ARTICLE INFO

Keywords: Social norms Influence Moral foundations theory Political divisions COVID-19

ABSTRACT

Many people practiced COVID-19-related safety measures in the first year of the pandemic, but Republicans were less likely to engage in behaviors such as wearing masks or face coverings than Democrats, suggesting radical disparities in health practices split along political fault lines. We developed an *"intervention tournament"* which aimed to identify the framings that would promote mask wearing among a representative sample of Republicans and Democrats in the U.S. from Oct 14, 2020, to Jan 14, 2021 (N = 4931). Seven different conditions reflecting different moral values and factors specific to COVID-19—including protection from harm (self), protection from harm (community), patriotic duty, purity, reviving the economy, threat, and scientific evidence—were implemented to identify which framings would "win" in terms of promoting mask wearing compared to a baseline condition. We found that Republicans had significantly more negative attitudes toward masks, lower intentions to wear them, and were less likely to sign or share pledges on social media than Democrats, which was partially mediated by Republicans, compared to Democrats, perceiving that the threat of COVID-19 was lower. None of our framing conditions significantly affected Republicans' or Democrats' attitudes, intentions, or behaviors compared to the baseline condition, illustrating the difficulty in overcoming the strength of political polarization during COVID-19.

enforcement of these safety practices.

political divisions have seeped into public attitudes on COVID-19 in-

terventions, with partisan divides shaping disparate compliance and

pandemic are related to political affiliation and beliefs. A survey of 3000

American citizens in late March of 2020 found partisanship (measured

by party affiliation, intended 2020 Presidential vote, and self-rated

ideology)¹ is "the most consistent factor that differentiates Americans'

health behaviors and policy preferences" (Gadarian, Goodman, &

Pepinsky, 2021, p 0.2). This partisan division has persisted over the

course of the pandemic and is evident with regards to preventive, pro-

A wealth of data indicates that individual responses to the COVID-19

Early in 2020, the novel coronavirus quickly spread around the world, and within months, over 28 million cases and 910,000 COVID-19-related deaths had been recorded worldwide (Worldometers.info, 2020). In the first year of the pandemic, governments implemented a wide variety of community interventions to slow the spread of the virus, including school and workplace closures, stay-at-home orders, and public information campaigns to encourage greater observation of public safety behaviors like wearing face coverings, social distancing, and avoiding large gatherings of people. Many countries enacted a similar set of interventions, however, responses to these measures have been particularly divisive with a large partisan gap in the U.S. The

¹ Due to the highly polarized nature of American politics, people often use party affiliation, ideology, and intended vote interchangeably as measures of political orientation. Republican voters are widely recognized as politically conservative and Democrats are recognized as politically liberal.

social health behaviors recommended by the CDC, such as wearing a face covering when in public. A Pew Research study in late June of 2020 confirmed that Republicans and Democrats perceived pandemic-related risks very differently, with less than half of Republicans worried about the health effects of COVID-19, a decline from April, compared to Democrats whose rate of concern remained high and stable from April to June (Pew Research Center, 2020). A late July 2020 poll by NBC News Survey Monkey showed 86% of Democrats reported wearing a face mask every time they left their homes and might be in contact with others, compared to 48% of Republicans (Wronski, 2020). Given the evidence that masks effectively reduce the spread of COVID-19 (CDC, 2020), these differences in attitudes and health behaviors can have substantial consequences on public health. In order to achieve compliance with mask wearing guidelines, more research on messaging that accounts for political divides is critical.

As communities continue to open up while COVID-19 remains a threat, particularly to unvaccinated individuals, it is urgent to understand how to persuade both Republicans and Democrats to engage in recommended health behaviors. While there are studies that have examined the effectiveness of different types of messaging about COVID-19 health behaviors (Capraro & Barcelo, 2020; Jordan, Yoeli, & Rand, 2020), there is a dearth of research that takes political affiliation into account. Here, we present an intervention tournament that includes seven different intervention conditions relative to a control to test which framings most effectively promote mask wearing among representative samples of Republicans and Democrats in the U.S. (N = 4, 931). While Republicans are more resistant to wearing masks than Democrats, polls show that neither party reported total compliance with pre-vaccine mask wearing guidelines (Pew Research Center, 2020). Moreover, from a theoretical point of view, we expect that different frames may be more or less effective depending on individuals' party affiliation as discussed below. As such, our research examined both Republicans and Democrats.

The current study builds on work that examines moral framings as a means to reduce attitudinal polarization between political groups (Day, Fiske, Downing, & Trail, 2014; Feinberg & Willer, 2013, 2015; Voelkel & Feinberg, 2018). According to Moral Foundations Theory (MFT), liberals and conservatives tend to emphasize different values when it comes to determining what is moral (Graham et al., 2011; Graham, Haidt, & Nosek, 2009). Liberals typically endorse moral values that stress protection from harm and fairness, whereas conservatives tend to adhere to moral values related to ingroup-loyalty, respect for authority, and protection of purity and sanctity (Graham et al., 2009, 2011; but see Schein & Gray, 2015, for an alternative perspective). In past work, researchers have successfully employed these differences to shift political attitudes on both sides of the political spectrum. Feinberg and Willer (2013), for example, examined the impact of moral messaging (purity and harm) on environmental attitudes, which tend to show a partisan split. They found that when framing pro-environmental arguments in terms of harm, a more liberal moral value, liberals reported significantly stronger pro-environmental attitudes than conservatives. However, when the argument was framed in terms of purity, a more conservative moral value, the significant difference between liberals' and conservatives' environmental attitudes was eliminated. In another set of studies, Feinberg and Willer (2015) found that conservatives held more positive attitudes toward same-sex marriage and universal healthcare-policies that conservatives don't typically support-when the arguments they read were framed in terms of conservative moral values (loyalty and purity). Likewise, liberals' attitudes toward military spending and adopting English as the nation's official language were more positive when arguments were framed in terms of fairness.

The present research expands on this work by testing the effectiveness of moral framings to persuade individuals to wear masks or facecoverings in the context of the COVID-19 pandemic before the vaccine was widely available in the U.S. As detailed below, we also include additional framings specific to the COVID-19 pandemic that reflect economic considerations, the danger of the virus, and effectiveness of masks that also show Republican-Democrat political divisions during COVID-19. Specifically, we developed a total of seven carefully constructed message framings which were pitched against a control condition in an intervention tournament of representative samples of Democrats and Republicans that aimed to identify the framings that best promote wearing a mask or face covering among Democrats and Republicans (Bruneau, Kteily, & Falk, 2018; Lai et al., 2014, 2016). Bruneau et al. (2018) coined the term "intervention tournament" as a method for testing not just a single strategy but pinpointing the best strategies out of a pool of strategies evaluated simultaneously. Below we advance specific hypotheses regarding which conditions may be more effective in persuading Republicans and Democrats to wear a mask or facial covering. We also examined which framings "win"—i.e., produce the highest mask wearing intentions and behaviors among Republicans and Democrats (see methods for details). While our tournament was conducted within the U.S., it may offer some insight into encouraging health behaviors in other countries, particularly given that similar political divides regarding COVID-19 behaviors have been found worldwide (Youngs, 2020).

