#### **Abstract**

**Objective**—Compassion is an imposant contributor to pro-social behavior and maintenance of interpersonal relationships that little is known about what factors influence compassion in late life. The aim of this study was to test theories about how past and current stressors and emotional functioning, resilience, and demographic indicators of life experiences are related to compassion among older adults.

**Methods—**One-thousand and since vider address (50-99 years) completed a comprehensive survey including self-report measures of compassion, resilience, past and present stress and emotional functioning (i.e., stressful life events, perceived stress, and current and prior depression and anxiety), and demographic information. The sample was randomly split, and exploratory and confirmatory regression analyses were conducted testing hypothesized relationships with compassion.

**Results**—Exploratory stepwise regression analysis (an 650) indicated that participants who reported higher levels of compassion were more likely to be temale, not currently in a married/married-like relationship, reported higher resilience levels, and had experienced more significant life events. Age, income level, past and current mental distress, and interactions between relations and other predictors were not significantly related to compassion. The associations between greater self-reported compassion and being remale, having greater resilience, and having experienced more significant life events were supported by a confirm atory step wis pregression analysis (n=356).

**Conclusions**—Older women report more compassion than older onen. Resilience and significant life events, independently, also appear to facilitate a desire to hop others, while cur ent stress and

past and present emotional finationing are less relevant. Specificity of findings to older adults is not yet linown.

Depression; And ieta Aging; Resilience; Life Events/Stress

Our human composion bind, us the one to the other – not in pity or patronizingly, by, as human beings who have learn how to turn our common suffering into hope for the future."

-Nelson Mandela

Over the last century a demographic revolution has occurred, which has drastically increased the number of individuals over the ago of 55, and the current number is expected to almost double by the mean 2030 (e.g., Administration on Aging (AOA) 2011). This rise in the number of order roults has created new concerns for society and health services (Hendrie, et al. 2010) and a need to conduct research that rocuses on factors that can potentially increase health related quality of the (HRQOL) mongroups adults.

Compossion may be one of those factors; it is often associated with approach-related beliavior and appears relevant to undersanding pro-social behaviors and the maintenance of interpers and relationships across the lifespan (Figurer and Fabes 1990; Schutte, et al. 2001, Spreicher and Fehr 2005; Ian Doesuin, et al. 2015). Compared with empathy, which is defined as having empathy for the suffering of another and additionally having a desire to lessen that persons' suffering (Marriam-Webster 2014c, o). To date, very little is known about what contributes to compassion in late life. Using self-report methods, the objective of this study was to test several theories about why some older adults may report higher levels of compassion than others.

"I cannot appreciate your pain and I have walked a mile in your shees" is a common adage in our society that refere to being able to have empathic concern for and in trinsically relate to the suffering of another person. For example, alcoholics often turn to recovered alcoholics for support, veterans turn to other veterant for support, and cancer patients seek support from cancer survivor, suggesting implicitor explicit beliefs that people vino have experienced similar situations will provide the most compassionate care. However, there is limited empirical evidence to support the notion that compassionate care. However, there is limited empirical evidence to support the notion that compassionate responding is facilitated by past suffering. Stigma literature has touched on this idea, with some findings that those who have been severely stigmatized report recognizing and developing compassion toward other stigmatized groups (e.g., Tennura 2000).

A recent study by Stellar et al. (2012) found that lower-status undergraduates ('ower status measured by a self-ranking of oneself as lower income, education, and jub status relative to one's peers) exhibited greater compassion towards others than upper-status incividuals in terms of trait and state self-reports of compassion as well as physiological responds to observing suffering of others. The authors attribute their findings to the theory that lower-status individuals, based on their own line experiences, are more attuned to negative external

stressors and abla to more accurately perceive others as in need of support as they have shared similar experiences. Further support for greater compassionate behavior in lower socioeconomic status (SES) individuals has been found in national surveys that indicate that the poor of fifth in the U.S. donate the largest percentage of their income to charity (Greve 2009, Pifil et al. 2010). Thus, there is the netical support for the idea that past suffering may lead to present compassion, but this has only rarely been tested, and not specifically in older adults. Based on these theories, we examined demographic features as indices of life experiences (e.g., incomplevel, race/eth/licity saudation, marital status) and also assessed recent stressful life events and history of mental disorders (anxiety and depression). We hypomesized that those reporting more negative experiences and history of mental distress modification from the most compression. To the extent that those older adults who have lived the longest have also experienced mode of life's ups and downs, we also examined older age as a possible predictor of greater compassion.

