Christopher et al. compares 15 acute myeloid leukemia patients who relapsed after allogeneic hematopoietic stem-cell transplantation (allo-HSCT) to 20 patients who relapsed after chemotherapy. All patients had exome sequencing on paired samples obtained at initial presentation and at relapse.\(^1\) RNA sequencing was performed on a subgroup. The authors’ note relapse after allo-HSCT is not associated with acquisition of unique mutations. However, RNA sequencing revealed dysregulation of immune pathways. One patient acquired \(PDL1/PDL2\) gene amplification after allo-HSCT. The authors conclude that this finding is not a common mechanism of immune escape in AML after transplantation. We would caution the authors’ regarding their conclusion as this is a small sample size (15 patients). A prior study revealed no \(PDL1/PDL2\) amplifications amongst 1273 AMLs.\(^2\) Further studies are needed to determine if \(PDL1/PDL2\) amplification is only seen in AML patients who relapse after allo-HSCT.

Hodgkin lymphoma is exquisitely sensitive to PD1 blockade due to the near-universal presence of \(PDL1/PDL2\) amplification.\(^3\) Whether or not patients with AML who relapse after allo-HSCT and show \(PDL1/PDL2\) amplification respond to immunotherapy warrants investigation.
