March 26, 2018
Abstract

UPC++ is a C++11 library providing classes and functions that support Partitioned Global Address Space (PGAS) programming. We are revising the library under the auspices of the DOE’s Exascale Computing Project, to meet the needs of applications requiring PGAS support. UPC++ is intended for implementing elaborate distributed data structures where communication is irregular or fine-grained. The UPC++ interfaces for moving non-contiguous data and handling memories with different optimal access methods are composable and similar to those used in conventional C++. The UPC++ programmer can expect communication to run at close to hardware speeds.

The key facilities in UPC++ are global pointers, that enable the programmer to express ownership information for improving locality, one-sided communication, both put/get and RPC, futures and continuations. Futures capture data readiness state, which is useful in making scheduling decisions, and continuations provide for completion handling via callbacks. Together, these enable the programmer to chain together a DAG of operations to execute asynchronously as high-latency dependencies become satisfied.

Acknowledgments

This research was supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. Department of Energy Office of Science and the National Nuclear Security Administration.

Early development of UPC++ was supported by the Director, Office of Science, Office of Advanced Scientific Computing Research, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

Chapter 1

Overview and Scope

1.1 Preliminaries

UPC++ is a C++11 library providing classes and functions that support Partitioned Global Address Space (PGAS) programming. The project began in 2012 with a prototype AKA V0.1, described in the IPDPS14 paper by Zheng et al. [3]. This document describes a production version, V1.0, with the addition of several features and a new asynchronous API.

Under the PGAS model, a distributed memory parallel computer is viewed abstractly as a collection of processing elements, an individual computing resource, each with local memory (see Fig. 1.1). A processing element is called a rank in UPC++. The execution model of UPC++ is SPMD and the number of UPC++ ranks is fixed during program execution.

As with conventional C++ threads programming, ranks can access their respective local memory via a pointer. However, the PGAS abstraction supports a global address space, which is allocated in shared segments distributed over the ranks. A global pointer enables the programmer to move data in the shared segments between ranks as shown in Fig. 1.1. As with threads programming, references made via global pointers are subject to race conditions, and appropriate synchronization must be employed.

UPC++ global pointers are fundamentally different from conventional C-style pointers. A global pointer refers to a location in a shared segment. It cannot be dereferenced using the * operator, and it does not support conversions between pointers to base and derived types. It also cannot be constructed by the address-of operator. On the other hand, UPC++ global pointers do support some properties of a regular C pointer, such as pointer arithmetic and passing a pointer by value.

Notably, global pointers are used in one-sided communication: bulk copying operations (RMA) similar to memcpy but across ranks (Ch. 8), and in Remote Procedure Calls.
(RPC, Ch. 9). RPC enables the programmer to ship functions to other ranks, which is useful in managing irregular distributed data structures. These ranks can push or pull data via global pointers. Futures and Promises (Ch. 5) are used to determine completion of communication or to provide handlers that respond to completion. Wherever possible, UPC++ will engage low-level hardware support for communication and this capability is crucial to UPC++’s support of lightweight communication.

UPC++’s design philosophy is to provide “close to the metal performance.” To meet this requirement, UPC++ imposes certain restrictions. In particular, non-blocking communication is the default for nearly all operations defined in the API, and all communication is explicit. These two restrictions encourage the programmer to write code that is performant and make it more difficult to write code that is not. Conversely, UPC++ relaxes some restrictions found in models such as MPI; in particular, it does not impose an in-order delivery requirement between separate communication operations. The added flexibility increases the possibility of overlapping communication and scheduling it appropriately.

UPC++ also avoids non-scalable constructs found in models such as UPC. For example, it does not support shared distributed arrays or shared scalars. Instead, it provides distributed objects, which can be used to similar ends (Ch. 13). Distributed objects are useful in solving the bootstrapping problem, whereby ranks need to distribute their local copies of global pointers to other ranks. Though UPC++ does not directly provide multidimensional arrays, applications that use UPC++ may define them. To this end, UPC++ supports non-contiguous data transfers: vector, indexed, and strided data (Ch. 14).

Because UPC++ does not provide separate concurrent threads to manage progress, UPC++ must manage all progress inside active calls to the library. UPC++ has been designed with a policy against the use of internal operating system threads. The strengths of this approach are improved user-visibility into the resource requirements of UPC++ and better interoperability with software packages and their possibly restrictive threading requirements. The consequence, however, is that the user must be conscientious to balance the need for making progress against the application’s need for CPU cycles. Chapter 10 discusses subtleties.
of managing progress and how an application can arrange for UPC++ to advance the state
of asynchronous communication.

Ranks may be grouped into teams (Ch. 12). A team can participate in collective
operations. Teams are also the interface that UPC++ uses to propagate the shared memory
capabilities of the underlying hardware and operating system and can let a programmer
reason about hierarchical processor-memory organization, allowing an application to reduce
its memory footprint. UPC++ supports atomic operations, currently on remote 32-bit and
64-bit integers. Atomics are useful in managing distributed queues, hash tables, and so
on. However, as explained in the discussion below on UPC++’s memory model, atomics are
split phased and not handled the same way as they are in C++11 and other libraries.

UPC++ will support memory kinds (Ch. 15), whereby the programmer can identify re-
gions of memory requiring different access methods or having different performance prop-
erties, such as device memory. Since memory kinds will be implemented in Year 2, we will
defer their detailed discussion until next year.

### 1.2 Execution Model

The UPC++ internal state contains, for each rank, internal unordered queues that are man-
aged for the user. The UPC++ progress engine scans these queues for operations initiated by
this rank, as well as externally generated operations that target this rank. The progress en-
geine is active inside UPC++ calls only and is quiescent at other times, as there are no threads
or background processes executing inside UPC++. This passive stance permits UPC++ to be
driven by any other execution model a user might choose. This universality does place a
small burden on the user: calling into the progress function. UPC++ relies on the user to
make periodic calls into the progress function to ensure that UPC++ operations are com-
pleted. progress is the mechanism by which the user loans UPC++ a thread of execution
to perform operations that target the given rank. The user can determine that a specific
operation completes by checking the status of its associated future, or by attaching a
completion handler to the operation.

UPC++ presents a thread-aware programming model. It assumes that only one thread
of execution is interacting with any UPC++ object. The abstraction for thread-awareness
in UPC++ is the persona. A future produced by a thread of execution is associated with
its persona, and transferring the future to another thread must be accompanied by trans-
ferring the underlying persona. Each rank has a master persona, initially attached to the
thread that calls init. Some UPC++ operations, such as barrier, require a thread to have
exclusive access to the master persona to call them. Thus, the programmer is responsible
for ensuring synchronized access to both personas and memory, and that access to shared
data does not interfere with the internal operation of UPC++. 
1.3 Memory Model

The UPC++ memory model differs from that of C++11 (and beyond) in that all updates are split-phased: every communication operation has a distinct initiate and wait step. Thus, atomic operations execute over a time interval, and the time intervals of successive operations that target the same datum must not overlap, or a data race will result.

UPC++ differs from MPI in that it doesn’t guarantee in-order delivery. For example, if we overlap two successive RPC operations involving the same source and destination rank, we cannot say which one completes first.

1.4 Organization of this Document

This specification is intended to be a normative reference - a Programmer’s Manual is forthcoming. For the purposes of understanding the key ideas in UPC++, we recommend that the novice reader skip Chapter 10 (Progress) and the advanced topics related to futures, personas, and continuation-based communication.

The organization for the rest of the document is as follows. Chapter 2 discusses the process of starting up and closing down UPC++. Global pointers (Ch. 3) are fundamental to the PGAS model, and Chapter 4 discusses storage allocation. Since UPC++ supports asynchronous communication only, UPC++ provides futures and promises (Ch. 5) to manage control flow and completion. Chapters 8 and 9 describe the two forms of asynchronous one-sided communication, rput/rget and RPC, respectively. Chapter 10 discusses progress. Chapter 11 discusses atomic operations. Chapter 12 discusses teams, which are a means of organizing UPC++ ranks. Chapter 13 discusses distributed objects. Chapter 14 discusses non-contiguous data transfers. Chapter 15 discusses memory kinds.

1.5 Conventions

1. C++ language keywords are in the color mocha.

2. UPC++ terms are set in the color bright blue except when they appear in a synopsis framebox.

3. All functions are declared noexcept unless specifically called out.

4. All entities are in the upcxx namespace unless otherwise qualified.
1.6 Glossary

**Affinity.** A binding of each location in a shared segment to a particular rank (generally the rank which allocated that shared object). Every byte of shared memory has affinity to exactly one rank (at least logically).

**C++ Concepts.** E.g. TriviallyCopyable. This document references C++ Concepts as defined in the C++14 standard [2] when specifying the semantics of types. However, compliant implementations are still possible within a compiler adhering to the earlier C++11 standard [1].

**Collective.** A constraint placed on some language operations which requires evaluation of such operations to be matched across all ranks. The behavior of collective operations is undefined unless all ranks execute the same sequence of collective operations.

A collective operation need not provide any actual synchronization between ranks, unless otherwise noted. The collective requirement simply states a relative ordering property of calls to collective operations that must be maintained in the parallel execution trace for all executions of any valid program. Some implementations may include unspecified synchronization between ranks within collective operations, but programs must not rely upon the presence or absence of such unspecified synchronization for correctness.

**DefinitelySerializable.** (6) A C++ type that is either DefinitelyTriviallySerializable, or for which there is a user-supplied implementation of the visitor function `serialize`.

**DefinitelyTriviallySerializable.** (6) A C++ type that is either TriviallyCopyable and has no user-supplied implementation of the visitor function, or for which the `is_definitely_trivially_serializable` trait is specialized to have a member `value` that is true.

**Futures (and Promises)** (5) The primary mechanisms by which a UPC++ application interacts with non-blocking operations. The semantics of futures and promises in UPC++ differ from the those of standard C++. While futures in C++ facilitate communicating between threads, the intent of UPC++ futures is solely to provide an interface for managing and composing non-blocking operations, and they cannot be used directly to communicate between threads or ranks. A future is the interface through which the status of the operation can be queried and the results retrieved, and multiple future objects may be associated with the same promise. A future thus represents the consumer side of a non-blocking operation. A promise represents the producer side of the operation,
and it is through the promise that the results of the operation are supplied and its dependencies fulfilled.

**Global pointer.** (3) The primary way to address memory in a shared memory segment of a UPC++ program. Global pointers can themselves be stored in shared memory or otherwise passed between ranks and retain their semantic meaning to any rank.

**Local.** (12.2) Refers to an object or reference with affinity to a rank in the local team.

**Operation completion.** (7) The condition where a communication operation is complete with respect to the initiating rank, such that its effects are visible and that resources, such as source and destination memory regions, are no longer in use by UPC++.

**Persona.** (10.4) The abstraction for thread-awareness in UPC++. A UPC++ persona object represents a collection of UPC++-internal state usually attributed to a single thread. By making it a proper construct, UPC++ allows a single OS thread to switch between multiple application-defined roles for processing notifications. Personas act as the receivers for notifications generated by the UPC++ runtime.

**Private object.** An object outside the shared space that can be accessed only by the rank that owns it (e.g. an object on the program stack).

**Progress.** (10) The means by which the application allows the UPC++ runtime to advance the state of outstanding operations initiated by this or other ranks, to ensure they eventually complete.

**Rank.** An OS process that is a member of a UPC++ parallel job execution. UPC++ uses a SPMD execution model, and the number of ranks is fixed during a given program execution. The placement of ranks across physical processors or NUMA domains is implementation-dependent.

**Referentially transparent.** A routine that is is a pure function, where inputs alone determine the value returned by the function. For the same inputs, repeated calls to a referentially transparent function will always return the same result.

**Remote.** Refers to an object or reference whose affinity is not local to the current rank.

**Remote Procedure Call.** A communication operation that injects a function call invocation into the execution stream of another rank. These injections are one-sided, meaning the target rank need not explicitly expect the incoming operation or perform any specific action to receive it, aside from invoking UPC++ progress.
**Source completion.** The condition where a communication operation initiated by the current rank has advanced to a point where serialization of the local source memory regions for the operation has occurred, and the contents of those regions can be safely overwritten or reclaimed without affecting the behavior of the ongoing operation. Source completion does not generally imply operation completion, and other effects of the operation (e.g., updating destination memory regions, or delivery to a remote rank) may still be in-progress.

**Shared segment.** A region of storage associated with a particular rank that is used to allocate shared objects that are accessible by any rank.

**Team.** A UPC++ object representing an ordered set of ranks.

**Thread (or OS thread).** An independent stream of executing instructions with private state. A rank process may contain many threads (created by the application), and each is associated with at least one persona.

**Serializable.** (6) A C++ type that is either DefinitelySerializable or TriviallySerializable.

**TriviallySerializable.** (6) A C++ type that is valid to serialize by making a byte copy of an object.
Chapter 2

Init and Finalize

2.1 Overview

The `init` function must be called before any other UPC++ function can be invoked. This can happen anywhere in the program, so long as it appears before any UPC++ calls that require the library to be in an initialized state. The call is *collective*, meaning every process in the parallel job must enter this function if any are to participate in UPC++ operations. While `init` can be called more than once by each process in a program, only the first invocation will initialize UPC++, and the rest will merely increment the internal count of how many times `init` has been called. For each `init` call, a matching `finalize` call must eventually be made. `init` and `finalize` are not re-entrant and must be called by only a single thread of execution in each process. The thread that calls `init` has the *master persona* attached to it (see section 10.5.1 for more details of threading behavior). After the number of calls to `finalize` matches the number of calls to `init`, no UPC++ function that requires the library to be in an initialized state can be invoked until UPC++ is reinitialized by a subsequent call to `init`.

All UPC++ operations require the library to be in an initialized state unless otherwise specified, and violating this requirement results in undefined behavior. Member functions, constructors, and destructors are included in the set of operations that require UPC++ to be initialized, unless explicitly stated otherwise.

2.2 Hello World

A UPC++ installation should be able to compile and execute the simple *Hello World* program shown in Figure 2.1. The output of *Hello World*, however, is platform-dependent and may vary between different runs, since there is no synchronization to order the output between processes. Depending on the nature of the buffering protocol of `stdout`, output from
```cpp
#include <upcxx/upcxx.hpp>
#include <iostream>

int main(int argc, char *argv[])
{
    upcxx::init(); // initialize UPC++

    std::cout << "Hello World"
               << " ranks:" << upcxx::rank_n() // how many UPC++ ranks?
               << " my rank: " << upcxx::rank_me() // which rank am I?
               << std::endl;

    upcxx::finalize(); // finalize UPC++
    return 0;
}
```

Figure 2.1: HelloWorld.cpp program

different processes may even be interleaved.

## 2.3 API Reference

### void init();

**Preconditions:** Called collectively by all processes in the parallel job. Calling thread must have the master persona (§10.5.1) if UPC++ is in an already-initialized state.

If there have been no previous calls to `init`, or if all previous calls to `init` have had matching calls to `finalize`, then this routine initializes the UPC++ library. Otherwise, leaves the library’s state as is. Upon return, the calling thread will be attached to the master persona (§10.5.1).

*This function may be called when UPC++ is in the uninitialized state.*

### void finalize();

**Preconditions:** Called collectively by all processes in the parallel job. Calling thread must have the master persona (§10.5.1), and UPC++ must be in an already-initialized state.
If this call matches the call to `init` that placed UPC++ in an initialized state, then this call uninitializes the UPC++ library. Otherwise, this function does not alter the library’s state.

Before uninitializing the UPC++ library, `finalize` shall execute a (blocking) `barrier()` over team `world()`. If this call uninitializes the UPC++ library while there are any asynchronous operations still in-flight (after the barrier), behavior is undefined. An operation is defined as in-flight if it was initiated but still requires internal-level or user-level progress from any persona on any rank in the job before it can complete. It is left to the application to define and implement their own specific approach to ensuring quiescence of in-flight operations. A potential quiescence API is being considered for future versions and feedback is encouraged.

UPC++ progress level: user
Chapter 3

Global Pointers

3.1 Overview

The UPC++ global ptr is the primary way to address memory in a remote shared memory segment of a UPC++ program. The next chapter discusses how memory in the shared segment is allocated to the user.

As mentioned in Chapter 1, a global pointer is a handle that may not be dereferenced. This restriction follows from the design decision to prohibit implicit communication. Logically, a global pointer has two parts: a raw C++ pointer and an associated affinity, which is a binding of each location in a shared segment to a particular rank (generally the rank which allocated that shared object). In cases where the use of a global ptr executes in a rank that has direct load/store access to the memory of the global.ptr (i.e. is_local is true), we may extract the raw pointer component, and benefit from the reduced cost of employing a local reference rather than a global one. To this end, UPC++ provides the local() function, which returns a raw C++ pointer. Calling local() on a global.ptr that references an address in a remote shared segment results in undefined behavior.

Global pointers have the following guarantees:

1. A global_ptr<T> is only valid if it is the null global pointer, it references a valid object, or it represents one element past the end of a valid array or non-array object.

2. Two global pointers compare equal if and only if they reference the same object, one past the end of the same array or non-array object, or are both null.

3. Equality of global pointers corresponds to observational equality, meaning that two global pointers which compare equal will produce equivalent behavior when interchanged.

These facts become important given that UPC++ allows two ranks which are local to each other to map the same memory into their own virtual address spaces but possibly
with different virtual addresses. They also ensure that a global pointer can be viewed from any rank to mean the same thing without need for translation.

