Aim: Endothelin-1 (ET-1) and angiotensin II (Ang II) are multifunctional peptide hormones that regulate the function of the cardiovascular and renal systems. Both hormones increase the intracellular production of inositol-1,4,5-trisphosphate (IP₃) by activating their membrane-bound receptors. We have previously demonstrated that IP₃-mediated sarcoplasmic reticulum (SR) Ca²⁺ release results in mitochondrial Ca²⁺ uptake and activation of ATP production. In this study, we tested the hypothesis that intact SR/mitochondria microdomains are required for metabolic IP₃-mediated SR/mitochondrial feedback in ventricular myocytes.

Methods: As a model for disrupted mitochondrial/SR microdomains, cardio-specific tamoxifen-inducible mitofusin 2 (Mfn2) knock out (KO) mice were used. Mitochondrial Ca²⁺ uptake, membrane potential, redox state, and ATP generation were monitored in freshly isolated ventricular myocytes from Mfn2 KO mice and their control wild-type (WT) littermates.

Results: Stimulation of ET-1 receptors in healthy control myocytes increases mitochondrial Ca²⁺ uptake, maintains mitochondrial membrane potential and redox balance leading to the enhanced ATP generation. Mitochondrial Ca²⁺ uptake upon ET-1 stimulation was significantly higher in interfibrillar (IFM) and perinuclear (PNM) mitochondria compared to subsarcolemmal mitochondria (SSM) in WT myocytes. Mfn2 KO completely abolished mitochondrial Ca²⁺ uptake in IFM and PNM mitochondria but not in SSM. However, mitochondrial Ca²⁺ uptake induced by beta-adrenergic receptors activation with isoproterenol (ISO) was highest in SSM, intermediate in IFM, and smallest in PNM regions. Furthermore, Mfn2 KO did not affect ISO-induced mitochondrial Ca²⁺ uptake in SSM and IFM mitochondria; however, enhanced mitochondrial Ca²⁺ uptake in PNM. In contrast to ET-1, ISO induced a decrease in ATP levels in WT myocytes. Mfn2 KO abolished ATP

generation upon ET-1 stimulation but increased ATP levels upon ISO application with highest levels observed in PNM regions.

Conclusion: When the physical link between SR and mitochondria by Mfn2 was disrupted, the SR/mitochondrial metabolic feedback mechanism was impaired resulting in the inability of the IP₃-mediated SR Ca²⁺ release to induce ATP production in ventricular myocytes from Mfn2 KO mice. Furthermore, we revealed the difference in Mfn2-mediated SR-mitochondrial communication depending on mitochondrial location and type of communication (IP₃R-mRyR1 vs. ryanodine receptor type 2-mitochondrial calcium uniporter).

INTRODUCTION

Heart failure (HF) is one of the most common chronic conditions associated with aging. Despite advances in HF treatment, it has a poor prognosis with a steady increase in mortality and incidence in the aging population (Lloyd-Jones et al., 2002; Nieminen et al., 2006). Current treatments of HF rely almost entirely on altering the neurohormonal milieu, using agents such as angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers, and beta-adrenergic blockers to improve cardiac function and reduce mortality. Importantly, there are no proven interventions that are directly targeted toward maintaining cardiac function and myocyte survival. The pathogenesis of HF is the result of numerous changes in the whole organism with striking subcellular modifications especially at the level of mitochondria: the number of cristae of the inner mitochondrial membrane (IMM) is reduced, and due to subcellular changes, the contact sites of mitochondria and the sarcoplasmic reticulum (SR) are significantly diminished. Depending on the type of cardiomyopathy, both decreased respiratory chain activity due to impaired mitochondrial complexes I and III (Ventura-Clapier et al., 2011; Thai et al., 2018) or increased respiratory chain activity due to increased expression of uncoupling proteins (Sebastiani et al., 2007), could lead to increased proton leak and decline in ATP generation. The heart has the highest energy demand by weight of any organ in the body, and its function fails within minutes if mitochondrial ATP production is interrupted. Therefore, addressing mitochondrial dysfunction and decrease in mitochondrial ATP generation may represent an effective

treatment for HF directly targeting the key features in its pathogenesis.

An increase in mitochondrial calcium (Ca²⁺) concentration ([Ca²⁺]_m) is thought to be one of the major factors responsible for the activation of Ca²⁺-dependent dehydrogenases eventually leading to stimulation of the oxidative phosphorylation and ATP generation (Balaban, 2009). Recent studies utilizing mitochondrial Ca²⁺ uniporter (MCU) knockout (KO) mice (Pan et al., 2013; Kwong et al., 2015) questioned this accepted dogma since mitochondrial bioenergetics and ATP generation were not significantly compromised in those animals. Only when cardiac myocytes were challenged with the beta-adrenergic agonist isoproterenol (ISO), MCU KO myocytes were not able to match ATP production and respiratory rates in response to an increased work load (Kwong et al., 2015). These data indicate that although MCU is considered the major pathway for mitochondrial Ca²⁺ uptake in cardiac myocytes, other pathways located in the inner mitochondrial membrane (IMM) may compensate for the lack of MCU and play a role in the regulation of mitochondrial Ca²⁺ uptake and ATP generation. The mitochondrial ryanodine receptor (mRyR1) was proposed to be an alternative mitochondrial Ca²⁺ uptake pathway in cardiac myocytes (Beutner et al., 2005; Jakob et al., 2014) while the physiological function and relevance of this pathway are still controversial. Recently, we were able to demonstrate that Ca²⁺ released from the sarcoplasmic reticulum (SR) *via* the inositol 1,4,5-trisphosphate receptor (IP₃R) is taken up into the mitochondrial matrix *via* the mRyR1 (Seidlmayer et al., 2016), where it activates ATP production. This IP₃-mediated mitochondria/SR feedback is essential for the adaptation of mitochondrial metabolism to chronic stress as induced by endothelin-1 (ET-1) or angiotensin (Ang II).

Ca²⁺ release from intracellular stores is the essential signal generated by electrical activation in cardiomyocytes, which is required to initiate cell contraction in the process known as excitation-contraction coupling (ECC). To release Ca²⁺ from the SR, cardiac myocytes express two different Ca²⁺ release channels: (1) the ryanodine receptor type 2 (RyR2), which is Ca²⁺ sensitive and releases Ca²⁺ from the SR during ECC upon Ca²⁺ entrance through the voltage-gated L-type Ca²⁺ channels and (2) the inositol 1,4,5-trisphosphate (IP₃) receptor (IP₃R), which releases Ca²⁺ after binding of IP₃ independently from

ECC. IP₃ is cleaved from phosphatidylinositol-4,5-bisphosphate (PIP₂) by phospholipase C when hormones like ET-1 or Ang II bind to their membrane bound G-protein-coupled receptors. Although IP₃Rs are less abundant in ventricular myocytes compared to RyR2s, their activation results in measurable Ca²⁺ increase during diastole and systole creating areas with highly, localized concentrations of Ca²⁺, known as microdomains. These microdomains are typically formed at the junction between the SR and mitochondria resulting in elevation of the cytosolic Ca²⁺ from 0.1 to ~30 μM, which leads to the activation of mitochondrial Ca²⁺ uptake (Szalai et al., 2000; Dedkova and Blatter, 2008; Dedkova et al., 2013; Dorn and Maack, 2013).

Cardiac myocytes display a highly organized structure: mitochondria, SR, and the contractile apparatus are tightly packed. Mitochondria occupy about 40% of the myocytes volume (Zhou et al., 1998). Based on the proximity of mitochondria to the Ca²⁺ release sites, mitochondria are divided into subsarcolemmal (SSM), interfibrillar (IFM) and perinuclear mitochondria (PNM). All three subgroups differ in enzymatic activity (Palmer et al., 1977; Matlib et al., 1978; McMillin-Wood et al., 1980) and shape (Fawcett and McNutt, 1969; Lukyanenko et al., 2009). SSM are located underneath the sarcolemma, PNM are located around nuclei, while IFM are localized between the myofilaments where they are in close contact to the Ca²⁺ release sites in the junctional SR (Chikando et al., 2011).

