78 Key Word Index - Papaver bracteatum; Papaveraceae; biosynthesis;
9 codeinone; codeine; morphine; reticuline; dehydroreticulium;
10 chloride; thebaine; oripavine; northebaine.11
12 Abstract - The known metabolic pathway for hydrophenanthrene
13 alkaloids in P. somniferum has been examined for occurrence in
14 P. bracteatum, a species reported to contain thebaine but no
15 codeine or morphine. 1,2-Dehydroreticulium-[3-¹⁴C] chloride
16 and (+)-reticuline-[3-¹⁴C] were fed to P. bracteatum plants and
17 both were incorporated, the former into reticuline and thebaine
18 and the latter into thebaine, suggesting that thebaine biosynthesis
19 is the same in the two species. Studies of the natural abundance
20 of morphinan alkaloids in P. bracteatum and the results from
21 feeding codeinone-[16-³H] and codeine-[16-³H] indicate that this
22 species can reduce codeinone to codeine but can not perform
23 either of the demethylations to produce codeinone or morphine.
24 Fed thebaine-[16-³H] was substantially metabolized but not by
25 pathways that involved demethylations to either oripavine or nor-
26 thebaine.
27

INTRODUCTION

1
2 The frequency of occurrence of thebaine-containing members of
3 the genus Papaver [1-5] invites the comparison of metabolic path-
4 ways for hydrophenanthrene alkaloids among the different species.
5 Most attention has focused on P. somniferum [6-8] in which
6 tyrosine is the precursor for the metabolic sequence of compounds
7 1 through 9. However, in most species containing thebaine (5),
8 no codeine (7) or morphine (8) have been detected. For these
9 species, the known scheme for thebaine metabolism may not be
10 applicable.

11 Investigations presented here were performed on P. bracteatum,
12 in which reportedly thebaine is the major alkaloid but codeine
13 and morphine are absent [5]. The relative abundances to thebaine
14 in the plant of codeine, morphine, and the other demethylation
15 derivatives of thebaine, oripavine (10) and northebaine (11), were
16 determined by analysis of solvent extracts by gas liquid chroma-
17 tography (GLC).

18 Injections into the plant of labeled alkaloids were followed
19 by searches for conversions to the subsequent compounds suggested
20 by the P. somniferum pathway. 1,2-Dehydroreticulium-[3-¹⁴C]
21 chloride (1) and reticuline-[3-¹⁴C] (2) were fed for investigation of
22 thebaine biosynthesis. Codeinone-[16-³H] (6) and codeine-[16-³H]
23 (7) were fed for examination of the thebaine pathway to morphine.
24 Similar experiments investigated the possibility that thebaine
25 metabolism involved direct demethylation to oripavine or to northebaine.

26

27

RESULTS

1
2 Natural abundance of thebaine and demethylated derivatives in
3 P. bracteatum

4 Standard procedures for alkaloid extraction on 1.44 kg
5 (fresh weight) from 48 plants, 5 to 7 months old, provided phenolic
6 and non-phenolic alkaloid fractions which were analyzed by GLC.
7 Calibration with pure alkaloid standards established the presence
8 of 820 mg of thebaine (0.06% of the fresh weight) and 4 mg of
9 oripavine (0.5% w/w of thebaine). No codeine, morphine, or nor-
10 thebaine were detected. Experimentally determined limits of
11 detection of these alkaloids were 1 ppm, 1 ppm, and 50 ppm,
12 respectively per unit of thebaine.

13

14 Thebaine biosynthesis

15 (\pm)-Reticuline-[3- 14 C] (2) and 1,2-dehydroreticulium-[3- 14 C]
16 chloride (1) were synthesized and injected into 5 month old plants.
17 The plants were allowed to grow for specific periods of time and
18 the labeled alkaloids extracted from them using carried dilution
19 techniques.

20 Both reticuline and 1,2-dehydroreticulium chloride were
21 found to be incorporated into thebaine (5) (Table 1). 1,2-Dehydro-
22 reticulium chloride was also found to be incorporated into
23 reticuline. Previously, Neubauer [9] demonstrated that tyrosine-
24 [2- 14 C] is incorporated by P. bracteatum into thebaine in 1.3 to
25 2.5% yield. This evidence together with our data confirms that the
26 biosynthetic pathway to thebaine in P. somniferum is also common
27 to P. bracteatum.

1 The incorporation rates of reticuline and 1,2-dehydroreticu-
2 linium chloride in P. bracteatum are substantially less than those
3 found for P. somniferum [10]. Though the pathways involve the same
4 chemical intermediates, the characteristics of the enzymes involved
5 may be noticeably different. On the other hand, corresponding
6 enzymes in the two species may be essentially the same but in lower
7 concentrations in P. bracteatum.