### 3.2 API Reference

```cpp
using intrank_t = /* implementation-defined */;
```

An implementation-defined signed integer type that represents a UPC++ rank ID.

```cpp
template<typename T>
struct global_ptr;
```

C++ Concepts: DefaultConstructible, TriviallyCopyable, TriviallyDestructible, EqualityComparable, LessThanComparable, hashable

UPC++ Concepts: DefinitelyTriviallySerializable

T must not have any cv qualifiers: `std::is_const<T>::value` and `std::is_volatile<T>::value` must both be false.

```cpp
template<typename T>
struct global_ptr {
    using element_type = T;
    // ...
};
```

Member type that is an alias for the template parameter T.

```cpp
template<typename T>
global_ptr<T>::global_ptr(T* ptr);
```

**Precondition:** `ptr` must be either null or an address in the shared segment (Ch. 4) of a rank in the local team (§12.2)

Constructs a global pointer corresponding to the given raw pointer. This constructor must be called explicitly.

**UPC++ progress level:** none

```cpp
template<typename T>
global_ptr<T>::global_ptr(std::nullptr_t = nullptr);
```

Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
CHAPTER 3. GLOBAL POINTERS

Constructs a global pointer corresponding to a null pointer.

This function may be called when UPC++ is in the uninitialized state.

UPC++ progress level: none

```cpp
template<typename T>
global_ptr<T>::~global_ptr();
```

Trivial destructor. Does not delete or otherwise reclaim the raw pointer that this global pointer is referencing.

This function may be called when UPC++ is in the uninitialized state.

UPC++ progress level: none

```cpp
template<typename T>
bool global_ptr<T>::is_local() const;
```

Returns whether or not the calling rank has load/store access to the memory referenced by this pointer. Returns true if this is a null pointer, regardless of the context in which this query is called.

UPC++ progress level: none

```cpp
template<typename T>
bool global_ptr<T>::is_null() const;
```

Returns whether or not this global pointer corresponds to the null value, meaning that it references no memory. This query is purely a function of the global pointer instance, it is not affected by the context in which it is called.

UPC++ progress level: none

```cpp
template<typename T>
T* global_ptr<T>::local() const;
```

Precondition: `this->is_local()`

Converts this global pointer into a raw pointer.

UPC++ progress level: none
template<typename T>
intrank_t global_ptr<T>::where() const;

Returns the rank in team world() with affinity to the T object pointed-to by this global pointer. The return value for where() on a null global pointer is an implementation-defined value. This query is purely a function of the global pointer instance, it is not affected by the context in which it is called.

UPC++ progress level: none

template<typename T>
global_ptr<T> global_ptr<T>::operator+(std::ptrdiff_t diff) const;
template<typename T>
global_ptr<T> operator+(std::ptrdiff_t diff, global_ptr<T> ptr);

template<typename T>
global_ptr<T>& global_ptr<T>::operator+=(std::ptrdiff_t diff);

Precondition: Either diff == 0, or the global pointer is pointing to the i'th element of an array of N elements, where i may be equal to N, representing a one-past-the-end pointer. At least one of the indices i+diff or i+diff-1 must be a valid element of the same array. A pointer to a non-array object is treated as a pointer to an array of size 1.

If diff == 0, returns a copy of the global pointer. Otherwise produces a pointer that references the element that is at diff positions greater than the current element, or a one-past-the-end pointer if the last element of the array is at diff-1 positions greater than the current.

operator+= modifies the global_ptr in-place and return a reference to itself after the operation.

These routines are purely functions of their arguments, they are not affected by the context in which they are called.

UPC++ progress level: none

template<typename T>
global_ptr<T> global_ptr<T>::operator-(std::ptrdiff_t diff) const;

template<typename T>
global_ptr<T>& global_ptr<T>::operator-=(std::ptrdiff_t diff);
Precondition: Either \( \text{diff} = 0 \), or the global pointer is pointing to the \( i \)th element of an array of \( N \) elements, where \( i \) may be equal to \( N \), representing a one-past-the-end pointer. At least one of the indices \( i - \text{diff} \) or \( i - \text{diff} - 1 \) must be a valid element of the same array. A pointer to a non-array object is treated as a pointer to an array of size 1.

If \( \text{diff} = 0 \), returns a copy of the global pointer. Otherwise produces a pointer that references the element that is at \( \text{diff} \) positions less than the current element, or a one-past-the-end pointer if the last element of the array is at \( \text{diff} + 1 \) positions less than the current.

\( \text{operator-=} \) modifies the global_ptr in-place and return a reference to itself after the operation.

These routines are purely a function of their arguments, they are not affected by the context in which they are called.

\textit{UPC++ progress level: none}

\begin{verbatim}
template<typename T>
std::ptrdiff_t global_ptr<T>::operator-(global_ptr<T> rhs) const;
\end{verbatim}

Precondition: Either \( *\text{this} = \text{rhs} \), or this global pointer is pointing to the \( i \)th element of an array of \( N \) elements, and \( \text{rhs} \) is pointing at the \( j \)th element of the same array. Either pointer may also point one past the end of the array, so that \( i \) or \( j \) is equal to \( N \). A pointer to a non-array object is treated as a pointer to an array of size 1.

If \( *\text{this} = \text{rhs} \), results in 0. Otherwise, returns \( i - j \).

This routine is purely a function of its arguments, it is not affected by the context in which it is called.

\textit{UPC++ progress level: none}

\begin{verbatim}
template<typename T>
global_ptr<T>& global_ptr<T>::operator++();
\end{verbatim}

Precondition: the global pointer must be pointing to an element of an array or to a non-array object

Modifies this pointer to have the value \( *\text{this} + 1 \) and returns a reference to this pointer.

This routine is purely a function of its instance, it is not affected by the context in which it is called.

\textit{UPC++ progress level: none}
template<typename T>
global_ptr<T> global_ptr<T>::operator++(int);

Precondition: the global pointer must be pointing to an element of an array or to a non-array object
Modifies this pointer to have the value *this + 1 and returns a copy of the original pointer.
This routine is purely a function of its instance, it is not affected by the context in which it is called.
UPC++ progress level: none

template<typename T>
global_ptr<T>& global_ptr<T>::operator--();

Precondition: the global pointer must either be pointing to the \textit{i}th element of an array, where \( i \geq 1 \), or one element past the end of an array or a non-array object
Modifies this pointer to have the value *this - 1 and returns a reference to this pointer.
This routine is purely a function of its instance, it is not affected by the context in which it is called.
UPC++ progress level: none

template<typename T>
global_ptr<T> global_ptr<T>::operator--(int);

Precondition: the global pointer must either be pointing to the \textit{i}th element of an array, where \( i \geq 1 \), or one element past the end of an array or a non-array object
Modifies this pointer to have the value *this - 1 and returns a copy of the original pointer.
This routine is purely a function of its instance, it is not affected by the context in which it is called.
UPC++ progress level: none
Returns the result of comparing two global pointers. Two global pointers compare equal if they both represent null pointers, or if they represent the same memory address with affinity to the same rank. All other global pointers compare unequal.

A pointer to a non-array object is treated as a pointer to an array of size one. If two global pointers point to different elements of the same array, or to subobjects of two different elements of the same array, then the pointer to the element at the higher index compares greater than the pointer to the element at the lower index. If one pointer points to an element of an array or to a subobject of an element of an array, and the other pointer points one past the end of the array, then the latter compares greater than the former.

If global pointers $p$ and $q$ compare equal, then $p == q$, $p <= q$, and $p >= q$ all result in true while $p != q$, $p < q$, and $p > q$ all result in false. If $p$ and $q$ do not compare equal, then $p != q$ is true while $p == q$ is false.

If $p$ compares greater than $q$, then $p > q$, $p >= q$, and $q < p$, and $q <= p$ all result in true while $p < q$, $p <= q$, $q > p$, and $q >= p$ all result in false.

All other comparisons result in an unspecified value.

These routines are purely functions of their arguments, they are not affected by the context in which they are called.

**UPC++ progress level:** none

```cpp
namespace std {
    template<typename T>
    struct less<global_ptr<T>>;
    template<typename T>
    bool global_ptr<T>::operator==(global_ptr<T> rhs) const;
    template<typename T>
    bool global_ptr<T>::operator!=(global_ptr<T> rhs) const;
    template<typename T>
    bool global_ptr<T>::operator<(global_ptr<T> rhs) const;
    template<typename T>
    bool global_ptr<T>::operator<=(global_ptr<T> rhs) const;
    template<typename T>
    bool global_ptr<T>::operator>(global_ptr<T> rhs) const;
    template<typename T>
    bool global_ptr<T>::operator>=(global_ptr<T> rhs) const;
}
```
struct less_equal<global_ptr<T>>;

template<typename T>
struct greater<global_ptr<T>>;

template<typename T>
struct greater_equal<global_ptr<T>>;

template<typename T>
struct hash<global_ptr<T>>;

Specializations of STL function objects for performing comparisons and computing hash values on global pointers. The specializations of `std::less`, `std::less_equal`, `std::greater`, and `std::greater_equal` all produce a strict total order over global pointers, even if the comparison operators do not. This strict total order is consistent with the partial order defined by the comparison operators.

UPC++ progress level: none

template<typename T>
std::ostream& operator<<(std::ostream &os, global_ptr<T> ptr);

Inserts an implementation-defined character representation of `ptr` into the output stream `os`. This function can be called on any valid global pointer, and the textual representation of two objects of type `global_ptr<T>` is identical if and only if the two global pointers compare equal.

UPC++ progress level: none

template<typename T, typename U>
global_ptr<T> reinterpret_pointer_cast(global_ptr<U> ptr);

Precondition: the expression `reinterpret_cast<T*>(U*)nullptr` must be well formed.

Constructs a global pointer whose underlying raw pointer is obtained by using a cast expression on that of `ptr`. The affinity of the result is the same as that of `ptr`.

If `rp` is the raw pointer of `ptr`, then the raw pointer of the result is constructed by `reinterpret_cast<T*>(rp)`.

UPC++ progress level: none
Chapter 4

Storage Management

4.1 Overview

UPC++ provides two flavors of storage allocation involving the shared segment. The pair of functions `new_` and `delete_` will call the class constructors and destructors, respectively, as well as allocate and deallocate memory from the shared segment. The pair `allocate` and `deallocate` allocate and deallocate dynamic memory from the shared segment, but do not call C++ constructors or destructors. A user may call these functions directly, or use placement new, or other memory management practices.

4.2 API Reference

```cpp
template <typename T, typename ... Args>
global_ptr<T> new_(Args &&... args);

Precondition: T(args...) must be a valid call to a constructor for T.

Allocates space for an object of type T from the shared segment of the current rank. If the allocation succeeds, returns a pointer to the start of the allocated memory, and the object is initialized by invoking the constructor T(args...).
If the allocation fails, throws `std::bad_alloc`.

Exceptions: May throw `std::bad_alloc` or any exception thrown by the call T(args...).

UPC++ progress level: none

```

```cpp
template <typename T, typename ... Args>
global_ptr<T> new_(const std::nothrow_t &tag, Args &&... args);

```

**Precondition:** T(args...) must be a valid call to a constructor for T.

Allocates space for an object of type T from the shared segment of the current rank. If the allocation succeeds, returns a pointer to the start of the allocated memory, and the object is initialized by invoking the constructor T(args...). If the allocation fails, returns a null pointer.

**Exceptions:** May throw any exception thrown by the call T(args...).

**UPC++ progress level:** none

```cpp
template<typename T>
global_ptr<T> new_array(size_t n);
```

**Precondition:** T must be DefaultConstructible.

Allocates space for an array of n objects of type T from the shared segment of the current rank. If the allocation succeeds, returns a pointer to the start of the allocated memory, and the objects are initialized by invoking their default constructors. If the allocation fails, throws std::bad_alloc.

**Exceptions:** May throw std::bad_alloc or any exception thrown by the call T(). If an exception is thrown by the constructor for T, then previously initialized elements are destroyed in reverse order of construction.

**UPC++ progress level:** none

```cpp
template<typename T>
global_ptr<T> new_array(size_t n, const std::nothrow_t &tag);
```

**Precondition:** T must be DefaultConstructible.

Allocates space for an array of n objects of type T from the shared segment of the current rank. If the allocation succeeds, returns a pointer to the start of the allocated memory, and the objects are initialized by invoking their default constructors. If the allocation fails, returns a null pointer.

**Exceptions:** May throw any exception thrown by the call T(). If an exception is thrown by the constructor for T, then previously initialized elements are destroyed in reverse order of construction.

**UPC++ progress level:** none

```cpp
template<typename T>
void delete_(global_ptr<T> g);
```
Precondition: \( T \) must be Destructible. \( g \) must be either a null pointer or a non-deallocated pointer that resulted from a call to \texttt{new\_T, Args...} on the current rank, for some value of \texttt{Args...}.

If \( g \) is not a null pointer, invokes the destructor on the given object and deallocates the storage allocated to it. Does nothing if \( g \) is a null pointer.

Exceptions: May throw any exception thrown by the the destructor for \( T \).

\( \text{UPC++ progress level: none} \)

\begin{verbatim}
template <typename T>
void delete_array (global_ptr<T> g);
\end{verbatim}

Precondition: \( T \) must be Destructible. \( g \) must be either a null pointer or a non-deallocated pointer that resulted from a call to \texttt{new\_array\_T} on the current rank.

If \( g \) is not a null pointer, invokes the destructor on each object in the given array and deallocates the storage allocated to it. Does nothing if \( g \) is a null pointer.

Exceptions: May throw any exception thrown by the the destructor for \( T \).

\( \text{UPC++ progress level: none} \)

\begin{verbatim}
void* allocate (size_t size,
     size_t alignment = alignof (std::max_align_t));
\end{verbatim}

Precondition: \( \text{alignment} \) is a valid alignment. \( \text{size} \) must be an integral multiple of \( \text{alignment} \).

Allocates \( \text{size} \) bytes of memory from the shared segment of the current rank, with alignment as specified by \( \text{alignment} \). If the allocation succeeds, returns a pointer to the start of the allocated memory, and the allocated memory is uninitialized. If the allocation fails, returns a null pointer.

\( \text{UPC++ progress level: none} \)

\begin{verbatim}
template<
typename T, size_t alignment = alignof(T)>
global_ptr<T> allocate(size_t n=1);
\end{verbatim}
Precondition: alignment is a valid alignment.

Allocates enough space for n objects of type T from the shared segment of the current rank, with the memory aligned as specified by alignment. If the allocation succeeds, returns a pointer to the start of the allocated memory, and the allocated memory is uninitialized. If the allocation fails, returns a null pointer.

UPC++ progress level: none

```c
void deallocate(void* p);
```

Precondition: p must be either a null pointer or a non-deallocated pointer that resulted from a call to the first form of allocate on the current rank.

Deallocates the storage previously allocated by a call to allocate. Does nothing if p is a null pointer.

UPC++ progress level: none

```c
template<typename T>
void deallocate(global_ptr<T> g);
```

Precondition: g must be either a null pointer or a non-deallocated pointer that resulted from a call to allocate<T, alignment> on the current rank, for some value of alignment.

Deallocates the storage previously allocated by a call to allocate. Does nothing if g is a null pointer. Does not invoke the destructor for T.

UPC++ progress level: none
Chapter 5

Futures and Promises

5.1 Overview

In UPC++, the primary mechanisms by which a programmer interacts with non-blocking operations are futures and promises. These two mechanisms, usually bound together under the umbrella concept of futures, are present in the C++11 standard. However, while we borrow some of the high-level concepts of C++’s futures, many of the semantics of upcxx::future and upcxx::promise differ from those of std::future and std::promise. In particular, while futures in C++ facilitate communicating between threads, the intent of UPC++ futures is solely to provide an interface for managing and composing non-blocking operations, and they cannot be used directly to communicate between threads or ranks.

A non-blocking operation is associated with a state that encapsulates both the status of the operation as well as any result values. Each such operation has an associated promise object, which can either be explicitly created by the user or implicitly by the runtime when a non-blocking operation is invoked. A promise represents the producer side of the operation, and it is through the promise that the results of the operation are supplied and its dependencies fulfilled. A future is the interface through which the status of the operation can be queried and the results retrieved, and multiple future objects may be associated with the same promise. A future thus represents the consumer side of a non-blocking operation.

5.2 The Basics of Asynchronous Communication

A programmer can invoke a non-blocking operation to be serviced by another rank, such as a one-sided get operation (Ch. 8) or a remote procedure call (Ch. 9). Such an operation

\footnote{Another mechanism, persona-targeted continuations, is discussed in §10.4.}
creates an implicit promise and returns an associated future object to the user. When the
operation completes, the future becomes ready, and it can be used to access the results.
The following demonstrates an example using a remote get (see Ch. 10 on how to make
progress with UPC++):

```cpp
global_ptr<double> ptr = /* obtain some remote pointer */;
future<double> fut = rget(ptr); // initiate a remote get
// ...call into upcxx::progress() elided...
if (fut.ready()) {
  double value = fut.result();  // retrieve result
  std::cout << "got: " << value << 'n'; // use result
}
```

In general, a non-blocking operation will not complete immediately, so if a user needs
to wait on the readiness of a future, they must do so in a loop. To facilitate this, we
provide the `wait` member function, which waits on a future to complete while ensuring
that sufficient progress (Ch. 10) is made on internal and user-level state:

```cpp
global_ptr<double> ptr = /* obtain some remote pointer */;
future<double> fut = rget(ptr); // initiate a remote get
fut.wait();  // wait for completion
double value = fut.result(); // retrieve result
std::cout << "got: " << value << 'n'; // use result
```

An alternative to waiting for completion of a future is to attach a `callback` or `completion
handler` to the future, to be executed when the future completes. This callback can be
any function object, including lambda (anonymous) functions, that can be called on the
results of the future, and is attached using `then`.

```cpp
global_ptr<double> ptr = /* obtain some remote pointer */;
auto fut = rget(ptr).then(  // initiate a remote get and register a callback
  // lambda callback function
  [](double value) {
    std::cout << "got: " << value << 'n'; // use result
  }
);
```

The return value of `then` is another future representing the results of the callback, if
any. This permits the specification of a sequence of operations, each of which depends on
the results of the previous one.

