In this review we discuss the localization and function of the known subtypes of calcium/calmodulin dependent protein kinase II $\delta$  (CaMKII $\delta$ ) and their role in cardiac physiology and pathophysiology. The CaMKII holoenzyme is comprised of multiple subunits that are encoded by four different genes called CaMKII $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$ . While these four genes have a high degree of sequence homology, they are expressed in different tissues. CaMKII $\alpha$  and  $\beta$  are expressed in neuronal tissue while  $\gamma$  and  $\delta$  are present throughout the body, including in the heart. Both CaMKII $\gamma$  and  $\delta$  are alternatively spliced in the heart to generate multiple subtypes. CaMKII $\delta$  is the predominant cardiac isoform and is alternatively spliced in the heart to generate the CaMKII $\delta_B$  subtype or the slightly less abundant  $\delta_C$  subtype. The CaMKII $\delta_B$  mRNA sequence contains a 33bp insert not present in  $\delta_C$  that codes for an 11-amino acid nuclear localization sequence. This review focuses on the localization and function of the CaMKII $\delta$  subtypes  $\delta_B$  and  $\delta_C$  and the role of these subtypes in arrhythmias, contractile dysfunction, gene transcription, and the regulation of Ca<sup>2+</sup> handling.

## EXPRESSION AND LOCALIZATION

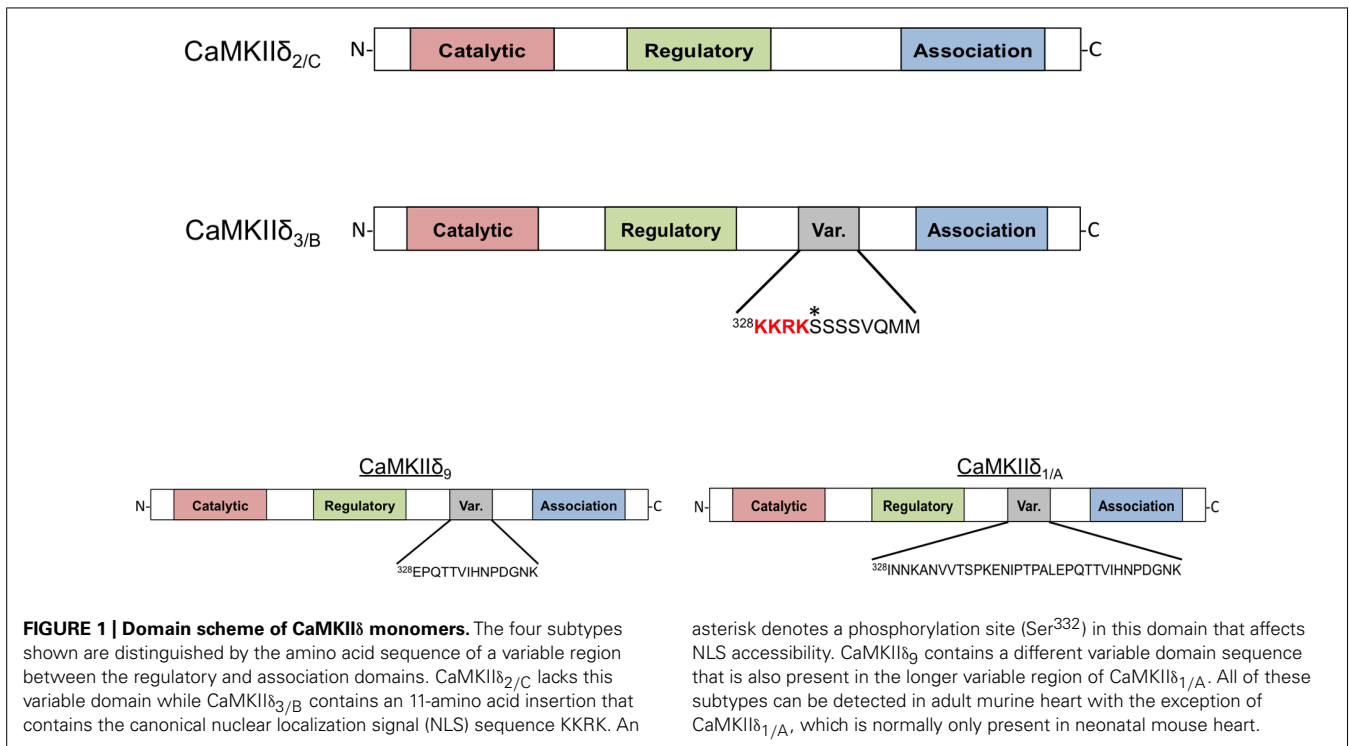

Calcium/calmodulin dependent protein kinase II (CaMKII) is a multimeric enzyme consisting of distinct subunits encoded by four different genes known as CaMKII $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$ . These genes have a high degree of sequence homology but show differential tissue expression. CaMKII $\alpha$  and  $\beta$  are predominantly expressed in neuronal tissue while  $\gamma$  and  $\delta$  are present throughout the body, including the heart (Bennett et al., 1983; Tobimatsu and Fujisawa, 1989). CaMKII $\delta$  is the predominant cardiac isoform and is alternatively spliced to generate multiple subtypes (Edman and Schulman, 1994).