In addition to this spatial relationship, mitochondria and the SR are linked physically by electron dense structures called tethers (Csordás et al., 2006). In mammalian cells, these tethers are formed by protein complexes containing IP₃R (Szabadkai et al., 2006) and mitofusins, mainly containing mitofusin 1 (Mfn1) and mitofusin 2 (Mfn2). Despite both molecules are homologues, Mfn1 mainly mediates mitochondrial fusion (Cipolat et al., 2004), whereas Mfn2 plays an important role in mitophagy (Schrepfer and Scorrano, 2016), controls the shape of the endoplasmic reticulum, and tethers mitochondria and the SR mechanically to each other to ensure the proper communication between the two organelles (de Brito and Scorrano, 2008). This latter function of Mfn2 has been challenged by Filadi et al. (2015) who suggested that Mfn2-tethers actually keep mitochondria far away from the SR to prevent mitochondrial Ca²⁺ overload. In a series of experiments, they demonstrated that KO of Mfn2 in cultured cells improved the communication between the two organelles, suggesting that Mfn2 is a negative regulator of tethering. Critical re-evaluation of Mfn2 function, however, confirmed the original discovery from Scorrano's group that Mfn2 tethers serve to mediate the proper transfer of Ca²⁺ from the SR to mitochondria (Naon et al., 2016). In non-excitabile cells, it has been shown that IP₃Rs-mediated Ca²⁺ tunneling to mitochondria is an essential modulator of cell bioenergetics and ATP production (Cárdenas et al., 2010). However, the role of Mfn2 in IP₃Rs-mediated Ca²⁺ tunneling to mitochondria and energetics in cardiac myocytes has not been evaluated yet.

In the present study, we aimed to examine the role of Mfn2 in the IP₃Rs-mediated SR/mitochondria metabolic feedback mechanism described above. The hypothesis is that an intact linkage of SR and mitochondria is required for basal metabolic

control of the IP₃-mediated Ca²⁺ release in cardiac myocytes. Our hypothesis was tested using the cardiac-specific, tamoxifen-induced knockout of Mfn2 (Mfn2 KO). We found that when the physical link between SR and mitochondria by Mfn2 was disrupted, the SR/mitochondrial metabolic feedback mechanism was impaired resulting in the inability of the IP₃-mediated SR Ca²⁺ release to induce ATP production in ventricular myocytes from Mfn2 KO mice. We further revealed the difference in Mfn-2 mediated SR-mitochondrial communication depending on mitochondrial location and type of receptor (IP₃R vs. Ryanodine receptor), which can explain the existing controversy in the field.

MATERIALS AND METHODS

Animal Model

Mfn2^{loxp/loxp/cre} (Mfn2 KO) mice were obtained from the laboratory of Prof. Gerald W. Dorn, II in St. Louis, Missouri, USA. For induction of Cre-mediated deletion of Mfn2, mice were fed 20 mg tamoxifen/kg body weight/day for 7 days. Littermates of Mfn2 KO mice (heterozygous for Mfn2) were used as control animals and designated as wild-type (WT) group. All experimental procedures were in accordance with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (8th Edition, 2011) and approved by the University of Würzburg Institutional Animal Care and Use Committee.

Cell Isolation

Adult left ventricular myocytes were isolated from 10- to 16-week-old Mfn2 KO mice and their healthy littermates. Mice were anesthetized with isoflurane and sacrificed by cervical dislocation. The excised heart was mounted to a Langendorff perfusion system and retrogradely perfused with Ca²⁺-free washing solution followed by enzyme solution containing Liberase TH (Research Grade, Roche, Basel, Switzerland) as described previously (Seidlmayer et al., 2016). Isolated myocytes were kept in Tyrode solution containing 1 mM Ca²⁺.

Immunoblot Analysis

Left ventricular tissue was homogenized in ice-cold lysis buffer (50 mM Tris pH 7.5, 1 mM EDTA, 1 mM EGTA, 10% glycerol, 1% Triton X-100, 50 mM NaF, 5 mM Na₄P₂O₇, 1 mM Na₃VO₄, 1 mM DTT, protease inhibitor cocktail), and protein content was determined using the BCA assay. About 30 μg of protein was separated by 10% SDS-PAGE and transferred onto 0.2 μm PVDF membrane and blocked with 5% nonfat dry milk in phosphate-buffered saline (PBS) containing 0.1% Tween-20 (PBS-T). Blocked membranes were exposed to primary antibodies toward total Mfn2 (Abcam mouse monoclonal anti-Mfn2, ab56889, 1:2000 dilution) and GAPDH (Cell Signaling antibodies, 36,835, 1:2000 dilution). Sheep anti-mouse immunoglobulin G (IgG) antibodies (GE Healthcare NA9310V) in 1:4000 dilution were used as secondary antibodies. Protein bands were visualized by enhanced chemiluminescence

(GE Healthcare Life Sciences). Mfn2 bands were normalized to GAPDH bands using the software ScanPack 3.0.

Real-Time PCR

After extraction of total RNA using a RNA fibrous tissue mini kit (Qiagen, Venlo, Netherlands), cDNA was synthesized from 1 μ g of RNA using the iScript™ cDNA synthesis kit (Bio-Rad, Hercules, CA). Quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed with commercial and customized TaqMan probes (Life Technologies™, Waltham, Massachusetts, USA). Target gene mRNA levels were normalized to glyceraldehyde 3-phosphate dehydrogenase (GAPDH), which served as housekeeping gene for comparison.

Confocal Microscopy

Laser scanning confocal microscopy (Leica SP5 and a Zeiss LSM 780) was used to follow the changes in cytosolic ($[Ca^{2+}]_i$) and mitochondrial ($[Ca^{2+}]_m$) Ca^{2+} concentration, mitochondrial membrane potential ($\Delta\Psi_m$), reactive oxygen species (ROS) generation, and mitochondrial ATP generation using specific fluorescent indicators. All fluorescent signals were recorded in electrically stimulated (0.5 Hz) single cardiac myocytes. For measurements, the myocytes were plated on laminin-covered coverslips and incubated in Tyrode solution containing 1 mM Ca^{2+} at room temperature. The fluorescence image was recorded every 10 s. Fluorescence levels were corrected for background fluorescence and normalized to untreated control (F_0) (F/F_0).

$[Ca^{2+}]_m$ Measurements

Changes in mitochondrial Ca^{2+} concentration ($[Ca^{2+}]_m$) were measured in intact cells using the Ca^{2+} -sensitive fluorescent probe X-Rhod-1/AM (molecular probes, $\lambda_{ex} = 543$ nm and $\lambda_{em} = 552$ –617 nm). Myocytes were loaded with the dye for 30 min at 37°C. This loading procedure favors mitochondrial localization of X-Rhod-1. To quench the remaining cytosolic fluorescence, the myocytes were incubated in 1 mM $CoCl_2$ -containing Tyrode during washout period as published before (Seidlmayer et al., 2015, 2016).

Analysis of Mitochondrial Subfractions

For the analysis of $[Ca^{2+}]_m$ levels in SSM, a longitudinal region of interest (ROI) was placed directly underneath the sarcolemma and for IFM in the center of the cell excluding the nuclei. Changes in $[Ca^{2+}]_m$ levels in perinuclear regions (PNM) were detected in the ROIs located from each side of the nucleus. Fluorescence changes over time were analyzed.

ATP Measurement

ATP concentration was measured indirectly *via* the free magnesium (Mg^{2+}) concentration using the fluorescent probe mag-fluo-4 AM (Invitrogen) and directly using a commercially available ATP luciferase assay (Invitrogen, Waltham, Massachusetts, USA, #A22066) (Seidlmayer et al., 2016). This indirect method is based on the fact that ATP forms complexes with Mg^{2+} . Since free $[Mg^{2+}]_i$ is kept constant within a rather narrow range, ATP hydrolysis leads to concomitant increase in free $[Mg^{2+}]_i$

as measured with fluorescent Mg^{2+} indicators such as mag-fluo-4. Therefore, an increase in mag-fluo-4 fluorescence indicates a decrease in ATP concentration. For indirect ATP measurements, myocytes were loaded with 10 μ M mag-fluo-4 ($\lambda_{ex} = 488$ nm and $\lambda_{em} = 565$ –605 nm) for 30 min at 37°C. All data are expressed as an inverted ratio $R = 1 - F/F_0$.