Gender differences in compassion have been noted in studies of younger adults (e.g., Mercadillo, e. al. 2011), with a tendency to find greater compassion among women. Less is known about whether such differences persist in old age. Viewing oneself as caring and nurraring is important to many women's self-concept and fits societal norms, however many order women have spent a lifetime caring tender and some may experience burnout (Takai, a al. 2011), which could reduce their repeated compassion levels. Our large sample allowed as to powerfully test whether women reported many compassion than men among older adults.

How current suffering (i.e., current depression, current anxiety perceived stress) relates to compassion is unknown, and the direction of the association between current distress and compassion is comewhat difficult to predict. On the one hand, one might expect that current suffering (similar to past partering) promotes compassion by making it easier to understand the troubles of others and come up with possible schauons ("I should do for him what I would want do to forme"). On the other 1 and, one could imagine that those who are currently experiencing stress, depression, and anxiety may be overwhelmed with these personal difficulties and unable to devote resources to caring about the we'l-being of others. Thus, we explored the relationship between compassion and current levels of perceived stress, depression, at a anxiety in our large sample of older adults without an a priori hypothesis regarding the direction of the relationship.

Protective factors are also an important consideration when attempting to uniderated the development and mainter and of compassionate behaviors. In the literature, the concert of resilience has been used to help understand individual differences in the ability to I ounce back after experiencing significant rife events and/or adversity (Campbell-Sills and Stein 2007; Rutten, et al. 2013). Additionally, resilience is believed to be an engoing process that is fostered throughout the lifespan. When faced with a significant hardship, such as depression, anxiety, stress, or a traumatic or stressful life event, it is muit possible for a person to experience a decline in nen al health functioning, and overall HRCO. However, it is also possible to develop a new perspective and grow from a psychologically discressing experience (Zautra, et al. 2010). To our knowledge the possible link between resilience and compassion has not been examined in older adults. Given that resilience is positively related

to life satisfaction, bealth, and longevity (Bowling and Iliffe 2011; Jeste, et al. 2013; Tugade, et al. 2004; Zeng and Shen 2010) we expected that it would also relate to greater compassion for others and may interact vith past and/or current emotional function, such that those who suffer but bounce back may be most motivated to help others do the same.

Rased on these theores about possible factors influencing compassion, we aimed to explore and that hypotheses about how past and current suffering, resilience, and demographic factors indicative of life explaience, are related to self-reported compassion levels among older adults. Our large sample allowed us to conduct exploratory analyses on a majority of the complete and then test the robusiness of the findings on the remaining subsample.

#### Method

#### Participants

On eith busard and six middle-aged and older adults (mean age = 77.3, SD = 12.2) enrolled in the Successful AGing Evaluation (SAGE) study. This investigation used a structured multi-cohort longitudinal design to study randomly selected, community-dwelling residents of San Diego County, ages, 50 years of older, with an over-representation of those in the 80s and 90s (Jeste et al. 2013); baseline data were used in this analysis. All assessments were self-repair surveys which were mailed to participalits, and stamped addressed envelopes were included for survey returns. In total, 1,300 curveys were mailed, yielding a 77% response rate. Of the 1,00% participants who completed the SAGE survey, 48 are not included in the present analyses because they did not complete the compassion inventory and 55 did not repair their psychiatric history, resulting in a finite sample size of 903.