Our seven conditions reflect different moral and COVID-19-specific framings. First, we built upon past framing work (Day et al., 2014; Feinberg & Willer, 2013, 2015; Voelkel & Feinberg, 2018) and used moral foundations theory (Graham et al., 2009, 2011) to develop four different moral-frame interventions, including individual harm, group harm, loyalty, and purity (Graham et al., 2009, 2011). Past research suggests that messages are more effective when they are designed to be consistent with people's moral inclinations (Day et al., 2014; Feinberg & Willer, 2013, 2015; Voelkel & Feinberg, 2018). Therefore, when directed at Republicans, messages that reflect moral foundations such as ingroup-loyalty and purity may be effective, while those that align with the moral foundation of liberals, such as harm, may not. Likewise, a message that focuses on harm may be effective for Democrats, while messages framed in terms of conservative moral values may not. Drawing on the model of moral motives (Janoff-Bulman & Carnes, 2013), we also included a hybrid group harm condition that integrates both having concern for the group and concern for harm at the same time, which may be appealing to both Republicans and Democrats.

In addition to our morally-framed messages, we also included three additional COVID-19 framing conditions that tap into specific concerns that Republicans and Democrats have regarding wearing face masks or coverings. While the aforementioned morally-framed messages tap into world-views that are differentially appealing to individuals, another viable approach is to target the specific psychological mechanism(s) that may underlie why Republicans or Democrats are reluctant to wear facial masks or coverings, or what has been termed "wise interventions" (Walton & Wilson, 2018). Based on extant polling data, we designed three additional conditions that are targeted to address these mechanisms.

First, we included an economic framing condition, as many Republicans are more worried about financial losses and shutdown due to the COVID-19 pandemic than public health (Shepard, 2020). A July 2020 poll of over 50,000 Americans by NBC News Survey Monkey finds that 67% of Republican respondents view the coronavirus outbreak as more of an economic crisis than a health crisis, compared to 17% of Democrats (Wronski, 2020). As such, it is possible that a message that

highlights the benefit of mask wearing for being able to open the economy more quickly may be effective among Republicans and less so among Democrats.

We also included a condition that highlights the devastating threat that COVID-19 continues to have on the U.S. in terms of cases and deaths (The New York Times, 2020). Ironically, although research has typically found that conservatives are more psychologically, perceptually, and neurologically sensitive to threat than liberals (Carraro, Castelli, & Macchiella, 2011; Hibbing, Smith, & Alford, 2014; Jost, 2017; Jost, Glaser, Kruglanski, & Sulloway, 2003; Kanai, Feilden, Firth, & Rees, 2011; Oxley et al., 2008; Vigil, 2010), polls show that Republicans are less likely to perceive COVID-19 as threatening as compared to Democrats. For example, a poll conducted in July 2020 found that only 64% of Republicans, compared to 95% of Democrats, are at least somewhat concerned that they or a family member will be infected with the coronavirus (Blood & Swanson, 2020), and 63% of Republicans believe the coronavirus outbreak has been made a bigger deal than it really is, compared to 18% of Democrats (Mitchell, Jurkowitz, Oliphant, & Shearer, 2020). Recent work shows that feeling realistic threat to physical or financial safety as a result of COVID-19 is related to greater adherence to public health guidelines among people in general (Kachanoff, Bigman, Kapsaskis, & Gray, 2021). Thus, highlighting the realistic threats of COVID-19 may effectively encourage mask wearing among threat-sensitive Republicans. We note that this prime may also be effective for Democrats, as threat has been shown to "tighten" individuals and cultures and promote norm abiding behavior (Gelfand et al., 2011; Jackson et al., 2019).

Finally, we included a condition that highlights the scientific evidence behind mask wearing. In the early stages of the pandemic, messaging from health officials in the U.S. largely told people that masks were not necessary (Gregorian, 2020), and President Donald Trump sent mixed messages on masks through late July of 2020 (Breuninger, 2020). Later, however, there was consensus among experts and evidence that face coverings do diminish the spread of the virus (CDC, 2020). Despite this, a June 2020 poll indicated that there was lingering confusion among Republicans with 47% of Republicans, compared to 31% of Democrats, saying that it was harder to tell what information was true three months in than it was in the first few weeks of the outbreak (Mitchell et al., 2020). To address lingering confusion and disbelief about the effectiveness of masks, our final experimental condition makes clear that there is definitive scientific evidence in support of mask wearing, which may promote these behaviors among Republicans.² Reminders of the effectiveness of masks may also promote mask wearing among Democrats given that they too have been exposed to conflicting information.

Our seven experimental messages, four moral and three specific to COVID-19, were compared to a control condition for a total of eight conditions. All eight conditions have been piloted extensively (see methods section below). We examined the effectiveness of the messages using four dependent variables: a) mask wearing attitudes, b) mask wearing intentions, c) signing a pledge to commit to wearing a mask/ face covering, and d) willingness to share the pledge with social networks. For c) we created a separate website to host the pledge (see https://covidpledge.wixsite.com/sign) to maximize the realism of this measure.

² We note that Republicans may distrust scientists because they believe they are politically motivated by their liberal agenda (Marsden, 2015). As a result, it is possible that the scientific evidence condition may not be as effective among Republicans.

1. Methods

1.1. Ethics information

This research was approved by the Institutional Review Board at the University of Maryland, College Park. All participants provided informed consent before participating in the study. We worked with Qualtrics to collect our data, so compensation was provided by the participants' panel company (hosted by the Qualtrics survey platform).

1.2. Design and hypotheses

We pre-registered our original study design and hypotheses (https://osf.io/4k8bf). The manuscript was accepted as a JESP registered report. For our tournament, participants were randomly assigned to one of eight conditions. Each condition included a standard message encouraging wearing a mask or face covering to minimize the spread of COVID-19 and an experimental framing about *why* masks are important. Each framing targeted a specific moral value or COVID-19-specific factor that may (or may not) be important to Democrats and Republicans. In addition to a message and framing, each condition included an image that represents the condition that was piloted. This image was displayed at the top of every subsequent page throughout the survey to reinforce the manipulation message. The eight conditions included the following:

1.2.1. Control (condition 1)

This was the baseline condition and included the standard message with no additional justification. Building on Capraro and Barcelo (2020), the message was as follows:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering."

The image that accompanied the message for this condition was:

1.2.2. Protection from Harm (Self) (Condition 2)

This condition highlighted the liberal moral value 'harm' as justification for engaging in prevention behaviors. It specifically stated:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because it will keep you safe."

The image that accompanied the message for this condition was:

1.2.3. Protection from harm (community) (condition 3)

This condition focused on preventing harm to others as the justification for wearing a mask or face covering. Although this framing touches on a liberal value (harm) and thus should be effective for Democrats, it is targeted toward the community which is a conservative moral foundation (ingroup-loyalty) and thus may also be effective among Republicans (Graham et al., 2009). This condition included the following message:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because it will keep our communities safe."

The image that accompanied the message for this condition was:

1.2.4. Patriotic duty (condition 4)

This condition was designed to tap into the moral foundation of 'ingroup-loyalty' at a broader level—i.e., making patriotic sacrifices for one's country. As noted, loyalty and sacrifice for one's group are more important to conservatives than liberals, and thus this may be more effective when targeted at Republicans. This condition included the following message:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because it is our patriotic duty to make sacrifices for our great country."

The image that accompanied the message for this condition was:

1.2.5. Purity (condition 5)

This condition employed the conservative moral value 'purity', which is based in the psychological desire to avoid contamination, and thus should be more effective when targeted at Republicans. This condition included the following message:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because it will keep our bodies from being contaminated by a disgusting virus."