Mitochondrial Membrane Potential Measurements

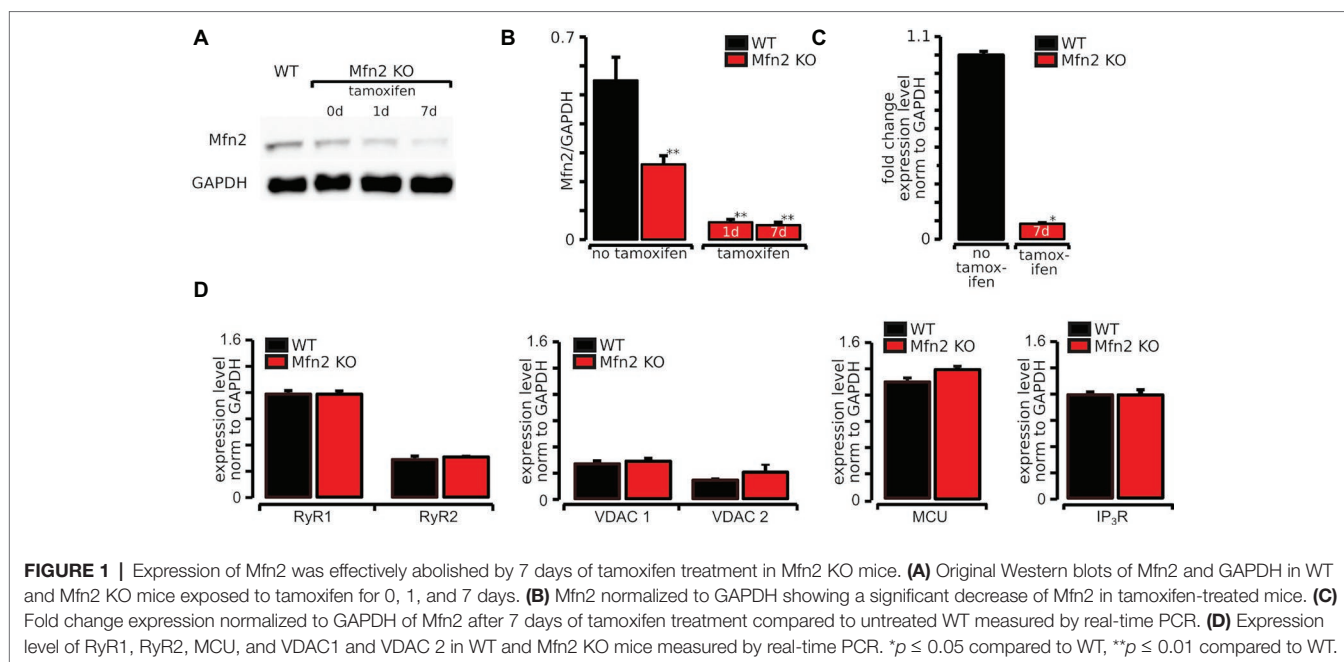

Mitochondrial membrane potential ($\Delta\Psi_m$) was measured in intact myocytes using the potentiometric probe tetramethylrhodamine methyl ester (TMRM) ($\lambda_{ex} = 543$ nm and $\lambda_{em} = 565$ –605 nm) (Dedkova and Blatter, 2012; Seidlmayer et al., 2015, 2016). The myocytes were loaded with 10 nM TMRM for 15 min at 37°C. 10 nM TMRM was present in all solutions during the experiments. In the end of each experiment, 5 μ M carbonyl cyanide p-(trifluoromethoxy) phenylhydrazone (FCCP) and 1 μ M oligomycin were added to calibrate the signal. All data were background corrected.

Redox Measurements

Isolated adult ventricular myocytes from WT mice were field-stimulated at 37°C with a stimulation rate of 0.5 Hz and superfused with normal Tyrode's (NT) solution containing (in mM) NaCl 130, KCl 5, $MgCl_2$ 1, $CaCl_2$ 1, Na-HEPES 10, glucose 10, sodium pyruvate 2, and ascorbic acid 0.3, pH 7.4. After 120 s, cardiac myocytes were superfused with NT solution containing either 10 nM endothelin or 500 nM isoproterenol. We monitored changes in redox status of cardiomyocytes by measuring autofluorescence of two endogenous tissue fluorophores: reduced form of nicotinamide adenine dinucleotide (NADH, transfers electrons to molecular oxygen) and flavin adenine dinucleotide (FAD^+ , which is an electron acceptor) (Dedkova and Blatter, 2012). NADH has fluorescence excitation and emission maxima at 350 and 460 nm, respectively. FAD^+ has fluorescence excitation and emission maxima at 450 and 535 nm, respectively. During this protocol, NADH ($\lambda_{ex} = 340$ nm; $\lambda_{em} = 450$ nm) and FAD^+ ($\lambda_{ex} = 480$ nm; $\lambda_{em} = 520$ nm) autofluorescence were recorded using an IonOptix set-up as described previously in (Kohlhaas et al., 2017). Calibration was performed with FCCP (5 μ mol/L) and cyanide (4 mmol/L). "Redox ratio," which represents approximation of the reduction-to-oxidation status of the mitochondrial matrix space, was calculated by dividing the fluorescence intensity of NADH to the fluorescence intensity of FAD^+ .

Statistics

The data are normalized to untreated control and background corrected. All data are presented as mean \pm standard error of the mean for the indicated number (n) of experiments. For comparisons of multiple groups in **Figure 1**, ANOVA was used. A significant overall F -test multi-group comparison was done *via* Tukey's test (including correction for multiple testing) for treatment vs. control. For comparisons of only two groups, Student's t -test was used. Data were considered significant at $p < 0.05$.

RESULTS

Expression of Mfn2 Was Effectively Abolished by Tamoxifen Treatment in Mfn2 KO Mice

To test our hypothesis that disturbed SR/mitochondrial contacts due to Mfn2 knockout affect the SR/mitochondrial metabolic feedback mechanism, experiments were performed in tamoxifen-inducible cardiac-specific Mfn2 knockout (Mfn2 KO) mice (Chen et al., 2011). To verify that Mfn2 protein was effectively reduced by tamoxifen, Western blot analysis was performed in heart tissue lysates collected 1 and 7 days after beginning of tamoxifen treatment. As shown in representative Western blot images in **Figure 1A**, Mfn2 expression was significantly reduced after 1 day of tamoxifen treatment and almost completely eliminated (90% decrease compared to WT myocytes) after 7 days of tamoxifen (**Figure 1B**). These results were confirmed by quantifying RNA levels of Mfn2 using real-time PCR. As shown in **Figure 1C**, the relative RNA in Mfn2 KO was 0.09 ± 0.07 ($n = 3$) compared to 1.0 ± 0.37 ($n = 4$), in WT mice. To verify that knockout of Mfn2 has no effect on the proteins involved in cardiac ECC, we tested the expression levels of RyR types 1 and 2, MCU, and voltage-dependent anion channel 1 (VDAC1) and 2 (VDAC2) by real-time PCR. As demonstrated in **Figure 1D**, expression levels of both RyR types 1 and 2, MCU, VDAC1, and VDAC2 were not altered by Mfn2 knockout.