#### Measures

Measures from the surrey that were included in this study were:

**Compassion**—The Santa Clara Brief Compassion State (SCPCs) is a 5-item adaptation of the Compassionate Love Scale (Hwritig, et al. 2008). The scale is presented in Table 1. Scores were averaged, with higher scores indicative of greater compassion. The Compassionate Love Scale was designed to n easure compassionate be relationships and for people in general (Speecher and Feh. 2003), and the brief version was developed to assess only compassion towards non-intimate of this (i.e., strangers). Our decision to use a brief self-reposition measure of compassion was in line with large scale survey research. Normed on a sample of college students, internal reliability of this calc is very strong ( $\alpha = 0.90$ ), as is the correlation between the original and brief version (r = 0.20) ((r = 0.96); Hwang et al. 2008).

Stressors and Emotional Fractioning—Participants were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed than with depression, the year they were diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed than with depression, the year they were diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, they are they were diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed than with depression, the year they were diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed than with depression, the year they were diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were currently depressed. The same questions were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed, and if they were asked to report (9 = no, 1 = yes) whether a doctor had ever diagnosed to report (9 = no, 1 = yes). The doctor had ever diagnosed to report (9 = yes) whether a doctor had ever diagnosed to report (9 = yes) whether a doctor had ever diagnosed to report (9 = yes). The doctor had ever diagnosed to report (9 = yes) whether a doctor had ever di

The Life Events Scale (LES, Tromes and Rahe 1967) asks participants to report how many stressful life events they experience a during the past year (e.g., death, divorce), and how and the trey were upset by each event. Trigher scores indicate a greater number of stressful life events and greater dictress as a consequence of recent life events. The Perceived Stress Scale (PS3; Cohen, et al. 1953) was used to evaluate participants' thoughts and feelings entring the past month in regard to statements such as, "How often have you felt nervous or stressed?" Statements a crated on a 5-1 oint Likert scale from 1 = Never to 5 = Very Often. Trigher scores indicate greater perceived stress

Positionice—The Connor-Davidson Reclinence Scala 10-item (CD-RISC-10) (Campbell-Sills and Stein 2007) used to assess resilience, asks participants to indicate how confident they are in dealing with challenges in life (e.g., 1 am ab'e to adapt to change;" "I believe coming with success strengthens me") an a scale from 1=no at all true to 5=true nearly all of the time 11:21. A scores on this scale indicate greater reducence.

#### **Data Analysis**

IBM SPSS Statistics version 20 was used to conduct all analyses. SPSS's random selection cat, function was used to split the san ple into two independent samples of two-thirds (n<sup>-</sup> 050) for the exploratory analysis and one-unitd (n<sup>-</sup> 356) for the confirmatory analysis. Sample comparisons were conducted to ensure that the samples did not statistically differ on key variables of interest, including demographic variables, compassion, resilience, and emotic nal distress variables. Data was screened for outliers and violation of statistical assumptions and variables were centered prior to model outry to facilitate interpretation of coefficients. For the exploratory analysis, compassion was the dependent variable and the following independent variables were entered into a stepwise tegression analysis: age, gender, education, marital straus, race/ethnicity, income, resilience, history of depression, history of anxisty significant life events, current cepression, current enxiety, and perceived stress. In order to investigate the potential for interactions between resilience and past suffering, we re an this model throutimes, each time including one of the following interaction terms: resilience × 1'i.e events, resilience × nistor, of degression, and resilience × history of anxiety. Next, using the remaining sub-sample of participant, the variables that were significant in the exploratory analysis were entered into a regression model (enter method) to confirm the findings.

#### Results

#### Sample 1: Exploratory Analysis (n-650)

Sample characteristics are presented in Table 2. Compassion scores followed a normal curve.

The overall stepwise regression model predicting compassion levels was significant (adjusted  $R^2 = 0.13$ , p < 0.001). Finally gender (t(398) = -0.01, p < 0.01), not married (t(398) = -3.00, p < 0.01), greater residence (t(398) = 4.91, p < 0.01), and a greater residence of significant life events (t(398) = 2.01, p = 0.045) were strong predictors of greater compassion. Refer to Table 3 for full regression results Age, in come level, reselectionicity.

and past or current depression and anxiety diagnosis were not significant predictors in the mode, and no significant interactions with resilience were found.