8 9 Thebaine metabolism to morphine

10 Preliminary experiments showed that the levels of incorpora-
11 tion to be anticipated in some cases might be very low. Thus,
12 ³H-labelled morphinan compounds of high specific activity were
13 produced [10]. Since even small but definite biosynthetic conver-
14 sions of the alkaloids had potential interest, methods were
15 developed for the preparation of highly purified materials. Puri-
16 fication procedures were tested with inactive compounds and radio-
17 active contaminants. These methods and results are presented in
18 Table 2.

19 Codeinone-[16-³H] and codeine-[16-³H] were fed to P. bracteatum
20 plants (Table 3, experiments 1 and 2). The lengths of growth
21 periods after injection and before harvest had been determined from
22 preliminary studies of metabolism rates with unlabeled alkaloids.
23 These preliminary studies of alkaloid metabolism rates also
24 suggested that morphine is metabolized in P. bracteatum slightly

25

26

27

1 more rapidly than is codeine. This implied the complication that
2 morphine produced in the plant from injected codeine may be mostly
3 lost by further metabolism. In view of this, an additional experi-
4 ment (experiment 3, Table 3) was performed in which unlabeled
5 morphine was injected at intervals into the codeine-fed plants to
6 create and maintain a morphine pool. Metabolically produced
7 morphine would thus be diluted and suffer less loss than in the
8 experiment in which codeine alone was injected.

9 The results show that P. bracteatum can perform only one of
10 the three established transformations of the post-thebaine path-
11 way found in P. somniferum, that of the reduction of codeinone to
12 codeine. For this reaction, the rate is comparable to that found
13 in P. somniferum. This ketone reduction step is basically similar
14 to the reduction of salutaridine (3) to salutaridinol (4), which
15 is observed in thebaine biosynthesis in P. somniferum [8] and, from
16 the previous conclusions of this paper, is implied to also occur in
17 P. bracteatum. Perhaps the reductase responsible for salutaridine
18 reduction is not totally specific and thus allows P. bracteatum
19 to deal with the foreign substance codeinone.

20 In P. bracteatum, the feedings of labeled codeine showed that
21 demethylation to morphine was insignificant. Though 50 and 65%
22 of the injected codeine in the experiments of concern were metabo-
23 lized, little activity was found in the morphine. The close
24 agreement in the two labeled morphine recovery figures suggests that
25 the observations were not merely the consequence of further morphine
26 metabolism. These results and the absence of naturally-occurring
27 morphine in crude extracts indicate morphine is not a short-lived

1 intermediate but is a foreign compound to P. bracteatum.

2 The pathway from thebaine to codeinone also suffers blockage.
3 In view of the facts that codeinone is rapidly converted to
4 codeine, that codeine is metabolized at only a modest rate, and
5 that the isolation techniques give close to quantitative recovery
6 of codeine, any significant biosynthesis of codeinone from thebaine
7 would have been indicated by the discovery of codeine in the
8 previous studies on the natural codeine content of P. bracteatum.
9 Thus, this step, thebaine to codeinone, is clearly absent.

10

11 Thebaine metabolism to oripavine and northebaine

12 Since, in P. somniferum, thebaine undergoes sequential de-
13 methylations at the O-6, O-3, and N-17 positions, we considered
14 the possibility that thebaine metabolism in P. bracteatum may also
15 be characterized by demethylation, but occurring in a different
16 sequence. Initial demethylation at the O-3 position would give
17 oripavine (10), while initial N-demethylation would lead to nor-
18 thebaine (11). Even though northebaine was not detected as a
19 natural product in P. bracteatum and oripavine was found only in
20 low concentration compared to thebaine, there was the possibility
21 of rapid metabolism and turnover through these compounds.

22 Oripavine and oripavine-[16-³H] were synthesized from morphine
23 and morphine-[16-³H] as described [11]. Northebaine and northebaine-
24 [16-³H] were obtained by the demethylation of thebaine [12].

25 Quantitative studies to develop methods of separation and purifi-
26 cation of oripavine and northebaine from labeled thebaine are
27 presented in Table 2.

1 In each of several experiments, thebaine-[16-³H] was
2 injected into 5 to 7 month old plants. After 5 days, the plants
3 were harvested and the alkaloids isolated to determine what
4 quantity of labeled thebaine had been metabolized and what proportion
5 of the metabolized thebaine had been incorporated into oripavine or
6 northebaine. Thebaine-[16-¹⁴C] and known quantities of cold
7 oripavine and northebaine were used as carriers to accurately
8 determine losses through isolations and purifications.