Ca²⁺ Released *via* the IP₃R Cannot Be Taken Up Into Mitochondria in Mfn2 KO mice

We have recently demonstrated (Seidlmayer et al., 2016) that Ca²⁺ released from the SR upon IP₃R activation is taken up

into the mitochondrial matrix in WT cardiomyocytes. 10 nM ET-1 induced a significant increase in mitochondrial Ca²⁺, which could be abolished by cell treatment with 3 μ M of the IP₃R antagonist 2-APB (Seidlmayer et al., 2016). Since IP₃-mediated global cytosolic Ca²⁺ changes are very small, experiments were designed to test the importance of the subcellular contacts between SR and mitochondria in Ca²⁺ tunneling directly from SR to mitochondria in Mfn2 KO mice in which the physical tethering of SR and mitochondria is disrupted. Consistent with our previous reports (Seidlmayer et al., 2016), addition of 10 nM ET-1 to electrically field-stimulated (0.5 Hz) ventricular myocytes induced a significant increase in mitochondrial Ca²⁺ uptake in WT myocytes ($+35 \pm 6\%$, $n = 7$, **Figures 2A,B**, solid green trace). This ET-1-induced mitochondrial Ca²⁺ uptake was significantly blunted in Mfn2 KO myocytes ($+17 \pm 4\%$, $n = 9$) (**Figures 2A,B**, dashed green trace) confirming the importance of Mfn2 in ET-1 mediated Ca²⁺ transfer to mitochondria. Furthermore, we confirmed that blocking mitochondrial Ca²⁺ uptake with the mRyR1 inhibitor dantrolene (1 μ M), led to a corresponding increase in systolic Ca²⁺ level in the cytosol (**Supplementary Figure S1**). This indicates that when mitochondrial Ca²⁺ uptake *via* mRyR1 is not possible, Ca²⁺ released from SR is leaking out into cytosol. This Ca²⁺ leak from the SR in cytosol could contribute to pro-arrhythmic events described before (Proven et al., 2006).

Control time recordings performed in untreated electrically field-stimulated (0.5 Hz) myocytes from WT (solid black trace, $-1 \pm 4\%$, $n = 6$) and Mfn2 KO mice (dashed black trace, $+3 \pm 5\%$, $n = 4$) confirmed that there was no measurable increase in mitochondrial Ca²⁺ levels in the absence of ET-1 stimulation (**Figure 2B**), confirming that the observed increase in mitochondrial Ca²⁺ was due to ET-1 activation of IP₃ receptors.

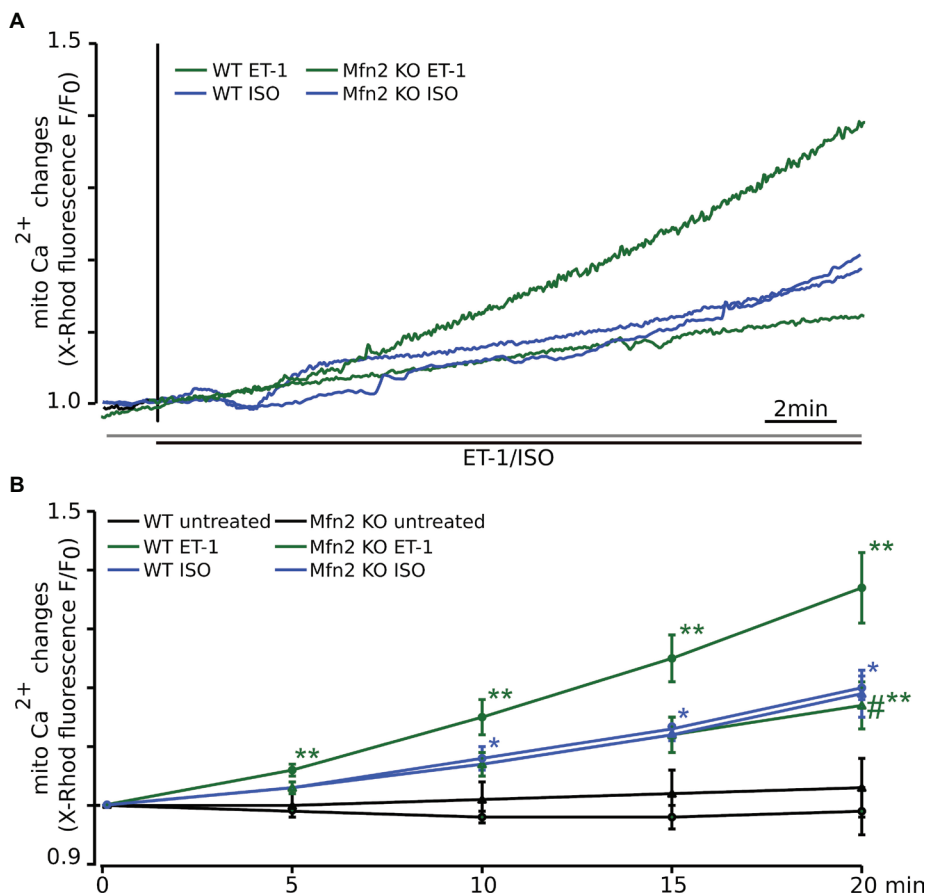

FIGURE 2 | In Mfn2 KO mice Ca²⁺ released *via* the IP₃R cannot be taken up into mitochondria. **(A)** The representative confocal traces recorded from adult ventricular myocytes loaded with the Ca²⁺-sensitive fluorescent dye X-Rhod-1 upon electrical field stimulation (FS, 0.5 Hz) and subsequent exposure to 10 nM ET-1 (WT: solid green, Mfn2 KO: dashed green) or 500 nM ISO (WT: solid blue, Mfn2 KO: dashed blue), respectively. Changes in fluorescence reflect changes in mitochondrial Ca²⁺. **(B)** Mean values of the mitochondrial Ca²⁺ levels change during 20 min of observation. ET-1 increased mitochondrial Ca²⁺ concentration ([Ca²⁺]_m) by +35 ± 6% (*n* = 7) in healthy WT myocytes, whereas ISO-induced elevation of [Ca²⁺]_m was significantly smaller (+20 ± 2%, *n* = 7). In Mfn2 KO myocytes, the mitochondrial Ca²⁺ uptake induced by ET-1 was significantly smaller compared to WT myocytes (ET-1: +17 ± 4%, *n* = 9). However, the effect of ISO on mitochondrial Ca²⁺ uptake was not altered by Mfn2 KO (ISO: +19 ± 4%, *n* = 7). No significant changes in [Ca²⁺]_m were observed in untreated WT (solid black) and Mfn2 KO (dashed black) myocytes during 20 min of observation. **p* < 0.05 compared to untreated WT, ***p* ≤ 0.05 compared to untreated WT, #*p* ≤ 0.05 compared to WT treated with ET-1.

Mfn2 KO Does Not Block Global ISO-Induced Mitochondrial Ca²⁺ Uptake

We have previously shown that when cytosolic Ca²⁺ was increased by the non-specific beta-adrenergic receptor agonist isoproterenol (ISO) in WT myocytes, which induces a global increase in cytosolic Ca²⁺ concentration, only a small increase in mitochondrial Ca²⁺ uptake was observed (Seidlmayer et al., 2016). In this study, we performed experiments in cardiomyocytes from Mfn2 KO mice, and their control littermates (WT) to examine whether intact Mfn-2-mediated contact sites are required for ISO-induced changes in [Ca²⁺]_m. As shown in **Figure 2A**, we found that mitochondrial Ca²⁺ increase induced by ISO (solid blue line) in electrically field-stimulated (0.5 Hz) ventricular myocytes was significantly smaller (+20 ± 2%, *n* = 7) compared to the ET-1-induced response (solid green line). Furthermore, in contrast to the data obtained with ET-1, Mfn2 KO had no effect on average

ISO-induced mitochondrial Ca²⁺ uptake (+19 ± 4%, *n* = 7, dashed blue line) (**Figures 2A,B**), indicating that intact spatial arrangement of SR and mitochondria was not critical for ISO-induced mitochondrial Ca²⁺ uptake.

