April, 1963

We have studied the production of 4.1-hr Tb<sup>149g</sup>, 7.4 min Dy<sup>150</sup> and 17.9 min Dy<sup>151</sup> by measurements of their  $\alpha$  radiations with  $2\pi$  ionization chambers. These nuclides were produced by two types of reactions involving heavy ions (HI): (a) (HI, xn) Tb<sup>149g</sup> with x = 3 to 8 (b) (HI, xn) Dy<sup>149</sup>, Dy<sup>150</sup> or Dy<sup>151</sup> with x = 3 to 9. The heavy ions employed were B<sup>10</sup>, B<sup>11</sup>, C<sup>12</sup>, N<sup>14</sup>, O<sup>16</sup>, F<sup>19</sup> and Ne<sup>20</sup>.

Three kinds of measurements have been made: (a) the range distribution from thin target layers in thin Al catcher foils (b) excitation functions by the stacked foil method (c) angular distribution from thin target layers. The objectives of these experiments were to test the consistency with the compound-nucleus and statistical models and to determine the effects of angular momentum and excitation energy on neutron emission.

I will now show some typical experimental results. First we will consider measurements of the average range  $R_0$ . The first figure (from previously reported work)<sup>1</sup> shows the average range of Tb<sup>149g</sup> produced in a large number of different reactions. These values of  $R_0$  follow a consistent trend when plotted against the recoil energy  $E_R$  calculated by assuming compound nucleus formation. In the second figure we present similar results for Dy<sup>150</sup> and Dy<sup>151</sup> products. The overall consistency of these data give strong evidence for compound-nucleus formation for all these reactions.

In Fig. 3 we show measured cross section  $\sigma$  divided by calculated total reaction cross section  $\sigma_R^2$  for many reactions of type  $(HI, xn)Tb^{149g}$ . Note that the peak cross sections are rather low and that they decrease with increasing  $x$ . Average angular momentum of the compound nuclei increases with  $x$ . It is interesting to compare an excitation function for  $(HI, xn)Tb^{149g}$  with that for a typical  $(HI, xn)Dy^{150}$  reaction. This comparison, given in Fig. 4, shows that the latter reaction has a much larger cross section and peaks at a much higher energy. This is a general feature of the reactions  $(HI, xn)Dy^{149}$ ,  $Dy^{150}$  or  $Dy^{151}$  as indicated in Fig. 5. The striking differences shown in Fig. 4 are attributed to the unobserved  $4.0 \text{ min } Tb^{149m}$  of higher spin.<sup>3</sup>

We can compare the decay of a compound nucleus, such as  $Dy^{156}$ , formed with different projectiles and therefore different average angular momenta. A comparison of the reactions  $C^{12} + Nd^{144}$  and  $Ne^{20} + Ba^{136}$  is shown in Fig. 6. The latter reactions lead to broader excitation functions and displacement toward higher excitation energies.

We have measured angular distributions for several of these reactions at various energies. The effect of target thickness on a measured angular distribution is shown in Fig. 7. For the average value of the laboratory angles  $\langle \theta_L \rangle$  and  $\langle \theta_L^2 \rangle^{1/2}$  it is possible to correct for target thickness by extrapolating to zero target thickness as shown in Fig. 8. Thus we can characterize each angular distribution by the average squared angle  $\langle \theta_L^2 \rangle$ .

These various measurements can be used to obtain information about

- (a) the effects of angular momentum
- (b) the average total energies of neutrons and photons
- (c) the nuclear temperature as a function of excitation energy
- (d) the average angular momenta removed by neutrons and photons.

As previously stated the average range data give evidence that these neutron emitting reactions proceed through a compound nucleus mechanism.<sup>1</sup>

From comparisons of the excitation functions for  $(\text{HI}, \text{xn})\text{Tb}^{149\text{G}}$  reactions with those for  $(\text{HI}, \text{xn})\text{Dy}$  reactions, we can infer that only compound systems of angular momentum less than 7.5  $\hbar$  contribute to the former reactions.<sup>4</sup> The compound nuclei of higher spin decay preferentially to 4.0 min  $\text{Tb}^{149\text{n}}$ .