The image that accompanied the message for this condition was:

1.2.6. Reviving the economy (condition 6)

This condition highlighted the importance of following health guidelines for a successful reopening of the economy. It may be especially relevant to Republicans as polls show that two-thirds of Republicans view the pandemic as more of an economic crisis than a health crisis (Wronski, 2020). Participants read:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because it will help us to reopen our economy more quickly."

The image that accompanied the message for this condition was:

1.2.7. Threat (Condition 7)

This condition emphasized the threat that COVID-19 continues to pose to Americans and the severity of the potential consequences of contracting the virus. It aimed to activate threat, given that Republicans have ironically been less likely to perceive COVID-19 as threatening as compared to Democrats (Blood & Swanson, 2020; Mitchell et al., 2020). This prime may also be effective among Democrats as well since threat has been shown to tighten individuals and promote norm abidance more generally (Gelfand et al., 2011; Jackson et al., 2019). The message for this condition read:

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because COVID-19 has killed over 211,000 Americans and continues to spread rapidly." (*Note: the number of deaths at survey launch was 211,000. We kept this number up to date over the course of data collection.*)

The image that accompanied the message for this condition was:

1.2.8. Scientific Evidence (Condition 8)

As the messages from health and political officials regarding the

importance of masks were unclear and often conflicting during earlier stages of the COVID-19 crisis (Breuninger, 2020; Gregorian, 2020), this condition emphasized that there is clear scientific evidence showing that masks effectively reduce the spread of the virus (CDC, 2020), and may be effective for Republicans and Democrats (but see footnote 2).

"Months after the start of the COVID-19 pandemic, many areas of the U.S. are opening to some degree and some segments of the population are starting to move around relatively freely. However, since a cure for COVID-19 has not been found and COVID-19 remains a serious threat, it is important to wear a mask or face covering because scientific evidence has proven that they can effectively prevent the spread of the virus."

The image that accompanied the message for this condition was³:

1.3. Pilot Data.

Prior to launching the intervention tournament, we sampled 601 American citizens through the online platform Prolific Academic (298 Republicans, 303 Democrats; $M_{age} = 35.7$, $SD_{age} = 13.6$; 51.2% women, 47.3% men, 1.5% other; 76.5% White, 8.2% Asian, 7.5% Black, 4.8% Hispanic, 3% multiracial/other) to pilot the stimuli. The purpose of the pilot was to ensure our manipulations were valid and not to specifically test the hypotheses. We asked all participants to evaluate each condition in a randomized order on the degree to which the text and image reflected the message. We asked participants to rate on a scale from 1 (Not at all) to 3 (Moderately) to 5 (Extremely) "to what extent do the text and image of each condition convey that wearing a mask or face covering is important because ..." (with the remaining part of the sentence reflecting each particular condition; e.g., because it will protect you from harm (in the Protection from Harm (Self) condition), and associated phrases for each condition). We also asked participants whether the text and image were respectful using the question: "Do you consider this message to be..." Disrespectful (1) to Respectful (5). Finally, we asked each participant to choose the three messages that they thought were most effective and the three that were least effective. Prior to our data collection, our criteria for excluding a condition were: a) if either the Democrats or Republicans sample's rating on how well the text and image reflected the message was significantly lower than the scale midpoint (3); b) if the rating on respectfulness of the message was significantly lower than the scale mid-point; or c) if the condition was rated in the top three for ineffectiveness by both Republicans and Democrats.

In addition to the seven experimental conditions and control condition depicted above, we also piloted four additional conditions. Two of these conditions were designed to appeal to the moral authority of

 3 Note that our original image for this condition was this, but the pilot (discussed below) determined it was ineffective.

religion to encourage mask wearing. Since research has found that views of God as punitive versus loving are influenced by threat (Caluori, Jackson, Gray, & Gelfand, 2020), we designed conditions that highlighted both the loving and punishing sides of God: "because God wants us to protect each other" (Loving God) and "because God tells us that it's a sin to harm each other" (Punishing God). We also tested a condition derived from cultural tightness-looseness theory, which suggests that people desire tighter norms and social order during times of threat (Gelfand et al., 2011; Jackson et al., 2019): "because it will help us to maintain a tight social order in our communities" (Tight Social Order). Finally, we tested a condition designed to appeal to the American value of freedom. Kachanoff et al. (2021) found that perceiving the coronavirus pandemic as a symbolic threat to one's American identity predicted less adherence to social distancing recommendations. Based on this, we designed a condition that aimed to reframe mask wearing as an action that would protect Americans' freedom: "because it protects our freedom to control our personal space" (Freedom).

Based on our criteria for exclusion, we examined whether the mean ratings for each condition were significantly lower than the mid-point (3) on the extent to which the text and image reflected the message and were respectful using one-tailed *t*-tests. We also calculated the percentage of people who listed the condition in the top three for ineffectiveness. All of the results are in a table presented in Appendix A. The results showed that the Protection from Harm (self), Protection from Harm (community), Patriotic Duty, Purity, Reviving the Economy, Threat, and Scientific Evidence conditions were all viable conditions (e. g., all of these conditions were not rated below the mid-point by either Democrats or Republicans on either item and were not rated among the three least effective by either Republicans or Democrats).

The four other conditions that we piloted, however, were excluded. The Punishing God condition was rated as below the mid-point on the text and image reflecting the message for the combined sample and among both Democrats and Republicans, was rated as below the midpoint on respectfulness among Democrats and was listed among the top 3 most ineffective messages by both Democrats and Republicans. The Loving God condition was also listed among the top 3 most ineffective messages by both Democrats and Republicans. The Tight Social Order condition was rated below the mid-point on whether the text and image reflect the message by Democrats and was listed among the top 3 most ineffective messages by both Democrats and Republicans. Finally, the Freedom condition was rated below the mid-point in terms of the image and text reflecting the message for the combined sample and for Democrats. Based on all of our criteria, we excluded the Punishing God,

Table 1

Mask wearing attitude and intention items.

| Measure |
|--|
| a) Mask Wearing Attitudes |
| Do you consider wearing a mask or face covering to be (1 to 7 scale) |
| 1. Unimportant Important |
| 2. BadGood |
| 3. Foolish Wise |
| 4. Negative Positive |
| 5. Undesirable Desirable |
| 6 Unnecessary Necessary |

b) Mask Wearing Intentions (adapted from Capraro and Barcelo, (2020))

In the next week, I intend to... (1 – Not at all to 7 – Very much)

1. wear a mask or face covering any time I leave home.

2. wear a mask or face covering any time I am engaged in essential activities and/ $\!$

or work, and physical distancing and staying at home are not possible. 3. wear a mask or face covering any time I'm around people outside my household.

4. wear a mask or face covering any time I can't maintain 6 ft from others outside my household.

5. wear a mask or face covering inside public buildings.

6. wear a mask or face covering in public outdoor spaces.

Loving God, Tight Social Order, and Freedom conditions.

We note that while the text and image for the Scientific Evidence condition were deemed acceptable based on our criteria, two anonymous reviewers suggested that the image (biceps and an X through a picture of the virus, as seen in Footnote 3) could be further improved. Based on this suggestion, we piloted a new image (N = 195) that was adapted from the Center for Disease Control (CDC) which shows the effectiveness of masks at blocking germs from others (Appendix B) through the online platform Prolific Academic (see image for Condition 8 above). This new image was also deemed acceptable and was used for the intervention tournament.⁴

1.4. Dependent Variables

Our dependent variables included a) mask wearing attitudes (see Table 1), b) mask wearing intentions (see Table 1), c) signing a pledge to commit to wearing a mask/face covering, and d) willingness to share the pledge on social media.