Interfibrillar and Perinuclear Mitochondria Take Up More Ca²⁺ Following IP₃-Mediated SR Ca²⁺ Release Compared to Subsarcolemmal Mitochondria

Since mitochondrial morphology and function vary between different mitochondrial subpopulations in the cell (Fawcett and McNutt, 1969; Palmer et al., 1977; Matlib et al., 1978; McMillin-Wood et al., 1980; Lukyanenko et al., 2009), we tested the importance of physical tethering of SR and mitochondria in different mitochondrial regions. As we mentioned before, subsarcolemmal mitochondria (SSM) exist below the cell membrane, interfibrillar mitochondria (IFM) reside in rows

between the myofibrils, and perinuclear mitochondria (PNM) are located around the nuclei. Electron microscopy studies revealed that the SR/mitochondrial cleft is only 10–25 nm (Chen et al., 2012). Since, due to their intracellular localization, the interorganellar contact differs between the different mitochondrial subpopulations, we analyzed differences in IP₃-mediated mitochondrial Ca²⁺ uptake in these mitochondrial subfractions. For the analysis of [Ca²⁺]_m levels in SSM, a longitudinal region of interest (ROI) was placed directly underneath the sarcolemma. For [Ca²⁺]_m levels in IFM, ROIs were placed in the center of the cell excluding the nuclei. Changes in [Ca²⁺]_m levels in perinuclear regions (PNM) were detected in the ROIs located from each side of the nucleus. As shown in **Figure 3**, subsarcolemmal mitochondria of WT myocytes take up significantly less Ca²⁺ than interfibrillar and perinuclear mitochondria following ET-1 stimulation (IFM: +47 ± 8% after 20 min, *n* = 6; PNM: +47 ± 6% after 20 min, *n* = 6 vs. SSM: +30 ± 8% after 20 min, *n* = 6). In Mfn2 KO mice, mitochondrial Ca²⁺ uptake was significantly inhibited in IFM (+24 ± 4%, *n* = 6, *p* < 0.05 compared to WT) and PNM (+19 ± 4%, *n* = 6, *p* < 0.05) mitochondria following ET-1 stimulation. There was no difference in [Ca²⁺]_m levels upon ET-1 treatment in Mfn2 KO mitochondria from SSM regions (+20 ± 2%, *n* = 8, *p* = 0.23) (**Figure 3**). These data indicate that disruption of the SR-mitochondrial tethering in specific regions abolishes the differences in mitochondrial Ca²⁺ uptake induced by IP₃-mediated Ca²⁺ release from SR in ventricular myocytes.

Interestingly, the effect of ISO on [Ca²⁺]_m levels in the three mitochondrial subgroups was different from ET-1. The highest mitochondrial Ca²⁺ uptake was detected in subsarcolemmal mitochondria (+44 ± 12% after 20 min, *n* = 7), which gradually declined in IFM (+20 ± 9% after 20 min, *n* = 7) and was the smallest in perinuclear (+11 ± 9% after 20 min, *n* = 7) mitochondria. Furthermore, while Mfn-2 KO had no effect on ISO-induced [Ca²⁺]_m levels in SSM and IFM mitochondrial regions (**Figures 3E,F**), mitochondrial Ca²⁺ uptake was actually increased in perinuclear mitochondria (**Figure 3G**) in cardiomyocytes from Mfn2 KO animals.

These data suggest that tethering between SR and mitochondria is heterogeneous within ventricular myocytes to support the privileged SR-mitochondrial communication between IP₃ receptors and mRyR1. When this communication was lost in Mfn-2 KO mice, perinuclear mitochondria were able to pick more Ca²⁺ upon ISO stimulation.

IP₃-Mediated Increase in Mitochondrial Membrane Potential Was Dependent on Mfn2

The Ca²⁺ taken up by mitochondria following ET-1 stimulation is activating mitochondrial oxidative phosphorylation, which results in a significant increase in ATP levels (Seidlmayer et al., 2016). Here, we measured changes in mitochondrial membrane potential ($\Delta\Psi_m$) following ET-1 stimulation using the potentiometric probe TMRM in cardiac myocytes from WT and Mfn2 KO mice (**Figure 4A**). In WT myocytes, ET-1

induced a significant hyperpolarization over 20 min (+37 ± 3%, *n* = 13, *p* < 0.01 compared to untreated controls), whereas in Mfn-2 KO $\Delta\Psi_m$ decreased upon exposure to ET-1 (−11 ± 6%, *n* = 4, *p* < 0.01 compared to WT + ET-1) myocytes, indicating the importance of intact SR-mitochondrial contacts for mitochondrial $\Delta\Psi_m$ maintenance.

To test if basal $\Delta\Psi_m$ was different in WT and Mfn2 KO myocytes, we measured TMRM fluorescence at the beginning of the experiment before cell treatment with ET-1. No significant difference in basal $\Delta\Psi_m$ was detected (**Figure 4B**), suggesting that there is no difference in basal respiratory activity in WT and Mfn2 KO mice.

In support of these data, we also found that while both ET-1 and ISO induced a decrease in reduced NADH (**Figure 4C**), changes in both reduced NADH and oxidized FAD⁺ levels (**Figure 4D**) were less pronounced upon ET-1 stimulation resulting in minimal net redox ratio NADH/FAD⁺ changes (**Figures 4E,F**) normalized to untreated conditions whereas, in cells treated with ISO, the ratio declined significantly. Altogether, these data indicate that ET-1 maintains mitochondrial membrane potential and respiratory chain activity.

IP₃-Mediated ATP Production Following ET-1 Stimulation Is Impaired in Mfn2 KO Mice

Next, we monitored changes in [ATP]_i indirectly using the [Mg²⁺]-sensitive dye mag-fluo-4 in WT and Mfn-2 KO cardiac myocytes treated with either 10 nM ET-1 or 100 nM ISO. This method takes advantage of the fact that ATP is a major Mg²⁺ buffer, such that an increase in [ATP]_i level reduces free [Mg²⁺]_i (Dedkova and Blatter, 2012). Therefore, increased ATP production causes mag-fluo-4 fluorescence to decline. In **Figure 5**, the mag-fluo-4 signal was inverted so that an increase in the signal reflects an increase in [ATP]_i. Similar to previous experiments, cardiac myocytes were electrically stimulated at the frequency of 0.5 Hz to maintain Ca²⁺ fluxes during ECC, and then ET-1 (10 nM) and ISO (500 nM) were applied to activate the correspondent receptors. As shown in **Figure 5A**, ET-1 but not ISO induced an increase in ATP generation in WT ventricular myocytes, which was abolished in Mfn2 KO myocytes emphasizing the importance of Mfn2 in Ca²⁺ transfer to mitochondria to mediate ATP production. As summarized in **Figure 5B**, ET-1 induced a significant increase in ATP levels over 20 min (+19.18 ± 3.7%, *n* = 6), whereas in Mfn2 KO myocytes the effect of ET-1 on ATP generation was completely abolished (+0.74 ± 1.5%, *n* = 5). To the contrary, ISO-treatment caused a significant decrease in ATP levels in WT (−8.7 ± 1.2%, *n* = 4, *p* < 0.01), while a significant increase in ATP (+13.1 ± 3%, *n* = 7, *p* < 0.01) was observed in Mfn-2 KO myocytes upon ISO stimulation.

We further analyzed the effect of ET-1 and ISO on ATP content in mitochondrial subgroups as we did for mitochondrial Ca²⁺ uptake. The results are summarized in **Figure 5C**. As expected, in Mfn2 KO myocytes, ET-1 was not able to induce a significant increase in ATP levels in all subgroups.

