. On the other hand, the trace anomaly that arises in the SM gauge groups by virtue of quantum effects enhances the couplings of the radion to gluons and photons over the naive v/Λ_φ rescaling of the Higgs couplings to these same particles. Thus, for example, one finds that the radion’s large coupling to gluons [30,43] enables a sizeable $gg \rightarrow r$ cross section even for Λ_φ large compared to m_{W} .

Another subtlety of the radion is its ability to mix with the Higgs boson through the curvature-scalar interaction [30],

$$S_{mix} = -\xi \int d^4x \sqrt{-\det g_{\text{ind}}} R(g_{\text{ind}}) H^+ H, \quad (14)$$

where g_{ind} is the four-dimensional induced metric. With $\xi \neq 0$, there is neither a pure Higgs boson nor pure radion mass eigenstate. Mixing between states enables decays of the heavier eigenstate into lighter eigenstates if kinematically allowed. Overall, the production cross sections, widths and relative branching fractions can all be affected significantly by the value of the mixing parameter ξ [30,42,43,44]. Despite the various permutations of couplings and branching fractions that the radion and the Higgs-radion mixed states can have into SM particles, the search strategies for these particles at high-energy colliders are similar to those of the SM Higgs boson.

IV Standard Model Fields in Flat Extra Dimensions

IV.1 TeV-Scale Compactification

Not only gravity, but also SM fields could live in an experimentally accessible higher-dimensional space [45]. This hypothesis could lead to unification of gauge couplings at a low scale [46]. In contrast with gravity, these extra dimensions must be at least as small as about TeV^{-1} in order to avoid incompatibility with experiment. The canonical extra-dimensional space of this type is a 5th dimension compactified on the interval S^1/Z_2 , where again the radius of the S^1 is denoted R , and the Z_2 symmetry identifies $y \leftrightarrow -y$ of the extra-dimensional coordinate. The two fixed points $y = 0$ and $y = \pi R$ define the end-points of the compactification interval.

Let us first consider the case in which gauge fields live in extra dimensions, while matter and Higgs fields are confined to a 3-brane. The masses M_n of the gauge-boson KK excitations are related to the masses M_0 of the zero-mode normal gauge bosons by

$$M_n^2 = M_0^2 + \frac{n^2}{R^2}. \quad (15)$$

The KK excitations of the vector bosons have couplings to matter a factor of $\sqrt{2}$ larger than the zero modes ($g_n = \sqrt{2}g$). Therefore, if the first KK excitation is $\sim \text{TeV}$, tree-level virtual effects of the KK gauge bosons can have a significant effect on precision electroweak observables and high-energy processes such as $e^+e^- \rightarrow f\bar{f}$. In this theory one expects that observables will be shifted with respect to their SM value by a fractional amount proportional to [47]

$$V = 2 \sum_n \left(\frac{g_n^2}{g^2} \right) \frac{M_Z^2 R^2}{n^2} \sim \frac{2}{3} \pi^2 M_Z^2 R^2. \quad (16)$$

More complicated compactifications lead to more complicated representations of V . A global fit to all relevant observables, including precision electroweak data, Tevatron, HERA and LEP2 results, shows that $R^{-1} \gtrsim 6.8 \text{ TeV}$ is required [48,49]. The LHC with 100 fb^{-1} integrated luminosity would be able to search nearly as high as $R^{-1} \sim 16 \text{ TeV}$ [48].

Fermions can also be promoted to live in the extra dimensions. Although fermions are vector-like in 5-dimension, chiral states in 4-dimensions can be obtained by using the Z_2 symmetry of the orbifold. An interesting possibility to explain the observed spectrum of quark and lepton masses is to assume that different fermions are localized in different points of the extra dimension. Their different overlap with the Higgs wavefunction can generate a hierarchical structure of Yukawa couplings [50], although there are strong bounds on the non-universal couplings of fermions to the KK gauge bosons from flavor-violating processes [51].

The case in which all SM particles uniformly propagate in the bulk of an extra-dimensional space is referred to as Universal Extra Dimensions (UED) [52]. The absence of a reference brane that breaks translation invariance in the extra dimensional direction implies extra-dimensional momentum conservation. After compactification and after inclusion of boundary terms at the fixed points, the conservation law preserves only a discrete Z_2 parity (called KK-parity). The KK-parity of the n^{th} KK mode of each particle is $(-1)^n$. Thus, in UED, the first KK excitations can only be pair-produced and their virtual effect comes only from loop corrections. Therefore the ability to search for and constrain parameter space is diminished. The result is that for one extra dimension the limit on R^{-1} is between 300 and 500 GeV depending on the Higgs mass [53].

Because of KK-parity conservation, the lightest KK state is stable. Thus, one interesting consequence of UED is the possibility of the lightest KK state comprising the dark matter. After including radiative corrections [54], it is found that the lightest KK state is the first excitation of the hypercharge gauge boson $B^{(1)}$. It can constitute the cold dark matter of the universe if its mass is approximately 600 GeV [55], well above current collider limits. The LHC should be able to probe UED up to $R^{-1} \sim 1.5 \text{ TeV}$ [56], and thus possibly confirm the UED dark matter scenario.

An interesting and ambitious approach is to use extra dimensions to explain the hierarchy problem through Higgs-gauge unification [57]. The SM Higgs doublet is interpreted as the extra-dimensional component of an extended gauge symmetry acting in more than four dimensions, and the weak scale is protected by the extra-dimensional gauge symmetry. There are several obstacles to make this proposal fully realistic, but ongoing research is trying to overcome them.

IV.2 Grand Unification in Extra Dimensions

Extra dimensions offer a simple and elegant way to break GUT symmetries [58] by appropriate field boundary conditions in compactifications on orbifolds. In this case the size of the relevant extra dimensions is much smaller than what has been considered so far, with compactification radii that are typically $\mathcal{O}(M_{\text{GUT}})$. This approach has several attractive features (for a review, see Ref. 59). The doublet-triplet splitting problem [60] is solved by projecting out the unwanted light Higgs triplet in the compactification. In the same way, one can eliminate

Searches Particle Listings

Extra Dimensions

the dangerous supersymmetric $d = 5$ proton-decay operators, or even forbid proton decay [61]. However, the prospects for proton-decay searches are not necessarily bleak. Because of the effect of the KK modes, the unification scale can be lowered to 10^{14} – 10^{15} GeV, enhancing the effect of $d = 6$ operators. The prediction for the proton lifetime is model-dependent.

V Standard Model Fields in Warped Extra Dimensions

V.1 Extra Dimensions and Strong Dynamics at the Weak Scale

In the original warped model of Ref. 2, all SM fields are confined on the IR brane, although to solve the hierarchy problem it is sufficient that only the Higgs field lives on the brane. The variation in which SM fermions and gauge bosons are bulk fields is interesting because it links warped extra dimensions to technicolor-like models with strong dynamics at the weak scale. This connection comes from the AdS/CFT correspondence [62], which relates the properties of AdS₅, 5-dimensional gravity with negative cosmological constant, to a strongly-coupled 4-dimensional conformal field theory (CFT). In the correspondence, the motion along the 5th dimension is interpreted as the renormalization-group flow of the 4-dimensional theory, with the UV brane playing the role of the Planck-mass cutoff and the IR brane as the breaking of the conformal invariance. Local gauge symmetries acting on the bulk of AdS₅ correspond to global symmetries of the 4-dimensional theory. The original warped model of Ref. 2 is then reinterpreted as an “almost CFT,” whose couplings run very slowly with the renormalization scale until the TeV scale is reached, where the theory develops a mass gap. In the variation in which SM fields, other than the Higgs, are promoted to the bulk, these fields correspond to elementary particles coupled to the CFT. Around the TeV scale the theory becomes strongly-interacting, producing a composite Higgs, which breaks electroweak symmetry. Notice the similarity with walking technicolor [63].

The most basic version of this theory is in conflict with electroweak precision measurements. To reduce the contribution to the ρ parameter, it is necessary to introduce an approximate global symmetry, a custodial $SU(2)$ under which the generators of $SU(2)_L$ transform as a triplet. Using the AdS/CFT correspondence, this requires the extension of the electroweak gauge symmetry to $SU(2)_L \times SU(2)_R \times U(1)$ in the bulk of the 5-dimensional theory [64]. Models along these lines have been constructed. The composite Higgs can be lighter than the strongly-interacting scale in models in which it is a pseudo-Goldstone boson [65]. Nevertheless, electroweak data provide strong constraints on such models.

When SM fermions are promoted to 5 dimensions, they become non-chiral and can acquire a bulk mass. The fermions are localized in different positions along the 5th dimension, with an exponential dependence on the value of the bulk mass (in units of the AdS curvature). Since the masses of the ordinary zero-mode SM fermions depend on their wavefunction overlap with the Higgs (localized on the IR brane), large hierarchies in

the mass spectrum of quarks and leptons can be obtained from order-unity variations of the bulk masses [66]. This mechanism can potentially explain the fermion mass pattern, and it can lead to new effects in flavor-changing processes, especially those involving the third-generation quarks [67]. The smallness of neutrino masses can also be explained, if right-handed neutrinos propagate in the bulk [68].

V.2 Higgsless Models

Extra dimensions offer new possibilities for breaking gauge symmetries. Even in the absence of physical scalars, electroweak symmetry can be broken by field boundary conditions on compactified spaces. The lightest KK modes of the gauge bosons corresponding to broken generators acquire masses equal to R^{-1} , the inverse of the compactification radius, now to be identified with M_W . In the ordinary 4-dimensional case, the SM without a Higgs boson violates unitarity at energies $E \sim 4\pi M_W/g \sim 1$ TeV. On the other hand, in extra dimensions, the breaking of unitarity in the longitudinal- W scattering amplitudes is delayed because of the contribution of the heavy KK gauge-boson modes [69]. The largest effect is obtained for one extra dimension, where the violation of unitarity occurs around $E \sim 12\pi^2 M_W/g \sim 10$ TeV. This is conceivably a large enough scale to render the strong dynamics, which is eventually responsible for unitarization, invisible to the processes measured by LEP experiments.

These Higgsless models, in their minimal version, are inconsistent with observations, because they predict new W gauge bosons with masses nM_W (with $n \geq 2$ integers) [70]. However, warping the 5th dimension has a double advantage [71]. The excited KK modes of the gauge bosons can all have masses in the TeV range, making them compatible with present collider limits. Also, by enlarging the bulk gauge symmetry to $SU(2)_L \times SU(2)_R \times U(1)$, one can obtain an approximate custodial symmetry, as described above, to tame tree-level corrections to ρ . If quarks and leptons are extended to the bulk, they can obtain masses through the electroweak-breaking effect on the boundaries. However at present, there is no model that reproduces the top quark mass and is totally consistent with electroweak data [72].

VI. Supersymmetry in Extra Dimensions

Extra dimensions have a natural home within string theory. Similarly, string theory and supersymmetry are closely connected, as the latter is implied by the former in most constructions. Coexistence between extra dimensions and supersymmetry is often considered a starting point for string model building. From a low-energy model-building point of view, perhaps the most compelling reason to introduce extra dimensions with supersymmetry lies in the mechanism of supersymmetry breaking.

When the field periodic boundary conditions on the compactified space are twisted using an R -symmetry, different zero modes for bosons and fermions are projected out and supersymmetry is broken. This is known as the Scherk-Schwarz

See key on page 405

mechanism of supersymmetry breaking [73]. In the simplest approach [74], a 5th dimension with $R^{-1} \sim 1$ TeV is introduced in which the non-chiral matter (gauge and Higgs multiplets) live. The chiral matter (quark and lepton multiplets) live on the three-dimensional spatial boundary. S^1/Z_2 compactification of the 5th dimension, which simultaneously employs the Scherk-Schwarz mechanism, generates masses for the bulk fields (gauginos and higgsinos) of order R^{-1} . Boundary states (squarks and sleptons) get mass from loop corrections, and are parametrically smaller in value. The right-handed slepton is expected to be the lightest supersymmetric particle (LSP), which being charged is not a good dark matter candidate. Thus, this theory likely requires R -parity violation in order to allow this charged LSP to decay and not cause cosmological problems.

By allowing all supersymmetric fields to propagate in the bulk of a $S^1/Z_2 \times Z'_2$ compactified space, it is possible to construct a model [75] taking advantage of the nonlocal breaking of supersymmetry. In this case, there are no quadratic divergences (except for a Fayet-Iliopoulos term [76]) and the Higgs mass is calculable. In the low-energy effective theory there is a single Higgs doublet, two superpartners for each SM particle, and the stop is the LSP, requiring a small amount of R -parity breaking.