If the neutron emission is isotropic the average squared angle  $\langle \theta_L^2 \rangle$  can be related to the average total kinetic energy,  $\langle T_n \rangle$  of the emitted neutrons.<sup>5</sup> The average total photon energy  $T_\gamma$  can then be obtained from the total available energy  $E_{\text{c.m.}} + Q$ ,  $T_\gamma = E_{\text{c.m.}} + Q - T_n$ .

For reactions of  $x = 3$  to 7 we show in Fig. 9 the values of  $T_\gamma$  (deduced from  $\langle \theta_L^2 \rangle$ ) as a function of available energy. There is a striking difference between the reactions  $(\text{HI}, \text{xn})\text{Tb}^{149\text{G}}$  involving compound nuclei of low spin and the "normal reactions"  $(\text{HI}, \text{xn})\text{Dy}^{149}$ ,  $\text{Dy}^{150}$ , or  $\text{Dy}^{151}$ . For the latter reactions  $T_\gamma$  increases rapidly with available energy from almost 0 to about 30 MeV. Another way of presenting the results is in terms of the average kinetic energy  $T_n/x$  of the neutrons as shown in Fig. 10. For the "normal reactions" average neutron energy increases slowly with available energy. We recall from Fig. 5 that the "normal reactions" peak at  $\sim 5.5$  to 6 MeV per neutron. Thus in Fig. 10 by comparison of the different reactions at a value of  $(E_{\text{c.m.}} + Q)/x$  of  $\sim 6$  MeV per neutron, an increase of average neutron energy with  $x$  is apparent. This reflects a nuclear temperature that increases with excitation energy.

The excitation functions can be used to obtain a quantity  $\langle E \rangle_x$ , defined as follows

$$\langle E \rangle_x = \frac{\int_0^{\infty} EF_x(E) dE}{\int_0^{\infty} F_x(E) dE}$$

The fraction of the reactions in which only neutrons are emitted is denoted by  $F_x$ . We show the differences between  $\langle E \rangle_x$  and the sum of the neutron binding energies in Fig. 11. An increase with average angular momentum can be seen. By comparing the displacements of the lines in Fig. 11 with the values of  $T_n/x$ , an indication is given that the average angular momentum removed by each neutron is  $\sim 3 \hbar$ .<sup>6</sup> An overall angular momentum and energy balance leads to  $1.8 \pm 0.6 \hbar$  for the average angular momentum removed by each photon.<sup>6,7</sup>