Schworer et al. (1993) were the first to demonstrate that there are different subtypes of CaMKII $\delta$  expressed in various tissues. The authors reported four distinct proteins with differential expression patterns and named them CaMKII $\delta_{1-4}$ . CaMKII $\delta_2$ , and CaMKII $\delta_3$  were shown to be identical except for the insertion of an 11-amino acid sequence in the variable domain of CaMKII $\delta_3$ , the more abundant of the two subtypes in the heart (Schworer et al., 1993). Around the same time, Edman and Schulman (1994) identified these same CaMKII $\delta$  subtypes in rat heart and characterized their catalytic activity and regulation by calcium-liganded calmodulin (Ca<sup>2+</sup>/CaM). They refer to the predominant cardiac subtypes as CaMKII $\delta_B$  and CaMKII $\delta_C$  (the convention that will be used in this review), which correspond to the  $\delta_3$  and  $\delta_2$  subtypes, respectively. The structure of these proteins is shown in **Figure 1**. CaMKII $\delta_B$  and  $\delta_C$  possess similar catalytic activity and sensitivity to Ca<sup>2+</sup>/CaM. Furthermore, both subtypes can undergo autophosphorylation and acquire a similar degree of Ca<sup>2+</sup>-independent or autonomous activity (Edman and Schulman, 1994). In the years that followed, seven additional splice variants of the CaMKII $\delta$  gene, referred to as CaMKII $\delta_{5-11}$ , were identified. Only one of these, CaMKII $\delta_9$ , is

expressed in the adult heart (**Figure 1**; Mayer et al., 1994, 1995; Hoch et al., 1998, 1999).

The 11-amino acid insert in CaMKII $\delta_B$  (<sup>328</sup>KKRKSSSSVQMM) is also present in some splice variants of CaMKII $\alpha$  and  $\gamma$ ; this conservation suggests an important function (Schworer et al., 1993). Srinivasan et al. (1994) showed that when constructs of CaMKII $\delta_B$  are transfected into fibroblasts the expressed protein is localized to the nucleus. This is not the case for constructs of CaMKII $\delta_C$ , implying that the additional amino acid sequence present in CaMKII $\delta_B$  is responsible for nuclear localization (Srinivasan et al., 1994). A similar differential localization pattern was also observed when CaMKII $\delta$  subtypes were expressed neonatal rat ventricular myocytes (NRVMs; Ramirez et al., 1997). Further studies showed that the 11-amino acid insert in CaMKII $\delta_B$  can confer nuclear localization when inserted into the variable domain of CaMKII $\alpha$  and that mutagenesis of the first two lysines in the insert abrogates the nuclear localization of these constructs. Thus it is widely accepted that the CaMKII $\delta_B$  variable domain contains a nuclear localization signal (NLS).

CaMKII heteromultimerization is permissive in that the CaMKII holoenzyme can include subunits from multiple CaMKII genes and multiple splice variants of those genes (Bennett et al., 1983; Yamauchi et al., 1989). It seems likely that more than a single CaMKII $\delta$  subtype is present in a single CaMKII $\delta$  multimer and accordingly the ratio of  $\delta_B$  to  $\delta_C$  in a multimer could regulate the localization of the holoenzyme. This has been demonstrated experimentally. When CaMKII $\delta_B$  and  $\delta_C$  are cotransfected into fibroblasts or NRVMs, the localization of the expressed protein can be shifted in accordance with the ratio of the expressed CaMKII $\delta$  subtypes, i.e., highly expressed  $\delta_C$  sequesters  $\delta_B$  in the cytosol and blocks its nuclear localization (Srinivasan et al., 1994; Ramirez et al., 1997). The opposite is also true: high relative expression

of  $\delta_B$  can localize  $\delta_C$  to the nucleus. While not well appreciated, CaMKII $\delta_B$  localization can also be regulated by phosphorylation. A serine (Ser<sup>332</sup>) immediately adjacent to the NLS of CaMKII $\delta_B$  was shown to be a site of phosphorylation by CaMKI and CaMKIV *in vitro*. Phosphorylation prevents association of  $\delta_B$  with the NLS receptor m-pendulin and thus limits localization of CaMKII $\delta_B$  to the nucleus (Heist et al., 1998). Remarkably this mode of regulation is also seen when the NLS is moved from the middle of the protein to the N-terminus, suggesting that conformational changes are not required for phosphorylation to block the NLS.