Supersymmetry in warped space is also an interesting possibility. Again, one can consider [77] the case of chiral fields confined to our ordinary 3+1 dimensions, and gravity and gauge fields living in the 5-dimensional bulk space. Rather than being TeV^{-1} size, the 5th dimension is strongly warped to generate the supersymmetry-breaking scale. In this case, the tree-level mass of the gravitino is $\sim 10^{-3}$ eV and the masses of the gauginos are $\sim \text{TeV}$. The sleptons and squarks get mass at one loop from gauge interactions and thus are diagonal in flavor space, creating no additional FCNC problems. It has also been proposed [78] that an approximately supersymmetric Higgs sector confined on the IR brane could coexist with non-supersymmetric SM fields propagating in the bulk of the warped space.

In conclusion, we should reiterate that an important general consequence of extra dimensional theories is retained in supersymmetric extensions: KK excitations of the graviton and/or gauge fields are likely to be accessible at the LHC if the scale of compactification is directly related to solving the hierarchy problem. Any given extra-dimensional theory has many aspects to it, but the KK excitation spectrum is the most generic and most robust aspect of the idea to test in experiments.

Limits on R from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian ($1/r^2$) gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form $V = -(G m m'/r) [1 + \alpha \exp(-r/R)]$. For δ toroidal extra dimensions of equal size, $\alpha = 8\delta/3$. Quoted bounds are for $\delta = 2$ unless otherwise noted.

1 MASUDA 09 obtain improved constraints on non-Newtonian forces with strengths $10^9 \lesssim |\alpha| \lesssim 10^{11}$ and length scales $R = 1.0\text{--}2.9 \mu\text{m}$. See their Fig. 3. This bound does not place limits on the size of extra flat dimensions.

2 GERACI 08 obtain improved constraints on non-Newtonian forces with strengths $|\alpha| > 14,000$ and length scales $R = 5\text{--}15 \mu\text{m}$. See their Fig. 9. This bound does not place limits on the size of extra flat dimensions.

3 TRENKEL 08 uses two independent measurements of Newton's constant G to constrain new forces with strength $|\alpha| \simeq 10^{-4}$ and length scales $R = 0.02\text{--}1 \text{ m}$. See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.

4 DECCA 07A search for new forces and obtain bounds in the region with strengths $|\alpha| \simeq 10^{13}\text{--}10^{18}$ and length scales $R = 20\text{--}86 \text{ nm}$. See their Fig. 6. This bound does not place limits on the size of extra flat dimensions.

5 KAPNER 07 search for new forces, probing a range of $\alpha \simeq 10^{-3}\text{--}10^5$ and length scales $R \simeq 10\text{--}1000 \mu\text{m}$. For $\delta = 1$ the bound on R is $44 \mu\text{m}$. For $\delta = 2$, the bound is expressed in terms of M_* , here translated to a bound on the radius. See their Fig. 6 for details on the bound.

6 TU 07 search for new forces probing a range of $|\alpha| \simeq 10^{-1}\text{--}10^5$ and length scales $R \simeq 20\text{--}1000 \mu\text{m}$. For $\delta = 1$ the bound on R is $53 \mu\text{m}$. See their Fig. 3 for details on the bound.

7 SMULLIN 05 search for new forces, and obtain bounds in the region with strengths $\alpha \simeq 10^3\text{--}10^8$ and length scales $R = 6\text{--}20 \mu\text{m}$. See their Figs. 1 and 16 for details on the bound. This work does not place limits on the size of extra flat dimensions.

8 HOYLE 04 search for new forces, probing α down to 10^{-2} and distances down to $10 \mu\text{m}$. Quoted bound on R is for $\delta = 2$. For $\delta = 1$, bound goes to $160 \mu\text{m}$. See their Fig. 34 for details on the bound.

9 CHIAVERINI 03 search for new forces, probing α above 10^4 and λ down to $3 \mu\text{m}$, finding no signal. See their Fig. 4 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

10 LONG 03 search for new forces, probing α down to 3, and distances down to about $10 \mu\text{m}$. See their Fig. 4 for details on the bound.

11 HOYLE 01 search for new forces, probing α down to 10^{-2} and distances down to $20 \mu\text{m}$. See their Fig. 4 for details on the bound. The quoted bound is for $\alpha \geq 3$.

12 HOSKINS 85 search for new forces, probing distances down to 4 mm . See their Fig. 13 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

Limits on R from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on R , the assumed common radius of the flat extra dimensions, for $\delta = 2$ extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons: $m_{\vec{n}} = |\vec{n}|/R$. See the Review on "Extra Dimensions" for details. Bounds are given in μm for $\delta=2$.

Extra Dimensions

Limits on R from On-Shell Production of Gravitons: $\delta \geq 3$

This section includes limits similar to those in the previous section, but for $\delta = 3$ extra dimensions. Bounds are given in nm for $\delta = 3$. Entries are also shown for papers examining models with $\delta > 3$.

VALUE (nm)	CL%	DOCUMENT ID	TECN	COMMENT

<p>13 AALTONEN 08AC search for $p\bar{p} \rightarrow \gamma G$ and $p\bar{p} \rightarrow jG$ at $\sqrt{s} = 1.96$ TeV with 2.0 fb⁻¹ and 1.1 fb⁻¹ respectively, in order to place bounds on the fundamental scale and size of the extra dimensions. See their Table III for limits on all $\delta \leq 6$.</p> <p>14 ABAZOV 08S search for $p\bar{p} \rightarrow \gamma G$, using 1 fb⁻¹ of data at $\sqrt{s} = 1.96$ TeV to place bounds on M_D for two to eight extra dimensions, from which these bounds on R are derived. See their paper for intermediate values of δ.</p> <p>15 DAS 08 obtain a limit on R from Kaluza-Klein graviton cooling of SN1987A due to plasmon-plasmon annihilation.</p> <p>16 ABULENCIA,A 06 search for $p\bar{p} \rightarrow jG$ using 368 pb⁻¹ of data at $\sqrt{s} = 1.96$ TeV. See their Table II for bounds for all $\delta \leq 6$.</p> <p>17 ABDALLAH 05B search for $e^+e^- \rightarrow \gamma G$ at $\sqrt{s} = 180$-209 GeV to place bounds on the size of extra dimensions and the fundamental scale. Limits for all $\delta \leq 6$ are given in their Table 6. These limits supersede those in ABREU 00Z.</p> <p>18 ACHARD 04E search for $e^+e^- \rightarrow \gamma G$ at $\sqrt{s} = 189$-209 GeV to place bounds on the size of extra dimensions and the fundamental scale. See their Table 8 for limits with $\delta \leq 8$. These limits supersede those in ACCIARRI 99R.</p> <p>19 ACOSTA 04C search for $\bar{p}p \rightarrow jG$ at $\sqrt{s} = 1.8$ TeV to place bounds on the size of extra dimensions and the fundamental scale. See their paper for bounds on $\delta = 4, 6$.</p> <p>20 CASSE 04 obtain a limit on R from the gamma-ray emission of point γ sources that arises from the photon decay of gravitons around newly born neutron stars, applying the technique of HANNESTAD 03 to neutron stars in the galactic bulge. Limits for all $\delta \leq 7$ are given in their Table I.</p> <p>21 ABAZOV 03 search for $p\bar{p} \rightarrow jG$ at $\sqrt{s} = 1.8$ TeV to place bounds on M_D for 2 to 7 extra dimensions, from which these bounds on R are derived. See their paper for bounds on intermediate values of δ. We quote results without the approximate NLO scaling introduced in the paper.</p> <p>22 HANNESTAD 03 obtain a limit on R from graviton cooling of supernova SN1987A. Limits for all $\delta \leq 7$ are given in their Tables V and VI.</p> <p>23 HANNESTAD 03 obtain a limit on R from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic γ background. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.</p> <p>24 HANNESTAD 03 obtain a limit on R from gravitons emitted in two recent supernovae and which subsequently decay, creating point γ sources. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits are corrected in the published erratum.</p> <p>25 HANNESTAD 03 obtain a limit on R from the heating of old neutron stars by the surrounding cloud of trapped KK gravitons. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.</p> <p>26 HEISTER 03C use the process $e^+e^- \rightarrow \gamma G$ at $\sqrt{s} = 189$-209 GeV to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with $\delta \leq 6$ for derived limits on M_D.</p> <p>27 FAIRBAIRN 01 obtains bounds on R from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from $R < 0.13 \mu\text{m}$ to $0.001 \mu\text{m}$ for $\delta=2$; bounds for $\delta=3,4$ can be derived from Table 1 in the paper.</p> <p>28 HANHART 01 obtain bounds on R from limits on graviton cooling of supernova SN1987A using numerical simulations of proto-neutron star neutrino emission.</p> <p>29 CASSISI 00 obtain rough bounds on M_D (and thus R) from red giant cooling for $\delta=2,3$. See their paper for details.</p> <p>30 ACCIARRI 99S search for $e^+e^- \rightarrow ZG$ at $\sqrt{s}=189$ GeV. Limits on the gravity scale are found in their Table 2, for $\delta \leq 4$.</p>				

Mass Limits on M_{TT}

This section includes limits on the cut-off mass scale, M_{TT} , of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter λ , which is taken to be $\lambda = \pm 1$ in the following analyses. Bounds for $\lambda = -1$ are shown in parenthesis after the bound for $\lambda = +1$, if appropriate. Different papers use slightly different definitions of the mass scale. The definition used here is related to another popular convention by $M_{TT}^2 = (2/\pi) \Lambda_{T,1}^2$, as discussed in the above Review on "Extra Dimensions."

<p>31 ABAZOV 09AE use dijet angular distributions in 0.7 fb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_S), here converted to M_{TT}.</p> <p>32 ABAZOV 09D use 1.05 fb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_S), here converted to M_{TT}.</p> <p>33 SCHAEI 07A use e^+e^- collisions at $\sqrt{s} = 189$-209 GeV to place lower limits on Λ_T, here converted to limits on M_{TT}.</p> <p>34 ABDALLAH 06C use e^+e^- collisions at $\sqrt{s} \sim 130$-207 GeV to place lower limits on M_{TT}, which is equivalent to their definition of M_S. Bound shown includes all possible final state leptons, $\ell = e, \mu, \tau$. Bounds on individual leptonic final states can be found in their Table 31.</p> <p>35 GERDES 06 use 100 to 110 pb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV, as recorded by the CDF Collaboration during Run I of the Tevatron. Bound shown includes a K-factor of 1.3. Bounds on individual e^+e^- and $\gamma\gamma$ final states are found in their Table I.</p> <p>36 ABAZOV 05V use 246 pb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for deviations in the differential cross section to $\mu^+\mu^-$ from graviton exchange.</p> <p>37 CHEKANOV 04B search for deviations in the differential cross section of $e^{\pm}p \rightarrow e^{\pm}X$ with 130 pb⁻¹ of combined data and Q^2 values up to 40,000 GeV² to place a bound on M_{TT}.</p> <p>38 ABBIENDI 03D use e^+e^- collisions at $\sqrt{s}=181$-209 GeV to place bounds on the ultraviolet scale M_{TT}, which is equivalent to their definition of M_S.</p> <p>39 ACHARD 03D look for deviations in the cross section for $e^+e^- \rightarrow ZZ$ from $\sqrt{s} = 200$-209 GeV to place a bound on M_{TT}.</p> <p>40 ADLOFF 03 search for deviations in the differential cross section of $e^{\pm}p \rightarrow e^{\pm}X$ at $\sqrt{s}=301$ and 319 GeV to place bounds on M_{TT}.</p> <p>41 GIUDICE 03 review existing experimental bounds on M_{TT} and derive a combined limit.</p> <p>42 GIUDICE 03 place bounds on Λ_6, the coefficient of the gravitationally-induced dimension-6 operator $(2\pi\lambda/\Lambda_6^2)(\sum \bar{T}_i\gamma_i^5\eta)(\sum \bar{T}_j\mu_j^5\eta)$, using data from a variety of experiments. Results are quoted for $\lambda=\pm 1$ and are independent of δ.</p> <p>43 HEISTER 03C use e^+e^- collisions at $\sqrt{s}=189$-209 GeV to place bounds on the scale of dim-8 gravitational interactions. Their M_S^{\pm} is equivalent to our M_{TT} with $\lambda=\pm 1$.</p> <p>44 ACHARD 02 search for s-channel graviton exchange effects in $e^+e^- \rightarrow \gamma\gamma$ at $E_{\text{cm}} = 192$-209 GeV.</p> <p>45 ABBOTT 01 search for variations in differential cross sections to e^+e^- and $\gamma\gamma$ final states at the Tevatron.</p> <p>46 ABBIENDI 00R uses e^+e^- collisions at $\sqrt{s} = 189$ GeV.</p> <p>47 ABREU 00A search for s-channel graviton exchange effects in $e^+e^- \rightarrow \gamma\gamma$ at $E_{\text{cm}} = 189$-202 GeV.</p> <p>48 ABREU 00S uses e^+e^- collisions at $\sqrt{s}=183$ and 189 GeV. Bounds on μ and τ individual final states given in paper.</p> <p>49 CHANG 00B derive 3σ limit on M_{TT} of (28,19,15) TeV for $\delta=(2,4,6)$ respectively assuming the presence of a torsional coupling in the gravitational action. Highly model dependent.</p> <p>50 CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for $\delta=4$. However, unknown UV theory renders δ dependence unreliable. Original paper works in HLZ convention.</p> <p>51 GRAESSER 00 obtains a bound from graviton contributions to $g-2$ of the muon through loops of 0.29 TeV for $\delta=2$ and 0.38 TeV for $\delta=4,6$. Limits scale as $\lambda^{1/2}$. However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."</p> <p>52 HAN 00 calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using S and T. Bounds on M_{TT} range from 0.5 TeV ($\delta=6$) to 1.1 TeV ($\delta=2$); see text. Limits have strong dependence, $\lambda^{\delta+2}$, on unknown λ coefficient.</p> <p>53 MATHEWS 00 search for evidence of graviton exchange in CDF and D0 dijet production data. See their Table 2 for slightly stronger δ-dependent bounds. Limits expressed in terms of $\bar{M}_S^4 = M_{TT}^4/8$.</p> <p>54 MELE 00 obtains bound from KK graviton contributions to $e^+e^- \rightarrow VV$ ($V=\gamma,W,Z$) at LEP. Authors use Hewett conventions.</p>