We checked whether the items measuring Mask Wearing Attitudes (6 items) and Mask Wearing Intentions (6 items) formed single factors using maximum likelihood factor analysis with an oblimin rotation.⁵ A pilot study conducted through the online platform Prolific $(N = 589)^6$ illustrated a clear one-factor solution and high reliability for both variables (Mask Wearing Attitudes: one-factor solution ($\lambda_1 = 5.17$, $\lambda_{2-6} < 1.0$), accounting for 86.15% of the variance, item loadings of 0.69 or greater, $\alpha = 0.96$; Mask Wearing Intentions: one-factor solution ($\lambda_1 = 4.41$, λ_{2-6} < 1.0), accounting for 73.43% of the variance, item loadings of 0.70 or greater, $\alpha = 0.92$). In the final sample, we confirmed that each scale was suited for factor analysis (KMO sampling adequacy coefficients >0.90, ps < 0.001). We confirmed a one-factor solution and high reliability for both variables (Mask Wearing Attitudes: one-factor solution ($\lambda_1 = 5.07$, $\lambda_{2-6} < 1.0$), accounting for 84.50% of the variance, item loadings of 0.69 or greater, $\alpha = 0.95$; Mask Wearing Intentions: onefactor solution ($\lambda_1\,{=}\,4.61,~\lambda_{2{-}6}\,{<}\,1.0),$ accounting for 76.82% of the variance, item loadings of 0.76 or greater, $\alpha = 0.93$).

1.4.1. Behavioral Measure – Signing a Pledge

We included a behavioral measure that asks participants to sign (initials only) a pledge to wear a mask or face covering to prevent the spread of COVID-19. We designed a website (https://covidpledge. wixsite.com/sign) modeled after existing ones. Participants' signatures were recorded in a Qualtrics survey accessible only to the research team, which enabled participants to maintain anonymity. The pledge was presented in the survey with the following information:

Signing a pledge helps us successfully take action. We have created a pledge that people can sign to commit to wearing a mask or face covering, which helps prevent the spread of COVID-19.

If you sign the pledge, only your initials and today's date will be recorded.

This pledge is completely optional. If you are not interested, please continue to the next page.

Would you like to sign the pledge? If you are interested, the pledge (https://covidpledge.wixsite.com/sign) will open on the next page (we have embedded it into the survey for your convenience). Once you have signed, please continue with the survey.

Once directed to the page, participants then chose: "Yes, I would like to sign the pledge" or "No, I would not like to sign the pledge".

1.4.2. Behavioral measure - sharing with social network

In addition to asking participants to sign a pledge, we also included a behavioral measure that asked participants to share the pledge with their social networks. To avoid potential privacy concerns, rather than having participants share the pledge directly from our survey, we embedded a link to our pledge website into the Qualtrics survey along with a "copy" button and the message: "Would you be willing to share this pledge with your social network? If yes, please copy the link to the pledge and share it with your social network when the survey is over." Participants' sharing behavior was measured by whether or not they copy the link to the pledge.

1.5. Exploratory variables

For exploratory analyses, which were pre-registered, we included measures of age, family income $(1 = Below \ 30 k, \ 2 = 30-60 k, \ 3 = 60-60 k)$ 90 k, 4 = 90-120 k, 5 = Above 120 k), socioeconomic status (SES, "Which letter corresponds to where you think you stand in society?", letters displayed vertically from A to K corresponding to different rungs of the McArthur ladder), gender (man or woman; responses to an option for other were excluded), religiosity (from 1 = not at all religious to 7 = extremely religious), race (White/Caucasian, Black, Hispanic, Asian, Pacific Islander, Multiracial, and other; for analyses, we compared White/ Caucasian to the remaining categories), health conditions (e.g., cardiovascular diseases, diabetes, and cancer; from 0 to 5 and above), timing of the 2020 presidential election (before and after), mask mandate in one's state (yes or no), and stay-at-home order in one's state (yes or no). We measured perceived threat using three items on a response scale ("How concerned are you by the spread of the new coronavirus (COVID-19)?", from 1 = not at all concerned to 7 = extremely concerned, "How dangerous do you think the Coronavirus is?", from 1 = not at all dangerous to 7 = *extremely dangerous*, "How contagious do you think the Coronavirus is?", from 1 = not at all contagious to 7 = extremely contagious). We measured objective COVID-19 cases and deaths at the county-level. We matched Zip Codes to county codes, then matched response dates to the nearest monthly data point for county cases and deaths per capita starting on the first day of data collection (from Oct 14, 2020 to Jan 14, 2021). To achieve a normal distribution of data, we log transformed cases and deaths. We also measured whether participants were infected by the Coronavirus (yes vs. no or unsure).

⁴ This pilot sample included 97 Republicans, 98 Democrats; $M_{age} = 33.8$, SDage = 13.6; 48.7% women, 50.8% men, 0.5% other; 72.8% White, 11.3% Asian, 6.7% Black, 6.7% Hispanic, 2.5% multiracial/other. Using one-tailed tests, the results of the combined sample, liberal sample, and conservative sample show that the mean rating of the extent to which the text and image reflect the message was not significantly lower than the mid-point, t (194) = 9.68, p = 1; t(97) = 8.05, p = 1; t(96) = 5.87, p = 1, respectively. The results of the combined sample, liberal sample, and conservative sample also show that the mean rating of the respectfulness of the message was not significantly lower than the mid-point, t(194) = 23.78, p = 1; t(97) = 19.03, p = 1; t(96) = 14.98, p = 1, respectively. All tests were one-tailed to determine the messages that were ineffective. We note that a high t-statistic in a two-tailed t-test may indicate statistical significance, but in a one-tailed t-test, a high tstatistic can result in a large *p*-value depending on the chosen tail. Accordingly, our alternative hypothesis was that the mean ratings for each condition are significantly less than 3. Given an alpha level of 1%, the mean is significantly less than 3 if the test statistic is in the bottom 1% of its probability distribution, resulting in a *p*-value less than 0.001. That is, the test statistic would need to be less than approximately -2.3 to achieve "statistical significance." The *p*-values are large because the test statistics are much larger than -2.3. Therefore, even though the t-statistics are high, we failed to reject the null and the alternative hypothesis was not supported (i.e., the mean ratings for each condition are not significantly less than 3).

⁵ The factor analyses were pre-registered. However, the type of factor analysis and rotation was not specified in the pre-registration. We choose maximum likelihood factor analyses post-hoc based on recommended practices (Goretzko, Pham, & Bühner, 2019). We also choose the oblimin rotation post-hoc based on our assumption that any potential latent factors for these scales could be correlated.

 $^{^6}$ 293 conservatives, 296 liberals; $M_{\rm age}=33.2,~SD_{\rm age}=13.2;$ 48.4% women, 50.1% men, 1.5% other; 72.7% White, 11.9% Asian, 5.1% Black, 6.6% Hispanic, 3.7% multiracial/other.

