# High Fidelity Data Collection Throughout the Deployment Lifecycle

Laura Balzano, Nithya Ramanathan, Tom Schoellhammer, Deborah Estrin, Eddie Kohler, Mani Srivastava

## What's the Problem?

### SensorNet Data Travels a Protracted and Perilous Path!

- (See Diagram Below!) Sensing channel ... through the sensor ... collected by the board ... transmitted across an ad-hoc wireless network ... collected at a base-station ... uploaded to a server ... cleaned ... uploaded to a data-base ... end-user

### System Pitfalls and Shortcomings Impact Collection and Delivery of Data

- E.g. bad sensor coupling, faulty communication channel
- Often, user intervention required to identify and fix such problems, resulting in drawn out deployment cycles, during which the impacts of faults accumulate as unusable data
- Often an end user cannot definitely determine if data are usable without better understanding the context in which they were collected

### Traditional Approach Focuses on Post-Deployment Operations

- Manual/visual cleaning of data and time-stamps
- Apply physical/statistical models to identify outliers
- Guesswork as to environmental context... e.g. "Did wind-blown grass or a truck trigger this motion sensor?"

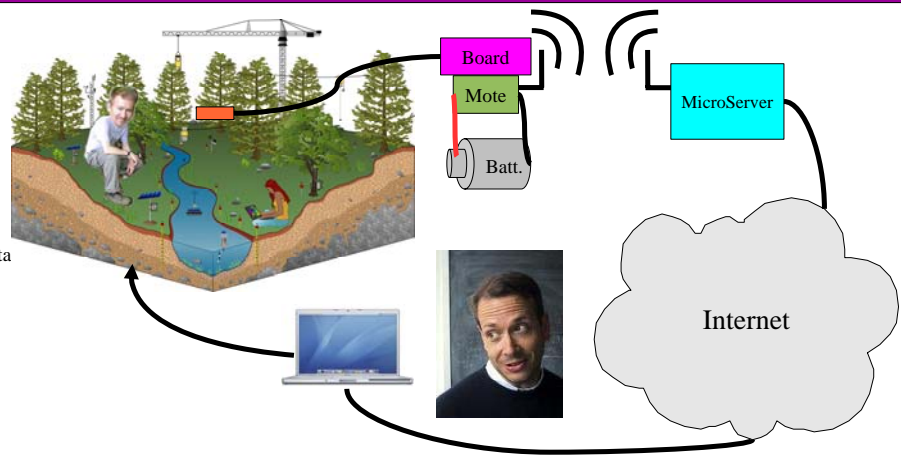

Carefully integrating human input into the collection path is more useful than completely autonomously collected data!!

## The Puzzle Comes Together

### Design Systems Incorporating Human Input into Collection Path

Design systems to work with humans to:

- **Diagnose and/or fix** problems impacting the *generation and delivery* of high quality data to the end-user
- **Document the context** by gathering extra sensory *observations, such as physical samples or human observations*, that provide contextual information useful for determining data integrity and easing data analysis

## Network Integrity: Sympathy as a Sensor Network Debugger

Sympathy is designed to identify faults impacting the *delivery* of data (i.e. network faults) by:

- **Collecting Metrics** from every node such as *neighbor table and number of packets received*
- **Identifying Network Failures** using a *decision tree* (right) to find the root cause
- **Localize Failures** to identify *where data is lost*

Sympathy then suggests **actions** associated with the fault **that a user can take in the field** to fix these network bugs

- Actions include: replacing the battery, moving a node, or tracking a software bug

## Confidence for Data Quality Management

Confidence is designed to identify **actions a user can take in the field** to remediate faults impacting the *generation* of data (i.e. data quality faults) by

- **Classifying data** based on 4 pre-specified attributes (e.g. gradient, standard deviation)
- Use *instance-based learning* techniques to identify data that most closely resembles current data point using euclidean distance in the attribute space
- Suggestion actions associated with closest resembling data points
  - Actions include: taking a physical sample, or checking sensor connections

## Deployment Buddy (Working Title)

Span the networked sensing deployment and analysis life cycle

- Explore *experimental design* strategies prior to deployment
  - Given a phenomenon model, what design seems best for parameter estimation?
- Capture **deployment metadata** and irregularities during deployment
- Decisions made in the field impact data analysis
- Facilitate data analysis, using *phenomenon specific models*, and recorded installation metadata