$> 3.3-3.8$	95	⁶⁵ RIZZO 00	RVUE	obtains limits from global electroweak fits in models with a Higgs in the bulk (3.8 TeV) or on the standard brane (3.3 TeV).

Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the graviton in the warped extra dimension model of Randall and Sundrum. Experimental bounds depend strongly on the warp parameter, k . See the "Extra Dimensions" review for a full discussion.

> 1.1	⁷¹ ABULENCIA 05a	CDF	$p\bar{p} \rightarrow G \rightarrow \ell\bar{\ell}$
> 1.1	⁶⁶ AALTONEN 08s	CDF	use $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to four electrons via two Z bosons using 1.1 fb^{-1} of data. See their Fig. 8 for limits on $\sigma \cdot B(G \rightarrow ZZ)$ versus the graviton mass.
> 1.1	⁶⁷ ABAZOV 08j	D0	use $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons and photons using 1 fb^{-1} of data. For warp parameter values of k/\overline{M}_P between 0.01 and 0.1 the lower limit on the mass of the lightest excitation is between 300 and 900 GeV. See their Fig. 4 for more details.
> 1.1	⁶⁸ AALTONEN 07g	CDF	use $p\bar{p}$ collisions at 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to photons using 1.2 fb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1, 0.05,$ and 0.01 the bounds on the graviton mass are 850, 694, and 230 GeV, respectively. See their Fig. 3 for more details.
> 1.1	⁶⁹ AALTONEN 07h	CDF	use $p\bar{p}$ collisions at 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons using 1.3 fb^{-1} of data. For a warp parameter value of $k/\overline{M}_P = 0.1$ the bound on the graviton mass is 807 GeV. See their Fig. 4 for more details. A combined analysis with the diphoton data of AALTONEN 07g yields for $k/\overline{M}_P = 0.1$ a graviton mass lower bound of 889 GeV.

- ⁷⁰ ABAZOV 05n use $p\bar{p}$ collisions at 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons, electrons or photons, using 260 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1, 0.05,$ and $0.01,$ the bounds on the graviton mass are 785, 650 and 250 GeV respectively. See their Fig. 3 for more details.
- ⁷¹ ABULENCIA 05a use $p\bar{p}$ collisions at 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons or electrons, using 200 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P = 0.1, 0.05,$ and $0.01,$ the bounds on the graviton mass are 710, 510 and 170 GeV respectively.

Limits on Mass of Radion

This section includes limits on mass of radion, usually in context of Randall-Sundrum models. See the "Extra Dimension Review" for discussion of model dependence.

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
> 35	⁷² ABBIENDI 05	OPAL	$e^+e^- \rightarrow Z$ radion

WIMPs and Other Particles Searches for

OMITTED FROM SUMMARY TABLE

WIMPS AND OTHER PARTICLE SEARCHES

Revised March 2002 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

1. Galactic WIMP (weakly-interacting massive particle) searches
2. Concentration of stable particles in matter
3. Limits on neutral particle production at accelerators
4. Limits on jet-jet resonance in hadron collisions
5. Limits on charged particles in e^+e^- collisions
6. Limits on charged particles in hadron reactions
7. Limits on charged particles in cosmic rays

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z' , leptoquarks, axiguons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, etc.

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

GALACTIC WIMP SEARCHES

Cross-Section Limits for Dark Matter Particles (X^0) on Nuclei

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of $0.3 \text{ GeV}/\text{cm}^3$ is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

For $m_{X^0} = 20 \text{ GeV}$

- 1 AHMED 09 give $\sigma < 0.06 \text{ pb}$ (90% CL) for spin-dependent X^0 -neutron cross section.
- 2 ARCHAMBAULT 09 give $\sigma < 0.2 \text{ pb}$ (90% CL) for spin-dependent X^0 -proton cross section.
- 3 LEBEDENKO 09A give $\sigma < 4 (0.04) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 4 See their Fig. 6(b) for limits on spin-dependent X^0 -neutron cross section for m_{X^0} between 2 and 10 GeV.
- 5 See their Fig. 2 for cross section limits for m_{X^0} between 4 and 10 GeV.
- 6 ANGLE 08A give $\sigma < 0.6 (0.007) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 7 ALNER 07 give $\sigma < 100 (0.5) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 8 LEE 07A give $\sigma < 1 (25) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 9 AKERIB 06 give $\sigma < 20 (0.3) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section. See also AKERIB 05.
- 10 SHIMIZU 06A give $\sigma < 2 (30) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 11 ALNER 05 give $\sigma < 0.5 (60) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 12 BARNABE-HEIDER 05 give $\sigma < 1.5 (20) \text{ pb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 13 BENOIT 05 give $\sigma < 10 \text{ pb}$ (90% CL) for spin-dependent X^0 -neutron cross section.
- 14 GIRARD 05 give $\sigma < 1.5 \text{ pb}$ (90% CL) for spin-dependent X^0 -proton cross section.
- 15 KLAPDOR-KLEINGROTHAUS 05 give $\sigma < 4 \text{ pb}$ (90% CL) for spin-dependent X^0 -neutron cross section.
- 16 MIUCHI 03 give model-independent limit $\sigma < 35 \text{ pb}$ (90% CL) for spin-dependent X^0 -proton cross section.
- 17 TAKEDA 03 give model-independent limit $\sigma < 0.03 (0.6) \text{ nb}$ (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 18 ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- 19 BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
- 20 KLIMENKO 98 limit is for inelastic scattering $X^0 \text{ } ^{73}\text{Ge} \rightarrow X^0 \text{ } ^{73}\text{Ge}^* (13.26 \text{ keV})$.
- 21 BELLI 96 limit for inelastic scattering $X^0 \text{ } ^{129}\text{Xe} \rightarrow X^0 \text{ } ^{129}\text{Xe}^* (39.58 \text{ keV})$.
- 22 BELLI 96c use background subtraction and obtain $\sigma < 150 \text{ pb}$ ($< 1.5 \text{ fb}$) (90% CL) for spin-dependent (independent) X^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- 23 BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- 24 SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- 25 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
- 26 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
- 27 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si . See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- 28 REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For $m_{X^0} = 100 \text{ GeV}$

- 1 AHMED 09 give $\sigma < 0.02$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 2 ARCHAMBAULT 09 give $\sigma < 0.4$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 3 LEBEDENKO 09A give $\sigma < 0.8$ (0.01) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 4 ANGLE 08A give $\sigma < 0.9$ (0.01) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 5 BEDNYAKOV 08 reanalyze KLAPDOR-KLEINGROTHAUS 05 and BAUDIS 01 data and give $\sigma < 0.05$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 6 ALNER 07 give $\sigma < 15$ (0.08) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 7 LEE 07A give $\sigma < 0.2$ (6) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 8 MIUCHI 07 give $\sigma < 1 \times 10^4$ pb (90% CL) for spin-dependent X^0 -proton cross section with a direction-sensitive detector.
- 9 AKERIB 06 give $\sigma < 5$ (0.07) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. See also AKERIB 05.
- 10 SHIMIZU 06A give $\sigma < 2$ (30) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 11 ALNER 05 give $\sigma < 0.3$ (10) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 12 BARNABE-HEIDER 05 give $\sigma < 2$ (30) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 13 BENOIT 05 give $\sigma < 100$ (0.7) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 14 GIRARD 05 give $\sigma < 1.5$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 15 GIULIANI 05 analyzes the spin-independent X^0 -nucleon cross section limits with both isoscalar and isovector couplings. See Figs. 3 and 4 for limits on the couplings.
- 16 GIULIANI 05A analyze available data and give combined limits $\sigma < 0.7$ (0.2) pb for spin-dependent X^0 -proton (neutron) cross section.
- 17 KLAPDOR-KLEINGROTHAUS 05 give $\sigma < 1.5$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 18 GIULIANI 04 reanalyze COLLAR 00 data and give limits for spin-dependent X^0 -proton and neutron couplings.
- 19 GIULIANI 04A gives limits for spin-dependent X^0 -proton and neutron couplings from existing data.
- 20 MIUCHI 03 give model-independent limit for spin-dependent X^0 -proton and neutron cross sections. See their Fig. 5.
- 21 MIUCHI 03 give model-independent limit $\sigma < 35$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 22 TAKEDA 03 give model-independent limit $\sigma < 0.04$ (0.8) nb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 23 ANGLÖHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- 24 BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.
- 25 BERNABEI 02c analyze the DAMA data in the scenario in which X^0 scatters into a slightly heavier state as discussed by SMITH 01.
- 26 GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.
- 27 ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.
- 28 BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
- 29 BERNABEI 00D limit is for inelastic scattering $X^0 ^{129}\text{Xe} \rightarrow X^0 ^{129}\text{Xe}^*$ (39.58 keV).
- 30 AMBROSIO 99 search for ongoing moon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.
- 31 BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.
- 32 KLIMENKO 98 limit is for inelastic scattering $X^0 ^{73}\text{Ge} \rightarrow X^0 ^{73}\text{Ge}^*$ (13.26 keV).
- 33 KLIMENKO 98 limit is for inelastic scattering $X^0 ^{73}\text{Ge} \rightarrow X^0 ^{73}\text{Ge}^*$ (66.73 keV).
- 34 BELLI 96 limit for inelastic scattering $X^0 ^{129}\text{Xe} \rightarrow X^0 ^{129}\text{Xe}^*$ (39.58 keV).

- 35 BELLI 96c use background subtraction and obtain $\sigma < 0.35$ pb (< 0.15 fb) (90% CL) for spin-dependent (independent) X^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- 36 BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- 37 SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- 38 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
- 39 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
- 40 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si . See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- 41 BECK 94 uses enriched ^{76}Ge (86% purity).
- 42 REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For $m_{X^0} = 1 \text{ TeV}$

- 1 ABBASI 09b search for neutrinos produced by X^0 annihilation in the Sun and give $\sigma < 8.7 \times 10^{-4}$ (2.2×10^{-2}) pb (90% CL) for spin-dependent X^0 -proton cross section, if X^0 pairs annihilate to $W^+ W^- (b\bar{b})$.
- 2 AHMED 09 give $\sigma < 0.2$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 3 ARCHAMBAULT 09 give $\sigma < 3$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 4 LEBEDENKO 09A give $\sigma < 6$ (0.1) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 5 ANGLE 08A give $\sigma < 8$ (0.1) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 6 BEDNYAKOV 08 reanalyze KLAPDOR-KLEINGROTHAUS 05 and BAUDIS 01 data and give $\sigma < 0.25$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 7 ALNER 07 give $\sigma < 100$ (0.6) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 8 LEE 07A give $\sigma < 0.8$ (30) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 9 MIUCHI 07 give $\sigma < 4 \times 10^4$ pb (90% CL) for spin-dependent X^0 -proton cross section with a direction-sensitive detector.
- 10 AKERIB 06 give $\sigma < 30$ (0.5) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. See also AKERIB 05.
- 11 ALNER 05 give $\sigma < 1.5$ (40) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 12 BARNABE-HEIDER 05 give $\sigma < 15$ (200) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.