Relative expression of CaMKII $\delta$  subtypes is altered during cardiomyocyte differentiation and maturation and in association with the development of heart failure and ischemia/reperfusion (I/R) injury (Hoch et al., 1998, 1999; Colomer et al., 2003; Peng et al., 2010). In humans CaMKII $\delta_B$  mRNA is selectively upregulated during heart failure (Hoch et al., 1999). The altered expression of particular subtypes suggests the possibility of a regulated process governing CaMKII $\delta$  mRNA splicing because transcriptional regulation would not be expected to alter the ratio of CaMKII $\delta$  subtypes. Alternative splicing factor/pre-mRNA-splicing factor SF2 (ASF/SF2) was initially described by Krainer and Maniatis (1985) and subsequently mice lacking ASF/SF2 expression were demonstrated to have incomplete processing of CaMKII $\delta$  mRNA (Krainer and Maniatis, 1985; Xu et al., 2005). Specifically, enhanced expression of the  $\delta_A$  subtype [ $\delta_1$  in the nomenclature of Schworer et al. (1993)] was observed while expression of CaMKII $\delta_B$  and  $\delta_C$  was diminished. **Figure 1** also depicts the structure of the  $\delta_A$  subtype, which is expressed in the fetal heart. ASF/SF2 can be regulated by phosphorylation. Protein kinase A (PKA)-mediated ASF/SF2 phosphorylation has been correlated with alternative splicing of CaMKII $\delta$  in heart and brain (Gu et al.,

2011). Additionally, regulation of ASF/SF2 by Protein phosphatase 1  $\gamma$  (PP1 $\gamma$ ) has been demonstrated to affect CaMKII $\delta$  splicing (Huang et al., 2013). CaMKII $\delta_A$  expression is increased in models of isoproterenol-induced cardiac hypertrophy and thus regulation of CaMKII $\delta$  splicing by PKA and PP1 $\gamma$  may be relevant in the context of chronic  $\beta$ -adrenergic stimulation (Li et al., 2011). The RNA binding proteins Fox 1 (RFX1) and 2 (RFX2) collaborate with ASF/SF2 to induce proper CaMKII $\delta$  splicing (Han et al., 2011) and factors that regulate these proteins could also influence the expression of CaMKII $\delta$  subtypes. Thus, CaMKII $\delta$  splicing is a dynamic and regulated process. The role of this system in the heart has not been extensively explored but could be of major importance since regulation of CaMKII $\delta$  splicing may account for altered subtype expression and CaMKII $\delta$  signaling in physiological and pathophysiological settings.

### CaMKII $\delta_B$ TRANSGENIC MICE

The differential localization and function of CaMKII $\delta$  subtypes could be of considerable importance to understanding the role of this enzyme in normal physiology and disease states. Early studies demonstrated that expression of CaMKII $\delta_B$  in NRVMs induced atrial natriuretic factor (ANF) expression and led to increased myofilament organization, both hallmarks of cardiac hypertrophy, while expression of CaMKII $\delta_C$  did not (Ramirez et al., 1997). This finding suggested that nuclear CaMKII $\delta$  localization is required to regulate gene expression. Consistent with this notion are data indicating that CaMKII $\delta_B$  signaling activates several transcription factors including myocyte enhancer factor 2 (MEF2), GATA4, and heat shock factor 1 (HSF1; Little et al., 2009; Lu et al., 2010; Peng et al., 2010). The significance of the hypertrophic responses elicited by  $\delta_B$  *in vitro* was explored further

by generation of CaMKII $\delta_B$  transgenic (TG) mice (Zhang et al., 2002). These animals, which overexpress  $\delta_B$  under the control of the cardiac-specific  $\alpha$ -myosin heavy chain ( $\alpha$ -MHC) promoter, demonstrate the enhanced expression of hypertrophic markers observed in NRVMs expressing CaMKII $\delta_B$ . CaMKII $\delta_B$ TG animals develop hypertrophy and moderate cardiac dysfunction by 4 months of age. Thus, CaMKII $\delta_B$  expression appears to be sufficient to induce cardiac hypertrophy. Surprisingly, despite the increased CaMKII activity in the CaMKII $\delta_B$ TG mouse heart, phosphorylation of the canonical cardiac CaMKII substrate phospholamban (PLN) at its CaMKII site (Thr<sup>17</sup>) was not increased but rather was decreased relative to WT mice. PLN phosphorylation at the PKA site (Ser<sup>16</sup>) was similarly reduced. These data were related to increases in phosphatase activity (Zhang et al., 2002), but also implied that CaMKII $\delta_B$  did not lead to robust phosphorylation of PLN. A subsequent paper that examined CaMKII $\delta_B$ TG animals at a younger age to avoid changes in phosphatase activity confirmed that phosphorylation of PLN and another cardiac CaMKII substrate, the cardiac ryanodine receptor (RyR2), was not increased by cardiac CaMKII $\delta_B$  expression (Zhang et al., 2007). This finding is consistent with a predominantly nuclear localization and function of the  $\delta_B$  subtype.

CaMKII $\delta_B$  has also been suggested to regulate expression of the Na<sup>+</sup>/Ca<sup>2+</sup> exchanger (NCX1) during the development of cardiac dysfunction following trans-aortic constriction (TAC; Lu et al., 2011). The conclusion that  $\delta_B$  was the subtype involved in NCX1 regulation relied on the use of a constitutively active construct of CaMKII $\delta_B$  in which a Thr to Asp mutation (T287D) simulates autophosphorylation. Interestingly, the authors found that this construct was excluded from the nucleus (Lu et al., 2010). This differs from the localization pattern described above (Srinivasan et al., 1994; Ramirez et al., 1997) and can be explained as a result of phosphorylation of Ser<sup>332</sup> in the 11-amino acid insert of  $\delta_B$  (Figure 1). The observation that mutation of Ser<sup>332</sup> to Ala restores nuclear localization of constitutively active CaMKII $\delta_B$  (Backs et al., 2006) confirms the role of this site in the cytosolic localization of the active construct. The possibility that phosphorylation of Ser<sup>332</sup> might regulate CaMKII $\delta_B$  localization in the intact heart has not been evaluated, but such a mechanism could contribute to the observation that CaMKII $\delta_B$  is found outside the nucleus even in the absence of multimerization with  $\delta_C$  (Mishra et al., 2011).