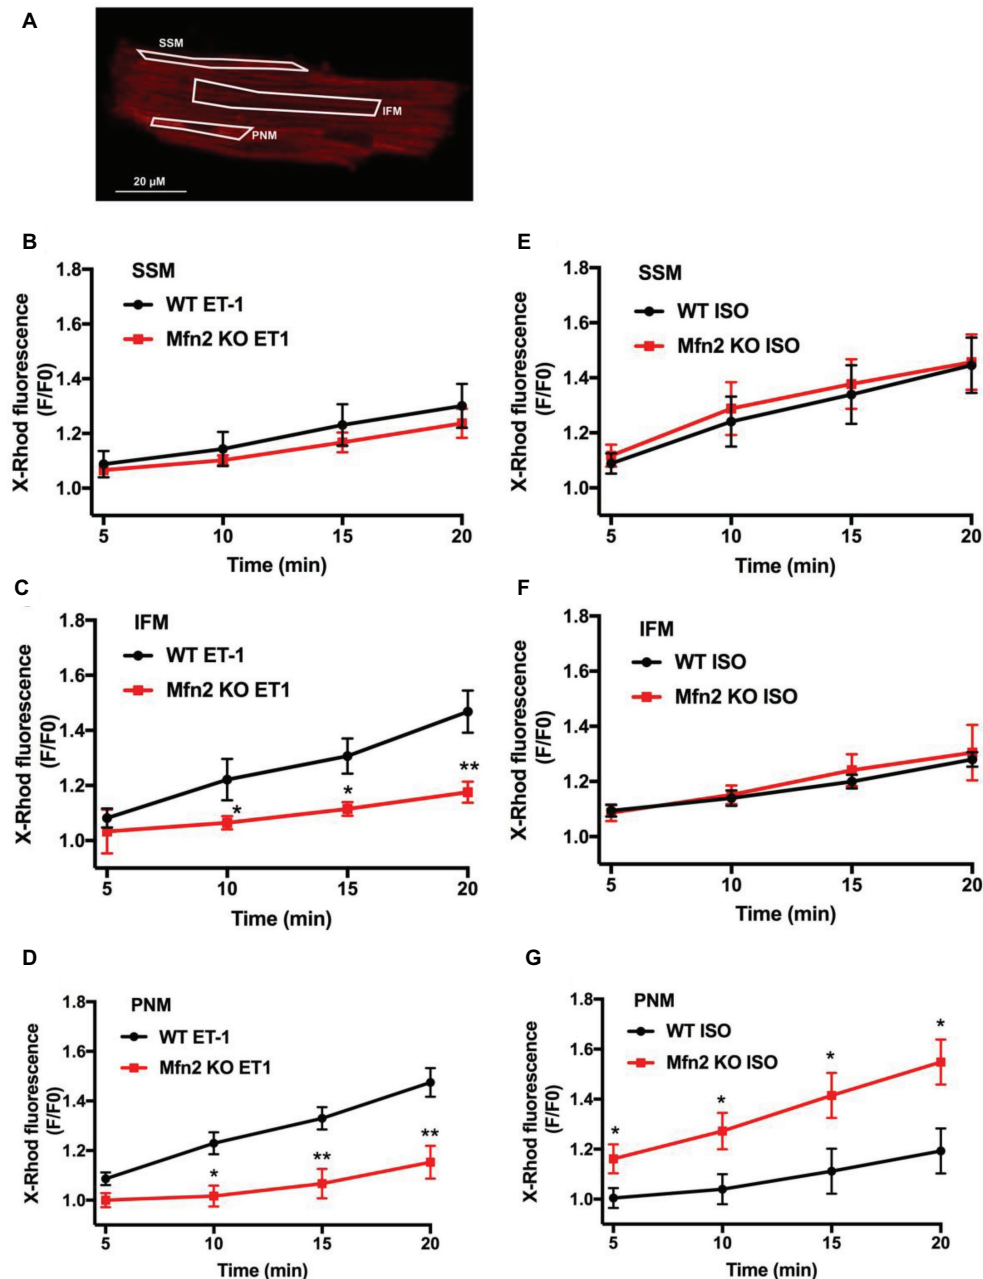

FIGURE 3 | IFM and PNM take up more Ca^{2+} than SSM following IP_3 -mediated SR Ca^{2+} release. **(A)** Original confocal image of an adult murine ventricular myocyte loaded with X-Rhod-1. Shown in white are regions of interest (ROIs) placed over SSM, IFM, and PNM for the analysis of Ca^{2+} changes in different mitochondrial regions. **(B)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in SSM normalized to untreated controls (black: WT myocytes+ET-1; red: Mfn2 KO myocytes + ET-1). **(C)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in IFM normalized to untreated controls (black: WT myocytes+ET-1; red: Mfn2 KO myocytes + ET-1). **(D)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in PNM normalized to untreated controls (black: WT myocytes+ET-1; red: Mfn2 KO myocytes + ET-1). **(E)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in SSM normalized to untreated controls (black: WT myocytes+ISO; red: Mfn2 KO myocytes + ISO). **(F)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in IFM normalized to untreated controls (black: WT myocytes+ISO; red: Mfn2 KO myocytes + ISO). **(G)** Mean values for mitochondrial Ca^{2+} changes measured as changes in X-Rhod-1 fluorescence in PNM normalized to untreated controls (black: WT myocytes+ISO; red: Mfn2 KO myocytes + ISO). * $p \leq 0.05$ compared to WT ET-1 or ISO vs. Mfn2 KO, ** $p \leq 0.001$ compared to WT ET-1 or ISO vs. Mfn2 KO.

However, there was no significant difference in ET-1-induced ATP increase between IFM, SSM, and PNM in myocytes from WT or Mfn2 KO mice.

A decrease in ATP levels upon ISO exposure was more pronounced in IFM and SSM mitochondrial subgroups but remained unchanged in PNM (Figure 5C). In agreement, with

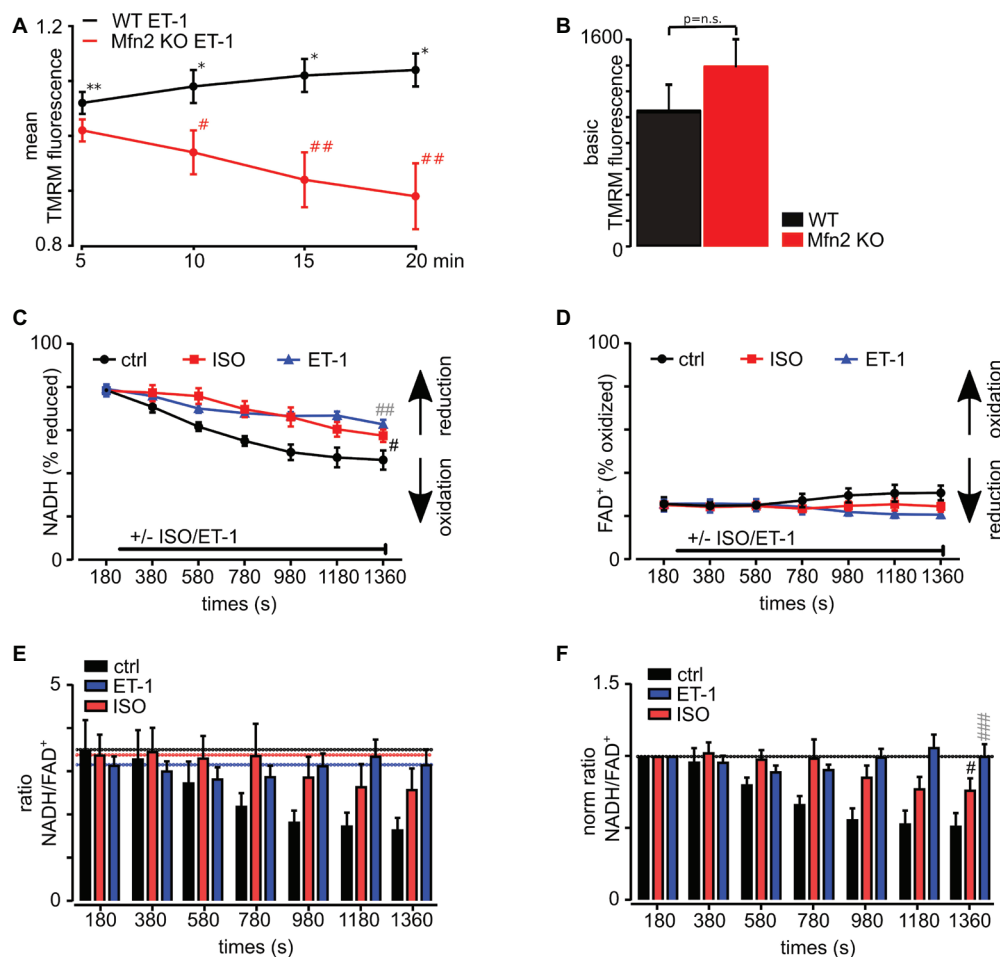

FIGURE 4 | IP₃R stimulation with ET-1 increases mitochondrial membrane potential in WT myocytes but not in Mfn2 KO myocytes. **(A)** Normalized mean values of TMRM fluorescence changes in WT (black line) and Mfn2 KO (red line) cardiac myocytes after exposure to 10 nM ET-1 for 20 min. the data presented in **Figure 5B**, ISO addition to Mfn2 KO myocytes increased ATP levels in all groups significantly compared to the corresponding groups in WT myocytes. Furthermore, PNM in Mfn 2 KO myocytes, which took more Ca²⁺ into the mitochondria, also increased ATP levels significantly higher than IFM and SSM from Mfn2 KO myocytes.