- 13 BENOIT 05 give $\sigma < 600$ (4) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 14 GIRARD 05 give $\sigma < 10$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 15 KLAPDOR-KLEINGROTHAUS 05 give $\sigma < 10$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 16 MIUCHI 03 give model-independent limit $\sigma < 260$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 17 TAKEDA 03 give model-independent limit $\sigma < 0.15$ (4) nb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 18 ANGLÖHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- 19 BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay Nal experiments.
- 20 BERNABEI 99p search for SIMPs (Strongly Interacting Massive Particles) in the mass range 10^3 - 10^{16} GeV. See their Fig. 3 for cross-section limits.
- 21 DERBIN 99 search for SIMPs (Strongly Interacting Massive Particles) in the mass range 10^2 - 10^{14} GeV. See their Fig. 3 for cross-section limits.
- 22 KLIMENKO 98 limit is for inelastic scattering $X^0 \text{ } ^{73}\text{Ge} \rightarrow X^0 \text{ } ^{73}\text{Ge}^*$ (13.26 keV).
- 23 KLIMENKO 98 limit is for inelastic scattering $X^0 \text{ } ^{73}\text{Ge} \rightarrow X^0 \text{ } ^{73}\text{Ge}^*$ (66.73 keV).
- 24 BELLI 96 limit for inelastic scattering $X^0 \text{ } ^{129}\text{Xe} \rightarrow X^0 \text{ } ^{129}\text{Xe}^*$ (39.58 keV).
- 25 BELLI 96 limit for inelastic scattering $X^0 \text{ } ^{129}\text{Xe} \rightarrow X^0 \text{ } ^{129}\text{Xe}^*$ (236.14 keV).
- 26 BELLI 96c use background subtraction and obtain $\sigma < 0.7$ pb (< 0.7 fb) (90% CL) for spin-dependent (independent) X^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- 27 BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- 28 SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- 29 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
- 30 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
- 31 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si . See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- 32 BECK 94 uses enriched ^{76}Ge (86% purity).
- 33 REUSSER 91 limit here is changed from published (5) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

- 1 YAMAGATA 93 used deep sea water at 4000 m since the concentration is enhanced in deep sea due to gravity.
- 2 VERKERK 92 looked for heavy isotopes in sea water and put a bound on concentration of stable charged massive particle in sea water. The above bound can be translated into a bound on charged dark matter particle (5×10^6 GeV), assuming the local density, $\rho=0.3 \text{ GeV/cm}^3$, and the mean velocity (v)=300 km/s.
- 3 See HEMMICK 90 Fig. 7 for other masses $100-10000 m_p$.

		0	5 GUSTAFSON 76	CNTR	$\tau > 10^{-7} \text{ s}$

- 1 ADAMS 97B search for a hadron-like neutral particle produced in pN interactions, which decays into a ρ^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_S^0 production for the mass range $1.2-5 \text{ GeV}$ and lifetime $10^{-9}-10^{-4} \text{ s}$. See also our Light Gluino Section.
- 2 GALLAS 95 limit is for a weakly interacting neutral particle produced in $800 \text{ GeV}/c pN$ interactions decaying with a lifetime of $10^{-4}-10^{-8} \text{ s}$. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section $10^{-29}-10^{-33} \text{ cm}^2$. See Fig. 10.
- 3 AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at $450 \text{ GeV}/c$ performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7} \text{ s}$. For $\tau > 10^{-9} \text{ s}$, $\sigma < 10^{-30} \text{ cm}^2/\text{nucleon}$ is obtained.
- 4 BADIÉ 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with $m > 2 \text{ GeV}$. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-X$, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass- τ plane for each mode.
- 5 GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy ($m > 2 \text{ GeV}$) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for $m = 3 \text{ GeV}$ and assumes an interaction cross section of 1 mb . Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non- ν Like States in Beam Dump

< 7	95	600	3 ABE	93G CDF	1.8 TeV $p\bar{p} \rightarrow 2 \text{ jets}$

1 ABE 99F search for narrow $b\bar{b}$ resonances in $p\bar{p}$ collisions at $E_{cm}=1.8$ TeV. Limits on $\sigma(p\bar{p} \rightarrow X + \text{anything}) \times B(X \rightarrow b\bar{b})$ in the range $3-10^3$ pb (95%CL) are given for $m_X=200-750$ GeV. See their Table I.

2 ABE 97G search for narrow dijet resonances in $p\bar{p}$ collisions with 106 pb^{-1} of data at $E_{cm} = 1.8$ TeV. Limits on $\sigma(p\bar{p} \rightarrow X + \text{anything}) \cdot B(X \rightarrow jj)$ in the range 10^4-10^{-1} pb (95%CL) are given for dijet mass $m=200-1150$ GeV with both jets having $|\eta| < 2.0$ and the dijet system having $|\cos\theta^*| < 0.67$. See their Table I for the list of limits. Supersedes ABE 93G.

3 ABE 93G gives cross section times branching ratio into light (d, u, s, c, b) quarks for $\Gamma = 0.02 M$. Their Table II gives limits for $M = 200-900$ GeV and $\Gamma = (0.02-0.2) M$.

LIMITS ON CHARGED PARTICLES IN e^+e^-

Heavy Particle Production Cross Section in e^+e^-

Ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ unless noted. See also entries in Free Quark Search and Magnetic Monopole Searches.

1 ACKERSTAFF 98P search for pair production of long-lived charged particles at E_{cm} between 130 and 183 GeV and give limits $\sigma < (0.05-0.2)$ pb (95%CL) for spin-0 and spin-1/2 particles with $m=45-89.5$ GeV, charge 1 and 2/3. The limit is translated to the cross section at $E_{cm}=183$ GeV with the s dependence described in the paper. See their Figs. 2-4.

2 ABREU 97D search for pair production of long-lived particles and give limits $\sigma < (0.4-2.3)$ pb (95%CL) for various center-of-mass energies $E_{cm}=130-136, 161,$ and 172 GeV, assuming an almost flat production distribution in $\cos\theta$.

3 BARATE 97K search for pair production of long-lived charged particles at $E_{cm} = 130, 136, 161,$ and 172 GeV and give limits $\sigma < (0.2-0.4)$ pb (95%CL) for spin-0 and spin-1/2 particles with $m=45-85$ GeV. The limit is translated to the cross section at $E_{cm}=172$ GeV with the E_{cm} dependence described in the paper. See their Figs. 2 and 3 for limits on $J = 1/2$ and $J = 0$ cases.

4 AKERS 95R is a CERN-LEP experiment with $W_{cm} \sim m_Z$. The limit is for the production of a stable particle in multihadron events normalized to $\sigma(e^+e^- \rightarrow \text{hadrons})$. Constant phase space distribution is assumed. See their Fig. 3 for bounds for $Q = \pm 2/3, \pm 4/3$.

5 BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.

6 ADACHI 90C is a KEK-TRISTAN experiment with $W_{cm} = 52-60$ GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.

7 ADACHI 90E is KEK-TRISTAN experiment with $W_{cm} = 52-61.4$ GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \rightarrow \mu^+\mu^-) \cdot \beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W_{cm}^2)^{1/2}$. See the paper for the assumption about the production mechanism.

8 KINOSHITA 82 is SLAC PEP experiment at $W_{cm} = 29$ GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.

9 BARTEL 80 is DESY-PETRA experiment with $W_{cm} = 27-35$ GeV. Above limit is for inclusive pair production and ranges between $1. \times 10^{-1}$ and $1. \times 10^{-2}$ depending on mass and production momentum distributions. (See their figures 9, 10, 11).

<0.19	95	5 AKTAS	04c H1	$m=3-10$ GeV
<0.05	95	6 ABE	92J CDF	$m=50-200$ GeV
<30-130		7 CARROLL	78 SPEC	$m=2-2.5$ GeV
<100		8 LEIPUNER	73 CNTR	$m=3-11$ GeV

1 AALTONEN 09Z search for long-lived charged particles in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV with $L = 1.0 \text{ fb}^{-1}$. The limits are on production cross section for a particle of mass above 100 GeV in the region $|\eta| \lesssim 0.7, p_T > 40$ GeV, and $0.4 < \beta < 1.0$.

2 Limit for weakly interacting charge-1 particle.

3 Limit for up-quark like particle.

4 ABAZOV 09M search for pair production of long-lived charged particles in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV with $L = 1.1 \text{ fb}^{-1}$. Limit on the cross section of $(0.31-0.04)$ pb (95%CL) is given for the mass range of 60-300 GeV, assuming the kinematics of stau pair production.

5 AKTAS 04c look for charged particle photoproduction at HERA with mean c.m. energy of 200 GeV.

6 ABE 92J look for pair production of unit-charged particles which leave detector before decaying. Limit shown here is for $m=50$ GeV. See their Fig. 5 for different charges and stronger limits for higher mass.

7 CARROLL 78 look for neutral, $S = -2$ dihyperon resonance in $pp \rightarrow 2K^+X$. Cross section varies within above limits over mass range and $p_{lab} = 5.1-5.9$ GeV/c.

8 LEIPUNER 73 is an NAL 300 GeV p experiment. Would have detected particles with lifetime greater than 200 ns.

1 BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at $\theta = 0$. For other charges in range -0.5 to -3.0 , CL = 90% limit is $(2.6 \times 10^{-36})/|[\text{charge}]|$ for mass range $(2.1-9.4 \text{ GeV}) \times |[\text{charge}]|$. Assumes stable particle interacting with matter as do antiprotons.

2 ALBROW 75 is a CERN ISR experiment with $E_{cm} = 53$ GeV. $\theta = 40$ mr. See figure 5 for mass ranges up to 35 GeV.

3 JOVANOVI... 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges $Q = 1/3$ to 2 and $m = 3$ to 26 GeV. Value is per GeV momentum.

4 APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24-200 GeV (-charge) and 40-150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

5 ALPER 73 is CERN ISR 26+26 GeV pp experiment. $p > 0.9$ GeV, $0.2 < \beta < 0.65$.

6 ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

7 ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

8 DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

- ¹BERNSTEIN 88 limits apply at $x = 0.2$ and $p_T = 0$. Mass and lifetime dependence of limits are shown in the regions: $m = 1.5\text{--}7.5$ GeV and $\tau = 10^{-8}\text{--}2 \times 10^{-6}$ s. First number is for hadrons; second is for weakly interacting particles.
- ²THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3 \times 10^{-9}$ s.
- ³ARMITAGE 79 is CERN-ISR experiment at $E_{cm} = 53$ GeV. Value is for $x = 0.1$ and $p_T = 0.15$. Observed particles at $m = 1.87$ GeV are found all consistent with being antideuterons.
- ⁴BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11-18 for production cross-section upper limits vs mass.
- ⁵CUTTS 78 is p Be experiment at FNAL sensitive to particles of $\tau > 5 \times 10^{-8}$ s. Value is for $-0.3 < x < 0$ and $p_T = 0.175$.
- ⁶VIDAL 78 is FNAL 400 GeV proton experiment. Value is for $x = 0$ and $p_T = 0$. Puts lifetime limit of $< 5 \times 10^{-8}$ s on particle in this mass range.

¹ALEKSEEV 76 and ALEKSEEV 76B are 61-70 GeV p Serpukhov experiment. Cross section is per Pb nucleus.

²FRANKEL 75 is extension of FRANKEL 74.

³FRANKEL 74 looks for particles produced in thick Al targets by 300-400 GeV/c protons.

Long-Lived Particle Search at Hadron Collisions
Limits are for cross section times branching ratio.

VALUE (pb/nucleon)	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
< 2	90	0	¹ BADIER 86	BDMP	$\tau = (0.05\text{--}1) \times 10^{-8}$ s

• • • We do not use the following data for averages, fits, limits, etc. • • •

¹BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass > 2 GeV. The limit applies for particle modes, $\mu^+ \pi^-, \mu^+ \mu^-, \pi^+ \pi^- X, \pi^+ \pi^- \pi^\pm$ etc. See their figure 5 for the contours of limits in the mass- τ plane for each mode.