### CaMKII $\delta_C$ TRANSGENIC MICE

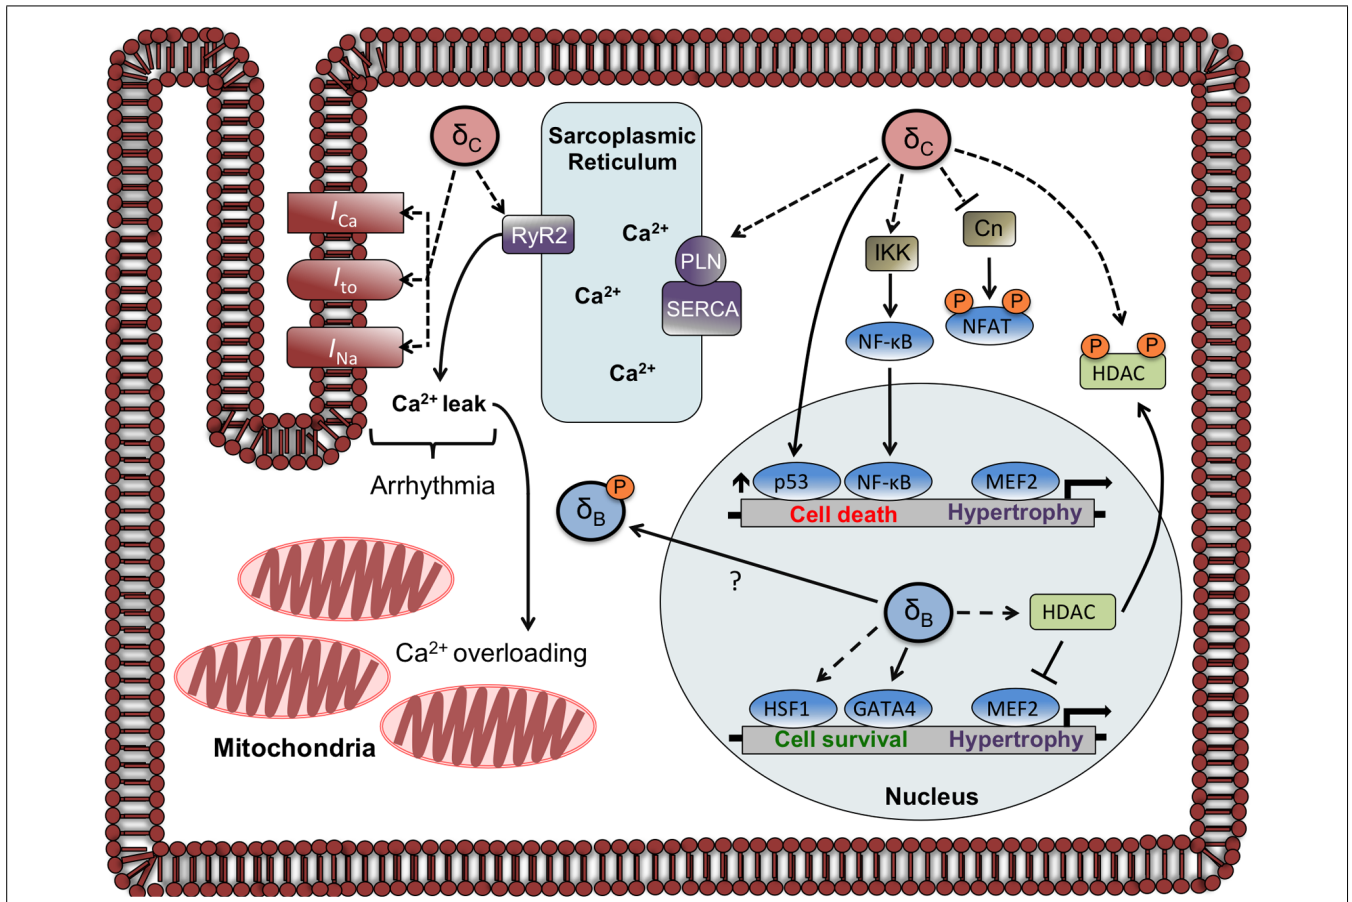

CaMKII $\delta_C$  transgenic mice have also been generated and demonstrate a strikingly different phenotype from mice that express CaMKII $\delta_B$ . While cardiac dysfunction is relatively moderate and takes months to develop in CaMKII $\delta_B$ TG animals, mice expressing  $\delta_C$  rapidly progress to heart failure and premature death (Zhang et al., 2003). By 6 weeks of age CaMKII $\delta_C$ TG animals display marked changes in cardiac morphology and by 12 weeks these animals display severe cardiac dysfunction and upregulation of hypertrophic genes.