A future can also represent the completion of a combination of several non-blocking
operations. Unlike the standard C++ future, `upcxx::future` is a variadic template, encaps-
sulating an arbitrary number of result values that can come from different operations. The
following example constructs a future that represents the results of two existing futures:
future<double> fut1 = /* one future */;
future<int> fut2 = /* another future */;
future<double, int> combined = when_all(fut1, fut2);

Here, combined represents the state and results of two futures, and it will be ready
when both fut1 and fut2 are ready. The results of combined are a std::tuple whose
components are the results of the source futures.

5.3 Working with Promises

In addition to the implicit promises created by non-blocking operations, a user may explicitly create a promise object, obtain associated future objects, and then register non-blocking
operations on the promise. This is useful in several cases, such as when a future is required
before a non-blocking operation can be initiated, or where a single promise is used to count
dependencies.

A promise can also be used to count anonymous dependencies, keeping track of operations
that complete without producing a value. Upon creation, a promise has a dependency
count of one, representing the unfulfilled results or, if there are none, an anonymous de-
dependency. Further anonymous dependencies can then be registered on the promise. When
registration is complete, the original dependency can then be fulfilled to signal the end of
registration. The following example keeps track of several remote put operations with a
single promise:

global_ptr<int> ptrs[10] = /* some remote pointers */;
// create a promise with no results
// the dependency count starts at one
promise<> prom;

// do 10 puts, registering each of them on the promise
for (int i = 0; i < 10; i++) {
    // rput implicitly registers itself on the given promise
    rput(i, ptrs[i], operation_cx::as_promise(prom));
}

// fulfill initial anonymous dependency, since registration is done
future<> fut = prom.finalize();

// wait for the rput operations to complete
fut.wait();
5.4 Advanced Callbacks

Polling for completion of a future allows simple overlap of communication and computation operations. However, it introduces the need for synchronization, and this requirement can diminish the benefits of overlap. To this end, many programs can benefit from the use of callbacks. Callbacks avoid the need for an explicit wait and enable reactive control flow: future completion triggers a callback. Callbacks allow operations to occur as soon as they are capable of executing, rather than artificially waiting for an unrelated operation to complete before being initiated.

Futures are the core abstraction for obtaining asynchronous results, and an API that supports asynchronous behavior can work with futures rather than values directly. Such an API can also work with immediately available values by having the caller wrap the values into a ready future using the make_future function template, as in this example that creates a future for an ordered pair of a double and an int:

```cpp
void consume(future<int, double> fut);
consume(make_future(3, 4.1));
```

Given a future, we can attach a callback to be executed at some subsequent point when the future is ready using the then member function:

```cpp
future<int, double> source = /* obtain a future */;
future<double> result = source.then([](int x, double y) {
    return x + y;
});
```

In this example, source is a future representing an int and a double value. The argument of the call to then must be a function object that can be called on these values. Here, we use a lambda function that takes in an int and a double. The call to then returns a future that represents the result of calling the argument of then on the values contained in source. Since the lambda function above returns a double, the result of then is a future<double> that will hold the double’s value when it is ready.

There is also another case, when the callback returns a future, rather than some non-future type. In previous case, the result of then() is obtained by wrapping return type inside a future. In this case, this step is not needed, as we are already returning a future. Thus, the result of the call to then has the same type as the return type of the callback. However, there is an important difference: the result is a future, which may or may not be ready. In the first case, it is the returned non-future value that may or may or may not be ready. This subtle difference, allows the UPC++ programmer to chain the results of one asynchronous operation into the inputs of the next, to arbitrary degree of nesting.

```cpp
future<int, double> source = /* obtain a future */;
```
future<double> result = source.then(
    [](int x, double y) {
        // return a future<double> that is ready
        return make_future(x + y);
    });
// result may not be ready, since the callback will not be executed
// until source is ready

A callback may also initiate new asynchronous work and return a future representing
the completion of that work:

global_ptr<int> remote_array = /* some remote array */;

// retrieve remote_array[0]
future<int> elt0 = rget(remote_array);

// retrieve remote_array[remote_array[0]]
future<int> elt_indirect = elt0.then(
    [=](int index) {
        return rget(remote_array + index);
    });

The then member function is a combinator for constructing pipelines of transformations
over futures. Given a future and a function that transforms that future’s value into another
value, then produces a future representing the post-transformation value. For example,
we can future transform the value of elt_indirect above as follows:

future<int> elt_indirect_squared = elt_indirect.then(
    [](int value) {
        return value * value;
    });

As the examples above demonstrate, the then member function allows a callback to
depend on the result of another future. A more general pattern is for an operation to
depend on the results of multiple futures. The when_all function template enables this
by constructing a single future that combines the results of multiple futures. We can then
register a callback on the combined future:

class Base {
public:
    void func() {
        future<int> value1 = /* ... */;
        future<double> value2 = /* ... */;
        future<int, double> combined = when_all(value1, value2);
    }
};
future<double> result = combined.then(
    [](int x, double y) {
        return x + y;
    });

In the more general case, we may need to combine heterogeneous mixtures of future and non-future types. The to_future function template wraps a non-future value in a future while leaving future values unchanged. Thus, we can use when_all along with to_future to construct a single future that represents the combination of both future and non-future values:

future<int> value1 = /* ... */;
double value2 = /* ... */;

future<int, double> combined = when_all(to_future(value1),
                                        to_future(value2));
future<double> result = combined.then(
    [](int x, double y) {
        return x + y;
    });

The results of a future can be obtained, if it is ready, as a std::tuple using the result_tuple member function of a future. Individual components can be retrieved by value with the result member function template or by r-value reference with result_moved. Unlike with std::get, it is not a compile-time error to use an invalid index with result or result_moved; instead, the return type is void for an invalid index. This simplifies writing generic functions on futures, such as the following C++14-compliant definition of wait:

```
template<typename ...T>
auto future<T...>::wait() {
    while (!ready()) {
        progress();
    }
    return result();
}
```

## 5.5 Execution Model

Futures have the capability to express dataflow/task-based programming, and other software frameworks provide thread-level parallelism by considering each callback to be a task.
that can be run in an arbitrary worker thread. This is not the case in UPC++. In order to maximize performance, our approach to futures is purposefully ambivalent to issues of concurrency. A UPC++ implementation is allowed to take action as if the current thread is the only one that needs to be accounted for. This gives rise to a natural execution policy: callbacks registered against futures are always executed as soon as possible by the thread that discovers them. There are exactly two scenarios in which this may happen:

1. When a promise is fulfilled.

2. A callback is registered onto a ready future using the `then` member function.

Fulfilling a promise (via `fulfill_result`, `fulfill_anonymous` or `finalize`) is the only operation that can take a future from a non-ready to a ready state, enabling callbacks that depend on it to execute. This makes promise fulfillment an obvious place for discovering and executing such callbacks. Thus, whenever a thread calls a fulfillment function on a promise, the user must anticipate that any newly available callbacks will be executed by the current thread before the fulfillment call returns.

The other place in which a callback will execute immediately is during the invocation of `then` on a future that is already in its ready state. In this case, the callback provided will fire immediately during the call to `then`.

There are some common programming contexts where it is not safe for a callback to execute during fulfillment of a promise. For example, it is generally unsafe to execute a callback that modifies a data structure while a thread is traversing the data structure. In such a situation, it is the user’s responsibility to ensure that a conflicting callback will not execute. One solution is create a promise that represents a thread reaching its safe-to-execute context, and then adding it to the dependency list of any conflicting callback.

```cpp
future<int> value = /* ... */;
// create a promise representing a safe-to-execute state
// dependency count is initially 1
promise<> safe_state;
// create a future that depends on both value and safe_state
future<int> combined = when_all(value, safe_state.get_future());
auto fut = // register a callback on the combined future
combined.then(/* some callback that requires a safe state */);
// do some work, potentially fulfilling value’s promise...
// signify a safe state
safe_state.finalize();
// callback can now execute
```

As demonstrated above, the user can wait to fulfill the promise until it is safe to execute the callback, which will then allow it to execute.
5.6 Anonymous Dependencies

As demonstrated previously, promises can be used to both supply values as well as signal completion of events that do not produce a value. As such, a promise is a unified abstraction for tracking the completion of asynchronous operations, whether the operations produce a value or not. A promise represents at most one dependency that produces a value, but it can track any number of anonymous dependencies that do not result in a value.

When created, a promise starts with an initial dependency count of 1. For an empty promise (promise<>), this is necessarily an anonymous dependency, since an empty promise does not hold a value. For a non-empty promise, the initial count represents the sole dependency that produces a value. Further anonymous dependencies can be explicitly registered on a promise with the require_anonymous member function:

```cpp
promise<int, double> pro; // initial dependency count is 1
pro.require_anonymous(10); // dependency count is now 11
```

The argument to require_anonymous must be strictly greater than the negation of the promise’s dependency count, so that a call to require_anonymous never causes the dependency count to reach zero, putting the promise in the fulfilled state. In the example above, the argument must be greater than -1, and the given argument of 10 is valid.

Anonymous dependencies can be fulfilled by calling the fulfill_anonymous member function:

```cpp
for (int i = 0; i < 5; i++) {
  pro.fulfill_anonymous(i);
} // dependency count is now 1
```

A non-anonymous dependency is fulfilled by calling fulfill_result with the produced values:

```cpp
pro.fulfill_result(3, 4.1); // dependency count is now 0
```

Both empty and non-empty promises can be used to track anonymous dependencies. A UPC++ operation that operates on a promise always increments its dependency count upon invocation, as if by calling require_anonymous(1) on the promise. After the operation completes\(^2\), if the completion produces values of type T..., then the values are supplied to the promise through a call to fulfill_result. Otherwise, the completion is signaled by fulfilling an anonymous dependency through a call to fulfill_anonymous(1).

The rationale for this behavior is to free the user from having to manually increment the dependency count before calling an operation on a promise; instead, UPC++ will implicitly perform this increment. This leads to the pattern, shown at the beginning of this chapter,

\(^2\)The notification will occur during user-level progress of the persona that initiates the operation. See Ch. 10 for more details.
of registering operations on a promise and then finalizing the promise to take it out of
registration mode:

```cpp
global_ptr<int> ptrs[10] = /* some remote pointers */;
promise<> prom; // dependency count is 1

for (int i = 0; i < 10; i++) {
  rput(i, ptrs[i],
       operation_cx::as_promise(prom)); // increment count
} // dependency count is now 11

future<> fut = prom.finalize(); // decrement count, making it 10
// wait for the 10 rput operations to complete
fut.wait();
```

A user familiar with UPC++ V0.1 will observe that empty promises subsume the ca-
pabilities of events in UPC++ V0.1. In addition, they can take part in all the machinery
of promises, futures, and callbacks, providing a much richer set of capabilities than were
available in V0.1.

### 5.7 Lifetime and Thread Safety

Understanding the lifetime of objects in the presence of asynchronous control flow can be
tricky. Objects must outlive the last callback that references them, which in general does
not follow the scoped lifetimes of the call stack. For this reason, UPC++ automatically man-
ages the state represented by futures and promises, and the state persists for as long as
there is a future, promise, or dependent callback that references it. Thus, a user can con-
struct intricate webs of callbacks over futures without worrying about explicitly managing
the state representing the callbacks’ dependencies or results.

Though UPC++ does not prescribe a specific management strategy, the semantics of
futures and promises are analogous to those of standard C++11 smart pointers. As with
`std::shared_ptr`, a future may be freely copied, and both the original and the copy
represent the same state and are associated with the same promise. Thus, if one copy
of a future becomes ready, then so will the other copies. On the other hand, a promise
can be mutated by the user through its member functions, so allowing a promise to be
copied would introduce the issue of aliasing. Instead, we adopt the same non-copyable, yet
movable, semantics for a promise as `std::unique_ptr`.

Given that UPC++ futures and promises are already thread-unaware to allow the ex-
cution strategy to be straightforward and efficient, UPC++ also makes no thread safety
guarantees about internal state management. This enables creation of copies of a future
to be a very cheap operation. For example, a future can be captured by value by a lambda
function or passed by value without any performance penalties. On the other hand, the
lack of thread safety means that sharing a future between threads must be handled with
great caution. Even a simple operation such as making a copy of a future, as when passing
it by value to a function, is unsafe if another thread is concurrently accessing an identical
future, since the act of copying it can modify the internal management state. Thus, a
mutex or other synchronization is required to ensure exclusive access to a future when
performing any operation on it.

Fulfilling a promise gives rise to an even more stringent demand, since it can set off a
cascade of callback execution. Before fulfilling a promise, the user must ensure that the
thread has the exclusive right to mutate not just the future associated with the promise,
but all other futures that are directly or indirectly dependent on fulfillment of the promise.
Thus, when crafting their code, the user must properly manage exclusivity for islands of
disjoint futures. We say that two futures are in disjoint islands if there is no dependency,
direct or indirect, between them.

A reader having previous experience with futures will note that UPC++’s formulation is
a significant departure from many other software packages. Futures are commonly used
to pass data between threads, like a channel that a producing thread can supply a value
into, notifying a consuming thread of its availability. UPC++, however, is intended for
high-performance computing, and supporting concurrently shareable futures would require
synchronization that would significantly degrade performance. As such, futures in UPC++
are not intended to directly facilitate communication between threads. Rather, they are
designed for a single thread to manage the non-determinism of reacting to the events
delivered by concurrently executing agents, be they other threads or the network hardware.

5.8 API Reference

UPC++ progress level for all functions in this chapter (unless otherwise noted) is: none

5.8.1 future

template<typename ...T>
class future;

C++ Concepts: DefaultConstructible, CopyConstructible, CopyAssignable,
Destructible

The types in T... must not be void.

template<typename ...T>
future<T...>::future();
Constructs a future that will never become ready. 

This function may be called when UPC++ is in the uninitialized state.

```cpp
template<typename ...T>
future<T...>::~future();
```

Destructs this future object.

This function may be called when UPC++ is in the uninitialized state.

```cpp
template<typename ...T>
future<T...> make_future(T ...results);
```

Constructs a trivially ready future from the given values.

```cpp
template<typename ...T>
bool future<T...>::ready() const;
```

Returns true if the future’s result values have been supplied to it.

```cpp
template<typename ...T>
std::tuple<T...> const & future<T...>::result_tuple() const;
```

Precondition: this->ready()

Retrieves the tuple of result values for this future.

```cpp
template<typename ...T>
template<int I=0>
future_element_t<I, future<T...>>
future<T...>::result() const;
```

Precondition: this->ready()

Retrieves the \( I \)th component (defaults to first) from the future’s results tuple. The return type is \( \text{void} \) if \( I \) is an invalid index. Otherwise it is of type \( U \), where \( U \) is the \( I \)th component of \( T \).
template<typename ...T>

template<int I=0>
future_element_moved_t<I, future<T...>>
future<T...>::result_moved();

Precondition: this->ready()

Retrieves the \( I \)th component (defaults to first) from the future’s results tuple as an r-value reference, as if by calling \texttt{std\texttt{:\{}move\texttt{\}}} on the component. The return type is \texttt{void} if \( I \) is an invalid index. Otherwise it is of type \texttt{U&&}, where \( U \) is the \( I \)th component of \( T \). \textit{Caution: this operation permits mutation of the value, via an rvalue reference which could be observed by further calls that return the result(s) of a future.}

template<typename ...T>

template<typename Func>
future_invoke_result_t<Func, T...>
future<T...>::then(Func func);

Preconditions: The call \texttt{func()} must not throw an exception.

Returns a new future representing the return value of the given function object \texttt{func} when invoked on the results of this future as its argument list. If \texttt{func} returns a future, then the result of \texttt{then} will be a semantically equivalent future, except that it will be in a non-ready state before \texttt{func} executes. If \texttt{func} does not return a future, then the return value of \texttt{then} is a future that encapsulates the result of \texttt{func}, and this future will also be in a non-ready state before \texttt{func} executes. If the return type of \texttt{func} is \texttt{void}, then the return type of \texttt{then} is \texttt{future<>}.

The function object will be invoked in one of two situations:

- Immediately before \texttt{then} returns if this future is in the ready state.
- During a promise fulfillment which would directly or indirectly make this future transition to the ready state.

template<typename ...T>
future_element_t<0, future<T...>> future<T...>::wait();

Waits for the future by repeatedly attempting \texttt{UPC++ user-level progress} and testing for readiness. See Ch. 10 for a discussion of progress. The return value is the same as that produced by calling \texttt{result()} on the future.

\textit{UPC++ progress level: user}
template<typename ...Futures>
future<CTypes...> when_all(Futures... fs);

Given a variadic list of futures as arguments, constructs a future representing
the readiness of all arguments. The results tuple of this future will be the
concatenated results tuples of the arguments. The type parameters of the
returned object (CTypes...) is the ordered concatenation of the type parameter
lists of the types in Futures.... If Futures... is empty, then the result is a
trivially ready future<>.

template<typename T>
future<CTypes...> to_future(T future_or_value);

Constructs a future that encapsulates the value represented by future_or_
value. If T is of type future<U...>, then CTypes... is the same as U..., and
the returned future is a copy of future_or_value. If T is not a future, then
CTypes... is T, and the function returns a ready future whose encapsulated
value is future_or_value.

5.8.2 promise

template<typename ...T>
class promise;

C++ Concepts: DefaultConstructible, MoveConstructible, MoveAssignable,
Destructible

The types in T... must not be void.

template<typename ...T>
promise<T...>::promise();

Constructs a promise with its results uninitialized and an initial dependency
count of 1.

This function may be called when UPC++ is in the uninitialized state.
Destructs this promise object.

*This function may be called when UPC++ is in the uninitialized state.*

```cpp
template< typename ...T>
void promise<T...>::require_anonymous(std::intptr_t count);
```

*Precondition:* `count` is nonnegative. The dependency count of this promise is greater than 0.