Long-Lived Heavy Particle Cross Section

• • • We do not use the following data for averages, fits, limits, etc. • • •

- ¹SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
- ²MINCER 85 is high statistics study of calorimeter signals delayed by 20-200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83b below may be due to this fake effect.
- ³SAKUYAMA 83b analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.
- ⁴BHAT 82 observed 12 events with delay $> 2. \times 10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
- ⁵MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
- ⁶YOCK 81 saw another 3 events with $Q = \pm 1$ and m about $4.5 m_p$ as well as 2 events with $m > 5.3 m_p, Q = \pm 0.75 \pm 0.05$ and $m > 2.8 m_p, Q = \pm 0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3) m_p, Q = \pm 0.89 \pm 0.06$ as possible heavy candidates.
- ⁷YOCK 80 events are with charge exactly or approximately equal to unity.
- ⁸BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.
- ⁹YOCK 74 events could be tritons.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- ¹AMBROSIO 00B searched for quark matter ("nuclearites") in the velocity range $(10^{-5}\text{--}1)$ c. The listed limit is for 2×10^{-3} c.
- ²ASTONE 93 searched for quark matter ("nuclearites") in the velocity range $(10^{-3}\text{--}1)$ c. Their Table 1 gives a compilation of searches for nuclearites.
- ³AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity $< 2.5 \times 10^{-3}$ c. See their Fig. 3 for other velocity/c and heavier mass range.
- ⁴NAKAMURA 91 searched for quark matter in the velocity range $(4 \times 10^{-5}\text{--}1)$ c.
- ⁵ORITO 91 searched for quark matter. The limit is for the velocity range $(10^{-4}\text{--}10^{-3})$ c.
- ⁶LIU 88 searched for quark matter ("nuclearites") in the velocity range $(2.5 \times 10^{-3}\text{--}1)$ c. A less stringent limit of 5.8×10^{-11} applies for $(1\text{--}2.5) \times 10^{-3}$ c.
- ⁷BARISH 87 searched for quark matter ("nuclearites") in the velocity range $(2.7 \times 10^{-4}\text{--}5 \times 10^{-3})$ c.
- ⁸NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity of $(10^{-4}\text{--}10^{-3})$ c.
- ⁹ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100-350 km/s.

Greek letters are alphabetized by their English-language spelling. Bold page numbers signify entries in the Particle Properties Summary Tables.

$f'_2(1525)$ [<i>was</i> $f'(1525)$]	34, 694	Gamma distribution, Monte Carlo algorithm for	362
$f_4(2050)$ [<i>was</i> $h(2030)$]	36, 724	Gamma distribution, table of	348
$f_4(2300)$ [<i>was</i> $\epsilon(2300)$]	732	Gas-filled detectors	308
$f_6(2510)$ [<i>was</i> $r(2510)$]	734	electron drift velocity	309
$f_J(2220)$ [<i>was</i> $\xi(2220)$]	730	gas properties	309
F_2 structure function, plots	207	high rate effects	311
Familon searches	508	mobility of ions	310
Fermi coupling constant	101	Townsend coefficient	309
Fermi plateau	288	Gauge bosons	25, 417
Feynman's x variable	373	(see individual entries for γ , W , Z , g , Axions, graviton, Higgs)	
Field equations, electromagnetic	110	Gauge couplings	126
Fine structure constant	101	Gaussian confidence intervals	357
Fit to Z electroweak measurements	426	Gaussian confidence intervals close to physical boundary	359
Fits to data	14	Gaussian distribution, Monte Carlo algorithm for	362
Flatness of Universe	102	Gaussian distribution, Multivariate	348
Flavor-changing neutral currents, tests for	89	Gaussian ellipsoid	349
Fluorescence, atmospheric	328	Gluino searches	87, 1335
Fly's Eye	274, 328	gluon, g	25, 417
Forbidden states in quark model	112	Gluonium candidates	1131
Force, Lorentz	110	Goldstone boson searches	508
Form factors, $K_{\ell 3}$, note on	753	Grand unified theories	193
Form factors, $\pi \rightarrow \ell\nu\gamma$ and $K \rightarrow \ell\nu\gamma$, note on	620	Gravitational	
Fourth generation (b') searches	30, 612	acceleration g	101
Fractional energy loss for electrons and positrons in lead	291	constant G_N	101, 102
Fragmentation functions	215	field in the strong field regime, dynamical tests	226
Fragmentation, heavy-quark	220	field in the weak field regime, dynamical tests	226
Fragmentation in e^+e^- annihilation	215	lensing	237, 252
Fragmentation, longitudinal	217	theory, experimental tests of	225
Fragmentation models	217	graviton	418
Free quark searches	30, 613	Gravitons	1354
Frequentist statistics	356	Gravity in extra dimensions	1354
Friedmann-Lemaître equations	230	Gray, unit of absorbed dose of radiation	341
Further States	735	GUTs	193
g (gluon)	25, 417	$h(2030)$ [<i>now called</i> $f_4(2050)$]	36, 724
$g(1690)$ [<i>now called</i> $\rho_3(1690)$]	35, 705	$h_1(1170)$ [<i>was</i> $H(1190)$]	33, 663
$g_T(2010)$ [<i>now called</i> $f_2(2010)$]	36, 723	$h_1(1380)$	679
$g'_T(2300)$ [<i>now called</i> $f_2(2300)$]	36, 732	$h_1(1595)$	698
$g''_T(2340)$ [<i>now called</i> $f_2(2340)$]	36, 733	$h_c(1P)$	1073
g_V, g_A vector, axial vector couplings	126	Hadron (average) multiplicities in e^+e^- annihilation events	387
Galaxy clustering	251	Hadronic	
Galaxy power spectrum	251	calorimeters	321
γ (Euler constant)	101	flavor conservation	89
γ (photon)	25, 417	shower detectors	321
γp and γd cross sections, plots of	401	Half-lives of commonly used radioactive nuclides	345
gamma production in $p\bar{p}$ interactions	385	Halo density	102
γ -rays, from radioactive sources	345	Harrison-Zel'dovich effect	246
Gamma distribution	349	Heavy boson searches	26, 480

Heavy lepton searches	29, 553	$J/\psi(1S)$ or $\psi(1S)$	60, 1044
Heavy-Neutral Leptons, Searches for	29, 577	K^+p , K^+n , and K^+d cross sections, plots of	400
Heavy particle searches	1368	K^-p , K^-n , and K^-d cross sections, plots of	399
Heavy-quark fragmentation	220	K stable mesons (see meson resonances below)	
HERA (DESY) collider parameters	284	K^\pm	36, 740
Hierarchy problem	1292, 1354	K^0, \bar{K}^0	37, 758
Higgs boson in Standard Model	126, 136, 448	K_L^0	37, 766
Higgs boson mass in electroweak analyses	136–138	K_S^0	37, 762
Higgs, M_H , constraints on	136–138	K stable mesons, notes therein	
Higgs production in e^+e^- annihilation, cross-section formula	378	K_L^0 CP -violation parameters, fits for, note on	779
Higgs searches	26, 448	K decay, CPT invariance tests in neutral	759
Higgs searches, note on	448	K^0 decay, note on $\Delta S = \Delta Q$ rule in	785
History of measurements, discussion	16	K_L^0 decay, CP violation in	154
Hubble constant (expansion rate)	102	$K_{\ell 3}$ form factors, note on	753
Hubble constant H_0	246	K^\pm mass, note on	740
Hubble expansion	231	K rare decay, note on	742
Hyperon baryons (see Λ and Σ baryons)	77, 1201	$K \rightarrow \ell\nu\gamma$ form factors, note on	620
Hyperon decays, nonleptonic decay amplitudes		$K \rightarrow 3\pi$ Dalitz plot parameters, note on	752
(see p. 286 in our 1982 edition, Phys. Lett. 111B)		$K_S^0 \rightarrow 3\pi$ decay, note on CP violation in	764
Hyperon decays, test of $\Delta I = 1/2$ rule for		K, K^* meson resonances	
(see p. 286 in our 1982 edition, Phys. Lett. 111B)		$K(1460)$ [<i>was</i> $K(1400)$]	796
Hyperon radiative decays, note on	1242	$K(1630)$	796

table of detectors 330
water-filled 331

Neutrino Telescopes	332	$\omega(1420)$	34 , 686
astrophysical neutrinos	333	$\omega(1650)$	35 , 701
ice	332	$\omega_3(1670)$	35 , 702
sea water	332	Opposite-side tag in $B^0\text{--}\bar{B}^0$ mixing, note on	974
Neutrinoless double- β decay, search for	562	Optical theorem	374
Neutrino mass density parameter, Ω_ν	246	Organic scintillators	303
Neutron	73 , 1143	Organization of Particle Listings and Summary Tables	11
Neutrons at accelerators	342	Oscillation analyses in $B^0\text{--}\bar{B}^0$ mixing, note on	974
Neutrons, from radioactive sources	345	Oscillation parameters, three-flavor, note	571
Newtonian gravitational constant G_N	102	Other particle searches	1365
Nomenclature for hadrons	13, 112	Other particle searches, note on	1365
Nonbaryonic dark matter	241	P (parity), tests of conservation	89
Non- $q\bar{q}$ candidates	1131	p (proton)	73 , 1135
Normal distribution	348	$pp, \bar{p}p$ average multiplicity, plot of	389
Normal distribution, table of	348	pp jet production	385
Neutrino Mixing	29 , 567	pp, pn , and pd cross sections, plots of	396, 397
Neutrino Properties	29 , 554	$\bar{p}p$	
νN and $\bar{\nu}N$ cross sections, plot of		average multiplicity, plot of	389
(see p. III.75 in our 1992 edition, Phys. Rev. D45 , Part II)		gamma production	385
Nuclear collision length, table	108	jet production	385
Nuclear interaction length, table	108	$\bar{p}n$, and $\bar{p}d$ cross sections, plots of	396, 397
Nuclear magneton	101	pseudorapidity	386
Nuclear (and atomic) properties of materials	108	Parameter estimation	350
Nucleon decay	193	Parity of $q\bar{q}$ states	184
Nucleon resonances (see N and Δ resonances)	74 , 1149	Parsec	102
Nucleon structure functions, plots of	207	Partial-wave expansion of scattering amplitude	374
Nuclides, radioactive, commonly used	345	Particle detectors	300
Number density of baryons	102	Particle detectors for non-accelerator physics	328
Number density of CBR photons	102	Particle ID numbers for Monte Carlos	364
Numbering scheme for particles in Monte Carlos	364	Particle Listings, key to reading	405
Occupational radiation dose, U.S. maximum permissible	342	Particle Listings, organization of	11
Omega baryons (Ω baryons)	81 , 1254	Particle nomenclature	13, 112
Ω^- resonances	1255	Particle Physics Booklet, how to get	11
Ω^-	81 , 1254	Particle symbol style conventions	112
Ω_c^0	1275	Parton distributions	204
Ω , cosmological density parameter	231	Passage of particles through matter	285
Ω_b , baryon mass density	252	Pauli exclusion principle, charge conservation, note on	
Ω_{dm} , dark matter density	247, 248	(see p. VI.10 in our 1992 edition, Phys. Rev. D45)	
Ω_i , density parameter for i th matter constituent	246	Penguin decays, electromagnetic, note on	883
Ω_Λ , scaled cosmological constant	102, 231	Periodic table of the elements	105
Ω_m , mass density parameter	102, 231, 247, 252	Permeability μ_0 of free space	101, 110
Ω_ν , neutrino mass density parameter	246	Permittivity ϵ_0 of free space	101, 110
$\Omega_m + \Omega_\Lambda$	102	Phase space, Lorentz invariant	371
Ω_{tot} , total energy density of Universe	102, 253	Phase space, relations for	371
Ω_Q , quintessence (dark) energy density	248, 249	$\phi(1020)$	32 , 656
Ω_v , vacuum energy parameter	231	$\phi(1680)$	35 , 704
$\omega(782)$	32 , 643	$\phi_3(1850)$ [<i>was</i> $X(1850)$]	36 , 719
		Photino searches	1319

Greek letters are alphabetized by their English-language spelling. Bold page numbers signify entries in the Particle Properties Summary Tables.