### Ca<sup>2+</sup> HANDING AND ARRHYTHMIA

Expression of the cardiac sarco/endoplasmic reticulum Ca<sup>2+</sup>-ATPase (SERCA) is diminished in  $\delta_C$ TG mice as occurs in other models of heart failure. Since SERCA regulates Ca<sup>2+</sup> reuptake

into the sarcoplasmic reticulum (SR), this decrease would diminish SR Ca<sup>2+</sup> loading. On the other hand, the CaMKII $\delta_C$ TG mice show hyperphosphorylation of PLN at Thr<sup>17</sup>, which should improve SERCA function. In addition  $\delta_C$ TG animals display marked increases in phosphorylation of the RyR2, the channel through which Ca<sup>2+</sup> exits the SR. Taken together, these changes would predict dysregulation of SR Ca<sup>2+</sup> cycling and excitation–contraction coupling. This was substantiated in an accompanying paper that systematically analyzed and demonstrated dysregulation of cardiac Ca<sup>2+</sup> handling in mice expressing  $\delta_C$  (Maier et al., 2003). Specifically it was shown that SR Ca<sup>2+</sup> stores were depleted in myocytes from these animals, explaining the observation that isolated myocytes displayed diminished twitch shortening amplitude. Furthermore, Maier et al. (2003) showed that the frequency and duration of Ca<sup>2+</sup> sparks, or spontaneous intracellular Ca<sup>2+</sup>-release events, was markedly increased in myocytes from animals expressing  $\delta_C$ . Hyperphosphorylation of RyR2 by CaMKII $\delta_C$  was hypothesized to underlie the enhanced leak of Ca<sup>2+</sup> from the SR, and this was verified by the demonstration that acute inhibition of CaMKII in  $\delta_C$ TG myocytes rescues the altered Ca<sup>2+</sup> handling (Maier et al., 2003). In other experiments, acute expression of  $\delta_C$  in rabbit cardiomyocytes was shown to be sufficient to induce SR Ca<sup>2+</sup> sparks and diminished SR Ca<sup>2+</sup> loading (Kohlhaas et al., 2006). These findings imply that direct regulation of Ca<sup>2+</sup> handling targets including RyR2 by CaMKII $\delta_C$  can account for the dysregulation of Ca<sup>2+</sup> and contractile function seen in myocytes from  $\delta_C$ TG animals (Figure 2).

Dysregulation of excitation–contraction coupling by CaMKII is thought to contribute to arrhythmogenesis in a variety of contexts, as supported by the increased incidence of arrhythmogenic events in CaMKII $\delta_C$ TG mice (Anderson et al., 1998; Wu et al., 2002; Wagner et al., 2006). Overexpression of CaMKII $\delta_C$  not only induces more spontaneous arrhythmias but also enhances the susceptibility of mice to arrhythmogenic challenge by  $\beta$ -adrenergic stimulation. Sag et al. (2009) found that much of the proarrhythmogenic effects of  $\beta$ -adrenergic stimulation on SR Ca<sup>2+</sup> leak were significantly inhibited by treatment of myocytes with KN-93, an inhibitor of CaMKII. Furthermore the SR Ca<sup>2+</sup> leak induced by isoproterenol did not occur in myocytes from mice lacking CaMKII $\delta$ . These findings collectively implicate SR Ca<sup>2+</sup> leak as one of the key mechanisms in  $\delta_C$ -mediated arrhythmias (Sag et al., 2009). The notion that hyperphosphorylation of RyR2 at the CaMKII site (Ser<sup>2814</sup>) contributes to arrhythmias and SR Ca<sup>2+</sup> leak is supported by the finding that mutation of Ser<sup>2814</sup> to Ala (S2814A) blocks the ability of CaMKII to induce Ca<sup>2+</sup> sparks (van Oort et al., 2010). The autosomal dominant form of catecholaminergic polymorphic ventricular tachycardia (CPVT) can be caused by the RyR2 mutation R4496C and mice carrying this mutation are predisposed to arrhythmia and ventricular fibrillation. Enhanced CaMKII $\delta_C$  expression and activity are implicated in the etiology of premature death in CPVT as expression of CaMKII $\delta_C$  exacerbates the effects of the R4496C mutation (Dybikova et al., 2011). As mentioned earlier RyR2 Ser<sup>2814</sup> phosphorylation is increased by expression of CaMKII $\delta_C$  (but not by  $\delta_B$ ) *in vivo* (Zhang et al., 2007) and the effects of mutating this site (van Oort et al., 2010) emphasize the importance of RyR2 phosphorylation by CaMKII in SR Ca<sup>2+</sup> leak and arrhythmia.