Adds `count` to this promise’s dependency count.

```cpp
template< typename ...T>
template< typename ...U>
void promise<T...>::fulfill_result(U &&... results);
```

*Precondition:* `fulfill_result` has not been called on this promise before, and the dependency count of this promise is greater than zero.

Initializes the promise’s result tuple with the given values and decrements the dependency counter by 1. Requires that `T` and `U` have the same number of components, and that each component of `U` is implicitly convertible to the corresponding component of `T`. If the dependency counter reaches zero as a result of this call, the associated future is set to ready, and callbacks that are waiting on the future are executed on the calling thread before this function returns.

```cpp
template< typename ...T>
void promise<T...>::fulfill_anonymous(std::intptr_t count);
```

*Precondition:* `count` is nonnegative. The dependency count of this promise is greater than zero and greater than or equal to `count`. If the dependency count is equal to `count` and `T` is not empty, then the results of this promise must have been previously supplied by a call to `fulfill_result`.

Subtracts `count` from the dependency counter. If this produces a zero counter value, the associated future is set to ready, and callbacks that are waiting on the future are executed on the calling thread before this function returns.

```cpp
template< typename ...T>
future<T...> promise<T...>::get_future() const;
```
Returns the future representing this promise being fulfilled. Repeated calls to 
\texttt{get\_future} return equivalent futures with the guarantee that no additional 
memory allocation is performed.

\begin{verbatim}
template<typename ...T>
future<T...> promise<T...>::finalize();
\end{verbatim}

Equivalent to calling \texttt{this->fulfill\_anonymous(1)} and then returning the 
result of \texttt{this->get\_future}.
Chapter 6

Serialization

As a communication library, UPC++ needs to send C++ types between ranks that might be separated by a network interface. The underlying GASNet networking interface sends and receives bytes, thus, UPC++ needs to be able to convert C++ types to and from bytes.

6.1 Class Serialization Interface

For standard TriviallyCopyable data types, UPC++ can serialize and deserialize these objects for the user without extra intervention on their part. For user data types that have more involved serialization requirements, the user needs to take two steps to inform UPC++ about how to serialize the object.

1. Declare their type to be a friend of access

2. Implement the visitor function serialize

The type must also satisfy the C++ CopyConstructible concept.

Figure 6.1 provides an example of this process. The definition of the & operator for the Archive class depends on whether UPC++ is serializing or deserializing an object instance. UPC++ provides implementations of operator& for the C++ built-in types. UPC++ serialization is compatible with a subset of the Boost serialization interface. This does not imply that UPC++ includes or requires Boost as a dependency. The reference implementation of UPC++ does neither of these, it comes with its own implementation of serialization that simply adheres to the interface set by Boost. It is acceptable to have friend boost::serialization::access in place of friend upcxx::access. UPC++ will use your Boost serialization in that case.

There are restrictions on which actions serialization/deserialization routines may perform. They are:
class UserType {
  // The user’s fields and member declarations as usual.
  int member1, member2;
  // ...

  // To enable the serializer to visit the member fields,
  // the user provides this...
  friend class upcxx::access;

  // ...and this
  template<typename Archive>
  void serialize(Archive &ar, unsigned) {
    ar & this->member1;
    ar & this->member2;
    // ...
  }
};

Figure 6.1: An example of using access in a user-defined class

1. Serialization/deserialization may not call any UPC++ routine with a progress level other than none.

2. UPC++ must perceive these routines as referentially transparent. Loosely, this means that the routines should be “pure” functions between the native representation and a flat sequence of bytes.

3. The routines must be thread-safe and permit concurrent invocation from multiple threads, even when serializing the same object.

6.2 Serialization Concepts

UPC++ defines the concepts DefinitelyTriviallySerializable, TriviallySerializable, DefinitelySerializable, and Serializable that describe what form of serialization a C++ type supports. Figure 6.2 helps summarize the relationship of these concepts.

A type T is DefinitelyTriviallySerializable if either of the following holds:

- T is TriviallyCopyable (i.e. std::is_trivially_copyable<T>::value is true), and if T is of class type, T does not implement the UPC++ serialization interface described above.
• `upcxx::is_definitely_trivially_serializable<T>` is specialized to provide a member constant `value` that is `true`.

In the latter case, UPC++ treats the type `T` as if it were TriviallyCopyable for the purposes of serialization. Thus, UPC++ will serialize an object of type `T` by making a byte copy, and it will assume `T` is TriviallyDestructible when destroying a deserialized object of type `T`.

A type `T` is TriviallySerializable if it is semantically valid to copy an object by copying its underlying bytes, and UPC++ serializes such types by making a byte copy. A type `T` that is DefinitelyTriviallySerializable is also TriviallySerializable.

A type `T` is DefinitelySerializable if one of the following holds:

• `T` is DefinitelyTriviallySerializable

• `T` is of class type and implements the UPC++ serialization interface

• `T` is explicitly described as DefinitelySerializable by this specification

A type `T` is Serializable if it is either TriviallySerializable or DefinitelySerializable.

The type trait `upcxx::is_definitely_trivially_serializable<T>` provides a member constant `value` that is `true` if `T` is DefinitelyTriviallySerializable and `false` otherwise. This trait may be specialized for user types (types that are not defined by the C++ or UPC++ standards).
The type trait `upcxx::is_definitely_serializable<T>` provides a member constant value that is `true` if `T` is DefinitelySerializable and `false` otherwise. This trait may not be specialized for any types.

Several UPC++ communication operations require that the objects to be transferred are of DefinitelyTriviallySerializable type. The C++ standard allows implementations to determine whether or not lambda functions are TriviallyCopyable, so whether or not such objects are DefinitelyTriviallySerializable is implementation-dependent.

### 6.3 Functions

In Chapter 7 (Completion) and Chapter 9 (Remote Procedure Calls) there are several cases where a C++ FunctionObject is expected to execute on a destination rank. In these cases the function arguments are serialized as described in this chapter. The FunctionObject itself (i.e. the `func` argument to `rpc`, `rpc_ff`, or `as_rpc`) is converted to a function pointer offset from a known sentinel in the source program’s code segment. The details of the implementation are not described here but typical allowed FunctionObjects are

- C functions
- C++ global and file-scope functions
- Class static functions
- lambda functions

### 6.4 Special Handling in Remote Procedure Calls

Remote procedure calls, whether standalone (§9) or completion based (§7), perform special handling on certain non-DefinitelySerializable UPC++ data structures. Arguments that are either a reference to `dist_object` type (see §13 Distributed Objects) or a `team` (see §12 Teams) are transferred by their `dist_id` or `team_id` respectively. Execution of the RPC is deferred until all of the id’s have a corresponding instance constructed on the recipient. When that occurs, `func` is enlisted for execution during user-level progress of the recipient’s master persona (see §10 Progress), and it will be called with the recipient’s instance references in place of those supplied at the send site. The behavior is undefined if the recipient’s instance of a `dist_object` or `team` argument is destroyed before the RPC executes.
6.5 View-Based Serialization

UPC++ also provides a mechanism for serializing the elements of a sequence. The following is an example of transferring a sequence with rpc:

```cpp
std::list<double> items = /* fill with elements */;
auto fut = rpc_ff(1, [](view<double> packedlist) {
    // target side gets object containing iterators
    for (double elem : packedlist) { // traverse network buffer
        process(elem); // process each element
    }
}, make_view(items.begin(), items.end()));
```

In this example, a `std::list<double>` contains the elements to be transferred. Calling `make_view` on its begin and end iterators results in a `view`, which can then be passed to a remote procedure call. The elements in the sequence are serialized and transferred as part of the RPC, and the target receives a `view` over the elements stored in the network buffer. The RPC can then iterate over `view` to obtain each element.

There is an asymmetry in the `view` types at the initiator and target of an RPC, reflecting the difference in how the underlying sequences are stored in memory. In the example above, the type of the value returned by `make_view` is `view<double, std::list<double>::iterator>`, since the initiator supplies iterators associated with a list. The target of the RPC, however, receives a `view<double, view_default_iterator_t<double>>`, with the `view_default_iterator_t<T>` type representing an iterator over a network buffer. The latter is the default argument for the second template parameter of `view`, so that a user can specify `view<T>` rather than `view<T, view_default_iterator_t<T>>`.

UPC++ provides different handling of `view<T>` based on whether the element type `T` is DefinitelyTriviallySerializable or not. For DefinitelyTriviallySerializable element type, deserialization is a no-op, and the `view<T>` on the recipient is a direct view over a network buffer, providing both random access and access to the buffer itself. The corresponding `view_default_iterator_t<T>` is an alias for `T*`. On the other hand, if the `view` element type is not DefinitelyTriviallySerializable, then an element must be nontrivially deserialized before it can be accessed by the user. In such a case, the `view<T>` only provides access through an InputIterator, which deserializes and returns elements by value, and `view_default_iterator_t<T>` is an alias for `deserializing_iterator<T>`.

As a non-owning interface, `view` only provides `const` access to the elements in the underlying sequence, analogous to C++17 `string_view`. However, in the case of a `view<T>` that is received by the target of an RPC, where `T` is DefinitelyTriviallySerializable, the underlying elements are stored directly in a network buffer as indicated above. There is no external owning container, so UPC++ permits a user to perform a `const_cast` conversion on an element and modify it.
The lifetime of the underlying data buffer and all view iterators on the target in both
the DefinitelyTriviallySerializable and non-DefinitelyTriviallySerializable cases is restricted
by default to the duration of the RPC. In this case, the elements must be processed or
copied elsewhere before the RPC returns. However, if the RPC returns a future, then the
lifetime of the buffer and view iterators is extended until that future is readied. This allows
an RPC to initiate an asynchronous operation to consume the elements, and as long as the
resulting future is returned from the RPC, the underlying buffer will remain alive until the
asynchronous operation is complete and the future readied.

While UPC++ manages the lifetime of the data underlying a view when it is an argument
to an RPC, the library does not support a view as the return type of an RPC due to the
lifetime issues it raises. Thus, an RPC is prohibited from returning a view even though it
is classified as DefinitelySerializable.

The behavior is unspecified when a view<T, IterType> is passed to rpc, rpc_ff, or
as_rpc if the type T is itself a view.

### 6.6 API Reference

```cpp
template<typename T>
struct is_definitely_trivially_serializable;
```

Provides a member constant value that is true if T is DefinitelyTriviallySerializ-
able and false otherwise. This trait may be specialized for user types.

```cpp
template<typename T>
struct is_definitely_serializable;
```

Provides a member constant value that is true if T is Definitel-
ySerializable and false otherwise. This trait may not be special-
ized. However, its value may be indirectly influenced by specializing
is_definitely_trivially_serializable<T> or implementing the class se-
rialization interface for T, as appropriate.

```cpp
template<typename T>
class deserializing_iterator {
public:
    // types
    using iterator_category = std::input_iterator_tag;
    using value_type = T;
    using difference_type = std::ptrdiff_t;
```
using pointer = T*;
using reference = T;

deserializing_iterator();

// accessors
T operator*() const;

// increment
deserializing_iterator& operator++();
deserializing_iterator operator++(int);

// comparisons
template<typename T>
bool operator==(const deserializing_iterator& x, const deserializing_iterator& y);
template<typename T>
bool operator!=(const deserializing_iterator& x, const deserializing_iterator& y);

C++ Concepts: InputIterator

An iterator over elements stored in a network buffer. Dereferencing the iterator causes the element to be deserialized and returned by value (i.e. deserializing_iterator<T>::reference is an alias for T).

While this iterator is classified as an InputIterator, it does not support operator->, as the underlying element must be materialized on demand and its lifetime would not extend beyond the application of the operator.

UPC++ progress level for all functions above: none

template<typename T>
using view_default_iterator_t = /* ... */;

A type alias that is equivalent to T* if T is DefinitelyTriviallySerializable (i.e. upcxx::is_definitely_trivially_serializable<T>::value is true), and deserializing_iterator<T> otherwise.

template<typename T, typename IterType = view_default_iterator_t<T>>
class view {
public:
  // types
  using iterator = IterType;
  using size_type = std::size_t;

  // iterators
  iterator begin();
  iterator end();

  // capacity
  size_type size() const;
};

C++ Concepts: DefaultConstructible, CopyConstructible, CopyAssignable, Destructible
UPC++ Concepts: DefinitelySerializable
A class template representing a view over an underlying sequence of elements of type T, delimited by begin() and end().

UPC++ progress level for all member functions of view: none

template<typename T>
class view<T, T*> {
public:
  // types
  using value_type = T;
  using pointer = T*;
  using const_pointer = const T*;
  using reference = T&;
  using const_reference = const T&;
  using const_iterator = const T*;
  using iterator = const_iterator;
  using const_reverse_iterator =
    std::reverse_iterator<const_iterator>;
  using reverse_iterator = const_reverse_iterator;
  using size_type = std::size_t;
  using difference_type = std::ptrdiff_t;

  // no explicit construct/copy/destroy for non-owning type
// iterators
const_iterator begin() const;
const_iterator cbegin() const;
const_iterator end() const;
const_iterator cend() const;
const_reverse_iterator rbegin() const;
const_reverse_iterator crbegin() const;
const_reverse_iterator rend() const;
const_reverse_iterator crend() const;

// capacity
bool empty() const;
size_type size() const;

// element access
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
const_reference front() const;
const_reference back() const;

const_pointer data() const;

C++ Concepts: DefaultConstructible, CopyConstructible, CopyAssignable, Destructible
UPC++ Concepts: DefinitelySerializable
A template specialization representing a view over a network buffer of elements of type T, delimited by begin() and end().

Exceptions: at(n) throws std::out_of_range if n is not in the range [0, size()).

UPC++ progress level for all member functions of view: none

template<typename T, typename IterType>
view<T, IterType>::view();

Precondition: IterType must satisfy the ForwardIterator C++ concept. The type std::iterator_traits<IterType>::value_type must be the same as T. T must be DefinitelySerializable.
Initializes this view to represent an empty sequence.

```cpp
template< typename IterType >
view< typename std::iterator_traits<IterType>::value_type, IterType >
make_view(IterType begin, IterType end,
          typename std::iterator_traits<IterType>::difference_type
          size = std::distance(begin, end));
```

**Precondition:** IterType must satisfy the ForwardIterator C++ concept. The underlying element type (std::iterator_traits<IterType>::value_type) must be DefinitelySerializable. size must be equal to the number of elements in [begin, end).

Constructs a view over the sequence delimited by begin and end.

**UPC++ progress level:** none

```cpp
template< typename Container >
view< typename Container::value_type, 
     typename Container::const_iterator>
make_view(const Container &container);
```

**Precondition:** Container must satisfy the Container C++ concept. The underlying element type (Container::value_type) must be DefinitelySerializable.

Constructs a view over the sequence delimited by container.cbegin() and container.cend().

**UPC++ progress level:** none
Chapter 7

Completion

7.1 Overview

Data movement operations come with the concept of completion, meaning that the effect of the operation is now visible on the source or target rank and that resources, such as memory on the source and destination sides, are no longer in use by UPC++. A single UPC++ call may have several completion events associated with it, indicating completion of different stages of a communication operation. These events are categorized as follows:

- **Source completion**: The source-side resources of a communication operation are no longer in use by UPC++, and the application is now permitted to modify or reclaim them.

- **Remote completion**: The data have been deposited on the remote target rank, and they can be consumed by the target.

- **Operation completion**: The operation is complete from the viewpoint of the initiator. The transferred data can now be read by the initiator, resulting in the values that were written to the target locations.

A completion event may be associated with some values produced by the communication operation, or it may merely signal completion of an action. Each communication operation specifies the set of completion events it provides, as well as the values that a completion event produces. Unless otherwise indicated, a completion event does not produce a value. UPC++ provides several alternatives for how completion can be signaled to the program:

- **Future**: The communication call returns a future, which will be readied when the completion event occurs. This is the default notification mode for communication operations. If the completion event is associated with some values of type T..., then
the returned future will have type `future<T...>`. If no value is associated with the
completion, then the future will have type `future<>`.

- **Promise:** The user provides a promise when requesting notification of a completion
event, and that promise will have one its dependencies fulfilled when the event occurs.
The promise must have a non-zero dependency count. If the completion event is asso-
ciated with some values of type `T...`, then it must be valid to call `fulfill_result()`
on the promise with values of type `T...`, and the promise must not have had
`fulfill_result()` called on it. The promise will then have `fulfill_result()`
called on it with the associated values when the completion event occurs. If no value
is associated with the completion, then the promise may have any type. It will have
an anonymous dependency fulfilled upon the completion event.

- **Local-Procedure Call (LPC):** The user provides a target persona and a callback func-
tion object when requesting notification of a completion event. If the completion
is associated with some values of type `T...`, then the callback must be invokable
with arguments of type `T...`. Otherwise, it must be invokable with no arguments.
The callback, together with the associated completion values if any, is enlisted for
execution on the given persona when the completion event occurs.

- **Remote-Procedure Call (RPC):** The user provides a Serializable function object when
requesting notification of a completion event, as well as the arguments on which the
function object should be invoked. Each argument must either be DefinitelySerial-
izable, a `dist_object<T>&`, or `team&`. The function object and arguments are
transferred as part of the communication operation, and the invocation is enlisted
for execution on the master persona of the target rank when the completion event
occurs.

- **Buffered:** The communication call consumes the source-side resources of the operation
before the call returns, allowing the application to immediately modify or reclaim
them. This delays the return of the call until after the source-completion event. The
implementation may internally buffer the source-side resources or block until network
resources are available to inject the data directly.

- **Blocking:** This is similar to buffered completion, except that the implementation is
required to block until network resources are available to inject the data directly.