Photon	25 , 417	ψ mesons	
and electron interactions with matter	291	$\psi(1S) = J/\psi(1S)$	60 , 1044
attenuation length	294	$\psi(2S)$	63 , 1082
collection efficiency, scintillators	303	$\psi(2S)$ and $\chi_{c0,1,1}$, branching ratios, note on	1060
coupling	126	$\psi(3770)$	64 , 1094
cross section in carbon and lead, contributions to	293	$X(3945)$	1101
pair production cross section	292	$\psi(4040)$	65 , 1102
to e^+e^- conversion probability	294	$\psi(4160)$	65 , 1103
total cross sections (C and Pb)	293	$\psi(4415)$	66 , 1107
Physical constants, table of	101	Pulsars, binary	227
Physical region, for confidence intervals	359	$Q(1280)$ or Q_1 [<i>now called</i> $K_1(1270)$]	38 , 790
π , value of	101	$Q(1400)$ or Q_2 [<i>now called</i> $K_1(1400)$]	39 , 792
$\pi^\pm p$ and $\pi^\pm d$ cross sections, plots of	398	and structure functions	202
$\pi \rightarrow \ell\nu\gamma$ form factors, note on	620	Quintessence (general dark energy of Universe)	248, 249
π mesons		Quantum mechanics in $B^0-\bar{B}^0$ mixing, note on	973
π^\pm	31 , 619	Quantum numbers in quark model	184
π^0	31 , 623	Quarks	30 , 583
$\pi(1300)$	33 , 672	and lepton compositeness searches	87 , 1347
$\pi(1800)$	716	and lepton substructure searches	87 , 1347
$\pi_1(1400)$	679	current masses of	126, 583
$\pi_1(1600)$	698	fragmentation in e^+e^- annihilation, heavy	220
$\pi_2(1670)$ [<i>was</i> $A(1680)$ or A_3]	35 , 702	and leptons, weak interactions of	126, 137
$\pi_2(2100)$ [<i>was</i> $A(2100)$]	726	mass, note on	583
Pion	31 , 619	model	184
Planck constant	101	model assignments	184
Planck mass	102	model, dynamical ingredients	190
Plasma energy	285	properties of	184
Plastic scintillators	303	Quark searches, free	30 , 613
Poisson distribution	347	Quark searches, note on	613
Poisson distribution, Monte Carlo algorithm for	362	R function, e^+e^- collisions, plot of	390
Poisson distribution, table of	348	$r(2510)$ [<i>now called</i> $f_6(2510)$]	734
Potentials, electromagnetic	110	Rad, unit of absorbed dose of radiation	341
Prefixes, metric, commonly used	104	Radiation	
Primary spectra, cosmic rays	269	Cherenkov	297
Probability	346	damage in Silicon detectors	318
Probability density function, definition	346	-dominated epoch	234
Production and spectroscopy of b -flavored hadrons, note on	878	length	291
Propagation of errors	353	length, approximate algorithm	291
Properties (atomic and nuclear) of materials	108	length of materials, table	108
Proton (see p)	73 , 1135	lethal dose from	342
Proton cyclotron frequency/field	101	weighting factor	341
Proton decay	193	Radiative corrections in Standard Model	126
Proton mass	73 , 101	Radiative decays, hyperons, note on	1242
Proton structure function	201	Radiative loss by muons	296
Proton structure function, plots	207, 210	Radioactive sources, commonly used	345
Pseudorapidity distribution in $\bar{p}p$ interactions, plot of	386	Radioactivity	
Pseudorapidity η , defined	373	and radiation protection	341
Pseudoscalar mesons, decay constants of charged, note on	861

Dynamical Electroweak Symmetry Breaking (Figure 6)	1422

Quantum Chromodynamics (p. 121)

Figure 9.1: A compilation of data-over-theory ratios for inclusive jet cross sections as a function of jet transverse momentum (p_T), measured in different hadron-induced processes at different center-of-mass energies; from Ref. 156, including some updates [157]. The various ratios are scaled by arbitrary numbers (indicated between parentheses) for better readability of the plot. The theoretical predictions have been obtained at NLO accuracy, for parameter choices (coupling constant, PDFs, renormalization, and factorization scales) as indicated at the bottom of the figure.

Electroweak model and constraints on new physics (p. 137)

Figure 10.2: One-standard-deviation (39.35%) uncertainties in M_H as a function of m_t for various inputs, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. $\alpha_s(M_Z) = 0.1183$ is assumed except for the fits including the Z lineshape or low energy data. The direct lower limit from LEP 2 and the excluded window from the Tevatron [221] (both at the 95% CL) are also shown.

Electroweak model and constraints on new physics (p. 137)

Figure 10.3: One-standard-deviation (39.35%) region in M_W as a function of m_t for the direct and indirect data, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. The SM prediction as a function of M_H is also indicated. The widths of the M_H bands reflect the theoretical uncertainty from $\alpha(M_Z)$.

Electroweak model and constraints on new physics (p. 139)

Figure 10.4: 1σ constraints (39.35%) on S and T from various inputs combined with M_Z . S and T represent the contributions of new physics only. (Uncertainties from m_t are included in the errors.) The contours assume $M_H = 117$ GeV, except for the central and upper 90% CL contours allowed by all data, which are for $M_H = 340$ GeV and 1000 GeV, respectively. Data sets not involving M_W are insensitive to U . Due to higher order effects, however, $U = 0$ has to be assumed in all fits. α_s is constrained using the τ lifetime as additional input in all fits. Because this has changed significantly since the 2008 edition of this *Review* (see the discussion in Sec. 10.5), the strongly α_s -dependent solid (green) contour from Z lineshape and cross-section measurements has moved significantly towards negative S and T . The long-dashed (magenta) contour from ν scattering has moved closer towards the global averages (see Sec. 10.3). The long-dash-dotted (indigo) contour from polarized e scattering [123,125] is the upper tip of an elongated ellipse centered at around $S = -15$ and $T = -21$. At first sight it looks as if it is deviating strongly but it is off by only 1.8σ . This illusion arises because $\Delta\chi^2 > 0.8$ everywhere on the visible part of the contour.

CKM quark-mixing matrix (p. 151)

Figure 11.2: Constraints on the $\bar{\rho}, \bar{\eta}$ plane. The shaded areas have 95% CL.

CP violation in meson decays (p. 161)

Figure 12.3: Summary of the results [21] of time-dependent analyses of $b \rightarrow q\bar{q}s$ decays, which are potentially sensitive to new physics. Subdominant corrections are expected to be smallest for the modes shown in green (darker). Results for final states including K^0 mesons combine CP -conjugate K_S and K_L measurements. The final state $K^+K^-K^0$ is not a CP eigenstate; the mixture of CP -even and CP -odd components is taken into account in obtaining an effective value for $\eta_f S_f$. Correlations between C_f and S_f are included when available.

Neutrino mass, mixing, and oscillations (p. 174)

Figure 13.3: Fluxes of ^8B solar neutrinos, $\phi(\nu_e)$, and $\phi(\nu_\mu \text{ or } \tau)$, deduced from the SNO's CC, ES, and NC results of the salt phase measurement [94]. The Super-Kamiokande ES flux is from Ref. 99. The BS05(OP) standard solar model prediction [86] is also shown. The bands represent the 1σ error. The contours show the 68%, 95%, and 99% joint probability for $\phi(\nu_e)$ and $\phi(\nu_\mu \text{ or } \tau)$. The figure is from Ref. 94.

Neutrino mass, mixing, and oscillations (p. 176)

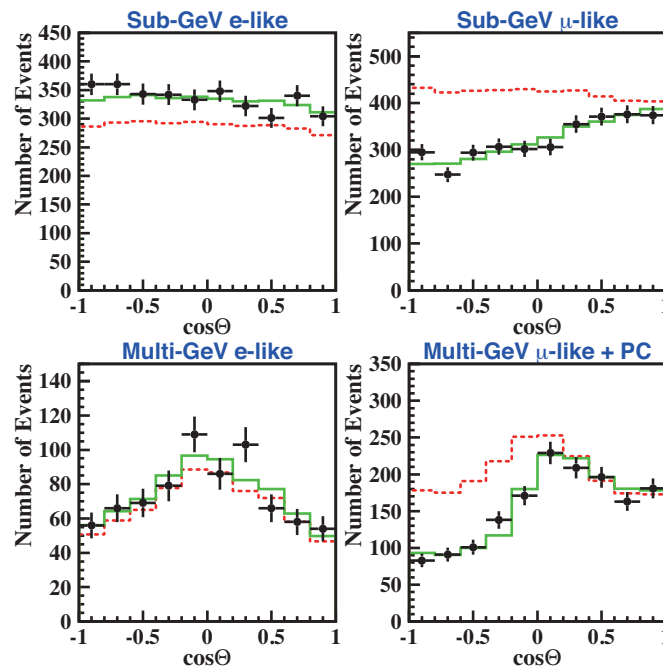

Figure 13.6: The zenith angle distributions for fully contained 1-ring e -like and μ -like events with visible energy < 1.33 GeV (sub-GeV) and > 1.33 GeV (multi-GeV). For multi-GeV μ -like events, a combined distribution with partially contained (PC) events is shown. The dotted histograms show the non-oscillated Monte Carlo events, and the solid histograms show the best-fit expectations for $\nu_\mu \leftrightarrow \nu_\tau$ oscillations. (This figure is provided by the Super-Kamiokande Collaboration.)

Neutrino mass, mixing, and oscillations (p. 178)

Figure 13.10: The regions of squared-mass splitting and mixing angle favored or excluded by various experiments. The figure was contributed by H. Murayama (University of California, Berkeley, and IPMU, University of Tokyo). References to the data used in the figure can be found at <http://hitoshi.berkeley.edu/neutrino>.

Neutrino mass, mixing, and oscillations (p. 181)

Figure 13.11: The effective Majorana mass $\langle m \rangle$ (including a 2σ uncertainty) as a function of $\min(m_j)$. The figure is obtained using the best fit values and 1σ errors of Δm_{21}^2 , $\sin^2 \theta_{12}$, and $|\Delta m_{31}^2| \cong |\Delta m_{32}^2|$ from Ref. 112, fixed $\sin^2 \theta_{13} = 0.01$ and $\delta = 0$. The phases $\alpha_{21,31}$ are varied in the interval $[0, \pi]$. The predictions for the NH, IH and QD spectra are indicated. The black lines determine the ranges of values of $\langle m \rangle$ for the different pairs of CP conserving values of $\alpha_{21,31}$: $(\alpha_{21}, \alpha_{31}) = (0, 0)$ solid, $(0, \pi)$ long dashed, $(\pi, 0)$ dash-dotted, (π, π) short dashed, lines. The red regions correspond to at least one of the phases $\alpha_{21,31}$ and $(\alpha_{31} - \alpha_{21})$ having a CP violating value. (Update by S. Pascoli of a figure from the last article quoted in Ref. 127.)

Structure functions (p. 204)

Figure 16.4: Distributions of x times the unpolarized parton distributions $f(x)$ (where $f = u_v, d_v, \bar{u}, \bar{d}, s, c, b, g$) and their associated uncertainties using the NNLO MSTW2008 parameterization [13] at a scale $\mu^2 = 10 \text{ GeV}^2$ and $\mu^2 = 10,000 \text{ GeV}^2$.

Big-Bang cosmology (p. 233)

Figure 19.2: Likelihood-based probability densities on the plane Ω_Λ (*i.e.*, Ω_v assuming $w = -1$) vs Ω_m . The colored Monte-Carlo points derive from WMAP [32] and show that the CMB alone requires a flat universe $\Omega_v + \Omega_m \simeq 1$ if the Hubble constant is not too high. The SNe Ia results [33] very nearly constrain the orthogonal combination $\Omega_v - \Omega_m$. The intersection of these constraints is the most direct (but far from the only) piece of evidence favoring a flat model with $\Omega_m \simeq 0.25$.

Big-Bang nucleosynthesis (p. 241)

Figure 20.1: The abundances of ^4He , D, ^3He , and ^7Li as predicted by the standard model of Big-Bang nucleosynthesis [11] – the bands show the 95% CL range. Boxes indicate the observed light element abundances (smaller boxes: $\pm 2\sigma$ statistical errors; larger boxes: $\pm 2\sigma$ statistical and systematic errors). The narrow vertical band indicates the CMB measure of the cosmic baryon density, while the wider band indicates the BBN concordance range (both at 95% CL).

Cosmic microwave background (p. 264)

Figure 23.2: Band-power estimates from the *WMAP*, *BOOMERANG*, *QUAD*, *CBI*, and *ACBAR* experiments. Some of the low- ℓ and high- ℓ band-powers which have large error bars have been omitted. Note also that the widths of the ℓ -bands varies between experiments and have not been plotted. This figure represent only a selection of available experimental results, with some other data-sets being of similar quality. The multipole axis here is linear, so the Sachs-Wolfe plateau is hard to see. However, the acoustic peaks and damping region are very clearly observed, with no need for a theoretical curve to guide the eye; the curve plotted is a best-fit model from *WMAP* 5-year plus other CMB data.