## FIGURE CAPTIONS

- MU-22787 Fig. 1. Average range as a function of calculated recoil energy for reactions leading to 4.1-hr  $Tb^{149}$ . The symbols are as follows:  $C^{12}$ ,  $\square$ ;  $n^{14}$ ,  $\diamond$ ;  $N^{15}$ ,  $D$ ;  $O^{16}$ ,  $\Delta$ ;  $O^{18}$ ,  $\nabla$ ;  $F^{19}$ ,  $\square$ ;  $Ne^{20}$ ,  $\circ$ ;  $Ne^{22}$ ,  $\bigcirc$ . Four bars are for reactions forming compound nuclei for  $Z = 69$ ; three bars for  $Z = 68$ ; two bars for  $Z = 67$ ; one bar for  $Z = 66$ ; no bars for  $Z = 65$ .
- MU-26039 Fig. 2. Average range  $R_p$  in Al vs the calculated recoil energy  $E_R$ . Symbols are as follows:  $Dy^{151}$ ,  $\square$ ;  $Dy^{150}$ ,  $\Delta$ ;  $Dy^{149}$ ,  $\bigcirc$ ; Open symbols are for the reactions  $C^{12} + Nd^{144}$ ; closed, for  $O^{16} + Ce^{140}$ . The smooth curve is from reference 1.
- MUB-1409 Fig. 3. Cross section  $\sigma$  divided by calculated total reaction cross section  $\sigma_R$  (reference 2) for  $(HI,xn)Tb^{149g}$  reactions. The various projectiles, targets, and reactions are indicated. Excitation energies were calculated from Seeger's mass formula; P.A. Seeger, Nucl. Phys. 22, 1 (1961).
- MU-26507 Fig. 4. Cross section  $\sigma$  divided by total reaction cross section  $\sigma_R$  (reference 2) versus available energy per emitted neutron  $(E_{c.m.} + Q)/x$  for two  $(HI,xn)$  reactions.
- MU-26040 Fig. 5. Fraction of the calculated reaction cross section vs available energy per emitted neutron. The symbols are as in Fig. 2. Total reaction cross sections are from reference 2.
- MUB-1575 Fig. 6. Measured cross section  $\sigma$  divided by calculated total reaction cross section  $\sigma_R$  as a function of excitation energy  $E$ .
- MU-26037 Fig. 7. The effect of target thickness on observed angular-distribution. The target thickness  $W$  is denoted for each curve in  $\mu g/cm^2$ . Those data are for the reaction  $Nd^{144} + 123\text{-MeV } C^{12} \rightarrow Dy^{149} + 7n$ .
- MU-26058 Fig. 8. The dependence of (a) the average angle  $\langle \theta_L \rangle$  and (b) the root-mean-square angle  $\langle \theta_L^2 \rangle^{1/2}$  on target thickness  $W$ . Curves A are for the reaction  $Nd^{146} + 104\text{-MeV } B^{11} \rightarrow Tb^{149g} + 8n$ ; B for  $Nd^{144} + 123\text{-MeV } C^{12} \rightarrow Dy^{149} + 7n$ ; C for  $Ce^{140} + 159\text{-MeV } O^{16} \rightarrow Dy^{149} + 7n$ ; and D for  $Ce^{140} + 111\text{-MeV } O^{16} \rightarrow Dy^{149} + 7n$ . The numbers in parentheses denote the slopes of the curves in  $\text{deg}/(\mu g/cm^2)$ .

MU-28462 Fig. 9. Total photon energy vs total available energy. The upper curves are for Tb compound nuclei and the product  $Tb^{149S}$ . The lower curves are for Dy compound nuclei and products  $Dy^{149}$ ,  $Dy^{150}$  and  $Dy^{151}$ . The number of emitted neutrons is indicated for each curve. Symbols are as follows:

$Pr^{141}(C^{12}, 4n)Tb^{149g}$  ◇;  $Nd^{146}(B^{10}, 7n)Tb^{149S}$  ◎ ;  
 $Nd^{146}(B^{11}, 8n)Tb^{149S}$  ▽;  $Nd^{142}(C^{12}, 3n)Dy^{151}$  × ;  
 $Nd^{142}(C^{12}, 4n)Dy^{150}$  ⊗ ;  $Nd^{142}(C^{12}, 5n)Dy^{149}$  ■ ;  
 $Nd^{144}(C^{12}, 5n)Dy^{151}$  □ ;  $Nd^{144}(C^{12}, 6n)Dy^{150}$  △ ;  
 $Nd^{144}(C^{12}, 7n)Dy^{149}$  ○ ;  $Ce^{140}(O^{16}, 5n)Dy^{151}$  ■ ;  
 $Ce^{140}(O^{16}, 6n)Dy^{150}$  ▲ ;  $Ce^{140}(O^{16}, 7n)Dy^{149}$  ▲ .

MUB-1408 Fig. 10. Average total energy of photons (a) and average energy of neutrons (b) vs available energy per emitted neutron ( $E_{c.m.} + Q$ )/x for reactions in which x neutrons are emitted. Symbols are as in Fig. 9.

MU-29076 Fig. 11. The average excitation energy  $\langle E \rangle_x$  minus the sum of the binding energies  $B_i$  of the neutrons as a function of the average angular momentum  $\langle J \rangle$ . Different symbols are used for the different (HI,xn) reactions ◇,  $x = 3$ ; ▽,  $x = 4$ ; ○,  $x = 5$ ; □,  $x = 6$ ; ■,  $x = 7$ ; ●,  $x = 8$ ; ▲,  $x = 9$ . Open points are for  $Dy^{149}$ ; closed for  $Dy^{150}$ ; and half open for  $Dy^{151}$ .