Future, promise, and LPC completions are only valid for completion events that occur
at the initiator of a communication call, namely source and operation completion. RPC
completion is only valid for a completion event that occurs at the target of a communication
operation, namely remote completion. Buffered and blocking completion are only valid for
source completion. More details on futures and promises are in Ch. 5, while LPC and RPC callbacks are discussed in Ch. 10.

Notification of completion only happens during user-level progress of the initiator or target rank. Even if an operation completes early, including before the initiation operation returns, the application cannot learn this fact without entering user progress. For futures and promises, only when the initiating thread (persona actually) enters user-level progress will the future or promise be eligible for taking on a readied or fulfilled state. LPC callbacks will execute once a thread enters user progress of the designated persona. See Ch. 10 for the full discussion on user progress and personas.

If buffered or blocking completion is requested, then the source-completion event occurs before the communication call returns. However, source-completion notifications, such as triggering a future or executing an LPC, are still delayed until the next user-level progress.

Operation completion implies both source and remote completion. However, it does not imply that the actions associated with source and remote completion have been executed.

### 7.2 Completion Objects

The UPC++ mechanism for requesting notification of completion is through opaque completion objects, which associate notification actions with completion events. Completion objects are CopyConstructible, CopyAssignable, and Destructible, and the same completion object may be passed to multiple communication calls. A simple completion object is constructed by a call to a static member function of the `source_cx`, `remote_cx`, or `operation_cx` class, providing notification for the corresponding event. The member functions `as_future`, `as_promise`, `as_lpc`, and `as_rpc` request notification through a future, promise, LPC, or RPC, respectively. Only the member functions that correspond to valid means of signaling notification of an event are defined in the class associated with that event.

The following is an example of a simple completion object:

```cpp
global_ptr<int> gp1 = /* some global pointer */;
promise<int> pro1;
auto csx = operation_cx::as_promise(pro1);
rget(gp1, csx);
pro1.finalize(); // fulfill the initial anonymous dependency
```

The `rget` function, when provided just a `global_ptr<int>`, transfers a single `int` from the given location to the initiator. Thus, operation completion is associated with an `int` value, and the promise used for signaling that event must have type compatible with an `int` value, e.g. `promise<int>`. The user constructs a completion object that requests operation notification on the promise `pro1` by calling `operation_cx::as_promise(pro1)`. Since a completion object is opaque, the `auto` keyword is used to deduce the type of the
completion object. The resulting completion object can then be passed to \texttt{rget}, which fulfills the promise with the transferred value upon operation completion.

A user can request notification of multiple completion events, as well as multiple notifications of a single completion event. The pipe (\texttt{|}) operator can be used to combine completion objects to construct a union of the operands. The following is an example:

```c
int foo () {
    return 0;
}

int bar (int x) {
    return x;
}

void do_comm (double *src, size_t count) {
    global_ptr<double> dest = /* some global pointer */;
    promise<> pro1;
    persona &per1 = /* some persona */;
    auto cxs = (operation_cx::as_promise (pro1) |
                source_cx::as_future () |
                operation_cx::as_future () |
                operation_cx::as_future () |
                source_cx::as_lpc(per1, foo) |
                remote_cx::as_rpc(bar, 3)
            ) ;
    std::tuple< future<> , future<> , future<> > result =
        rput (src, dest, count, cxs);
    pro1.finalize ().wait (); // finalize promise, wait on its future
}
```

This code initiates an \texttt{rput} operation, which provides source-, remote-, and operation-completion events. A unified completion object is constructed by applying the pipe operator to individual completion objects. When \texttt{rput} is invoked with the resulting unified completion object, it returns a tuple of futures corresponding to the individual future completions requested. The ordering of futures in this tuple matches the order of application of the pipe operator (this operator is associative but not commutative). In the example above, the first future in the tuple would correspond to source completion, and the second and third would be for operation completion. If no future-based notification is requested, then the return type of the communication call would be \texttt{void} rather than a tuple.

When multiple notifications are requested for a single event, the order in which those notifications occur is unspecified. In the code above, the order in which \texttt{pro1} is fulfilled and the two futures for operation completion are readied is indeterminate. Similarly, if
both source and operation completion occur before the next user-level progress, the order
in which the notifications occur is unspecified, so that operation-completion requests may
be notified before source-completion requests.

Unlike a direct call to the \texttt{rpc} function (Ch. 9), but like a call to \texttt{rpc_ff}, an RPC
completion callback does not return a result to the initiator. Thus, the value returned by
the RPC invocation of \texttt{bar} above is discarded.

Arguments to \texttt{remote\_cx::as\_rpc} are serialized at an unspecified time between the
invocation of \texttt{as\_rpc} and the source completion event of a communication operation that
accepts the resulting completion object. If multiple communication operations use a single
completion object resulting from \texttt{as\_rpc}, then the arguments may be serialized multiple
times. For arguments that are not passed by value, the user must ensure that they re-
main valid until source completion of all communication operations that use the associated
completion object.

\section*{7.2.1 Restrictions}

The API reference for a UPC++ call that supports the completion interface lists the comple-
tion events that the call provides, as well as the types of values associated with each event,
if any. The result is undefined if a completion object is passed to a call and the object
contains a request for an event that the call does not support. Passing a completion object
that contains a request whose type does not match the types provided by the corresponding
completion event, as described in \S 7.1, also results in undefined behavior.

If a UPC++ call provides both operation and remote completion, then at least one must
be requested by the provided completion object. If a call provides operation but not remote
completion, then operation completion must be requested. The behavior of the program is
undefined if neither operation nor remote completion is requested from a call that supports
one or both of operation or remote completion.

A promise object associated with a promise-based completion request must have a
dependency count greater than zero when the completion object is passed to a UPC++
operation. The result is undefined if the same promise object is used in multiple requests
for notifications that produce values.

\section*{7.2.2 Completion and Return Types}

In subsequent API-reference sections, the opaque type of a completion object is denoted
by \texttt{CType}. Similarly, \texttt{RType} denotes a return type that is dependent on the completion
object passed to a UPC++ call. This return type is as follows:

\begin{itemize}
  \item \texttt{void}, if no future-based completions are requested
\end{itemize}
• `future<T...>`, if a single future-based completion is requested, where `T...` is the sequence of types associated with the given completion event

• `std::tuple<future<T...>...>`, if multiple future-based completions are requested, where each future’s arguments `T...` is the sequence of types associated with the corresponding completion event

Type deduction, such as with `auto`, is recommended when working with completion objects and return types.

7.2.3 Default Completions

If a completion object is not explicitly provided to a communication call, then a default completion object is used. For most calls, the default is `operation_cx::as_future()`. However, for `rpc_ff`, the default completion is `source_cx::as_buffered()`, and for `rpc`, it is `source_cx::as_buffered() | operation_cx::as_future()`. The default completion of a UPC++ communication call is listed in its API reference.

7.3 API Reference

```cpp
struct source_cx;
struct remote_cx;
struct operation_cx;

[static] CType source_cx::as_future();
[static] CType operation_cx::as_future();

Constructs a completion object that represents notification of source or operation completion with a future.

UPC++ progress level: none
```

```cpp
template<typename ...T>
[static] CType source_cx::as_promise(promise<T...> &pro);
template<typename ...T>
[static] CType operation_cx::as_promise(promise<T...> &pro);
```
Precondition: pro must have a dependency count greater than zero.
Constructs a completion object that represents signaling the given promise
upon source or operation completion.
UPC++ progress level: none

```
template<typename Func>
[static] CType source_cx::as_lpc(persona &target, Func func);
```

```
template<typename Func>
[static] CType operation_cx::as_lpc(persona &target, Func func);
```

Preconditions: Func must be a function-object type and CopyConstructible.
func must not throw an exception when invoked.
Constructs a completion object that represents the enqueuing of func on the
given local persona upon source or operation completion.
UPC++ progress level: none

```
template<typename Func, typename ...Args>
[static] CType remote_cx::as_rpc(Func func, Args... &args);
```

Precondition: Func must be Serializable and CopyConstructible and a function-
object type. Each of Args... must either be a DefinitelySerializable and Copy-
Constructible type, or dist_object<T>&, or team&. The call func(args...) must
not throw an exception.
Constructs a completion object that represents the enqueuing of func on a
target rank upon remote completion.
UPC++ progress level: none

```
[static] CType source_cx::as_buffered();
```

Constructs a completion object that represents buffering source-side resources
or blocking until they are consumed before a communication call returns, de-
laying the return until the source-completion event occurs.
UPC++ progress level: none

```
[static] CType source_cx::as_blocking();
```

Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
Constructs a completion object that represents blocking until source-side re-
sources are consumed before a communication call returns, delaying the return
until the source-completion event occurs.

**UPC++ progress level:** none

```
template <typename CTypeA, CTypeB>
CType operator|(CTypeA a, CTypeB b);
```

*Precondition:* CTypeA and CTypeB must be completion types.

Constructs a completion object that is the union of the completions in a and
b. Future-based completions in the result are ordered the same as in a and b,
with those in a preceding those in b.

**UPC++ progress level:** none
Chapter 8

One-Sided Communication

8.1 Overview

The main one-sided communication functions for UPC++ are rput and rget. Where possible, the underlying transport layer will use RDMA techniques to provide the lowest-latency transport possible. The type $T$ used by rput or rget needs to be DefinitelyTriviallySerializable, as described in Chapter 6 (Serialization).

8.2 API Reference

8.2.1 Remote Puts

```cpp
template<typename T,
         typename Completions = decltype(operation_cx::as_future())>
RType rput(T value, global_ptr<T> dest,
           Completions cx = Completions{});
```

*Precondition:* $T$ must be DefinitelyTriviallySerializable. dest must reference a valid object of type $T$.

Initiates a transfer of value that will store it in the memory referenced by dest.

*Completions:*

- *Remote:* Indicates completion of the transfer of value.
- *Operation:* Indicates completion of all aspects of the operation: the transfer and remote stores are complete.

*C++ memory ordering:* The writes to dest will have a happens-before relationship with the operation-completion notification actions (future readying,
promise fulfillment, or persona LPC enlistment) and remote-completion actions
(RPC enlistment). For LPC and RPC completions, all evaluations sequenced-
before this call will have a happens-before relationship with the execution of the
completion function.

UPC++ progress level: internal

template<typename T,
    typename Completions=decltype(operation_cx::as_future())>
RType rput(T const *src, global_ptr<T> dest, std::size_t count,
    Completions cxs=Completions{});

Precondition: T must be DefinitelyTriviallySerializable. Addresses src+i and
dst+i for i in [0,count) must all reference valid and non-overlapping objects
of type T.

Initiates an operation to transfer and store the count items of type T begin-
ning at src to the memory beginning at dest. The values referenced in the
[src,src+count) interval must not be modified until either source or operation
completion is indicated.

Completions:

- Source: Indicates completion of injection or internal buffering of the source
  values, signifying that the src buffer may be modified.
- Remote: Indicates completion of the transfer of the values, implying readiness of the target buffer [dest,dest+count).
- Operation: Indicates completion of all aspects of the operation: the trans-
  fer and remote stores are complete.

C++ memory ordering: The reads of src will have a happens-before relationship
with the source-completion notification actions (future readying, promise ful-
fillment, or persona LPC enlistment). The writes to dest will have a happens-
before relationship with the operation-completion notification actions (future
readying, promise fulfillment, or persona LPC enlistment) and remote-comple-
tion actions (RPC enlistment). For LPC and RPC completions, all evaluations
sequenced-before this call will have a happens-before relationship with the exec-
ution of the completion function.

UPC++ progress level: internal
8.2.2 Remote Gets

template<typename T,
         typename Completions=decltype(operation_cx::as_future())>
RType rget(global_ptr<T> src,
            Completions cx=Completions{});

Precondition: T must be DefinitelyTriviallySerializable. src must reference a
valid object of type T.

Initiates a transfer to this rank of a single value of type T located at src. The
value will be transferred to the calling rank and delivered in the operation-
completion notification.

Completions:

- Operation: Indicates completion of all aspects of the operation, including
  transfer and readiness of the resulting value. This completion produces a
  value of type T.

C++ memory ordering: The read of src will have a happens-before relationship
with the operation-completion notification actions (future readying, promise
fulfillment, or persona LPC enlistment). All evaluations sequenced-before this
call will have a happens-before relationship with the invocation of any LPC
associated with operation completion.

UPC++ progress level: internal

template<typename T,
         typename Completions=decltype(operation_cx::as_future())>
RType rget(global_ptr<T> src, T *dest, std::size_t count,
            Completions cx=Completions{});

Precondition: T must be DefinitelyTriviallySerializable. Addresses src+i and
dst+i for i in [0,count) must all reference valid and non-overlapping objects
of type T.

Initiates a transfer of count values of type T beginning at src and stores them
in the locations beginning at dest. The source values must not be modified
until operation completion is notified.

Completions:

- Operation: Indicates completion of all aspects of the operation, including
  transfer and readiness of the resulting values.
C++ memory ordering: The reads of src and writes to dest will have a
happens-before relationship with the operation-completion notification actions
(future readying, promise fulfillment, or persona LPC enlistment). All evalu-
tions sequenced-before this call will have a happens-before relationship with the
invocation of any LPC associated with operation completion.

UPC++ progress level: internal
Chapter 9

Remote Procedure Call

9.1 Overview

UPC++ provides remote procedure calls (RPCs) for injecting function calls into other ranks. These injections are one-sided, meaning the recipient is not required to explicitly acknowledge which functions are expected. Concurrent with a rank’s execution, incoming RPCs accumulate in an internal queue managed by UPC++. The only control a rank has over inbound RPCs is when it would like to check its inbox for arrived function calls and execute them. Draining the RPC inbox is one of the many responsibilities of the progress API (see Ch. 10, Progress).

There are two main flavors of RPC in UPC++: fire-and-forget (rpc_ff) and round trip (rpc). Each takes a function Func together with variadic arguments Args.

The rpc_ff call serializes the given function and arguments into a message destined for the recipient, and guarantees that this function call will be placed eventually in the recipient’s inbox. The round-trip rpc call does the same, but also forces the recipient to reply to the sender of the RPC with a message containing the return value of the function, providing the value for operation completion of the sender’s invocation of rpc. Thus, when the future is ready, the sender knows the recipient has executed the function call. Additionally, if the return value of func is a future, the recipient will wait for that future to become ready before sending its result back to the sender.

There are important restrictions on what the permissible types for func and its bound arguments can be for RPC functions. First, the Func type must be a function object (has a publicly accessible overload of the function call operator, operator()). Second, Func must be Serializable, and all Args... types must be DefinitelySerializable (see Ch. 6, Serialization).
9.2 Remote Hello World Example

Figure 9.1 shows a simple alternative Hello World example where each rank issues an \texttt{rpc} to its neighbor, where the last rank wraps around to 0.

```cpp
#include <upcxx/upcxx.hpp>
#include <iostream>

void hello_world(intrank_t num)
{
    std::cout << "Rank " << num << " told rank " << upcxx::rank_me()
        << " to say Hello World" << std::endl;
}

int main(int argc, char** argv[])
{
    upcxx::init(); // Start UPC++ state
    intrank_t remote = (upcxx::rank_me()+1)%upcxx::rank_n();
    auto f = upcxx::rpc(remote, hello_world, upcxx::rank_me());
    f.wait();
    upcxx::finalize(); // Close down UPC++ state
    return 0;
}
```

Figure 9.1: HelloWorld with Remote Procedure Call

9.3 API Reference

```cpp
template<typename Func, typename ...Args>
void rpc_ff(intrank_t recipient, Func &&func, Args &&...args);
template<typename Completions, typename Func, typename ...Args>
RType rpc_ff(intrank_t recipient, Completions cxs,
        Func &&func, Args &&...args);
```

\textit{Precondition:} Func must be a Serializable type and a function-object type. Each of Args\ldots must be a DefinitelySerializable type, or \texttt{dist_object<T>}, or \texttt{team}. The call func(args\ldots) must not throw an exception.

In the first variant, the func and args\ldots are serialized and internally buffered before the call returns. The call \texttt{rpc_ff(rank, func, args\ldots)} is equivalent to \texttt{rpc_ff(rank, source_cx::as_buffered(), func, args\ldots)}.

In the second variant, if buffered source completion is not requested, the func and args\ldots are serialized at an unspecified time between the invocation of
rpc_ff and source completion. The serialized results are retained internally until they are eventually sent.

After their receipt on recipient, the data are deserialized and func(args...) is enlisted for execution during user-level progress of the master persona. So long as the sending persona continues to make internal-level progress it is guaranteed that the message will eventually arrive at the recipient. See §10.5.3 progress_required for an understanding of how much internal-progress is necessary.

The execution of func(args...) is never performed synchronously, even if the target is the same as the calling rank and this function is invoked during user-level progress.

Special handling is applied to those members of args which are either a reference to dist_object type or a team, as described in §6.4.

Completions:

- Source: Indicates completion of serialization of the function object and arguments.

C++ memory ordering: All evaluations sequenced-before this call will have a happens-before relationship with the source-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment) and the recipient’s invocation of func.

UPC++ progress level: internal

```cpp
template<typename Func, typename ...Args>
future_invoke_result_t<Func, Args...>
rpc(intrank_t recipient, Func &&func, Args &&...args);
template<typename Completions, typename Func, typename ...Args>
RType rpc(intrank_t recipient, Completions cxs,
          Func &&func, Args &&...args);
```

Precondition: Func must be a Serializable type and a function-object type. Each of Args... must be either a DefinitelySerializable type, or dist_object<T>&, or team&. Additionally, std::result_of<Func(Args...)>::type must be either a DefinitelySerializable type that is not view<U, IterType>, or future<T...>, where each type in T... must be DefinitelySerializable but not view<U, IterType>. The call func(args...) must not throw an exception.
Similar to \texttt{rpc\_ff}, this call sends \texttt{func} and \texttt{args...} to be executed remotely, but additionally provides an operation-completion event that produces the value returned from the remote invocation of \texttt{func(args...)}, if it is non-void.