1.6. Power analysis

An a-priori power analysis for a MANOVA with 2 dependent variables (mask wearing attitudes and intentions), power of 0.95, $\alpha = 0.01$, and a small effect size (Cohen's $f^2 = 0.005$) indicated that we needed a total sample of 4477 participants in order to detect statistically significant effects. The dependent variables in this power analysis were considered to be a function of the main effect of political party, the main effects of 7 dummy coded variables that directly compare each framing condition to the control condition, and the interaction effects between political party and each of the 7 dummy coded variables. For the dichotomous variables (pledge signing and willingness to share pledge on one's social network), a power analysis for a z-test for a 2 (pledge signing vs. not) X 2 (political ideology groups) X 8 (framing and control conditions) contingency table, a-priori power of 0.95, $\alpha = 0.01$, and a small effect size (OR = 1.50) indicated that we need a total sample of at least 2703 participants in order to detect statistically significant effects. We used the standard small effect size in power analyses as we were not aware of any work that examines the effectiveness of the types of framings that we are implementing to encourage mask wearing among Republicans and Democrats. We also specified an α level of 0.01 to correct for multiple comparisons across tests.

1.7. Sampling

We contracted Qualtrics to recruit 5000 individuals for this study (2500 Republicans; 2500 Democrats) as our target sample size. Within each political group, participants were randomly assigned to one of our eight conditions. Within each condition, Qualtrics recruited a sample of Americans that fulfilled quotas for region, gender, age, race, and education level matched to the demographics of the specific political group. The Republican sample followed the demographic trends of Republican/ Republican leaning voters: region (16% Northeast, 23% Midwest, 41% South, 23% West), gender (54% men, 46% women),⁷ race (81% White, 5% Black, 7% Hispanic, 7% Other), and education (35% HS or less, 35% some college, 19% college degree, 10% postgrad) (Pew Research Center, 2014, 2020a). The Democrat sample followed the demographic trends of Democrat/Democrat leaning voters: region (21% Northeast, 22% Midwest, 34% South, 26% West), gender (40% men, 60% women), race (59% White, 19% Black, 13% Hispanic, 8% Other), and education (28% HS or less, 31% some college, 22% college degree, 19% postgrad) (Pew Research Center, 2014, 2020a). As registered voters tend to be older than the average population, rather than using the age distribution of register voters, we used a censused-matched age distribution (provided by Qualtrics) for both political groups: 18-34 (~33%), 35-55 (~33%), 55+ (\sim 33%). Recruiting a sample based on representative quotas within each condition, rather than across the whole sample, allowed us to compare the effects of the framings as closely as possible.

To recruit our sample, Qualtrics targeted respondents who have previously indicated that they are Republican or Democrat. To confirm that participants identified as Republican or Democrat, respondents began the survey by indicating their party affiliation (i.e., Republican, Democrat, Independent, other, or none). When we began the survey, we

also asked participants to report where they fall on the political spectrum (1 = very liberal, 5 = neutral, 9 = very conservative), and participants who chose Republican and 6-9 on the political spectrum qualified as Republican and participants who chose Democrat and 1-4 on the political spectrum qualified as Democrat. However, we found that screening participants on both political party and political ideology made our rejection rate much higher than Qualitrics originally anticipated. Of our first 2865 respondents, 1690 (59%) were deemed ineligible due to their political party and/or ideology. Of 908 Republicans who responded, 604 (66.5%) were conservative, 194 (21.4%) were neutral, and 110 (12.1%) were liberal. Out of 1236 Democrats, only 571 (46.2%) classified themselves as liberal, 434 (35.1%) were neutral, and 231 (18.7%) were conservative. Due to the nested nature of our quotas (participants were divided by political party, then randomly assigned to an experimental condition, and then within each experimental condition, there were specific quotas for region, gender, age, race, and education level to gather a representative sample), we decided to deviate from our pre-registered plan and classified participants as Republican or Democrat based only on their self-reported political party in order to increase the feasibility of the data collection. Across the final sample, we found general trends toward matching among Republicans (conservative Republicans = 1869; moderate Republicans = 416; liberal Republicans = 178; mean ideology = 7.01, 95% CI [6.93, 7.09]) and Democrats (liberal Democrats = 1591; moderate Democrats = 599; conservative Democrats = 278; mean ideology = 3.51, 95% CI [3.43, 3.60]). We also found no evidence that ideology interacted with our interventions across the four dependent variables (ps > 0.05; Appendix C). We screened out respondents who were not US citizens and/or not Republican/Democrat. Finally, participants also reported their age, gender, race, education level, and region.

We excluded data from participants who failed any of our quality/ attention checks, as pre-registered on OSF. These include quality checks provided by Qualtrics, such as checks for speeding through the survey or straight-lining (e.g., answering all "2"s). We also included our own attention checks throughout the survey that ask people to choose a specific response option (e.g., "Choose strongly agree" or "Choose the response option furthest to the right"). Finally, we included an openended question at the end of the survey that asks participants to write the first five words that come to mind when they think about the meaning of masks. This served as a quality check, and we excluded and replaced participants who wrote gibberish (i.e., non-words or irrelevant, grammatically incorrect phrases). Thus, any participant who failed even one of these checks was excluded. Qualtrics replaced participants in the correct conditions and quotas.

We screened the data to identify participants who met at least one of the four predetermined exclusion criteria discussed above. Specifically, participants' data were excluded if a) the time they took to complete the survey was less than half the median of the first 100 responses or 3 standard deviations above the median⁸; b) the same answer choice was selected across most or all of the questions (i.e. straight-lining), as per Qualtrics policy; c) they did not choose the indicated response to one of

⁷ Pew Research Center (2020a) reported only the political breakdown within gender (e.g., 38% of women voters in the US are Republican/Republican leaning, 56% are Democrat/Democrat leaning). The gender breakdown within each party was not reported. We calculated an estimate of within-party gender breakdown using the within-gender statistics from Pew Research Center combined with data on registered voters from the Center for American Women and Politics, 2019 (https://cawp.rutgers.edu/facts/voters/turnout). Specifically, we multiplied the within-gender party affiliation statistics from Pew by the number of male and female registered voters as of 2018 and divided by the total number of male and female voters who identified as Republican or Democrat from the Center for American Women and Politics, 2019.

⁸ The lower limit was determined by Qualtrics' standard speeding check. After collecting the first 100 "good completes" (responses that pass our other exclusion checks), Qualtrics calculated one half the median duration and used that as their speeding check. Anyone who completed the survey faster than this was screened out and replaced. For the upper bound, we used 3 standard deviations above the median, rather than one half the median, in order to account for the fact that our duration data was skewed right (skewness = 2.34, SE = 0.04). If we were to have used one half the median to determine the upper bound, we would have lost a substantial amount of data. Our intention with the upper bound is to eliminate people who may stop the survey part way through and resume it later. As such, 3 SD above the median is more appropriate than one half the median. These decisions were pre-registered on OSF.