Cosmic microwave background (p. 265)

Figure 23.3: Cross power spectrum of the temperature anisotropies and E-mode polarization signal from *WMAP* [47], together with estimates from *BOOMERANG*, *DASI*, *QUAD*, *CBI* and *BICEP*, several of which extend to higher ℓ . Note that the widths of the bands have been suppressed for clarity, but that in some cases they are almost as wide as the features in the power spectrum. Also note that the y -axis here is not multiplied by the additional ℓ , which helps to show both the large and small angular scale features.

Cosmic microwave background (p. 265)

Figure 23.4: Power spectrum of E-mode polarization from several different experiments, plotted along with a theoretical model which fits *WMAP* plus other CMB data.

Cosmic Rays (p. 269)

Figure 24.1: Major components of the primary cosmic radiation from Refs. [1–12]. The figure was created by P. Boyle and D. Muller.

Cosmic Rays (p. 273)

Figure 24.8: The all-particle spectrum from air shower measurements. The shaded area shows the range of the the direct cosmic ray spectrum measurements.

Particle detectors at accelerators (p. 323)

Figure 28.23: Mean profiles of π^+ (mostly) induced cascades in the CDHS neutrino detector [137].

Particle detectors for non-accelerator physics (p. 333)

Figure 29.5: Measured atmospheric neutrino fluxes above 100 GeV are shown together with a few generic models for astrophysical neutrinos and some limits.

Radioactivity and radiation protection (p. 342)

Figure 30.2: Neutron energy spectra calculated with the FLUKA code [6,7] from 25 GeV proton and electron beams on a thick copper target. Spectra are evaluated at 90° to the beam direction behind 80 cm of concrete or 40 cm of iron. All spectra are normalized per beam particle. In addition, spectra for electron beam are multiplied by a factor of 100.

Radioactivity and radiation protection (p. 343)

Figure 30.5: Contribution of individual gamma-emitting nuclides to the total dose rate at 12.4 cm distance to an activated copper sample [12].

Radioactivity and radiation protection (p. 344)

Figure 30.6: Contribution of individual positron-emitting nuclides to the total dose rate at 12.4 cm distance to an activated copper sample [12].

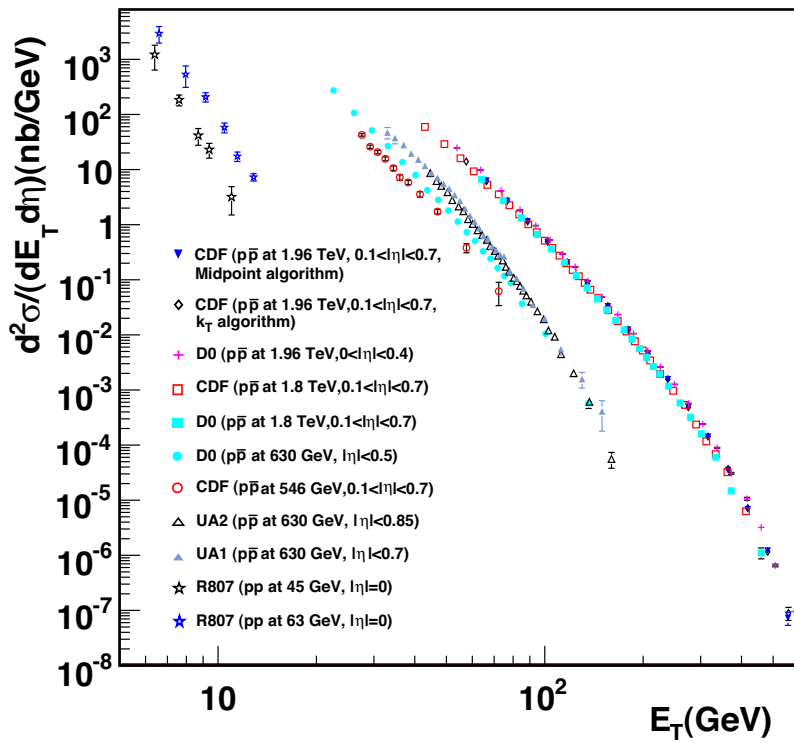

Jet Production in pp and $p\bar{p}$ Interactions (p. 385)

Figure 41.1: Inclusive differential jet cross sections plotted as a function of the jet transverse energy. The CDF and D0 measurements use a cone algorithm of radius 0.7 for all results shown except for the CDF measurements at 1.96 TeV which also use k_T with a D parameter of 0.7 and midpoint algorithms. The cone/ k_T results should be similar if $R_{cone} = D$. UA1 (UA2) uses a non-iterative cone algorithm with a radius of 1.0 (1.3). Recent NLO QCD predictions (such as CTEQ6M) provide a good description of the CDF and D0 jet cross sections, Rept. on Prog. in Phys. **70**, 89 (2007). Comparisons with the older cross sections are more difficult due to the nature of the jet algorithms used. **CDF**: Phys. Rev. **D75**, 092006 (2007), Phys. Rev. **D64**, 032001 (2001), Phys. Rev. Lett. **70**, 1376 (1993); **D0**: Phys. Rev. **D64**, 032003 (2001); **UA2**: Phys. Lett. **B257**, 232 (1991); **UA1**: Phys. Lett. **B172**, 461 (1986); **R807**: Phys. Lett. **B123**, 133 (1983). (Courtesy of J. Huston, Michigan State University, 2010)

Direct γ Production in $p\bar{p}$ Interactions (p. 385)

Figure 41.2: Isolated photon cross sections plotted as a function of the photon transverse momentum. The errors are either statistical only (CDF, D0 (1.96 TeV), UA1, UA2, UA6) or uncorrelated (D0 1.8 TeV, 630 GeV). The data are generally in good agreement with NLO QCD predictions, albeit with a tendency for the data to be above (below) the theory for lower (large) transverse momenta, Phys. Rev. **D59**, 074007 (1999). **D0**: Phys. Lett. **B639**, 151 (2006), Phys. Rev. Lett. **87**, 251805 (2001); **CDF**: Phys. Rev. **D65**, 112003 (2002); **UA6**: Phys. Lett. **B206**, 163 (1988); **UA1**: Phys. Lett. **B209**, 385 (1988); **UA2**: Phys. Lett. **B288**, 386 (1992). (Courtesy of J. Huston, Michigan State University, 2007)

Plots of cross sections and related quantities (p. 390)

 σ and R in e^+e^- Collisions

Figure 41.6: World data on the total cross section of $e^+e^- \rightarrow \text{hadrons}$ and the ratio $R(s) = \sigma(e^+e^- \rightarrow \text{hadrons}, s) / \sigma(e^+e^- \rightarrow \mu^+\mu^-, s)$. $\sigma(e^+e^- \rightarrow \text{hadrons}, s)$ is the experimental cross section corrected for initial state radiation and electron-positron vertex loops, $\sigma(e^+e^- \rightarrow \mu^+\mu^-, s) = 4\pi\alpha^2(s)/3s$. Data errors are total below 2 GeV and statistical above 2 GeV. The curves are an educative guide: the broken one (green) is a naive quark-parton model prediction, and the solid one (red) is 3-loop pQCD prediction (see “Quantum Chromodynamics” section of this *Review*, Eq. (9.7) or, for more details, K. G. Chetyrkin *et al.*, Nucl. Phys. **B586**, 56 (2000) (Erratum *ibid.* **B634**, 413 (2002)). Breit-Wigner parameterizations of J/ψ , $\psi(2S)$, and $\Upsilon(nS)$, $n = 1, 2, 3, 4$ are also shown. The full list of references to the original data and the details of the R ratio extraction from them can be found in [arXiv:hep-ph/0312114]. Corresponding computer-readable data files are available at <http://pdg.lbl.gov/current/xsect/>. (Courtesy of the COMPAS (Protvino) and HEPDATA (Durham) Groups, May 2010.)

Plots of cross sections and related quantities (p. 391)

 R in Light-Flavor, Charm, and Beauty Threshold Regions

Figure 41.7: R in the light-flavor, charm, and beauty threshold regions. Data errors are total below 2 GeV and statistical above 2 GeV. The curves are the same as in Fig. 41.6. **Note:** CLEO data above $\Upsilon(4S)$ were not fully corrected for radiative effects, and we retain them on the plot only for illustrative purposes with a normalization factor of 0.8. The full list of references to the original data and the details of the R ratio extraction from them can be found in [arXiv:hep-ph/0312114]. The computer-readable data are available at <http://pdg.lbl.gov/current/xsect/>. (Courtesy of the COMPAS (Protvino) and HEPDATA (Durham) Groups, May 2010.)

Plots of cross sections and related quantities (p. 395)

Figure 41.10: Summary of hadronic, γp , and $\gamma\gamma$ total cross sections, and ratio of the real to imaginary parts of the forward hadronic amplitudes. Corresponding computer-readable data files may be found at <http://pdg.lbl.gov/current/xsect/>. (Courtesy of the COMPAS group, IHEP, Protvino, August 2005)

The Mass and Width of the W boson (p. 418)Figure 1: Measurements of the W -boson mass by the LEP and Tevatron experiments.The Mass and Width of the W boson (p. 419)Figure 2: Measurements of the W -boson width by the LEP and Tevatron experiments.

Searches for Higgs Bosons (p. 450)

Figure 1: SM Higgs boson production cross sections for $p\bar{p}$ collisions at 1.96 TeV, from Ref. [29] and references therein.

Searches for Higgs Bosons (p. 450)

Figure 2: SM Higgs boson production cross sections for pp collisions at 14 TeV [29].

Searches for Higgs Bosons (p. 451)

Figure 5: The 95% confidence level upper bound on the ratio $\xi^2 = (g_{HZZ}/g_{HZZ}^{\text{SM}})^2$ [17]. The solid line indicates the observed limit, and the dashed line indicates the median limit expected in the absence of a Higgs boson signal. The dark and light shaded bands around the expected limit line correspond to the 68% and 95% probability bands, indicating the range of statistical fluctuations of the expected outcomes. The horizontal line corresponds to the Standard Model coupling. Standard Model Higgs boson decay branching fractions are assumed.

Searches for Higgs Bosons (p. 453)

Figure 6: Upper bound on the SM Higgs boson cross section obtained by combining CDF and DØ search results, as a function of the mass of the Higgs boson sought [78]. The limits are shown as a multiple of the SM cross section. The ratios of the different production and decay modes are assumed to be as predicted by the SM. The solid curve is the observed upper bound, and the dashed black curve is the median expected upper bound assuming no signal is present. The shaded bands show the 68% and 95% probability bands around the expected upper bound.

Searches for Higgs Bosons (p. 454)

Figure 7: Upper bound on the SM Higgs boson cross section obtained by combining CDF and D0 search results in the $H \rightarrow W^+W^-$ decay mode, as a function of the mass of the Higgs boson sought [19]. The limits are shown as a multiple of the SM cross section. The ratios of the different production and decay modes are assumed to be as predicted by the SM. The solid curve shows the observed upper bound, the dashed black curve shows the median expected upper bound assuming no signal is present. The shaded bands show the 68% and 95% probability bands around the expected upper bound.

Searches for Higgs Bosons (p. 454)

Figure 8: Upper bound on the Higgs boson cross section of the 4th generation sequential model obtained by combining CDF and D0 search results in the $H \rightarrow W^+W^-$ decay mode, as a function of the mass of the Higgs boson sought [87]. The limits are shown as a multiple of the cross section obtained in this extended model. The solid curve shows the observed upper bound, the dashed black curve shows the median expected upper bound assuming no signal is present, and the colored bands show the 68% and 95% probability bands around the expected upper bound.

Searches for Higgs Bosons (p. 458)

Figure 9: The MSSM exclusion contours, at 95% C.L. (light-green) and 99.7% CL (dark-green), obtained by LEP for the *CPC* m_h -max benchmark scenario, with $m_t = 174.3$ GeV. The figure shows the excluded and theoretically inaccessible regions in the $(m_h, \tan\beta)$ projection. The upper edge of the theoretically allowed region is sensitive to the top quark mass; it is indicated, from left to right, for $m_t = 169.3, 174.3, 179.3$ and 183.0 GeV. The dashed lines indicate the boundaries of the regions which are expected to be excluded on the basis of Monte Carlo simulations with no signal (from Ref. [18]).