In the first variant, the \texttt{func} and \texttt{args...} are serialized and internally buffered before the call returns. The call \texttt{rpc(rank, func, args...)} is equivalent to

\begin{verbatim}
rpc(rank, 
    source\_cx::as\_buffered() | operation\_cx::as\_future(), 
    func, args...)
\end{verbatim}

In the second variant, if buffered source completion is not requested, the \texttt{func} and \texttt{args...} are serialized at an unspecified time between the invocation of \texttt{rpc} and source completion. The serialized results are retained internally until they are eventually sent.

After their receipt on \texttt{recipient}, the data are deserialized and \texttt{func(args...)} is enlisted for execution during user-level progress of the master persona.

In the first variant, the returned future is readied upon operation completion.

For futures provided by an operation-completion request, or promises used in promise-based operation-completion requests, the type of the future or promise must correspond to the return type of \texttt{func(args...)} as follows:

- If the return type is of the form \texttt{future<T...>}, then a future provided by operation completion also has type \texttt{future<T...>}, and promises used in operation-completion requests must permit invocation of \texttt{fulfill\_result} with values of type \texttt{T...}.

- If the return type is some other non-void type \texttt{T}, then a future provided by operation completion has type \texttt{future<T>}, and promises used in operation-completion requests must permit invocation of \texttt{fulfill\_result} with a value of type \texttt{T}.

- If the return type is \texttt{void}, then a future provided by operation completion has type \texttt{future<>}, and promises used in operation-completion requests may have any type \texttt{promise<T...>}

Within user-progress of the recipient’s master persona, the result from invoking \texttt{func(args...)} will be immediately serialized and eventually sent back to the initiating rank. Upon receipt, it will be deserialized, and operation-completion notifications will take place during subsequent user-progress of the initiating persona.
The execution of `func(args...)` is never performed synchronously, even if the target is the same as the calling rank and this function is invoked during user-level progress.

The same special handling applied to `dist_object&` and `team&` arguments by `rpc_ff` is also done by `rpc`.

**Completions:**

- **Source:** Indicates completion of serialization of the function object and arguments.
- **Operation:** Indicates completion of all aspects of the operation: serialization, deserialization, remote invocation, transfer of any result, and destruction of any internally managed values are complete. This completion produces a value as described above.

**C++ memory ordering:** All evaluations sequenced-before this call will have a happens-before relationship with the invocation of `func`. The return from `func`, will have a happens-before relationship with the operation-completion actions (future readying, promise fulfillment, or persona LPC enlistment). For LPC completions, all evaluations sequenced-before this call will have a happens-before relationship with the execution of the completion function.

**UPC++ progress level:** `internal`
Chapter 10

Progress

10.1 Overview

UPC++ presents a highly-asynchronous interface, but guarantees that user-provided callbacks will only ever run on user threads during calls to the library. This guarantees a good user-visibility of the resource requirements of UPC++, while providing a better interoperability with other software packages which may have restrictive threading requirements. However, such a design choice requires the application developer to be conscientious about providing UPC++ access to CPU cycles.

Progress in UPC++ refers to how the calling application allows the UPC++ internal runtime to advance the state of its outstanding asynchronous operations. Any asynchronous operation initiated by the user may require the application to give UPC++ access to the execution thread periodically until the operation reports its completion. Such access is granted by simply making calls into UPC++. Each UPC++ function’s contract to the user contains its progress guarantee level. This is described by the members of the \texttt{upcxx::progress\_level} enumerated type:

\texttt{progress\_level::user} \quad UPC++ may advance its internal state as well as signal completion of user-initiated operations. This may entail the firing of remotely injected procedure calls (RPCs), or readying/fulfillment of futures/promises and the ensuing callback cascade.

\texttt{progress\_level::internal} \quad UPC++ may advance its internal state, but no notifications will be delivered to the application. Thus, an application has very limited ways to “observe” the effects of such progress.

\textit{Progress level: none} \quad UPC++ will not attempt to advance the progress of asynchronous operations. (Note this level does not have an explicit entry in the \texttt{progress\_level} enumerated type).
The most common progress guarantee made by UPC++ functions is `progress_level::internal`. This ensures the delivery of notifications to remote ranks (or other threads) making user-level progress in a timely manner. In order to avoid having the user contend with the cost associated with callbacks and RPCs being run anytime a UPC++ function is entered, `progress_level::user` is purposefully not the common case.

`progress` is the notable function enabling the application to make user-level progress. Its sole purpose is to look for ready operations involving this rank or thread and run the associated RPC/callback code.

```
upcxx::progress(progress_level lev = progress_level::user)
```

UPC++ execution phases which leverage asynchrony heavily tend to follow a particular program structure. First, initial communications are launched. Their completion callbacks might then perform a mixture of compute or further UPC++ communication with similar, cascading completion callbacks. Then, the application spins on `upcxx::progress()`, checking some designated application state which monitors the amount of pending outgoing/incoming/local work to be done. For the user, understanding which functions perform these progress spins becomes crucial, since any invocation of user-level progress may execute RPCs or callbacks.

### 10.2 Restricted Context

During user-level progress made by UPC++, callbacks may be executed. Such callbacks are subject to restrictions on how they may further invoke UPC++ themselves. We designate such restricted execution of callbacks as being in the restricted context. The general restriction is stated as:

```
User code running in the restricted context must assume that for the duration of the context all other attempts at making user-level progress, from any thread on any rank, may result in a no-op every time.
```

The immediate implication is that a thread which is already in the restricted context should assume no-op behavior from further attempts at making progress. This makes it pointless to try and wait for UPC++ notifications from within restricted context since there is no viable mechanism to make the notifications visible to the user. Thus, calling any routine which spins on user-level progress until some notification occurs will likely hang the thread.
CHAPTER 10. PROGRESS

10.3 Attentiveness

Many UPC++ operations have a mechanism to signal completion to the application. However, a performance-oriented application will need to be aware of an additional asynchronous operation status indicator called progress-required. This status indicates that for a particular operation further advancements of the current rank or thread’s internal-level progress are necessary so that completion regarding remote entities (e.g. notification of delivery) can be reached. Once an operation has left the progress-required state, UPC++ guarantees that remote entities will see their side of the operations’ completion without any further progress by the current compute resource. Applications will need to leverage this information for performance, as it is inadvisable for a compute resource to become inattentive to UPC++ progress (e.g. long bouts of arithmetic-heavy computation) while other entities depend on operations that require further servicing.

As said previously, nearly all UPC++ operations track their completion individually. However, it is not possible for the programmer to query UPC++ if individual operations no longer require further progress. Instead, the user may ask UPC++ when all operations initiated by this rank have reached a state at which they no longer require progress. This is achieved by using the following functions:

```cpp
bool upcxx::progress_required();
void upcxx::discharge();
```

The `progress_required` function reports whether this rank requires progress, allowing the application to know that there are still pending operations that will not achieve remote completion without further advancements to internal progress. This is of particular importance before an application enters a lapse of inattentiveness (for instance, performing expensive computations) in order to prevent slowing down remote entities.

The `discharge` function allows an application to ensure that UPC++ does not require progress anymore. It is equivalent to the following:

```cpp
void upcxx::discharge() {
    while (upcxx::progress_required())
        upcxx::progress(upcxx::progress_level::internal);
}
```

A well-behaved UPC++ application is encouraged to call `discharge` before any long lapse of attentiveness to progress.

10.4 Thread Personas/Notification Affinity

As explained in Chapter 5 Futures and Promises, futures require careful consideration when used in the presence of thread concurrency. It is crucial that UPC++ is very explicit
about how a multi-threaded application can safely use futures returned by UPC++ calls.

The most important thing an application has to be aware of is which thread UPC++ will use to signal completion of a given future. It is therefore extremely important to know that UPC++ will use the same thread to which the future was returned by the UPC++ operation (i.e. the thread which invoked the operation in the first place). This means that the thread which invoked a future-returning operation will be the only one able to see that operation’s completion. As UPC++ triggers futures only during a call which makes user-level progress, the invoking thread must continue to make such progress calls until the future is satisfied. This requirement has the drawback of banning the application from doing the following: initiating a future-returning operation on one thread, allowing that thread to terminate or become permanently inattentive (e.g. sleeping in a thread pool), and expecting a different thread to receive the future’s completion. This section will focus on two ways the application can still attain this use-case.

The notion of “thread” has been used in a loose fashion throughout this document, the natural interpretation being an operating system (OS) thread. More precisely, this document uses the notion of “thread” to denote a UPC++ device referred to as thread persona which generalizes the notion of operating system threads.

A UPC++ thread persona is a collection of UPC++-internal state usually attributed to a single thread. By making it a proper construct, UPC++ allows a single OS thread to switch between multiple application-defined roles for processing notifications. Personas act as the receivers for notifications generated by the UPC++ runtime.

Values of type `upcxx::persona` are non-copyable, non-moveable objects which the application can instantiate as desired. For each OS thread, UPC++ internally maintains a stack of active persona references. The top of this stack is the current persona. All asynchronous UPC++ operations will have their notification events (signaling of futures or promises) sent to the current persona of the OS thread invoking the operation. Calls that make user-level progress will process notifications destined to any of the active personas of the invoking thread. The initial state of the persona stack consists of a single entry pointing to a persona created by UPC++ which is dedicated to the current OS thread. Therefore, if the application never makes any use of the persona API, notifications will be processed solely by the OS thread that initiates the operation.

Pushing and popping personas from the persona stack (hence changing the current persona) is done with the `upcxx::persona_scope` type.

```cpp
namespace upcxx {

    struct persona_scope {
        // Make 'p' the new current persona for this OS thread.
        persona_scope(persona &p);

        // Acquire 'lock', then make 'p' the new current persona for
```

Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
CHAPTER 10. PROGRESS

```cpp
// this OS thread.
template<typename Lock>
persona_scope(Lock &lock, persona &p);

// Pop 'p' from persona stack, release 'lock' if any.
// Calling thread must be same for constructor and destructor.
~persona_scope();

persona_scope& top_persona_scope();
persona_scope& default_persona_scope();

bool progress_required(persona_scope &ps = top_persona_scope());

void discharge(persona_scope &ps = top_persona_scope());
}

// Example demonstrating persona_scope.
persona scheduler_persona;
std::mutex scheduler_lock;

// Scope block delimits domain of persona_scope instance.
auto scope = persona_scope(scheduler_lock, scheduler_persona);

// All following upcxx actions will use 'scheduler_persona'
// as current.

// ...

// 'scope' destructs:
// - 'scheduler_persona' dropped from active set if it
// wasn't active before the scope's construction.
// - Previously current persona revived.
// - Lock released.
```

Since UPC++ will assume an OS thread has exclusive access to all of its active personas, it is the user’s responsibility to ensure that no OS threads share an active persona concurrently. The use of the `persona_scope` constructor, which takes a lock-like synchronization primitive, is strongly encouraged to facilitate in enforcing this invariant.
There are two ways that asynchronous operations can be initiated by a given OS thread but retired in another. The first solution is simple:

1. The user defines a persona $P$.
2. Thread 1 activates $P$, initiates the asynchronous operation, and releases $P$.
3. Thread 1 synchronizes with Thread 2, indicating the operation has been initiated.
4. Thread 2 activates $P$, spins on `progress` until the operation completes.

Care must be taken that any futures created by phase 2 are never altered (uttered) concurrently. The same synchronization that was used to enforce exclusivity of persona acquisition can be leveraged to protect the future as well.

While this technique achieves our goal of different threads initiating and resolving asynchronous operations, it fails a different but also desirable property. It is often desirable to allow multiple threads to issue communication `concurrently` while delegating a separate thread to handle the notifications. To achieve this, it is clear that multiple personas are needed. Indeed, the exclusivity of a persona being current to only one OS thread prevents the application from concurrent initiation of communication.

In order to issue operations and concurrently retire them in a different thread, the user is strongly encouraged to use the LPC completion mechanism described in Chapter 7, as opposed to the future or promise variants. An example of such a call is:

```cpp
rget(gptr_src, operation_cx::as_lpc(some_persona, callback_func));
```

In addition to the arguments necessary for the particular operation, the `as_lpc` completion mechanism takes a persona reference and a C++ function object (lambda, etc.) such that upon completion of the operation, the designated persona shall execute the function object during its user-level progress. Using this mechanism, it is simple to have multiple threads initiating communication concurrently with a designated thread receiving the completion notifications. To achieve this, each operation is initiated by a thread using the agreed-upon persona of the receiver thread together with a callback that will incorporate knowledge of completion into the receiver’s state.

### 10.5 API Reference

```cpp
tenum class progress_level {
    /*none, -- not an actual member, conceptual only*/
    internal,
    user
};
```

Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
\begin{verbatim}
void progress(progress_level lev = progress_level::user);

This call will always attempt to advance internal progress.

If lev == progress_level::user then this thread is also used to execute any
available user actions for the personas currently active. Actions include:

1. Either future-readying or promise-fulfilling completion notifications for
   asynchronous operations initiated by one of the active personas. By the
   execution model of futures and promises this can induce callback cascade.

2. Continuation-style completion notifications from operations initiated by
   any persona but designating one of the active personas as the completion
   recipient.

3. RPCs destined for this rank but only if the master persona is among the
   active set.

4. lpc’s destined for any of the active personas.

UPC++ progress level: internal or user
\end{verbatim}

\section*{10.5.1 persona}

\begin{verbatim}
class persona;

C++ Concepts: DefaultConstructible, Destructible

persona::persona();

Constructs a persona object with no enqueued operations.

This function may be called when UPC++ is in the uninitialized state.

UPC++ progress level: none

persona::~persona();

Destructs this persona object. If this persona is a member of any thread’s
persona stack, the result of this call is undefined. If any operations are currently
enqueued on this persona, or if any operations initiated by this persona require
further progress, the result of this call is undefined.

This function may be called when UPC++ is in the uninitialized state.

UPC++ progress level: none
\end{verbatim}
template<typename Func>
void persona::lpc_ff(Func func);

Precondition: Func must be a function-object type that can be invoked on zero arguments, and the call func() must not throw an exception.

std::move's func into an unordered collection of type-erased function objects to be executed during user-level progress of the targeted (this) persona. This function is thread-safe, so it may be called from any thread to enqueue work for this persona.

The execution of func is never performed synchronously, even if the target persona is a member of the caller's persona stack and this function is invoked during user-level progress.

C++ memory ordering: All evaluations sequenced-before this call will have a happens-before relationship with the invocation of func.

UPC++ progress level: none

template<typename Func>
future_invoke_result_t<Func> persona::lpc(Func func);

Precondition: Func must be a function-object type that can be invoked on zero arguments, and the call func() must not throw an exception.

std::move's func into an unordered collection of type-erased function objects to be executed during user-level progress of the targeted (this) persona. The return value of func is asynchronously returned to the currently active persona in a future. If the return value of func is a future, then the targeted persona will wait for that future before signaling the future returned by lpc with its value. This function is thread-safe, so it may be called from any thread to enqueue work for this persona. Note that the future returned by lpc is considered to be owned by the currently active persona, the future returned by func (if any) will be considered owned by the target (this) persona.

The execution of func is never performed synchronously, even if the target persona is a member of the caller's persona stack and this function is invoked during user-level progress.

C++ memory ordering: All evaluations sequenced-before this call will have a happens-before relationship with the invocation of func, and the invocation of func will have a happens-before relationship with evaluations sequenced after the signaling of the final future.

UPC++ progress level: none
persona& master_persona();

Returns a reference to the master persona automatically instantiated by the 
UPC++ runtime. The thread that executes upcxx::init implicitly acquires this 
persona as its current persona. The master persona is special in that it is the 
only one which will execute RPCs destined for this rank. Additionally, some 
UPC++ functions may only be called by a thread with the master persona in its 
active stack.

UPC++ progress level: none

persona& current_persona();

Returns a reference to the persona on the top of the thread’s active persona 
stack.

UPC++ progress level: none

persona& default_persona();

Returns a reference to the persona instantiated automatically and uniquely for 
this OS thread. The default persona is always the bottom of and can never be 
removed from its designated OS thread’s active stack.

UPC++ progress level: none

void liberate_master_persona()

Precondition: This thread must be the one which called upcxx::init, it must 
have not altered its persona stack since calling init, and it must not have 
called this function already since calling init.

The thread which invokes upcxx::init implicitly has the master persona at 
the top of its active stack, yet the user has no persona_scope to drop to allow 
other threads to acquire the persona. Thus, if the user intends for other threads 
to acquire the master persona, they should have the init-calling thread release 
the persona with this function so that it can be claimed by persona_scope’s. 
Generally, if this function is ever called, it is done soon after init and then the 
master persona should be reacquired by a persona_scope.

UPC++ progress level: none
10.5.2 persona_scope

```cpp
class persona_scope;

C++ Concepts: Destructible, MoveConstructible

persona_scope::persona_scope(persona &p);

Precondition: Excluding this thread, p is not a member of any other thread’s active stack.
PUSHES p onto the top of the calling OS thread’s active persona stack.

UPC++ progress level: none
```

```cpp
template <typename Mutex>
persona_scope::persona_scope(Mutex &mutex, persona &p);

C++ Concepts of Mutex: Mutex

Precondition: p will only be a member of some thread’s active stack if that thread holds mutex in a locked state.
Invokes mutex.lock(), then pushes p onto the OS thread’s active persona stack.

UPC++ progress level: none
```

```cpp
persona_scope::~persona_scope();

Precondition: All persona_scope’s constructed on this thread since the construction of this instance have since destructed.
The persona supplied to this instance’s constructor is popped from this thread’s active stack. If this instance was constructed with the mutex constructor, then that mutex is unlocked.

UPC++ progress level: none
```

```cpp
persona_scope& top_persona_scope();

Reference to the most recently constructed but not destructed persona_scope for this thread. Every thread begins with an implicitly instantiated scope pointing to its default persona that survives for the duration of the thread’s lifetime.

UPC++ progress level: none
```
persona_scope & default_persona_scope();

Every thread begins with an implicitly instantiated scope pointing to its default persona that survives for the duration of the thread’s lifetime. This function returns a reference to that bottommost persona_scope for the calling thread, which points at the calling thread’s default_persona().