DISCUSSION

In this study, we examined the role of SR-mitochondrial tethering by Mfn2 in activation of mitochondrial Ca²⁺ uptake and metabolism using mice with a cardiac-specific deletion of Mfn2 (**Figure 1**). We tested the hypothesis that physical linkage of SR and mitochondria *via* Mfn2 is essential for

IP₃R-mediated signal transduction to mitochondria to maintain ATP levels in cardiac myocytes under physiological conditions (i.e., normal levels of IP₃R expression and circulating ET-1). In our previous study (Seidlmayer et al., 2016), we found that the stimulation of cardiac myocytes with IP₃R agonists induced mitochondrial Ca²⁺ uptake *via* mRyR1 and increased ATP content. In contrast, under basal conditions, beta-adrenergic stimulation with ISO was not able to induce measurable ATP production. Since the global changes in cytosolic Ca²⁺ concentration produced by IP₃-mediated SR Ca²⁺ release are very small compared to RyR-mediated Ca²⁺ changes, here, we examined the significance of intact SR-mitochondrial tethering by Mfn2 for IP₃-mediated stimulation of mitochondrial Ca²⁺ uptake and ATP generation.

We found that the ability of ET-1 to induce a significant IP₃-dependent mitochondrial Ca²⁺ uptake was lost in myocytes from

FIGURE 5 | ATP production following IP₃-mediated SR Ca²⁺ release is impaired in Mfn2 KO mice. **(A)** Original confocal traces of ATP levels recorded in WT myocytes stimulated with 10 nM ET-1 (black) or 500 nM ISO (blue) and Mfn2 KO cardiac myocytes stimulated with ET-1 (red) or ISO (green), respectively. Mg²⁺-sensitive fluorescent dye mag-fluo-4 was used to monitor ATP levels inside cardiac myocytes. As free Mg²⁺ and ATP form complexes, increase in ATP concentration reduces free Mg²⁺ and thus mag-fluo-4 fluorescence. Traces are inverted for better understanding and presented as 1-F/F₀. **(B)** Mean values of the experiment described in **(A)** in %. **p* ≤ 0.05 compared to untreated WT; ***p* ≤ 0.01 compared to untreated WT; #*p* ≤ 0.05 compared to WT treated with ET-1 or ISO, respectively; ##*p* ≤ 0.01 compared to WT treated with ET-1 or ISO, respectively. **(C–H)** Subgroup analysis of subsarcolemmal (SSM, **C,D**), interfilibrillar (IFM, **E,F**), and perinuclear (PNM, **G,H**) mitochondria in myocytes from WT (black) and Mfn2 KO (red) mice loaded with mag-fluo-4 as described in **(A)**. The myocytes were treated with either ET-1 (left) or ISO (right). **p* ≤ 0.05 compared to WT, ***p* ≤ 0.01 compared to WT.

Mfn2 KO mice (**Figure 2**). Interestingly, when myocytes from Mfn2 KO mice were stimulated with the beta-adrenergic receptor agonist ISO, mitochondrial Ca²⁺ uptake was not affected in SSM and IFM but significantly increased in PNM regions. When the influence of beta-adrenergic and IP₃R stimulation on ATP content was examined (**Figure 5**), ET-1 did not induce an increase in ATP in myocytes from Mfn2 KO mice, indicating the importance of physical tethering of mitochondria and the SR for metabolic control by IP₃ under physiological conditions. To the contrary, in Mfn2 KO myocytes, ISO significantly increased ATP content under conditions of electrical field stimulation, whereas in WT myocytes ISO led to a decrease in mitochondrial ATP content.

The latter finding agrees with previous studies showing that sudden increase in work load causes a decrease in mitochondrial NADH (and presumably ATP levels), which recovered slowly over the time in a Ca²⁺-dependent manner (Brandes and Bers, 1997). Furthermore, another study demonstrated that beta-adrenergic stimulation with ISO induced only a transient MCU-dependent increase in oxygen consumption, suggesting that MCU only plays a role in acute matching of the mitochondrial energy output with increase in cardiac metabolic demand (Kwong et al., 2015). However, over the time, oxygen consumption was not different between WT and MCU KO cardiac myocytes, indicating that another mitochondrial Ca²⁺ influx pathway contributes to the

FIGURE 6 | Summary of the proposed metabolic IP₃-mediated SR/mitochondrial signaling pathway in the presence (upper panel) or absence (lower panel) of intact Mfn2-tethers. IP₃-mediated mitochondrial Ca²⁺ uptake in WT myocytes (upper panel), which is followed by an increase in ATP generation. When the physical contact of mitochondria and the SR is disturbed by knockout of Mfn2 (lower panel), Ca²⁺ released from the SR by IP₃ cannot be taken up into mitochondria anymore leading to the decrease in ATP level. Yellow circles: Ca²⁺, yellow arrow: Ca²⁺ movement, green arrow: IP₃ movement.

sustained energy generation in cardiac myocytes. Our data demonstrate that IP₃R-mRyR1-mediated mitochondrial Ca²⁺ uptake contributes to the sustained ATP generation (Figure 6) and that this Ca²⁺ transfer from SR is regulated by Mfn2 under physiological conditions. When this regulation is lost in Mfn2 KO mice, IP₃-mediated Ca²⁺ release is not capable to stimulate ATP generation anymore, as observed in pathological conditions. Altogether, our data suggest that Mfn2 can provide a fine tuning to regulate Ca²⁺-dependent energy production under physiological conditions upon ET-1 stimulation, but when Mfn2-mediated tethering is disrupted, mitochondria can adapt to respond to global Ca²⁺ elevation induced by ISO with increase in ATP generation.

The disruption of Mfn2-mediated intact ER-mitochondrial contacts exists in conditions of heart failure induced by transverse aortic constriction (TAC), which is associated with a decreased excitability and force generation in cardiac myocytes (Goh et al., 2016). ET-1 levels are typically increased in chronic stress as in the setting of congestive heart failure (CHF) (Wei et al., 1994) along with increased myocardial expression of ET_A receptors (Picard et al., 1998; Pieske et al., 1999). To determine if this increase in the ET-1 axis is pathological, a mouse model was developed to conditionally overexpress ET-1 in

the myocardium that led to nearly 10-fold increase in ET-1 concentration in the heart, without any significant increase in circulating ET-1 levels (Yang et al., 2004). Mice with elevated cardiac ET-1 expression presented with severe heart inflammation, hypertrophy leading to dilated cardiomyopathy, CHF, and death within 5 weeks of induction. However, a whole body ET-1 KO (ET-1^{-/-}) homozygous mice developed by disrupting exon 2 of the ET-1 gene were neonatally lethal (Kurihara et al., 1994). ET-1^{-/-} mice delivered by caesarean section at day 18.5 postcoitum, all displayed significant craniofacial and cardiac abnormalities, highlighting the critical role of ET-1 in the development (Kurihara et al., 1994, 1995b). Moreover, ET-1^{-/-} mice had reduced neonatal weight, impaired thyroid and thymus development (Kurihara et al., 1995a), and reduced cardiac sympathetic innervation (Ieda et al., 2004). Mice heterozygous for ET-1 deletion, ET-1^{+/-}, appeared normal, were fertile, and had reduced lung and plasma ET-1 concentration; however, they had elevated systolic, diastolic, and mean arterial blood pressure (Kurihara et al., 1994). These observations suggest that while 10-fold elevation in ET-1 levels in cardiac myocytes is clearly pathological, basal levels of ET-1 are required for maintaining normal physiological function in cardiac myocytes.

Indeed, myocardial ET-1 depicts beneficial effects depending on the physiological situation. In the myocardium, ET-1 prevents excessive apoptosis after cardiac overload induced by aortic banding (Zhao et al., 2006). Signaling of the anti-apoptotic effects of ET-1 involves calcineurin, the mitochondrial function, and the classical MEK1/2-ERK1/2 and PI3 kinase pathways (Iwai-Kanai and Hasegawa, 2004). It has been reported that ET-1 prevents the early phase of doxorubicin-induced cytotoxicity *via* the upregulation of the antioxidant manganese superoxide dismutase through the ET_A receptor in cultured cardiomyocytes (Suzuki and Miyauchi, 2001). Preconditioning infusion of ET-1 can reduce infarct size in rats subjected to ischemia-reperfusion (Gourine et al., 2005). The transgenic expression of ET-1 in mice lacking a functional gene for eNOS restores diastolic function presumably through modulation of oxidative stress and a change of metabolic substrate from fatty acid oxidation toward enhanced glycolysis (Vignon-Zellweger et al., 2011). In line with this, the enhanced glycolysis in the failing heart, which is a beneficial compensatory mechanism, is accompanied by a hypoxia-inducible factor-1 α -dependent elevation of ET-1 expression (Kakinuma et al., 2001).