9 Significant metabolism of labeled thebaine was observed in
10 each of the experiments. Rates ranged from 2 to 3 mg per plant
11 over 5 day periods. However, little of the metabolized thebaine
12 was recovered as oripavine or northebaine (Table 3, experiments 4
13 and 5). To check the possibility of rapid secondary metabolism in
14 these experiments, labeled oripavine and labeled northebaine were
15 fed and the quantities metabolized after 5 days determined. Two
16 quantities covering a 100 fold mass range for each alkaloid were
17 tested to check the possibility of mass-dependent inhibition of
18 metabolic enzymes. The results (Table 3, experiments 6-9) suggest
19 that oripavine and northebaine metabolisms are sufficiently slow
20 to have allowed detection of significant thebaine-[16-³H] incor-
21 porations in the prior feeding experiments, had such incorporations
22 occurred.

23 The possibility exists, however, that the sites of alkaloid
24 metabolism are compartmented and the metabolism rates from these
25 experiments really reflect transportation rates. If such compart-
26 mentation exists, it seems that it would have to occur within the
27 latex itself. Studies with P. somniferum have suggested active

1 alkaloid metabolism in the latex, perhaps in organelles [13]. In
2 addition, since both oripavine and northebaine are slowly but
3 definitely metabolized, transportation of these alkaloids is not
4 specifically inhibited. One may speculate that resistance to
5 transportation would then be due to availability of specific trans-
6 portation sites. Contrary to our observations, this hypothesis
7 would suggest that significantly greater proportions of the small
8 quantities of injected alkaloids should have been metabolized as
9 compared to the metabolized proportions in the experiment involving
10 large alkaloid quantities. Thus we are left with the conclusion
11 that, although thebaine is metabolized at a reasonable rate in
12 P. bracteatum, neither O-6 nor O-3, nor N-demethylation is a major
13 initial step of this metabolism.

14 The metabolism of thebaine and oripavine, naturally occurring
15 in P. bracteatum, as well as the metabolism of codeine, morphine,
16 and northebaine, either foreign or trace components, suggests that
17 there may exist a non-specific enzyme system which can metabolize a
18 variety of thebaine-like compounds. Since the metabolism rates
19 for all of these alkaloids are not strikingly different, the
20 enzyme may have similar affinities for these compounds. The obser-
21 vation that roughly half of the injected oripavine and northebaine
22 is metabolized in 5 days whether 5 or 0.05 mg per plant is fed
23 supports the proposal that an injected alkaloid disperses through-
24 out a larger general alkaloid pool and is processed randomly by
25 an enzyme with little specificity among the morphinan alkaloids.

26

27

EXPERIMENTAL

1
2 Plant materials. P. bracteatum were grown from seeds obtained
3 from Dr. D. Lavie, Weizman Institute, to whom we are grateful.

4 P. somniferum L. var. alba were started from seeds of USDA No. 40.
5 All plants were sprouted and grown in a greenhouse with supple-
6 mentary lighting to give a daily light period of 15 hrs.

7 Preparation of labeled alkaloids. 1,2-Dehydroreticulium
8 chloride (1) and (\pm)-reticuline (2) labeled at the 3 position with
9 either ^{14}C or ^3H were synthesized in these laboratories [10].
10 Feeding 1,2-dehydroreticulium-[3- ^3H] to P. somniferum gave after
11 3 days metabolism thebaine-[16- ^3H], codeine-[16- ^3H], and morphine-
12 [16- ^3H] in 3.4, 1.8, and 2.2% yields respectively. These were
13 isolated by the extraction procedures and further purified by
14 sequential pTLC separations detailed below.

15 Codeinone was prepared from codeine by Seki's modification
16 of the Oppenauer oxidation [14]. Oripavine was synthesized from
17 morphine by the method of Barber and Rapoport [11], and thebaine
18 was demethylated by known procedures [12] to give northebaine.

19 Feeding of alkaloids. The portion of alkaloid to be fed was
20 dissolved in 0.4 ml 1M H_3PO_4 , the pH adjusted to 5.5-6.5 with sat.
21 K_2CO_3 , and the solution diluted with water to give 0.7 ml total
22 volume. The solution was loaded for injection into gas-tight
23 syringes because the high turgor pressures of these plants caused
24 standard syringes to leak. The plants were readied simply by
25 washing the roots free of soil. Injections were then made into the
26 hypocotyls and steady deliveries of the feeding solution were
27 made over 1.5 hr periods using motorized syringe pumps. Afterwards,

1 the plants were allowed to grow in aerated nutrient solutions until
2 harvest. Freshly harvested plants were either extracted directly
3 or frozen and stored at -20°C until used.