UPC++ progress level: none

10.5.3 Outgoing Progress

bool progress_required(persona_scope &ps = top_persona_scope());

Precondition: ps has been constructed by this thread.

For the set of personas included in this thread’s active stack section bounded inclusively between ps and the current top, nearly answers if any UPC++ operations initiated by those personas require further advancement of internal-progress of their respective personas before their completion events will be eventually available to user-level progress on the destined ranks. The exact meaning of the return value depends on which personas are selected by ps:

- If ps does not include the master persona: A return value of true means that one or more of the personas indicated by ps requires further internal-progress to achieve completion of its outgoing operations. A value of false means that none of the personas indicated by ps require internal-progress, but internal-progress of the master persona might still be required.
- If ps does include the master persona: A return value of true means that one or more of the personas indicated by ps requires further internal-progress to achieve completion of its outgoing operations. A return value of false means that none of the non-master personas indicated by ps requires further internal-progress, but the master persona may or may not require further internal-progress.

UPC++ progress level: none

void discharge(persona_scope &ps = top_persona_scope());

Advances internal-progress enough to ensure that progress_required(ps) returns false.

UPC++ progress level: internal
Chapter 11

Atomics

11.1 Overview

UPC++ supports atomic operations on shared memory locations. Atomicity entails that a read-modify-write sequence on a memory location will happen without interference or interfering with other concurrently executing atomic operations. Atomicity is not guaranteed if a memory location is concurrently targeted by both atomic and non-atomic operations. The order in which concurrent atomics update the same memory is not guaranteed, not even for successively issued operations by a single rank. Ordering of atomics with respect to other asynchronous operations is also not guaranteed. The only means to ensure such ordering is by waiting for one operation to complete before initiating its successor. Note that UPC++ atomics do not interoperate with std::atomic.

At this time, it is unclear how UPC++ will support mixing of atomic and non-atomic accesses to the same memory location. Until this is resolved, users must assume that for the duration of the program, once a memory location is accessed via a UPC++ atomic, only further atomic operations to that location will have meaningful results (note that even global barrier synchronization does not grant an exception to this rule). This unfortunately implies that deallocation of such memory is unsafe, as that would allow the memory to be reallocated to a context unaware of its constrained condition.

All atomic operations are associated with an atomic domain. An atomic domain is defined for an integer type and a set of operations. Currently, the allowed types are std::int32_t, std::uint32_t, std::int64_t, and std::uint64_t. The list of operations is detailed in the API section below. The atomic domain is an instance of a atomic_domain class, and the operations are defined as methods on that class.

The use of atomic domains permits selection (at construction) of the most efficient available implementation which can provide correct results for the given set of operations on the given data type. This is important because the best possible implementation of a
operation "X" may not be compatible with operation "Y". So, this best "X" can only be
used when it is known that "Y" will not be used. This issue arises because a NIC may
offload "X" (but not "Y") and use of a CPU-based implementation of "Y" would not be
coherent with the NIC performing a concurrent "X" operation.

Similar to a mutex, an atomic domain exists independent of the data it applies to.
User code is responsible for ensuring that data accessed via a given atomic domain is only
accessed via that domain, never via a different domain or without use of a domain.

Users may create as many domains as needed to describe their uses of atomic operations,
so long as there is at most one domain per atomic datum. If distinct data of the same type
are accessed using differing sets of operations, then creation of distinct domains for each
operation set is recommended to achieve the best performance on each set.

For example, to use atomic fetch-and-add, load and store operations on an int64_t, a
user must first define a domain as follows:

```cpp
atomic_domain<int64_t> ad_i64({ atomic_op::load,
                                 atomic_op::store,
                                 atomic_op::fetch_add });
```

Each atomic operation works on a *global pointer* to the integer type given when the
domain was constructed.

All atomic operations are non-blocking and provide an operation-completion event to
indicate completion of the atomic. By default, all operations return futures. So, for
example, this is the way to call an atomic operation for the previous example’s domain:

```cpp
global_ptr<int64_t> x = new_<int64_t>(0);
future<int64_t> f = ad_i64.fetch_add(x, 2,
                       std::memory_order_relaxed);
int64_t res = f.wait();
```

Atomic domains enable a user to select a subset of operations that are supported in
hardware on a given platform, and hence more performant.

### 11.2 API Reference

```cpp
enum class atomic_op : int {
  load, store,
  add, fetch_add,
  sub, fetch_sub,
  inc, fetch_inc,
  dec, fetch_dec,
  compare_exchange
};
```
template<typename T>
class atomic_domain;

C++ Concepts: DefaultConstructible, MoveConstructible, MoveAssignable, Destructible

template<typename T>
atomic_domain<T>::atomic_domain();

Precondition: T must be one of the approved atomic types: std::int32_t, std::uint32_t, std::int64_t, or std::uint64_t.
Constructs an empty domain. This domain is not yet functional; it must be overwritten through a move assignment.
This function may be called when UPC++ is in the uninitialized state.
UPC++ progress level: none

template<typename T>
atomic_domain<T>::atomic_domain(
    std::vector<atomic_op> const &ops,
    team &team = world());

Precondition: T must be one of the approved atomic types: std::int32_t, std::uint32_t, std::int64_t, or std::uint64_t.
Constructs an atomic domain for integer type T, with supported operations ops.
This constructor is a collective function over the specified team.
UPC++ progress level: internal

template<typename T>
atomic_domain<T>::~atomic_domain();

Precondition: All operations initiated on the atomic domain must be complete prior to any rank making this call (or the behavior is undefined). In practice, this means completing (syncing) all atomic operation at their initiators, followed by a barrier prior to calling this function.
Destructs this atomic domain object.
This destructor is a collective function over the team used in the constructor.
UPC++ progress level: internal
CHAPTER 11. ATOMICS

template<typename T, typename Completions = decltype(operation_cx::as_future())> 
RType atomic_domain<T>::load(global_ptr<T> p, 
   std::memory_order order, 
   Completions cxs=Completions{});

Precondition: p must reference a valid object of type T. T must be the only type
used by any atomic referencing any part of p’s target memory for the entire life-
time of UPC++. order must be std::memory_order_relaxed or std::memory_ 
order_acquire. The atomic_op::load operation must have been included in
the ops used to construct this atomic_domain.

Initiates an atomic read of the object at location p and produces its value as
part of operation completion.

Completions:

- Operation: Indicates completion of all aspects of the operation: the remote
  atomic read and transfer of the result are complete. This completion
  produces a value of type T.

C++ memory ordering: If order is std::memory_order_acquire then the
read performed will have a happens-before relationship with the operation-
completion notification actions (future readying, promise fulfillment, or persona
LPC enlistment).

UPC++ progress level: internal

template<typename T, typename Completions = decltype(operation_cx::as_future())> 
RType atomic_domain<T>::store(global_ptr<T> p, 
   T val, 
   std::memory_order order, 
   Completions cxs=Completions{});

Precondition: p must reference a valid object of type T. T must be the only
type used by any atomic referencing any part of p’s target memory for the
entire lifetime of UPC++. order must be std::memory_order_relaxed or std::
memory_order_release. The atomic_op::store operation must have been
included in the ops used to construct this atomic_domain.
Initiates an atomic write of \texttt{val} to the location \texttt{p}. Completion of the write is indicated by operation completion.

\textit{Completions}:

- \textit{Operation}: Indicates completion of all aspects of the operation: the transfer of the value and remote atomic write are complete.

\textit{C++ memory ordering}: If \texttt{order} is \texttt{std::memory_order_release} then all evaluations \texttt{sequenced-before} this call will have a \texttt{happens-before} relationship with the write performed. The write performed will have a \texttt{happens-before} relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

\textit{UPC++ progress level}: \texttt{internal}

\begin{verbatim}
template<typename T, typename Completions = decltype(operation_cx::as_future())>
Type atomic_domain<T>::add(global_ptr<T> p,
    T val,
    std::memory_order order,
    Completions cxs=Completions{});
\end{verbatim}

\textit{Precondition}: \texttt{p} must reference a valid object of type \texttt{T}. \texttt{T} must be the only type used by any atomic referencing any part of \texttt{p}'s target memory for the entire lifetime of \texttt{UPC++}. \texttt{order} must be \texttt{std::memory_order_relaxed}, \texttt{std::memory_order_acquire}, \texttt{std::memory_order_release}, or \texttt{std::memory_order_acq_rel}. The \texttt{atomic_op::add} operation must have been included in the \texttt{ops} used to construct this \texttt{atomic_domain}.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at \texttt{p}, adding \texttt{val} to it, and writing the new value back.

\textit{Completions}:

- \textit{Operation}: Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, and remote atomic update are complete.

\textit{C++ memory ordering}: If \texttt{order} is either \texttt{std::memory_order_release} or \texttt{std::memory_order_acq_rel} then all evaluations \texttt{sequenced-before} this call will have a \texttt{happens-before} relationship with the atomic action. If \texttt{order} is \texttt{std::memory_order_relaxed}, \texttt{std::memory_order_acquire}, \texttt{std::memory_order_release}, or \texttt{std::memory_order_acq_rel} then all evaluations \texttt{sequenced-before} this call will have a \texttt{happens-before} relationship with the atomic action.

80 Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
memory_order_acquire or std::memory_order_acq_rel then the atomic action will have a happens-before relationship with the operation-completion notification actions (future reading, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal

template<typename T,
    typename Completions=decltype (operation_cx::as_future())>
Type atomic_domain<T>::fetch_add(global_ptr<T> p,
    T val,
    std::memory_order order,
    Completions cxs=Completions{});

Precondition: p must reference a valid object of type T. T must be the only type used by any atomic referencing any part of p’s target memory for the entire lifetime of UPC++. order must be std::memory_order_relaxed, std::memory_order_acquire, std::memory_order_release, or std::memory_order_acq_rel. The atomic_op::fetch_add operation must have been included in the ops used to construct this atomic_domain.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at p, adding val to it, and writing the new value back. The value produced by operation completion is the one initially read.

Completions:

- Operation: Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, remote atomic update, and transfer of the old value to the initiator are complete. This completion produces a value of type T.

C++ memory ordering: If order is either std::memory_order_release or std::memory_order_acq_rel then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If order is std::memory_order_acquire or std::memory_order_acq_rel then the atomic action will have a happens-before relationship with the operation-completion notification actions (future reading, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal

    typename Completions=decltype(operation_cx::as_future())>
Type atomic_domain<T>::sub(global_ptr<T> p,
    T val,
    std::memory_order order,
    Completions cx=Completions{});

Precondition: p must reference a valid object of type T. T must be the only type
used by any atomic referencing any part of p’s target memory for the entire life-
time of UPC++. order must be std::memory_order_relaxed, std::memory_ 
order_acquire, std::memory_order_release, or std::memory_order_acq_ 
rel. The atomic_op::sub operation must have been included in the ops used 
to construct this atomic_domain.

Initiates the atomic read-modify-write operation consisting of: reading the
value of the object located at p, subtracting val from it, and writing the new
value back.

Completions:

- Operation: Indicates completion of all aspects of the operation: the transfer
  of the given value to the recipient, and remote atomic update are
  complete.

C++ memory ordering: If order is either std::memory_order_release or
std::memory_order_acq_rel then all evaluations sequenced-before this call
will have a happens-before relationship with the atomic action. If order is std::
memory_order_acquire or std::memory_order_acq_rel then the atomic action
will have a happens-before relationship with the operation-completion not-
fication actions (future readying, promise fulfillment, or persona LPC enlist-
ment).

UPC++ progress level: internal

template<typename T>,
    typename Completions=decltype(operation_cx::as_future())>
Type atomic_domain<T>::fetch_sub(global_ptr<T> p,
    T val,
    std::memory_order order,
    Completions cx=Completions{});
Precondition: \( p \) must reference a valid object of type \( T \). \( T \) must be the only type used by any atomic referencing any part of \( p \)’s target memory for the entire lifetime of UPC++. \( \text{order} \) must be \texttt{std::memory\_order\_relaxed}, \texttt{std::memory\_order\_acquire}, \texttt{std::memory\_order\_release}, or \texttt{std::memory\_order\_acq\_rel}. The \texttt{atomic\_op::fetch\_sub} operation must have been included in the \texttt{ops} used to construct this \texttt{atomic\_domain}.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at \( p \), subtracting \( \text{val} \) from it, and writing the new value back. The value produced by operation completion is the one initially read.

Completions:

- **Operation**: Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, remote atomic update, and transfer of the old value to the initiator are complete. This completion produces a value of type \( T \).

**C++ memory ordering**: If \( \text{order} \) is either \texttt{std::memory\_order\_release} or \texttt{std::memory\_order\_acq\_rel} then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If \( \text{order} \) is \texttt{std::memory\_order\_acquire} or \texttt{std::memory\_order\_acq\_rel} then the atomic action will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

**UPC++ progress level**: internal

```cpp
template<typename T,
         typename Completions = decltype(operation_cx::as_future())>
Type atomic_domain<T>::inc(global_ptr<T> p,
                          std::memory_order order,
                          Completions cxs=Completions{});
```

Precondition: \( p \) must reference a valid object of type \( T \). \( T \) must be the only type used by any atomic referencing any part of \( p \)’s target memory for the entire lifetime of UPC++. \( \text{order} \) must be \texttt{std::memory\_order\_relaxed}, \texttt{std::memory\_order\_acquire}, \texttt{std::memory\_order\_release}, or \texttt{std::memory\_order\_acq\_rel}. The \texttt{atomic\_op::inc} operation must have been included in the \texttt{ops} used to construct this \texttt{atomic\_domain}.
Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at \( p \), adding 1 to it, and writing the new value back.

**Completions:**

- **Operation:** Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, and remote atomic update are complete.

**C++ memory ordering:** If `order` is either `std::memory_order_release` or `std::memory_order_acquire` or `std::memory_order_acq_rel` then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If `order` is `std::memory_order_release` or `std::memory_order_acq_rel` then the atomic action will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

**UPC++ progress level:** internal

```cpp
template<typename T,
    typename Completions = decltype(operation_cx::as_future())>
Type atomic_domain<T>::fetch_inc(global_ptr<T> p,  
    std::memory_order order,  
    Completions cxs=Completions{});
```

**Precondition:** `p` must reference a valid object of type `T`. `T` must be the only type used by any atomic referencing any part of `p`'s target memory for the entire lifetime of UPC++. `order` must be `std::memory_order_release`, `std::memory_order_acq_rel`, or `std::memory_order_acquire`. The `atomic_op::fetch_inc` operation must have been included in the `ops` used to construct this `atomic_domain`.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at \( p \), adding 1 to it, and writing the new value back. The value produced by operation completion is the one initially read.

**Completions:**

- **Operation:** Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, remote atomic update, and transfer of the old value to the initiator are complete. This completion produces a value of type `T`.
CHAPTER 11. ATOMICS

