In Cooperation with:

American Institute of Architects/Foundation

and

Steven Winters Associates, Inc.

June 1983

This work was supported by the Assistant Secretary for Conservation and Renewable Energy, Office of Buildings Energy Research and Development, Building Systems Division of the U.S. Department of Energy under Contract Number DE-AC03-76SF00098.

The DOE-2.1a data base for the five residential prototypes has been analyzed by means of a computer program and reduced to a set of matrices that cover 45 locations. The matrix method for calculating the heating and cooling loads for residential buildings was developed by analyzing the data base load results and running test models to determine the effect of each building component independently of the rest of the building. All of the residential data that we have produced by doing DOE-2.1a computer simulations, including the window sensitivity data, was processed through the matrix program and was broken down into six basic components for each prototype: 1). ceiling insulation, 2). wall insulation, 3). foundation insulation, 4). infiltration (in air changes per hour), 5). window pane, sash type, gap, and area, and 6). the floor area of the house. These six components were manipulated separately for heating and cooling.

In the matrix program, it was assumed that there was no interaction between the six components, and that the effect of the components on load was linear. Applying this assumption to the data base, the program goes through a series of subtractions to arrive at deltas for individual levels for each component. The deltas represent the difference in the load for that component between the given level and the base case level. The base case was selected for the sake of simplicity, so that the energy impact of all conservation measures would be in the negative direction. The deltas provided by the matrix data base are the basis for, and intermediate stage of the slide rule.

The program produced a base heating load and a base cooling load for each prototype in a given location. This load represented the load for a building with no insulation, 1 ach infiltration, and 20 percent window area (20% of the floor area) with single pane glass, 0.5 inch air gap, and aluminum sash. From this base load, the user subtracts values corresponding to the insulation levels for the proposed building for ceiling, wall, foundation, infiltration, and window. The resulting number is multiplied by an area multiplier representing the floor area of the house. The end result is the total heating or cooling load for the building in mBtus per year.

The Data Base for Simplified Energy Analysis is printed on the following pages in matrix format.

Summary of Steps for Calculating Building
Loads Using the Data Base Matrix

1. Pick the prototype that most closely corresponds to your proposed building.
2. Turn to the page with the city and foundation type corresponding to your building needs.
3. Read the base load number for heating.
4. Subtract from the base load the number corresponding to the R-Value of your ceiling insulation.
5. Subtract the number corresponding to the R-Value of your wall insulation.
6. Subtract the number corresponding to your foundation insulation.
7. Subtract the number corresponding to the infiltration rate (in air changes per hour) of your building.
8. Subtract the number corresponding to the correct window area (percent of floor area), number of panes, sash type, and gap size for your building.
9. Multiply the resulting value by the area multiplier that most closely corresponds to the floor area of your building.

The result is the total load for the the building in mBtus per year.
The same process is repeated for cooling loads.

Example of Steps for Calculating the Heating and
Cooling Loads for a Ranch House
in Kansas City

The following examples assume a house with R-19 ceiling insulation, R-19 wall insulation, R-5 insulation 4 feet deep (basement foundation), medium infiltration (0.7 ach), double pane glass with 0.5 inch air gap on windows that have area equal to 15% of the floor area with wood sash,

and a floor area of 2000 square feet.

Kansas City, with a basement foundation, is on page 25 of the Ranch section of the matrix. The base load for heating is 131.94 mBtu/yr. The base load for cooling is 41.11 mBtu/yr. From these loads, the savings from insulation are subtracted as follows:

<u>HEATING</u>	<u>COOLING</u>	
131.94	41.11	- base load
- 34.27	- 8.21	- savings from ceiling insulation
<hr/>	<hr/>	
97.67	32.90	
- 19.65	- 3.07	- savings from wall insulation
<hr/>	<hr/>	
78.02	29.83	
- 4.46	- 0.73	- savings from floor insulation
<hr/>	<hr/>	
73.56	29.10	
- 8.44	- 1.05	- saving from reduced infiltration (ach)
<hr/>	<hr/>	
65.12	28.05	
- 20.46	- 6.09	- savings from window construction
<hr/>	<hr/>	
44.66	21.96	- SUBTOTAL

The subtotal is then multiplied by a floor area multiplier to match the size of the house:

44.66	21.96	
x 1.257	x 1.171	
<hr/>	<hr/>	
56.138	25.715	- Total load for the building in mBtu per year.