4 To assess how much of the labelled alkaloid was actually
5 delivered into the plants, residual solution left in the vials
6 and syringes was collected and analyzed. Leakage of the fed
7 solution from the wound after injection was collected either by
8 covering the wound with a paper bandage until harvest, or, more
9 conveniently, by keeping the wound submerged in the root nutrient
10 solution. Activity analysis of the paper bandages by combustion
11 procedures or direct liquid scintillation of the root solution
12 showed that the wounds often leaked up to 10% of the injected
13 solution.

14 Extraction procedures. As much as 200 g (fresh weight) of
15 plant material was frozen in liquid N_2 and blended in a steel
16 container to give finely chopped material. Carrier alkaloids
17 were added, followed by 30 ml 10% K_2CO_3 and 400 ml of n-butanol/
18 benzene, 1/1. Blending, decanting of the organic solution, and
19 repeating the butanol/benzene addition to effect four extractions
20 completely separated the alkaloids. The organic solution was
21 extracted with 4 x 100 ml 1M H_3PO_4 , the aqueous fraction was basi-
22 fied to pH 13 using 8M KOH with continuous cooling to keep the
23 solution below room temperature at all times, and this solution
24 was extracted with 5 x 100 ml CHCl_3 to give the non-phenolic
25 fraction. Adjustment of the pH to 8.6 with 1M H_3PO_4 and cooling
26 followed by extraction with 5 x 100 ml CHCl_3 /isopropanol (IPA),
27 3/1, gave the phenolic alkaloid fraction. The organic phases were

1 dried over anhydrous Na_2SO_4 , filtered, and evaporated.

2 Alkaloid purifications. A specific combination of steps were
3 used to purify a particular alkaloid. The steps, as designated
4 by letter symbols in Table 2 were: (a) standard plant extraction;
5 (b) chromatography on a 60 x 2 cm column of 106 g basic Woelm
6 Alumina (III) in benzene using successively as eluent 250 ml of
7 benzene/ CHCl_3 , 9/1, 400 ml of benzene/ CHCl_3 /IPA, 88.5/10/1.5,
8 and 600 ml of benzene/ CHCl_3 /IPA/ CH_3OH , 87.5/10/1.5/1: (c) the
9 impure material was dissolved in benzene and shaken for 1.5 hrs
10 with 1M NaHSO_3 at 25°C under N_2 . The aqueous layer was separated,
11 basified with sat. K_2CO_3 to pH 8.5, and extracted with benzene.
12 The next steps involved prep TLC on plates of Camag silica with
13 UV phosphors or on Brinkmann SIL G-UV₂₅₄ plates. TLC steps, by
14 solvent systems, were: (d) toluene/ CH_3OH / Et_3N , 4/1/1%; (e) toluene/
15 CH_3OH / Et_3N , 3/1/1%; (f) 4 x development in acetone containing 0.5%
16 conc. ammonia.

17 In the thebaine biosynthesis experiments, reticuline was
18 purified by the sequence of steps a, e, d and thebaine by a, d,
19 d. Each product was one component by TLC and greater than 99.5%
20 pure by GLC.

21 Alkaloidal starting materials for synthesis were purified with
22 the following steps: thebaine, a, b, d; codeine, a, b, e;
23 morphine, a, e, e. Purifications of alkaloids isolated after
24 metabolism in the thebaine-metabolism experiments are summarized
25 in Table 2.

26 Analyses. GLC analyses were performed with 2 m x 3 mm glass
27 columns packed with 3% OV-17 on Varaport 30 (Varian Aerograph),

1 100-200 mesh. Column preparation included purging overnight at
2 300°C with He, and then treatment at 250°C with 400 mg morphine
3 in CHCl_3 , introduced by several injections. The determinations
4 were made at 230°C or 250°C on an instrument equipped with FID.

5 Radioactivity in the metabolic products was determined by
6 adding known amounts of carrier alkaloids to the pulverized plant
7 material before extraction, performing the isolations and
8 purifications, and counting by liquid scintillation techniques
9 representative portions of the purified alkaloids. In the case of
10 the thebaine-metabolism experiments, ^{14}C -labelled thebaine was
11 used as carrier material to avoid complication of the analyses
12 with the large quantities of cold thebaine from the plant material.
13 The ^{14}C and ^3H in these samples were separated and prepared for
14 counting by combustion in a Packard Sample Oxidizer, Model 306.

15