Table 2

Sample Characteristics across Political Party.

| Name | Republican ($n = 2463$) | Democrat ($n = 2468$) |
|----------------------------|---------------------------|-------------------------|
| Gender | | |
| Man | 1261 (51%) | 978 (40%) |
| Woman | 1202 (49%) | 1490 (60%) |
| Age | 47.87 [47.14, 48.60] | 45.71 [45.98, 46.44] |
| Race | | |
| Asian | 132 (5%) | 133 (5%) |
| Black | 118 (5%) | 499 (20%) |
| White | 2006 (81%) | 1460 (59%) |
| Hispanic | 153 (6%) | 309 (13%) |
| Multiracial | 25 (1%) | 49 (2%) |
| Other | 23 (<1%) | 12 (<1%) |
| Pacific Islander | 6 (<1%) | 6 (<1%) |
| Region | | |
| Midwest | 570 (23%) | 537 (22%) |
| Northeast | 396 (16%) | 516 (21%) |
| South | 1040 (42%) | 835 (34%) |
| West | 457 (19%) | 580 (24%) |
| Religiosity | 4.58 [4.50, 4.66] | 3.76 [3.67, 3.84] |
| Religion | | |
| Agnostic | 84 (3%) | 216 (9%) |
| Atheist | 90 (4%) | 226 (9%) |
| Buddhist | 15 (1%) | 36 (1%) |
| Christian | 2073 (83%) | 1658 (66%) |
| Hindu | 10 (<1%) | 17 (<1%) |
| Jewish | 49 (2%) | 83 (3%) |
| Muslim | 26 (1%) | 56 (2%) |
| Sikh | 2 (<1%) | 4 (<1%) |
| Other | 160 (6%) | 218 (9%) |
| Highest Education | | |
| College (No Degree) | 592 (24%) | 601 (24%) |
| Graduate (4-year) | 506 (21%) | 560 (23%) |
| Grammar School | 22 (1%) | 10 (<1%) |
| High School | 872 (35%) | 712 (29%) |
| M.A./M.S. | 191 (8%) | 340 (14%) |
| M.D./J.D. | 35 (1%) | 50 (2%) |
| Ph.D. | 31 (1%) | 37 (2c%) |
| Technical/Vocational | 214 (9%) | 158 (6%) |
| Family Income | 2.51 [2.46, 2.56] | 2.46 [2.41, 2.51] |
| Socioeconomic Status (SES) | 6.07 [5.98, 6.16] | 5.82 [5.73, 5.92] |

Note: Values are either counts (relative frequencies) or means [95% CI]. Values for Religion do not add up to the N for each political party because participants were allowed to choose multiple religions.

the attention check questions interleaved among other questions (e.g. "From the following answers, please select "3"); and d) they did not pass the quality check question ("What are the first five words that come to mind when you think about masks?"). Responses were considered low-quality if they met any of the following criteria: 1) wrote gibberish/non-words in any of the five questions, 2) wrote non-responses (e.g., "none", "don't know") in three or more of the questions, 3) repeated the same word(s) multiple times, or 4) wrote responses that are irrelevant to the question. After cleaning the data, our final sample size consisted of 4931 participants (2463 Republicans; 2468 Democrats). Data collection occurred from Oct 14, 2020, to Jan 14, 2021.

2. Results

The descriptive statistics for all demographic variables (i.e., gender, age, race, region, religion, education, family income, and socioeconomic status) within each political group are presented in Table 2. The sample characteristics are representative of Republicans and Democrats in the US (deviation from quotas <3%). The descriptive statistics for all of the outcomes and covariates within each political group are presented in Table 3 and the outcomes across the experimental conditions are presented in Table 4.

We conducted a MANOVA with the political party variable, the categorical intervention variable that contrasts each of the intervention conditions to the control condition using SPSS's contrast feature, and the interaction terms between the contrast coded intervention variable and

Table 3

Descriptive Statistics on Dependent Variables and Covariates across Political Party.

| Name | Republicans ($n = 2463$) | Democrats ($n = 2468$) |

political party as predictors.⁹ We included mask wearing attitudes and mask wearing intentions as dependent variables.

We found a statistically significant main effect of political party such that Republicans reported less positive attitudes (*mean*

⁹ In our pre-registration, we originally planned to use dummy coding, but we later determined that contrast coding was more appropriate for multi-categorical variables. This function is built into the multivariate general linear model function in SPSS and compares categories of a variable to a reference category.

Table 5

MANOVA on Attitudes and Intentions to Wear a Mask.

| | | | Mean Difference [95% CI] | | |

Note: V = Pillai's Trace. Subscript _a indicates the *p*-values for the hypothesis tests and corresponding mean differences describing the influence of the interventions on attitudes. Subscript _i indicates the *p*-values for hypothesis tests and corresponding mean differences describing the influence of the interventions. The mean differences for the intervention between political party and the intervention vs. control condition represent the differences between the differences (*z*-tests).

Fig. 1. Attitudes to Wear a Mask across Intervention Conditions.

Fig. 2. Attitudes to Wear a Mask across Intervention Conditions and Political Parties.

difference = -1.02, 95% CI [-1.09, -0.94], p < .001) and lower intentions (mean difference = -0.89, 95% CI [-0.96, -0.82], p < .001) to wear a mask compared to Democrats ($\eta^2 = 0.13$, p < .001). We found no statistically significant effect of the intervention conditions on attitudes and intentions to wear a mask (p = .157). We also found no statistically significant interaction between the intervention conditions and political party (p = .912). The results of the MANOVA are presented in Table 5. Effect sizes are displayed as unstandardized mean differences between the intervention and control conditions on attitudes and intentions. The effects of the intervention and control conditions on attitudes and intentions in the original response scale across the entire sample are illustrated in Figs. 1 and 3 and the effects across political parties are significantly different from the control condition, there were no "winning" conditions in the tournament.

Finally, we conducted a hierarchical loglinear model (HLM) analysis to examine whether there was a three-way interaction between the seven framing conditions (relative to the control condition), participants' political party (Democrat or Republican), and participants'

Fig. 3. Intentions to Wear a Mask across Intervention Conditions.

Fig. 4. Intentions to Wear a Mask across Intervention Conditions and Political Parties.

pledge signing behavior (signed or not).

The HLM is an extension of the χ^2 test and models a multidimensional structure of categorical variables using an iterative proportionalfitting algorithm developed for SPSS (Version 24; IBM, 2021). The χ^2 test evaluates the difference between observed and expected cell counts of one or more categorical variables given a probabilistic distribution of values. With a single variable, the χ^2 tests if the difference between the observed and expected cell counts across the response categories. With more than one variable, the χ^2 test evaluates a continency table (i.e., pairs of responses across categorical variables) and tests for independence between variables. Unlike a MANOVA, a HLM does not differentiate between dependent and independent variables. In line with the tradition of χ^2 tests, we specify the model for the contingency table as a variable-by-variable interaction (e.g., row * column) rather than label them as dependent and independent variables as we do in other sections of the paper.

The HLM is split up into K-way effects and partial associations. In the current study, the *K*-way effects represent χ^2 tests for the main effects (pooled), two-way interactions (pooled), and the three-way interaction. The *K*-way effects include χ^2 tests of lower order effects with and without the inclusion of higher order effects. The HLM decomposes the main effects and two-way interactions by providing partial associations or additional χ^2 tests that evaluate each main effect and interaction. The main effects test whether the observed distribution of values for each of the variables (i.e., political party, intervention condition, and pledge signing) significantly differs from the expected distribution of values. The two-way interaction effects tests whether one of the variables (e.g., pledge signing) is predicted by one of the other two variables (e.g.,

Note: OR = Odds ratios [95% CIs] and chi-square (χ^2) tests for the Republican and Democrat subgroups were calculated using logistic regression.

political party *or* intervention condition). The three-way interaction effect tests whether one of the variables (e.g., pledge signing) is predicted by the interactive effect of the other two variables (e.g., intervention condition *and* political party).