Searches for Higgs Bosons (p. 459)

Figure 10: The 95% C.L. limits on $\sigma(b\bar{b}\phi) \times \text{BR}(\phi \rightarrow b\bar{b})$ and $\sigma(\phi + X) \times \text{BR}(\phi \rightarrow \tau^+\tau^-)$ from the Tevatron collaborations. The $D\bar{O}$ limit on $\sigma(b\bar{b}\phi) \times \text{BR}(\phi \rightarrow \tau^+\tau^-)$ and the Tevatron combined limit on $\sigma(\phi + X) \times \text{BR}(\phi \rightarrow \tau^+\tau^-)$ are also shown. The observed limits are indicated with solid lines, and the expected limits are indicated with dashed lines. The limits are to be compared with the sum of signal predictions for Higgs bosons with similar masses. The decay widths of the Higgs bosons are assumed to be much smaller than the experimental resolution.

Searches for Higgs Bosons (p. 460)

Figure 11: The 95% C.L. MSSM exclusion contours obtained by a combination of the CDF and DØ searches for $H \rightarrow \tau^+\tau^-$ in the m_h -max (left) and *no-mixing* (right) benchmark scenarios, both with $\mu = 200$ GeV, projected onto the $(m_A, \tan\beta)$ plane [147]. The regions above the solid black line are excluded, and the shaded and hatched bands centered on the lighter line show the distributions of expected exclusions in the absence of a signal. Also shown are the regions excluded by LEP searches [18], assuming a top quark mass of 174.3 GeV. The Tevatron results are not sensitive to the precise value of the top quark mass.

Searches for Higgs Bosons (p. 462)

Figure 12: The MSSM exclusion contours, at the 95% C.L. (light-green) and the 99.7% CL (dark-green), obtained by LEP for the CPX scenario defined in the text. Here, $m_t = 174.3$ GeV. The figure shows the excluded and theoretically inaccessible regions in the $(m_{H_1}, \tan\beta)$ projection. The dashed lines indicate the boundary of the region which is expected to be excluded at the 95% C.L. in the absence of a signal.

Searches for Higgs Bosons (p. 463)

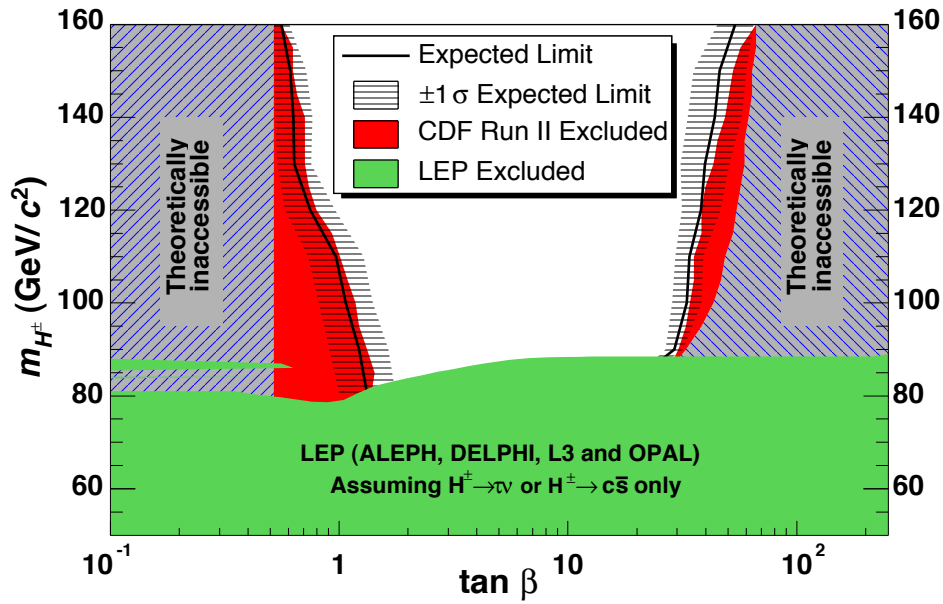

Figure 13: Summary of the 95% C.L. exclusions in the $(m_{H^\pm}, \tan \beta)$ plane obtained by LEP [195] and CDF [214]. The benchmark scenario parameters used to interpret the CDF results are very close to those of the m_h^{\max} scenario, and m_t is assumed to be 175 GeV. The full lines indicate the median limits expected in the absence of a H^\pm signal, and the horizontal hatching represents the $\pm 1\sigma$ bands about this expectation.

Searches for Higgs Bosons (p. 464)

Figure 14: The 95% C.L. exclusion limits on the masses and couplings to leptons of right- and left-handed doubly-charged Higgs bosons, obtained by LEP and Tevatron experiments (from Ref. [223]).

W' -boson searches (p. 481)

Figure 1: 95% CL exclusion limit from CDF [17] in the gauge coupling versus $M_{W'}$ plane, using the $t\bar{b}$ and $\bar{t}b$ final states.

Leptoquarks (p. 491)

Figure 1: Limits on two typical first-generation scalar leptoquark states in the mass-coupling plane. The upper figure is for a weak-isodoublet, weak-hypercharge $7/6$, $3B + L = 0$ leptoquark state, while the lower figure for a weak-isosinglet, weak-hypercharge $-1/3$, $3B + L = 2$ state.

CP Violation in K_L Decays (p. 780)

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the $\chi^2 = 1$ contour of the fit result.

CP Violation in K_L Decays (p. 781)

Figure 2: ϕ_{+-} vs τ_S . τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the fit result’s $\chi^2 = 1$ contour.

$D^0-\bar{D}^0$ Mixing (p. 825)

Figure 1: Two-dimensional 1σ - 5σ contours for (x, y) from measurements of $D^0 \rightarrow K^{(*)}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [10]).

 $D^0-\bar{D}^0$ Mixing (p. 825)

Figure 2: Two-dimensional 1σ - 5σ contours for $(|q/p|, \text{Arg}(q/p))$ from measurements of $D^0 \rightarrow K^{(*)}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [10]).

$B^0-\bar{B}^0$ Mixing (p. 976)

Figure 2: Combined measurements of the B_s^0 oscillation amplitude as a function of Δm_s . Top: CDF result based on Run II data, published in 2006 [19]. Middle: Average of all preliminary $D\bar{O}$ results available at the end of 2007 [21]. Bottom: Average of all other results (mainly from LEP and SLD) published between 1997 and 2004. All measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated.

V_{cb} and V_{ub} CKM Matrix Elements (p. 1016)

Figure 1: Measurements of $|V_{cb}|\mathcal{F}(1)$ vs. $\rho_{A_1}^2$ are shown as $\Delta\chi^2 = 1$ ellipses.

 V_{cb} and V_{ub} CKM Matrix Elements (p. 1017)

Figure 2: Measurements of $|V_{cb}|\mathcal{G}(1)$ vs. ρ^2 are shown as $\Delta\chi^2 = 1$ ellipses.

Supersymmetry, Part I (Theory) (p. 1301)

Figure 1: Mass spectrum of supersymmetric particles and Higgs bosons for the mSUGRA reference point SPS 1a'. The masses of the first and second generation squarks, sleptons, and sneutrinos are denoted collectively by \tilde{q} , $\tilde{\ell}$ and $\tilde{\nu}_\ell$, respectively. Taken from Ref. 100.

Supersymmetry, Part II (Experiment) (p. 1311)

Figure 1: Region in the $(m_{\tilde{\mu}_R}, m_{\tilde{\chi}_1^0})$ plane excluded by the searches for smuons at LEP.

Supersymmetry, Part II (Experiment) (p. 1315)

Figure 3: Region in the $(m_{\tilde{g}}, m_{\tilde{q}})$ plane excluded by CDF Run II and by earlier experiments.

Supersymmetry, Part II (Experiment) (p. 1317)

Figure 6: Regions in the $(m_0, m_{1/2})$ plane excluded by the $D\bar{0}$ search for tripletons and by the LEP experiments.

Dynamical Electroweak Symmetry Breaking (p. 1341)

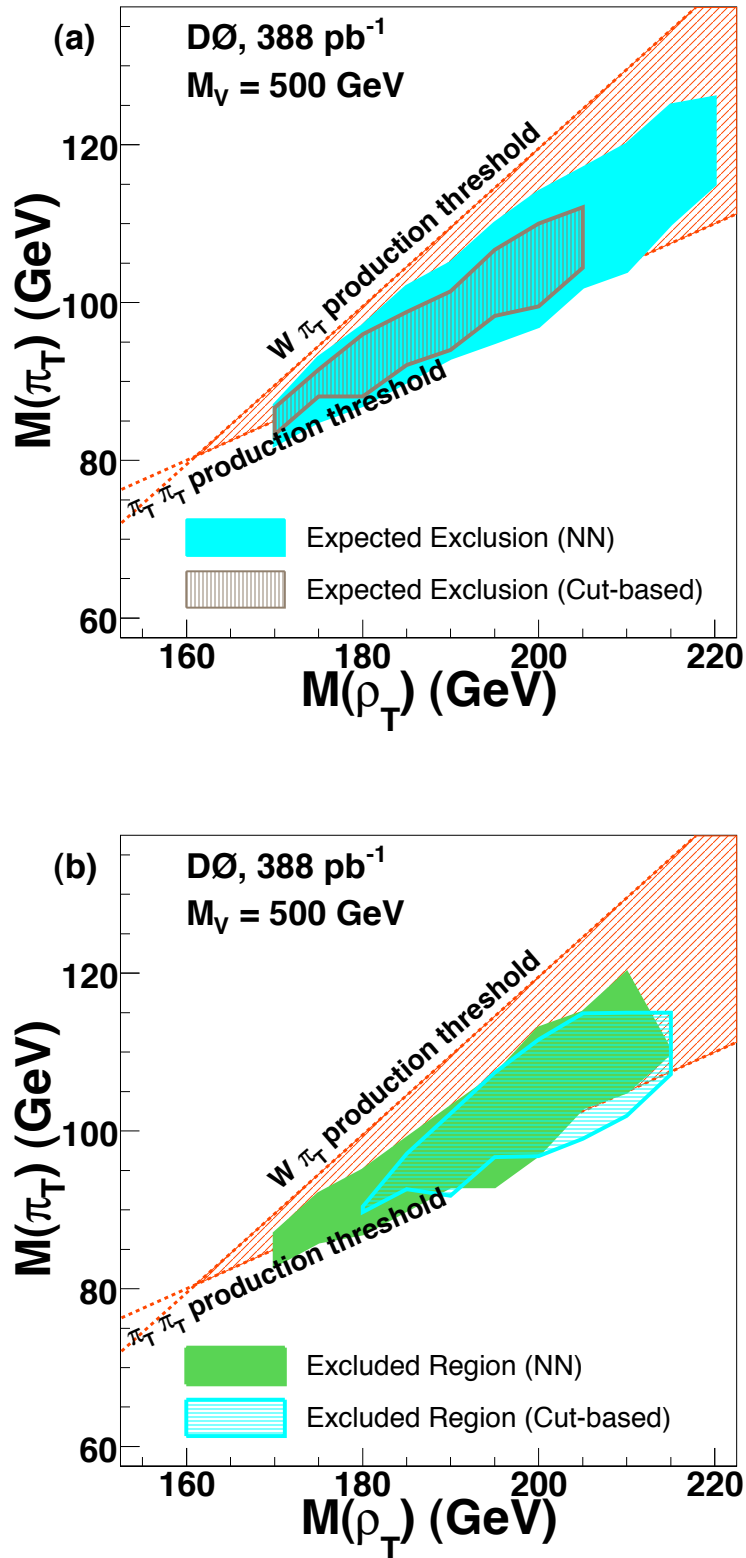

Figure 1: Search for a light technirho decaying to W^\pm and a π_T , and in which the π_T decays to two jets including at least one b quark [19]. Expected region of exclusion (a) and excluded region (b) at the 95% C.L. in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T \rightarrow W\pi_T \rightarrow e\nu b\bar{b}(\bar{c})$ production with $M_V = 500 \text{ GeV}$. Kinematic thresholds from $W\pi_T$ and $\pi_T\pi_T$ are shown on the figures.

Dynamical Electroweak Symmetry Breaking (p. 1343)

Figure 4: 95% CL exclusion region [23] in the technirho-technipion mass plane obtained from searches by the DELPHI collaboration at LEP 2, for nine technifermion doublets. The dashed line shows the expected limit for the 4-jet analysis.

Dynamical Electroweak Symmetry Breaking (p. 1343)

Figure 6: 95% CL exclusion region [28] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to $b\nu$.