**FIGURE 2 | Localization and function of CaMKII $\delta$  subtypes in the adult cardiomyocyte.** The circles labeled  $\delta_C$  and  $\delta_B$  represent CaMKII $\delta$  multimers that are composed primarily of  $\delta_C$  and  $\delta_B$  subunits, respectively. Documented phosphorylation events are indicated by dashed lines. CaMKII $\delta_C$  regulates  $Ca^{2+}$  homeostasis and currents involved in arrhythmogenesis through phosphorylation of  $Ca^{2+}$  handling proteins and channels. CaMKII $\delta_C$  can also affect gene transcription through direct and indirect mechanisms including

phosphorylation of NFAT and HDAC (sequestering them in the cytosol), increases in p53, and increased nuclear import of NF- $\kappa$ B. The CaMKII $\delta_B$  subtype has little effect on phosphorylation of  $Ca^{2+}$  handling proteins but increases gene expression through HDAC phosphorylation and nuclear export and activation of HSF1 and GATA4. A putative mechanism for  $\delta_B$  redistribution is depicted, showing  $\delta_B$  exiting or being excluded from the nucleus due to phosphorylation at a site (Ser<sup>332</sup>) adjacent to its NLS.

Other targets besides those at the SR may contribute to the arrhythmogenic phenotype of CaMKII $\delta_C$  mice. The cardiac sodium channel Nav1.5 is physically associated with CaMKII $\delta_C$  based on coimmunoprecipitation of these proteins from CaMKII $\delta_C$ TG animals and Nav1.5 is phosphorylated in mice expressing  $\delta_C$  (Wagner et al., 2006). CaMKII $\delta_C$  phosphorylates Nav1.5 at multiple sites and phosphorylation appears to elicit the loss-of-function changes in Nav1.5 gating that are observed in the context of CaMKII $\delta_C$  expression *in vitro* (Ashpole et al., 2012; Koval et al., 2012). Incomplete inactivation of Nav1.5 generates a late Na<sup>+</sup> current ( $I_{Na}$ ), which can prolong the duration of the action potential and contribute to arrhythmias. Additionally, increased  $I_{Na}$  can lead to Na<sup>+</sup>-overloading of the cardiomyocyte, which contributes to diminished diastolic contractile performance (Maltsev et al., 1998). Late  $I_{Na}$  is observed in CaMKII $\delta_C$ TG mice and inhibition of this current ameliorates arrhythmia and diastolic dysfunction in these animals (Sossalla et al., 2011). Modulation of  $I_{Na}$  therefore appears to contribute to the phenotype of CaMKII $\delta_C$  mice with respect

to arrhythmia development; additionally the CaMKII $\delta_C$  subtype likely regulates the L-type  $Ca^{2+}$  channel (LTCC) and repolarizing potassium currents ( $I_{to}$  and  $I_{K1}$ ; McCarron et al., 1992; Wagner et al., 2009). Thus, a multitude of mechanisms link CaMKII $\delta_C$  to arrhythmogenesis.

#### CONTRACTILE DYSFUNCTION

Arrhythmias may contribute to the premature death of CaMKII $\delta_C$ TG mice but there are also marked decreases in contractile function in these animals. Since alterations to cardiomyocyte  $Ca^{2+}$  handling are seen in relatively young CaMKII $\delta_C$ TG mice and precede the development of heart failure, it is possible that dysregulated  $Ca^{2+}$  homeostasis (specifically SR  $Ca^{2+}$  leak) is an initiating event in  $\delta_C$ -induced heart failure. Specifically, as a consequence of SR  $Ca^{2+}$  leak and SERCA downregulation, the SR  $Ca^{2+}$  load is diminished which would compromise contractile function. To determine whether diminished SR  $Ca^{2+}$  load is the primary causal event leading to contractile dysfunction and premature death in response to  $\delta_C$  overexpression, we crossed the

$\delta_C$ TG mice with mice in which the SERCA regulatory protein PLN was deleted (PLN-KO). Deletion of PLN in the context of  $\delta_C$  overexpression normalized SR  $Ca^{2+}$  levels and the contractile function of isolated myocytes was restored (Zhang et al., 2010). Remarkably the development of cardiac dysfunction *in vivo* was not rescued but instead was accelerated in the  $\delta_C$ TG/PLN-KO mice. In addition SR  $Ca^{2+}$  leak was enhanced. It was hypothesized that the increased SR  $Ca^{2+}$  load, in the context of RyR2 hyperphosphorylation, precipitated greater  $Ca^{2+}$  leak and further suggested that the accelerated development of cardiac dysfunction was due to mitochondrial  $Ca^{2+}$  overloading (Zhang et al., 2010). These observations and their interpretation places central importance on the  $Ca^{2+}$  leak elicited by  $\delta_C$ -mediated phosphorylation of RyR2 in the development of heart failure. Further support for this hypothesis comes from the finding that CaMKII $\delta$  knockout mice have attenuated contractile dysfunction in response to pressure overload induced by TAC and myocytes from these animals show diminished SR  $Ca^{2+}$  leak in response to TAC (Ling et al., 2009). Additionally, mice expressing the RyR2 S2814A mutation are protected from the development of heart failure in response to pressure overload (Respress et al., 2012) consistent with a critical role for CaMKII-mediated RyR2 phosphorylation. We recently crossed CaMKII $\delta_C$  mice with those expressing RyR2 S2814A; if the hypothesis is correct these mice will show diminished SR  $Ca^{2+}$  leak and improved contractile function when compared to CaMKII $\delta_C$ TG mice.