#### Samp! 2: Confirmatory Analysis 'n=356'

Character stics of this sample are presented in Table 2. As with the first sample, compassion scores folio wed a non reacure.

's line?' regression model that included only the significant predictors from the initial armysis was significant overall (adjusted  $R^2=0.0^\circ$ , p<0.001). Significant individual redictors of greater compassion were fermine gender (t(290)=-3.49, p<0.01), greater rediffered (t(290)=2.80, p<0.01), and more life events (t(290)=2.77, p<0.01). Marital status did not load in the confirmatory model.

### Discussion

In a large sample of older adults, we tested how factors that are theoretically linked to cor.passica, such as life experiences, cu.rent emotional functioning, and resilience, were issociated with claer adults' views of heir own leve of compassion. The results of the exploratory regression analysis suggested that older adults who are female, are not married or in a manage-like relationship, are more resilient, and have experienced a higher number of significant life events report the most compassion. The moustness of these findings was tested in a second, independent lample, an call variables but marital status were confirmed to be a sociated with compaction levels. The findings were got erally consistent with our hypotheses about the potential role of past suffering and protective psychological factors in promoting current compassion in and t more significant line events and higher resilience were related to reat r compassion. Also consistent with our prediction as well as with findings in younger samples (e.g. Avercadillo et al. 2011), women regard higher levels of compassion than men. That this strong gender difficence was observed in an older adult sample suggests that the life experiences of women either polstered maintain levels of compassion. However, contrary to our hypotheses, we did not find associations with demographic factors such as age, in some, race/ethnicity, or education, which could serve as proxies for lifetime experiences that might change con passion. In addition, our prediction that history of mental disorders would promote compassion was not supported and current depression and anxiet were also unrelated. Finally, we had expected that individuals with both past suffering and resilience might have the highest reported compassion, but interactions between rescuence and past depression or anxiety or recent life even were not significant contributors to me model.

Our findings suggest that when a person has experienced significant the events over the past year (e.g., divorce, death of a loved one, ich loss) they are also likely to report a desire to provide support to others. The relationship we found with stressful life events may be criven by heightened awareness of the potential for suffering in others or could be a reaction to the compassion (or lack thereof) that the older adult received following these life events. These who received adequate help might be motivated to pay it forward" and/or might reel more equipped to give effective assistance after seeing what did or did not help them of the with their own negative events.

We also found that older addies who report higher levels of resilience, independent of the level of recent stressful events, are more motivated to help others. It may be that people who are then selves adept at events, are more motivated to help others. It may be that people who are then selves adept at events, are more more willingness to assist others because they predict a tai gible benefit from doing so based on their own experience. Said another why, people who are less resilient may not believe that recovery from adversity is possible and therefore are not mouvated to sugage in useless helping behavior.

Age was not related to compassion within this sample of older adults. More years alive may not be a good proxy for greater number of compassion-promoting life experiences. Also, factors such as cognitive and physical decline in some older adults might have the opposite effect of reducing compassion, making it difficult to see any trends with age. Our results differ from some studies that have demonstrated a climit ished empathic and compassionate understanding in older adults (Labouric-Vief, et al. 1989, Labouvie-Vief and Marquez 2004; Phillips et al. 2002), but are consistent with others that have not found evidence for agerented differences (Carstensen, et al. 2000; Grühn, et al. 2008; Keightley, et al. 2006). We also failed to see a strong relationship with income, which differs from studies showing that lower SFS adults engage in a greater number of pro-social behaviors than their high SES counterparts (Greve 2000, Piff et al. 2010 Stellar et al. 2012). Possibly, current income of order adults is not an accurate proxy for litetime economic hardship. There was also not a relation mp of compassion with race/ethnicity in the context of the model, again potentially due to this being only an indirect indicator of lifetime expenses.