We calculated the K-way effects, which tests if there are any main effects (K = 1), two-way interactions (K = 2), or a three-way interaction between signing the pledge, the intervention condition, and political party (K = 3). We found evidence for significant main effects and twoway effects (ps < 0.001) but not a three-way interaction (p = .577; Table 6). Because K-way effects are pooled across effects and intervention conditions, they provide only a limited amount of information. Accordingly, we used partial associations to help us better understand which main effects or interactions were significant overall, which were significant across intervention conditions, and which were significant within and across political parties (see Table 7). Effect sizes are displayed as odds ratios (OR), or the odds of an outcome compared to the odds of an alternative outcome. An odds ratio equal to 1 is equivalent to a probability of 50% (i.e., a coin flip). We found a statistically significant main effect for signing the pledge, such that there were statistically significantly greater odds of signing the pledge compared to not signing the pledge (OR = 1.30, 95% CI [1.27, 1.34], p < .001). We found a

statistically significant two-way interaction between political party and signing the pledge, such that the odds of signing the pledge was lower among Republicans compared to Democrats (OR = 0.83, 95% CI [0.81, 0.85], p < .001). We found marginally significant evidence that the interventions (vs. the baseline control condition) influence pledge signing behavior (p = .064). There was a significant main effect for the threat intervention decreasing the odds of signing the pledge (OR = 0.90, 95% CI [0.84, 0.97], p = .008), an effect that was in the opposite direction of our predictions. The effects of the interventions and control condition on signing the pledge to wear a mask across the entire sample and across political parties are illustrated in Figs. 5 and 6.

We next conducted the same analyses for whether participants were willing to share the pledge with their social network. For the *K*-way effects, we again found main effects and two-way interactions (p < 0.001) but no three-way interaction (p = .435) (Table 8). For the partial associations (Table 9), we found a statistically significant main effect for sharing the pledge, such that there were statistically significantly lower odds of sharing the pledge compared to not sharing the pledge (OR = 0.51, 95% CI [0.53, 0.50], p < .001). We also found a statistically significant interaction between political party and sharing the pledge, such that the odds of sharing the pledge was lower among

Fig. 5. Probability of Signing the Pledge for Each Intervention Condition.

Republicans compared to Democrats (OR = 0.88, 95% CI [0.85, 0.92], p < .001). There was no statistically significant evidence that the intervention (vs. the control) conditions influenced pledge sharing behavior (p = .653). The effects of the interventions and baseline control condition on sharing the pledge to wear a mask are illustrated across the entire sample (Figs. 5 and 7) and by political party (Figs. 6 and 8). As with mask attitudes and intentions, because none of the interventions were significantly different from the control condition, there were no "winning" conditions in the tournament for signing and sharing the pledge.

2.1. Other exploratory measures: threat and demographics

Our exploratory measures and analyses were pre-registered on OSF (https://osf.io/e89fv). We explored whether the interventions were more or less effective based on sample demographics such as income, age, gender, race, religiosity, and pre-existing health conditions. We included a time variable for the 2020 presidential election (before or after), which occurred during data collection. We also examined whether participants' reports of whether masks and stay-at-home orders

Fig. 6. Probability of Signing the Pledge across Intervention Condition and Political Party.

Note. Number of iterations = 2. *K*-way and Higher Order Effects include tests of all effects at level *K* and higher.

were mandatory in their communities to see if interventions were more or less effective based on community responses. Finally, since communities have been differentially affected by COVID-19, we measured the number of county-level cases and deaths using zip codes, as well as perceptions of COVID-19 threat and personal infection, to see if the interventions were more or less effective based on perceived and actual levels of threat.¹⁰ Although the demographic variables, the community response variables, perceived threat, and county-level COVID-19 cases all correlated with some of the outcomes (Table 10), we still found no statistically significant evidence that our interventions produced an effect when including these covariates in our models (Tables 11–13).

Finally, we ran a pre-registered image-only control condition of a mask with no text promoting the importance of wearing face masks in a separate study (https://osf.io/e89fv, see Appendix D). With this new control condition, we tested whether our original control condition with the text and an image may have been too strong given that it did state that wearing masks was important (without a rationale for why which was the purpose of the intervention conditions) (N = 636; *Republican* = 316; *Democrat* = 320; *mean attitudes* = 6.06, 95% CI [5.95, 6.18]; *mean intentions* = 6.23, 95% CI [6.13, 6.32]; *signed pledge* [Y, N] = 401, 235 [63%]; *shared pledge* [Y, N] = 98,538 [15%]). We used the following image for this new control condition:

We found a statistically significant main effect for the interventions (vs. the new control condition) on attitudes and intentions to wear a mask (p = .001, Table D1). However, upon conducting multiple comparison tests, we found only one marginally statistically significant effect, such that the scientific evidence condition decreased intentions to wear a mask (*mean difference* = -0.17, 95% CI [-0.31, -0.03], p = .02); which was in the opposite direction of our hypothesis. We did not find any effects of the interventions on signing or sharing a pledge to wear a mask (Tables D2-D3), nor did we find any interactions between the interventions and political party.

¹⁰ The total sample size was lower with covariates (N = 4344; 2176 Republicans; 2168 Democrats) due to incompatibility in matching zip codes with county-level objective threat (7 cases) and excluding "unsure" responses for stay-at-home order and mask mandates (582 cases) (two cases had both variables missing).

Note: OR = Odds ratios [95% CIs] and chi-square (χ^2) tests for the Republican and Democrat subgroups were calculated using logistic regression.

Fig. 7. Probability of Sharing the Pledge across Each Intervention Condition.

3. Discussion

Given the threat of COVID-19 and its emerging variants, finding methods to encourage people to engage in effective health behaviors—such as wearing a mask or face covering—is critical to managing the risk of infection (CDC, 2020). However, in the United States, there has been a political divide in the likelihood to follow recommended health behaviors used to fight COVID-19, with Republicans being less concerned about the virus (Pew Research Center, 2020) and less likely to follow recommended health behaviors (Wronski, 2020) compared to Democrats. Therefore, finding solutions to persuade individuals across the political spectrum to adhere to the recommended health behaviors is critical for dealing with the spread of COVID-19. Based on moral foundations theory (Graham et al., 2009, 2011) and past message framing traditions (Day et al., 2014; Feinberg & Willer, 2013, 2015; Voelkel & Feinberg, 2018), we developed seven different messages and tested them in a tournament to determine which ones could persuade a representative sample of Republicans and Democrats in the U.S. to wear masks from October 2020 to January 2021. These messages promoted masks with subsequent rationales either focusing on protection from harm (self), protection from harm (community), patriotic duty, purity, reviving the economy, threat, and scientific evidence.

Across multiple dependent variables, we found no evidence that the

Table 10

Pearson correlations between the dependent variables and covariates.

interventions persuaded Republicans or Democrats in the U.S. to wear masks compared to a baseline message condition. None of the messages significantly increased attitudes and intentions to wear a mask or behaviors to sign and share a pledge to wear a mask. Indeed, in contrast, we only found a marginal effect that the threat message was associated with less pledging behavior compared to the baseline message, which was in the opposite direction of our hypotheses. The strongest effect on mask attitudes and behaviors was by far political party affiliation, such that Republicans reported having more negative attitudes and intentions toward wearing masks and were less likely to sign and share a pledge as compared to Democrats. Quite clearly, the interventions were not able to override the deep-seated partisanship that has existed in the U.S. during the COVID-19 pandemic.