Another approach used to determine the role of RyR2 phosphorylation and SR  $Ca^{2+}$  leak in the phenotype of CaMKII $\delta_C$ TG mice was to cross the CaMKII $\delta_C$ TG mice with mice expressing SR-targeted autocalmitide-2-related inhibitory peptide (SR-AIP; Huke et al., 2011). AIP simulates the regulatory domain of CaMKII and inhibits the kinase, and SR-AIP mice have been shown to display diminished phosphorylation of CaMKII substrates at the SR (Ji et al., 2003). A reduction in the extent of PLN and RyR2 hyperphosphorylation observed in CaMKII $\delta_C$ TG mice was conferred by SR-AIP. There were associated changes in  $Ca^{2+}$  handling that indicated a modest improvement in SR  $Ca^{2+}$  leak. Despite the salutary effects of SR-AIP in cells from  $\delta_C$ TG mice, *in vivo* cardiac function was not improved. One possible explanation for these findings is that the degree of inhibition of RyR2 phosphorylation conferred by SR-AIP was insufficient to prevent the effects of CaMKII $\delta_C$  overexpression. Alternatively, while  $\delta_C$ -mediated phosphorylation of targets at the SR including RyR2 and PLN is of considerable consequence, targets of CaMKII elsewhere in the cell may also contribute to the pathogenesis of cardiac dysfunction induced by CaMKII $\delta_C$ .

Mitochondrial  $Ca^{2+}$  is elevated in mice overexpressing  $\delta_C$  in the context of intact SR  $Ca^{2+}$  load (Zhang et al., 2010) and increases in mitochondrial  $Ca^{2+}$  are known to induce opening of the mitochondrial permeability transition pore (MPTP) and cell death (Halestrap and Davidson, 1990). Considering the central importance of mitochondria in the regulation of cell death and of cell death in the development of heart failure (Wencker et al., 2003), any pathway by which CaMKII $\delta_C$  induces mitochondrial  $Ca^{2+}$  overloading and subsequent loss of mitochondrial integrity would be predicted to contribute to the development of contractile dysfunction and heart failure. To test the role of

mitochondrial dysregulation in the cardiomyopathy that develops in  $\delta_C$ TG animals, CaMKII $\delta_C$ TG mice were crossed with mice lacking expression of cyclophilin D, a mitochondrial protein required for the formation of the MPTP. The ability of high  $Ca^{2+}$  to induce swelling of isolated mitochondria, an index of MPTP opening, was impaired in the CaMKII $\delta_C$ TG mice lacking cyclophilin D, but development of dilated cardiomyopathy and premature death of these mice was not diminished. Indeed these responses were exacerbated when compared to  $\delta_C$ TG mice with intact cyclophilin D expression. The authors suggest that cyclophilin D may actually play a beneficial role in stress responses, as they observed that TAC-induced heart failure development was also made more severe by genetic deletion of cyclophilin D (Elrod et al., 2010). However, CaMKII $\delta_C$  is found at mitochondria and a recent seminal study by Joiner et al. (2012) identified the mitochondrial  $Ca^{2+}$  uniporter (MCU) as a potential target of CaMKII (Mishra et al., 2011; Joiner et al., 2012). While phosphorylation of the MCU by CaMKII was not shown to occur *in vivo*, a CaMKII-dependent change in the function of the MCU was evidenced by data demonstrating that a CaMKII inhibitory peptide targeted to the mitochondria diminished mitochondrial  $Ca^{2+}$  uptake and inhibited apoptosis in mice subjected to myocardial infarction and I/R injury.

### CaMKII $\delta$ SUBTYPES IN GENE TRANSCRIPTION

The discussion above, and indeed most of the literature, considers the role of CaMKII $\delta$ -mediated phosphorylation and regulation of  $Ca^{2+}$  handling proteins and ion channels. Chronic elevations in CaMKII $\delta$  expression and activity are observed in humans with heart failure (Hoch et al., 1999) and these long-term changes are likely to elicit altered gene expression. As discussed earlier, CaMKII $\delta_B$  induces the expression of hypertrophic genes in myocytes and transgenic mice, consistent with its primarily nuclear localization (Ramirez et al., 1997; Zhang et al., 2002). Other work showed that the CaMKII $\delta_B$  subtype is required for GATA-4 binding to the B cell lymphoma 2 (Bcl-2) promoter and subsequent gene expression (Little et al., 2009). Furthermore, CaMKII $\delta_B$  was shown to phosphorylate the transcription factor HSF1 thereby increasing its transcriptional activity (Peng et al., 2010). Taken together, these observations imply that it is the CaMKII $\delta_B$  subtype that regulates gene expression as a result of its actions in the nucleus.