Surprisingly, history of diagnosed depression and anxiety, as well as currently suffering from these did not relate to compassion levels. The numbers of people in these categories were small and we did not measure somethy or verify these diagnoses. However, there does not seem to be strong support for the idea that experiencing significant mental distress encourages compassion (for e.g., Gleichgerricht and Decety 2010). Exphaps for some, mental distress acts like life events and resilience to make the more willing to help, but in others who are more severely affected by the deficits in motivation and chain on psychological resources that accompany repression, arxiety, and stress, compassional responding is too difficult. Future work should examine how severity of current psychological distress relates to compassion.

There are several limitations to this study. The design of the SAGE struly, however, involves inferences of causality cannot be made. The design of the SAGE struly, however, involves yearly follow-up assessments which will allow us to examine causal medictors of change in compassion within individuals in future studies. Furthermore, while the compassion scale we used in this study was designed to measure complission, some of the queetions also asked about "feelings toward" others and the instrument is likely to also measure an individual's self-assessment of empathy. Therefore, we are unable to report with certainty whether our results are solely specific to compassion or wholic, they represent a combination of compassion and empathy. In future studies, we plan to measure empt thy and compassion with other suitable instruments and be navioral scenarios, to explore more care in the Gobolist a self-report measure of compassion, and outside informant rations of the participants compassion were not obtained, which is another limitation. Future studies would benefit

from having family members or cross rriends complete the SCBCS about the participant to see if difference, in salf-report arom others emerge. Finally, expanding the age tange to include younger adults would enhance the ability to examine age-related differences in relationships with compassion.

#### Conclusion

Older adults are often in a unione position to contribute to the greater good given their amass of resources, including life experience. Than ial resources, greater availability of time to spend on helping behaviors, and a greater value of generativity and affiliation in late life (Harlow and Cantor 1996). Understanding why older adults differ in their level compassion is complicated, as the human ampathic experience and response is unique for each individual (Kerem, et al. 2001). Our findings indicate several factors -- gender, stressful life events, and resilience — that should be examined further. In order to improve HRQoL among older adults, interventions should be tested that capitalize on associations between resilience and contrassion, either by promoting caring acts or by fostering resilience. Stressful life ever to in late life are inevitable and yet may be able to be capitalized upon as opportunities for personal growth and social mastery.

# Key Points

The personal relationships, yet lime is known about what contributes to compassion in late life. 2) In a large sample of relatively healthy community-dwelling older adults, smale gender, greate resilience, and more chessful life events were related to higher self-reported levels in compassion in both exploratory and confirmatory analyses. Other temographic factors and contional functioning (e.g., depression, anxiety, perceived stress) did not contribute to the mode'. 3) Older women report more compassion than the men. In addition, resilience and significant life, vents, independently, appear to facilitate a desire to help others, while current stress and past and present emotional functioning are less relevant.

#### Table 1

Santa Clara Brief Compa. sion Scale (Hwang, Flante, & Lackey, 2008).

When I he ir about some (a strange) going arough a difficult time, I hel a great deal of compassion for him or her.

- I tend Sieel comparsion for people, even though I do not know them.
- 3 One of the activities the provide me with the most recanning to my life is helping others in the world when they need help.
- 4 I would ather engage in actions that help others, even though the various strangers, than engage in actions that would help me.
- 5 I ten have tender feelings toward people (strangers) when they seem to be in need

Note. Responses made on a scale ranging from 1=not at all true of me to 7=11.1 y true of me

Table 2
Punographic and Sample Characteristics of Participants.

	Sa mple 1 (n=650)	Sample 2 (n=356)
De nographic Characteristics		
Age 'year')	77.2 (12.1)	77.5 (12.3)
Sex (% female)	48.2	49.2
Race/Ethnici <sup>+</sup> , (% Car. casian)	S1.1	80.1
Marital Status (% Presently Married or Living in a Marriag Like Relationship)	40 -	53.9
Income (%).		
\$0-\$34,999	2 0.6	24.1