Our study indicates that stimulation of ET-1 receptors in healthy control myocytes leads to mitochondrial Ca²⁺ uptake, maintains mitochondrial membrane potential, and activates ATP generation. Furthermore, we determined that intact Mfn2 tethers were required to mediate Ca²⁺ uptake into mitochondria and stimulate ATP production. The significance of a physical linkage of SR and mitochondria in cardiac myocytes is still debated. Our data add new aspects to this discussion revealing the importance of Mfn2 tethers in IP₃-mediated SR/mitochondrial metabolic feedback in ventricular myocytes. As shown by our group before (Seidlmayer et al., 2016), Ca²⁺ released from the SR *via* the IP₃R is taken up into mitochondria where it increases ATP content. Here, we were able to demonstrate that this metabolic feedback is severely disturbed in Mfn2-deficient mice. When cardiac myocytes from these mice were stimulated with the IP₃R agonist ET-1, no mitochondrial Ca²⁺ uptake could be detected. In agreement with this finding, IP₃-mediated SR Ca²⁺ release in Mfn2-deficient myocytes was not able to increase cellular ATP content. These results clearly show that intact tethering of SR and mitochondria *via* Mfn2 is crucial for the channeling of intracellular Ca²⁺ signals from IP₃R to mRyR1 located in mitochondria. In support of this, data presented in **Supplementary Figure S1** demonstrate that when cells were treated with the mRyR1 inhibitor, 1 μ M Dantrolene, the systolic Ca²⁺ level in cytosol was significantly elevated.

It is generally accepted that Ca²⁺ crosses the outer mitochondrial membrane *via* non-specific high-conductance voltage-dependent anion channels (VDAC) (see Shoshan-Barmatz et al., 2008, for review). Specifically, it has been demonstrated that VDAC1 plays a major role in ER/mitochondria-Ca²⁺ cross-talk (Shoshan-Barmatz et al., 2017) by forming a supra-molecular complex with the IP₃ receptor in the SR and VDAC1 in the OMM, linked by a chaperone called GRP75 (Csordás et al., 2006), together with Mfn2 (de Brito and Scorrano, 2008). It is plausible that Mfn2-mediated tethering creates a microenvironment with highly elevated Ca²⁺ levels to enhance Ca²⁺ transfer *via* VDAC1; however, the direct experimental

evidence of the enhanced Ca²⁺ channeling *via* VDAC1 by Mfn2 is lacking. Several studies, however, demonstrated that VDAC1 is highly Ca²⁺-permeable and modulates the accessibility of Ca²⁺ to the intermembrane space (IMS) (Gincel et al., 2001; Rapizzi et al., 2002; De Stefani et al., 2012). The importance of the 18-kDa outer mitochondrial membrane transporter protein (TSPO) in mitochondrial Ca²⁺ transport and its role in heart failure have been recently revealed by Thai et al. (2018) ringing attention to the outer mitochondrial membrane proteins in regulation of the mitochondrial Ca²⁺ uptake and bioenergetics.

Interestingly, not all mitochondria within the myocyte take up Ca²⁺ into their matrix following IP₃R activation to the same extent. Detailed analysis of mitochondrial subpopulations revealed that in WT cardiac myocytes IFM and PNM take up almost two times more Ca²⁺ following IP₃-mediated SR Ca²⁺ release compared to the SSM regions (**Figure 3**). In Mfn2-deficient myocytes, mitochondrial Ca²⁺ uptake following IP₃R activation was not different between all three mitochondrial subpopulations. This finding is supported by several studies providing evidence for not only structural differences of IFM (Fawcett and McNutt, 1969; Shimada et al., 1984; Lukyanenko et al., 2009), PNM, and SSM but also functional differences between these mitochondrial populations. It has been suggested that IFM produce ATP primarily for contraction, PNM for nuclear processes, and SSM provide ATP for active transport processes across the sarcolemma (Müller, 1976; Palmer et al., 1977; Shimada et al., 1984; Rosca and Hoppel, 2013). Since ET-1 has a positive inotropic effect and activates pathological gene transcription in the nucleus, a preferential effect of ET-1 on IFM and PNM is in agreement with these findings.

As expected, since mitochondrial Ca²⁺ uptake following ET-1 stimulation was abolished in Mfn-2 KO mice, ATP production was not detectable in Mfn2-deficient cardiomyocytes. Interestingly, the basal mitochondrial membrane potential measured with TMRM was not different between the two genotypes, which is in accordance with the results of Chen et al. (2012); however, ET-1 stimulation led to the increase in mitochondrial membrane potential (**Figure 4**), which contributes to the enhanced electron transfer chain coupling and ATP generation (**Figure 5**). Taken together, these results indicate a crucial role of physical tethering of SR and mitochondria by Mfn2 for adaptation of energy production to chronic stress. Interestingly, the effect of ISO on [Ca²⁺]_m levels in the three mitochondrial subgroups was different from ET-1. The highest mitochondrial Ca²⁺ uptake was detected in subsarcolemmal mitochondria, which gradually declined in IFM and was the smallest in perinuclear mitochondria. Furthermore, while Mfn-2 KO had no effect on ISO-induced [Ca²⁺]_m levels in SSM and IFM mitochondrial regions (**Figures 3E,F**), mitochondrial Ca²⁺ uptake actually increased in perinuclear mitochondria (**Figure 3G**) in cardiomyocytes from Mfn2 KO animals.

These data suggest that tethering between SR and mitochondria is heterogeneous within ventricular myocytes to support the privileged SR-mitochondrial communication between IP₃R receptors and mRyR1. When this communication was lost in Mfn-2 KO mice, perinuclear mitochondria picked up significantly more Ca²⁺ upon ISO stimulation. This increase in mitochondrial Ca²⁺

during ISO stimulation in PNM regions in Mfn-2 KO mice was also associated with the highest ATP levels in Mfn-2 deficient myocytes (see **Figure 5**). This difference between ET-1 and ISO responses in WT and Mfn-2 KO mice could explain the existent controversy in the field [(Filadi et al., 2015) vs. (de Brito and Scorrano, 2008) and (Naon et al., 2016)] on the role of Mfn2-mediated tethers in SR-mitochondrial Ca²⁺ communication.

CONCLUSIONS

Our study demonstrates that in ventricular myocytes, basal ET-1 signaling is required for maintaining normal cardiac function and bioenergetics (**Figure 6**). We have shown that when the physical linkage between SR and mitochondria Mfn-2 is disrupted, the SR/mitochondrial metabolic feedback mechanism is severely impaired resulting in the inability of the IP₃-mediated SR Ca²⁺ release to induce ATP production. These findings could explain the impaired cardiac function observed in aged mice and young mice following TAC (Goh et al., 2016) where Mfn2 levels were decreased leading to an impaired metabolic IP₃-mediated SR/mitochondrial feedback.

ETHICS STATEMENT

This study was carried out in accordance with the recommendations of the National Institutes of Health (NIH

Publication NO. 85-23, revised 1996). The protocol was approved by the University of Würzburg Institutional Animal Care and Use Committee.

AUTHOR CONTRIBUTIONS

LS and ED designed the study and wrote the manuscript. LS, CMag, AB, and MKa performed the experiments. LS, CMag, MKa, and ED analyzed the data. MS and GD provided Mfn 2 KO mice. PE-N and PA-L supported equipment. ED, LS, BG, Cmaa, and MKo edited the manuscript. BG and SF provided financial support.

FUNDING

This project was supported by the German Heart Research Foundation award number F/40/15 (to LS) and by the American Heart Association Grant-In-Aid 15GRNT25090220 (to ED).