It is not necessarily the case, however, that gene regulation requires CaMKII $\delta$  to be localized to the nuclear compartment. Despite its primarily cytosolic localization, CaMKII $\delta_C$  overexpressed in mouse heart increased phosphorylation of histone deacetylase 4 (HDAC4), resulting in activation of the transcription factor MEF2 (Zhang et al., 2007). CaMKII $\delta_C$  has also been demonstrated to regulate nuclear localization of nuclear factor of activated T cells (NFATs) in NRVM. The ability of CaMKII $\delta_C$  to decrease nuclear NFAT was blocked by coexpression of a dominant-negative construct of CaMKII $\delta_C$  and was shown to be elicited by phosphorylation and inhibition of the  $Ca^{2+}$ /CaM dependent phosphatase calcineurin (Cn; MacDonnell et al., 2009), presumably in the cytosol. Alteration of  $Ca^{2+}$  homeostasis by cytosolic CaMKII $\delta_C$  expression may indirectly affect gene expression and additionally the constitutively active CaMKII $\delta_B$  utilized in the studies discussed

above (Lu et al., 2011) is cytosolic and yet regulates expression of NCX1.

Regulation of gene expression by CaMKII $\delta_B$  has been demonstrated to promote cardiomyocyte survival while the opposite is true for CaMKII $\delta_C$ . CaMKII $\delta_B$  was shown to protect cardiomyocytes from doxorubicin-induced cell death via transcriptional upregulation of Bcl-2 (Little et al., 2009). Along similar lines, CaMKII $\delta_B$  contributes to cardioprotection from H<sub>2</sub>O<sub>2</sub> by increasing inducible heat shock protein 70 (iHSP70) expression (Peng et al., 2010). Conversely, CaMKII $\delta_C$  activation is implicated in cell death elicited by a variety of stimuli (Zhu et al., 2007). It has been suggested that CaMKII $\delta_C$  (but not  $\delta_B$ ) upregulates the proapoptotic transcription factor p53 (Toko et al., 2010), and recent work from our laboratory demonstrates that CaMKII $\delta_C$  expression in NRVMs activates the proinflammatory transcription factor nuclear factor  $\kappa$ B (NF- $\kappa$ B; Ling et al., 2013). We demonstrated that CaMKII $\delta_C$  increased phosphorylation of I $\kappa$ B Kinase (IKK) and since IKK activation can also upregulate p53 (Jia et al., 2013), this pathway may contribute to the proapoptotic response reported by Toko et al. (2010).

## FUTURE DIRECTIONS

There is compelling evidence that the CaMKII $\delta_B$  and  $\delta_C$  subtypes differentially regulate cardiomyocyte Ca<sup>2+</sup> handling and survival *in vitro*. Whether this occurs *in vivo* under physiological or pathophysiological conditions, and whether  $\delta_B$  and  $\delta_C$  subserve different functions based on their localization or selective activation, remains to be determined.

It seems likely that the relative levels of endogenous  $\delta_B$  and  $\delta_C$  determine localization and could therefore impact CaMKII $\delta$  signaling. Hypothetically, a selective increase in CaMKII $\delta_C$  would result in accumulation of cytosolic CaMKII $\delta$  and depletion of nuclear CaMKII $\delta$  while a selective increase in CaMKII $\delta_B$  would have the opposite effect. CaMKII $\delta$  redistribution in this manner may contribute to the phenotype of mice that overexpress  $\delta_B$  and  $\delta_C$  and importantly there are changes in the relative expression of  $\delta_B$  and  $\delta_C$  in models of heart failure and I/R injury. In both models  $\delta_C$  expression is enhanced relative to that of  $\delta_B$  (Zhang et al., 2003; Peng et al., 2010). It is not known how this occurs but it is of interest to postulate that in heart failure and during I/R regulation of CaMKII $\delta$  splicing is altered. ASF/SF2 and RBFOX1/2 regulate the splicing of the CaMKII $\delta$  gene and thus expression of  $\delta_B$  and  $\delta_C$ , but whether changes in splicing occur in and contribute to the development of heart failure or I/R injury remains to be determined. It is likely that the increased  $\delta_C$  expression observed in these models is pathogenic.

While CaMKII $\delta_B$  contains an NLS, this subtype is not completely sequestered in the nucleus (Mishra et al., 2011). As mentioned previously the NLS within the variable domain of  $\delta_B$  can be regulated by phosphorylation, which prevents nuclear localization. This type of regulation could be of considerable importance since the nuclear localization of  $\delta_B$  appears to correlate with enhanced expression of protective genes and cell survival while cytosolic localization does not (Little et al., 2009; Peng et al., 2010; Lu et al., 2011).

Of additional interest is the neglected CaMKII $\delta_9$ . The pioneering work of (Hoch et al., 1998; Mayer et al., 1995) identified

$\delta_9$  as one of the three subtypes of CaMKII $\delta$  in the adult heart and showed that it is expressed at similar levels to those of CaMKII $\delta_B$ .  $\delta_9$  contains a sequence (<sup>328</sup>EPQTTVIHNPDGNK) not present in  $\delta_B$  or  $\delta_C$  and thus may possess unique properties that merit further investigation, as the function and localization of  $\delta_9$  *in vivo* has not been explored. Along similar lines, CaMKII $\delta_A$  expression is increased in a model of cardiac hypertrophy (Li et al., 2011), but the possibility that this splice variant is upregulated in and contributes to cardiovascular disease has not been investigated.

## ACKNOWLEDGMENTS

The authors would like to thank Stephanie Dusaban B.A. for her help regarding the figures.