There are several possible reasons for the null effects of our interventions. First, the interventions may have been too weak. Though many framing studies involve reading a brief message or nudge for only a few minutes (Thaler & Sunstein, 2021), it is possible that this approach is limited in contexts where attitudes are strongly engrained. Indeed, other interventions also found no evidence for changing COVID-19 related health attitudes or behaviors when using brief messages targeting selfish versus altruistic motivation (Sasaki, Kurokawa, & Ohtake, 2021), prevention versus promotion motivation (Utych, 2021), social norms (Bilancini, Boncinelli, Capraro, Celadin, & Paolo, 2020), or appeals to civic responsibility or limited health care system capacity (Pink et al., 2020). The messages might have been more effective if they were delivered in multiple instances over time or came from an elite, trusted source (see Pink, Chu, Druckman, Rand, & Willer, 2021). Second, and relatedly, the timing of the study may have impacted our results. We conducted the intervention tournament across four months (from Oct 14, 2020, to Jan 14, 2021), after attitudes had become polarized, and this may have been further amplified during the U.S. Presidential election and continued through the attack on the Capitol on January 6, 2021. Finally, while our interventions were grounded in theory on moral foundations and wise interventions, it is possible that there are other interventions that would have been more effective. There is some evidence, for example, that using messages that focus on the community-

wide benefits of face coverings (Capraro & Barcelo, 2020), promote reasoning over emotional responses (Capraro & Barcelo, 2021), discuss COVID-19 as a public (vs. personal) threat (Jordan et al., 2020; c.f., Miyajima & Murakami, 2021), evoke empathy through storytelling about how the virus affected the elderly (Pfattheicher, Nockur, Böhm, Sassenrath, & Petersen, 2020), or use written reflection exercises (Hume, John, Sanders, & Stockdale, 2020) show some efficacy in promoting COVID-19 health behaviors. Future research using meta-analysis will be useful in discerning which interventions had the most powerful impact during COVID-19 and whether they were effective for both Republicans and Democrats.

The most robust finding of the tournament was that Republicans were much more resistant to mask wearing across our dependent variables than Democrats, raising the question of why this was the case. Though it is likely multiply determined, Republicans' resistance to virus mitigating interventions may be due to the lack of perceived threat of COVID-19. Collective threats motivate norm abiding behavior when there is a reliable fear signal (Gelfand, 2021). When this signal is thwarted or manipulated, strict abidance of new norms is less likely to evolve. Consistent with this, we found Republicans did, in fact, perceive lower threat of COVID-19 and this partially mediated the partisan differences in mask wearing attitudes, intentions, and behaviors (see Appendix E, Fig. 9). We note that this meditation analysis was exploratory and not pre-registered, and we caution drawing conclusions about the casual direction from this model as the variables were measured cross-sectionally. We did test an alternative model by switching the order of the mediator (i.e., perceived threat) and the outcomes (see Appendix F). We found that the proportion of mediation accounted for by the indirect effect was significantly smaller for the alternative model (Table F9).

At first glance, the lower perceived COVID-19 threat levels among

Fig. 8. Probability of Sharing the Pledge across Intervention Condition and Political Party.

Republicans may seem puzzling given the large body of evidence in psychology and neuroscience that has shown that conservatives are more sensitive to threats such as pathogens and negative stimuli when compared to liberals (Aarøe, Petersen, & Arceneaux, 2020; Hibbing et al., 2014; Jost, 2017; Mendez, 2017; cf., Bakker, Schumacher, Gothreau, & Arceneaux, 2020; Brandt, Wetherell, & Reyna, 2014; Elad-Strenger, Halperin, & Saguy, 2019). Yet these studies were not able to account for some important contextual moderators, including the effect of leadership on perceived threat during an actual pandemic. Indeed, during COVID-19, the pathogen threat signal was repeatedly diminished by U.S. President Donald Trump who failed to adequately convey that the threat was dire. As Trump said on March 2020 "Just stay calm. It will go away." Even by January 2021, well after more than 300,000 Americans had died, Trump complained of the Center for Disease Control and Preventions supposed exaggerations. As the death toll climbed to staggering levels in the United States, those Americans who supported Trump felt even more empowered to ignore the warning signs. In this respect, they were more tightly following their leader than any fear instincts about pathogens. It's worth noting that the condition where we did attempt to activate COVID-19 threat (e.g., Condition 7: "It is

important to wear a mask or face covering because COVID-19 has killed over 211,000 Americans and continues to spread rapidly") showed some evidence of *backfiring* among both Republicans and Democrats. Threat messages may evoke people's fear of the virus, but inadvertently promote maladaptive behaviors (e.g., denial or avoidance; Rippetoe & Rogers, 1987; Witte, 1992).

In addition, previous studies also generally have looked at how conservatives and liberals react to threats in isolation of other threats. It is possible that when examining multiple threats simultaneously that conservatives are more sensitive to threats of perceived infringements of freedom and/or other types of threat (e.g., conflict. Brandt et al., 2020; Kahn, Björklund, & Hirschberger, 2020) and/or that conservatives express their fear in different ways (e.g., xenophobia) that support their party's values (Brandt et al., 2014).

The results also have some important practical implications. Given that none of the seven interventions worked, we need to continue to develop more ecologically valid interventions to help promote mask wearing and social distancing as the pandemic continues to evolve. As research shows, behavior change with light-touch interventions is particularly challenging when individual attitudes are already unsupportive to begin with (Dewies, Schop-Etman, Rohde, & Denktaş, 2021), which was the case for Republicans in our sample.

As scientists, we overestimated the extent to which participants would overcome the partisan divide and assumed that at least some conditions had the potential "to win". Indeed, in a separate forecasting study in which over 1000 participants predicted the effects of the interventions presented in this study, we found that academics, behavioral science practitioners, and laypeople alike overpredicted the results of our tournament (Dimant, Pieper, Clemente, Dreber, & Gelfand, 2021). In particular, when examining the accuracy of predictions across political parties, forecasters predicted larger effects for Democrats than we found, yet were more accurate in their predictions for Republicans. Existing research suggests that political polarization runs deep in the U. S., that Democrats and Republicans hold incorrect beliefs about each other, and that it is highly challenging to reduce polarization via behavioral interventions (Dimant, 2021). During events that require an urgent response, such as a global pandemic, holding accurate beliefs about the outcomes of behavioral interventions is crucial to reduce the costs and maximize the success of identifying effective behavioral interventions.

Fig. 9. Perceived Threat Mediates the Effect of Political Party on Mask Wearing Attitudes and Behaviors. Note: We used 1000 bootstrap samples for estimating SEs.

Data availability and code statement

All data and analysis codes are available through the Open Science Framework (https://osf.io/xr9ka/). The study was pre-registered prior to data collection and approved as a pre-registered report at JESP.

Appendix B. We retrieved the following information and image from the CDC during September 2020 to adapt for our "Scientific Evidence" condition. This image is no longer on the CDC website

Evidence for Effectiveness of Masks

Your mask helps protect those around you

COVID-19 spreads mainly from person to person through respiratory droplets. Respiratory droplets travel into the air when you cough, sneeze, talk, shout, or sing. These droplets can then land in the mouths or noses of people who are near you or they may breathe these droplets in.

Masks are a simple barrier to help prevent your respiratory droplets from reaching others. Studies show that masks reduce the spray of droplets when worn over the nose and mouth.

You should wear a mask, even if you do not feel sick. This is because several

studies have found that people with COVID-19 who never develop symptoms (asymptomatic) and those who are not yet showing symptoms (pre-symptomatic) can still spread the virus to other people. Wearing a mask helps protect those around you, in case you are infected but not showing symptoms.

It is especially important to wear a mask when you are indoors with people you do not live with and when you are unable to stay at least 6 feet apart since COVID-19 spreads mainly among people who are in <u>close contact</u> with one another.

Appendix C. Interactions between Intervention Conditions and Ideology on Outcomes

| Outcome | Test Statistic (Name) | Test Statistic (Value) | df | р |
|-----------------------------------|-----------------------|------------------------|------------|--------|