C++ memory ordering: If order is either `std::memory_order_release` or `std::memory_order_acq_rel` then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If order is `std::memory_order_acquire` or `std::memory_order_acq_rel` then the atomic action will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal

```

template<typename T,
    typename Completions = decltype(operation_cx::as_future())>

Type atomic_domain<T>::dec(global_ptr<T> p,
    std::memory_order order,
    Completions cxs=Completions{});

Precondition: p must reference a valid object of type T. T must be the only type used by any atomic referencing any part of p’s target memory for the entire lifetime of UPC++. order must be `std::memory_order_relaxed`, `std::memory_order_acquire`, `std::memory_order_release`, or `std::memory_order_acq_rel`. The `atomic_op::dec` operation must have been included in the ops used to construct this `atomic_domain`.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at p, subtracting 1 from it, and writing the new value back.

Completions:

- **Operation**: Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, and remote atomic update are complete.

C++ memory ordering: If order is either `std::memory_order_release` or `std::memory_order_acq_rel` then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If order is `std::memory_order_acquire` or `std::memory_order_acq_rel` then the atomic action will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal
template<typename T,
  typename Completions=decltype(operation_cx::as_future())>
Type atomic_domain<T>::fetch_dec(global_ptr<T> p,
  std::memory_order order,
  Completions cxs=Completions{});

**Precondition:** p must reference a valid object of type T. T must be the only type
used by any atomic referencing any part of p’s target memory for the entire life-
time of UPC++. order must be std::memory_order_relaxed, std::memory_
order_acquire, std::memory_order_release, or std::memory_order_acq_ rel. The atomic_op::fetch_dec operation must have been included in the
ops used to construct this atomic_domain.

Initiates the atomic read-modify-write operation consisting of: reading the
value of the object located at p, subtracting 1 from it, and writing the new
value back. The value produced by operation completion is the one initially
read.

**Completions:**

- **Operation:** Indicates completion of all aspects of the operation: the trans-
  fer of the given value to the recipient, remote atomic update, and transfer
  of the old value to the initiator are complete. This completion produces a
  value of type T.

**C++ memory ordering:** If order is either std::memory_order_release or
std::memory_order_acq_rel then all evaluations sequenced-before this call
will have a happens-before relationship with the atomic action. If order is std:::
memory_order_acquire or std::memory_order_acq_rel then the atomic ac-
tion will have a happens-before relationship with the operation-completion no-
tification actions (future readying, promise fulfillment, or persona LPC enlist-
ment).

**UPC++ progress level:** internal

template<typename T,
  typename Completions=decltype(operation_cx::as_future())>
Type atomic_domain<T>::compare_exchange(
  global_ptr<T> p,
  T val1,
  T val2,
  std::memory_order order,
  Completions cxs=Completions{});
Precondition: p must reference a valid object of type T. T must be the only type used by any atomic referencing any part of p’s target memory for the entire lifetime of UPC++. order must be std::memory_order_relaxed, std::memory_order_acquire, std::memory_order_release, or std::memory_order_acq_rel. The atomic_op::compare_exchange operation must have been included in the ops used to construct this atomic_domain.

Initiates the atomic read-modify-write operation consisting of: reading the value of the object located at p, and if it is equal to val1, writing val2 back. The value produced by operation completion is the one initially read.

Completions:

• Operation: Indicates completion of all aspects of the operation: the transfer of the given value to the recipient, remote atomic update, and transfer of the old value to the initiator are complete. This completion produces a value of type T.

C++ memory ordering: If order is either std::memory_order_release or std::memory_order_acquire then all evaluations sequenced-before this call will have a happens-before relationship with the atomic action. If order is std::memory_order_acquire or std::memory_order_acq_rel then the atomic action will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal
Chapter 12

Teams

12.1 Overview

UPC++ provides *teams* as a means of grouping ranks. UPC++ uses *teams* for collective operations. *team* construction is collective and should be considered moderately expensive and done as part of the set-up phase of a calculation. *teams* are similar to MPI _Groups_ and the default *team* is *world()*. *teams* are considered special when it comes to serialization. Each *team* has a unique *team_id* that is equal across the *team* and acts as an opaque handle. Any rank that is a member of the *team* can retrieve the *team* object with the *team_id::here()* function. Hence, coordinating ranks can reference specific *teams* by their *team_id*.

While a rank within a UPC++ SPMD program can have multiple *intrank_t* values that represent their relative placement in several *teams*, it is the *intrank_t* in the *world()* that is used in all UPC++ functions, unless otherwise specifically noted. For example, *broadcast* uses the team-relative rank.

12.2 Local Teams

Each rank can obtain a reference to a special team by calling *local_team*. *global_ptr*’s to objects allocated by ranks within this *team* will report *is_local()* == true and *local()* will return a valid T* to that memory. The *global_ptr where()* function will report the rank (in team *world()* ) that originally acquired that memory using the functions in chapter 4. It is not guaranteed that the T*’s obtained by different ranks to the same shared object will have bit-wise identical pointer values. In the general case, peers may have different virtual addresses for the same physical memory.
12.3 API Reference

12.3.1 team

class team;

C++ Concepts: MoveConstructible, Destructible

intrank_t team::rank_n() const;

Returns the number of ranks that are in the given team.

UPC++ progress level: none

intrank_t team::rank_me() const;

Returns the peer index of the caller in the given team.

UPC++ progress level: none

intrank_t team::operator[](intrank_t peer_index) const;

Precondition: peer_index >= 0 and peer_index < rank_n().
Returns the index in the world() team for the rank associated with peer_index in this team.

UPC++ progress level: unspecified between none and internal

intrank_t team::from_world(intrank_t world_index) const;
intrank_t team::from_world(intrank_t world_index, intrank_t otherwise) const;

Precondition: world_index >= 0 and world_index < world().rank_n(). For the single argument overload, the rank associated with world_index must be a member of this team.

Returns the peer index in this team of the rank associated with world_index in the world() team. For the two argument overload, if the rank is not a member of this team then the value of otherwise is returned.

UPC++ progress level: unspecified between none and internal
team team::split(intrank_t color, intrank_t key);

Precondition: This function must be called collectively by all the ranks in this
team, and it must be called by the thread that has the master persona (§10.5.1).
No two ranks in the collective call may specify the same combination of color
and key.

Splits the given team into subteams based on the color and key arguments.
All ranks that call the function with the same color value will be separated
into the same subteam. Ranks in the same subteam will be numbered according
to their position in the sequence of sorted key values. The return value is the
team representing the calling rank’s new subteam. This call will invoke user-
level progress, so the caller may expect incoming RPCs to fire before it returns.

C++ memory ordering: With respect to all threads participating in this col-
llective, all evaluations which are sequenced-before their respective thread’s in-
vocation of this call will have a happens-before relationship with all evaluations
sequenced after the call.

UPC++ progress level: user

team::team(team &&other);

Precondition: Calling thread must have the master persona.
Makes this instance the calling rank’s representative of the team associated with
other, transferring all state from other. Invalidates other, and any subsequent
operations on other, except for destruction, produce undefined behavior.

UPC++ progress level: none

team::~team();

Precondition: Calling thread must have the master persona.
If this instance has not been invalidated by being passed to the move construc-
tor, then this will destroy the current rank’s state associated with the team.
Further lookups on this rank using the team_id corresponding to this team will
have undefined behavior. If this instance has been invalidated by a move, then
this call will have no effect.

UPC++ progress level: none

team_id team::id() const;

Returns the universal name associated with this team.

UPC++ progress level: none
12.3.2 team_id

```cpp
class team_id;
```

C++ Concepts: DefaultConstructible, TriviallyCopyable, StandardLayoutType,
EqualityComparable, LessThanComparable, hashable

UPC++ Concepts: DefinitelyTriviallySerializable

A universal name representing a team.

team_id::team_id();

Initializes this name to be an invalid ID.

*UPC++ progress level: none*

```cpp
team& team_id::here() const;
```

*Precondition:* This name must be a valid ID. The current rank must be a
member of the `team` associated with this name, and it must have completed
creation of the `team`. The `team` must not have been destroyed.

Retrieves a reference to the `team` instance associated with this name.

*UPC++ progress level: none*

```cpp
future<team &> team_id::when_here() const;
```

*Precondition:* This name must be a valid ID. The current rank must be a
member of the `team` associated with this name. The calling thread must have
the master persona. The `team` must not have been destroyed.

Retrieves a future representing when the current rank constructs the `team` cor-
responding to this name.

*UPC++ progress level: none*
12.3.3 Fundamental Teams

```cpp
team & world();

Returns a reference to the team representing all the ranks in the program. The
result is undefined if a move is performed on the returned team.

UPC++ progress level: none
```

```cpp
intrank_t rank_n();

Returns the number of ranks that are in the world team.

Equivalent to: world().rank_n().

UPC++ progress level: none
```

```cpp
intrank_t rank_me();

Returns the peer index of the caller in the world team.

Equivalent to: world().rank_me().

UPC++ progress level: none
```

```cpp
team & local_team();

Returns a reference to the local team containing this rank. A local team rep-
resents a set of ranks which share physical memory (§12.2). The result is
undefined if a move is performed on the returned team.

UPC++ progress level: none
```

```cpp
bool local_team_contains(intrank_t world_index);

Precondition: world_index >= 0 and world_index < world().rank_n().

Determines if world_index is a member of the local team containing the this
rank (§12.2).

Equivalent to: local_team().from_world(world_index,-1) >= 0

UPC++ progress level: none
```
12.3.4 Collectives

```c
void barrier(team &team = world());
```

Precondition: This function must be called collectively by all the ranks in the given team, and it must be called by the thread that has the master persona (§10.5.1).

Performs a barrier operation over the given team. The call will not return until all ranks in the team have entered the call. There is no implied relationship between this call and other in-flight operations. This call will invoke user-level progress, so the caller may expect incoming RPCs to fire before it returns.

C++ memory ordering: With respect to all threads participating in this collective, all evaluations which are sequenced-before their respective thread’s invocation of this call will have a happens-before relationship with all evaluations sequenced after the call.

UPC++ progress level: user

```c
template<typename Completions = decltype(operation_cx::as_future())> RType barrier_async(team &team = world(),
    Completions cxs=Completions{});
```

Precondition: This function must be called collectively by all the ranks in the given team, and it must be called by the thread that has the master persona (§10.5.1).

Initiates an asynchronous barrier operation over the given team. The call will return without waiting for other ranks to make the call. Operation completion will be signaled after all other ranks in the team have entered the call.

Completions:

- Operation: Indicates completion of the collective from the viewpoint of the caller, implying that all ranks in the given team have entered the collective.

C++ memory ordering: With respect to all threads participating in this collective, all evaluations which are sequenced-before their respective thread’s invocation of this call will have a happens-before relationship with all evaluations sequenced after the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal
template<typename T, typename BinaryOp, 
    typename Completions = decltype(operation_cx::as_future())> 
RType allreduce(T &&value, BinaryOp &&op, team &team = world(), 
    Completions cxs = Completions{});

Precondition: This function must be called collectively by all the ranks in the 
given team, and it must be called by the thread that has the master per-
sona (§10.5.1). T must be DefinitelyTriviallySerializable. BinaryOp must be a 
function-object type representing an associative and commutative mathemat-
ical operation taking two values of type T and returning a value implicitly 
convertible to T. BinaryOp must be referentially transparent and concurrently 
invocable. BinaryOp may not invoke any UPC++ routine with a progress level 
other than none.

Performs a reduction operation over the ranks in the given team. If the team 
contains only a single rank, then the resulting operation completion will produce 
value. Otherwise, initiates an asynchronous reduction over the values provided 
by each rank. The reduction is performed in some non-deterministic order by 
applying op to combine values and intermediate results. Each rank receives the 
result of the reduction as part of operation completion.

Completions:

- Operation: Indicates completion of the collective from the viewpoint of 
  the caller, implying that the result of the reduction is available at this 
  rank. This completion produces a value of type T.

C++ memory ordering: With respect to all threads participating in this col-
lective, all evaluations which are sequenced-before their respective thread’s in-
vocation of this call will have a happens-before relationship with all evaluations 
sequenced after the operation-completion notification actions (future readying, 
promise fulfillment, or persona LPC enlistment).

UPC++ progress level: internal

template<typename T, 
    typename Completions = decltype(operation_cx::as_future())> 
RType broadcast(T &&value, intrank_t sender, 
    team &team = world(), 
    Completions cxs = Completions{});

template<typename T, 
    typename Completions = decltype(operation_cx::as_future())>
RType broadcast(T *buffer, std::size_t count,
   intrank_t sender, team &team = world(),
   Completions cxs = Completions{});

**Precondition:** The function must be called collectively by the ranks in the
given team, and it must be called by the thread that has the master persona
(§10.5.1). The value of sender, and count in the second variant, must be the
same across all callers. In the second variant, the addresses in the interval
[buffer,buffer+count) must all reference valid objects of type T. The type
T must be DefinitelyTriviallySerializable.

Initiates an asynchronous broadcast (one-to-all) operation, with rank sender
of team acting as the producer of the broadcast. In the first variant, value
will be asynchronously sent to all ranks in the team, encapsulated in operation
completion, which will be signaled upon receipt of the value. In the second
variant, the objects in [buffer,buffer+count) on rank sender are sent to the
addresses [buffer,buffer+count) provided by the receiving ranks. Operation
completion signals completion of the operation with respect to the calling rank.
For the sender, this indicates that the given buffer is available for reuse, and
for a receiver, it indicates that the data have been received in its buffer.

**Completions:**

- **Operation:** In the first variant, indicates that the value provided by the
  sender is available at the caller. This completion produces a value of type
  T.

  In the second variant, indicates completion of the collective from the view-
  point of the caller as described above.

**C++ memory ordering:** With respect to all threads participating in this col-
lective, all evaluations which are sequenced-before the producing thread’s invo-
cation of this call will have a happens-before relationship with all evaluations
sequenced after the operation-completion notification actions (future readying,
promise fulfillment, or persona LPC enlistment).

**UPC++ progress level:** internal
Chapter 13

Distributed Objects

13.1 Overview

In distributed-memory parallel programming, the concept of a single logical object partitioned over several ranks is a useful capability in many contexts: for example, geometric meshes, vectors, matrices, tensors, and associative maps. Since UPC++ is a communication library, it strives to focus on the mechanisms of communication as opposed to the various programming idioms for managing distribution. However, a basic framework for users to implement their own distributed objects is useful and also enables UPC++ to provide the user with the following valuable features:

1. Universal distributed object naming: per-object names that can be transmitted to other ranks while retaining their meaning.

2. Name-to-this mapping: Mapping between the universal name and the current rank’s memory address holding that distributed object’s state for the rank (the current rank’s this pointer).

The need for universal distributed object naming stems primarily from RPC-based communication. If one rank needs to remotely invoke code on a peer’s partition of a distributed object, there needs to be some mutually agreeable identifier for referring to that distributed object. For simplicity, this identifier value should be: identical across all ranks so that it may be freely communicated while maintaining its meaning. Moreover, the name should be TriviallyCopyable so that it may be serialized into RPCs efficiently (including with the auto-capture [=] lambda syntax), hashable, and comparable so that it works well with standard C++ containers. UPC++ provides distributed object names meeting these criteria as well as the registry for mapping names to and from the current rank’s partition of the distributed object.
13.2 Building Distributed Objects

Distributed objects are built with the \texttt{upcxx::dist_object<T>} type. For all ranks in a given team, each rank constructs an instance of \texttt{dist_object<T>}, supplying a value of type \texttt{T} representing this rank's instance value. All ranks in the team must call this constructor collectively. Once construction completes, the distributed object has a universal name which can be used on any rank in the team to locate the resident instance. When the \texttt{dist_object<T>} is destructed the \texttt{T} value is also destructed. At this point the name will cease to carry meaning on this rank. Thus, the programmer should ensure that no rank destructs a distributed object until all name lookups destined for it complete and all hanging references of the form \texttt{T} or \texttt{T*} to the value have expired.

The names of \texttt{dist_object<T>}'s are encoded by the \texttt{dist_id<T>} type. This type is TriviallyCopyable, EqualityComparable, LessThanComparable, hashable, and DefinitelyTriviallySerializable. It has the members \texttt{.here()} and \texttt{.when_here()} for retrieving the resident \texttt{dist_object<T>} instance registered with the name.

13.3 Ensuring Distributed Existence

The \texttt{dist_object<T>} constructor requires it be called in a collective context, but it does not guarantee that, after the call, all other ranks in the team have exited or even reached the constructor. Thus users are required to guard against the possibility that when an RPC carrying an distributed object's name executes, the recipient rank may not yet have an entry for that name in its registry. Possible ways to deal with this include:

1. Barrier: Before issuing communication containing a \texttt{dist_id<T>} for a newly created distributed object, the relevant team completes a \texttt{barrier} to ensure global existence of the \texttt{dist_object<T>}.

2. Point to point: Before communicating a \texttt{dist_id<T>} with a given rank, the initiating rank uses some two-party protocol to ensure that the peer has constructed the \texttt{dist_object<T>}.

3. Asynchronous point-to-point: The user performs no synchronization to ensure remote existence. Instead, an RPC is sent which, upon arrival, must wait asynchronously via a continuation for the peer to construct the distributed object.

\texttt{UPC++} enables the asynchronous point-to-point approach implicitly when \texttt{dist_object<T>&} arguments are given to any of the RPC family of functions (see Ch. 9).
13.4 API Reference

```cpp
template<typename T>
class dist_object;
```

C++ Concepts: MoveConstructible, Destructible

```cpp
template<typename T>
dist_object<T>::dist_object(T value, team &team = world());
```

**Precondition:** Calling thread must have the master persona.

Constructs this rank’s member of the distributed object identified by the collective calling context across `team`. The initial value for this rank is given in `value`. The future returned from `dist_id<T>::when_here` for the corresponding `dist_id<T>` will be readied during this constructor. This implies that continuations waiting for that future will execute before the constructor returns.

**UPC++ progress level:** none

```cpp
template<typename T>
template<typename ...Arg>
dist_object<T>::dist_object(team &team, Arg &&...arg);
```

**Precondition:** Calling thread must have the master persona.

Constructs this rank’s member of the distributed object identified by the collective calling context across `team`. The initial value for this rank is constructed with `T(std::forward<Arg>(arg)...)` . The result is undefined if this call throws an exception. The future returned from `dist_id<T>::when_here` for the corresponding `dist_id<T>` will be readied during this constructor. This implies that continuations waiting for that future will execute before the constructor returns.

**UPC++ progress level:** none

```cpp
template<typename T>
dist_object<T>::dist_object(dist_object<T> &&other);
```

Base revision c18711b, Mon Mar 26 22:08:25 2018 -0400.
Precondition: Calling thread must have the master persona.

Makes this instance the calling rank’s representative of the distributed object associated with other, transferring all state from other. Invalidates other, and any subsequent operations on other, except for destruction, produce undefined behavior.

UPC++ progress level: none

template<typename T>
dist_object<T>::~dist_object();

Precondition: Calling thread must have the master persona.

If this instance has not been invalidated by being passed to the move constructor, then this will destroy the current rank’s member of the distributed object. ~T() will be invoked on the resident instance, and further lookups on this rank using the dist_id<T> corresponding to this distributed object will have undefined behavior. If this instance has been invalidated by a move, then this call will have no effect.

UPC++ progress level: none

template<typename T>
dist_id<T> dist_object<T>::id() const;

Returns the dist_id<T> representing the universal name of this distributed object.

UPC++ progress level: none

template<typename T>
team& dist_object<T>::team() const;

Precondition: The team associated with this distributed object must not have been destroyed.

Retrieves a reference to the team instance associated with this distributed object.

UPC++ progress level: none

template<typename T>
T* dist_object<T>::operator ->() const;
Access to the current rank’s value instance for this distributed object.

`UPC++ progress level: none`

```cpp
template<typename T>
T& dist_object<T>::operator*() const;
```

Access to the current rank’s value instance for this distributed object.

`UPC++ progress level: none`

```cpp
template<typename T>
future<T> dist_object<T>::fetch(inrank_t rank) const;
```

**Precondition:** `rank` must be a valid ID in the team associated with this distributed object. T must be `DefinitelySerializable` but not `view<U, IterType>`. `rank`’s instance of this distributed object must not have been destroyed. The `team` associated with this distributed object must not have been destroyed.

Asynchronously retrieves a copy of the instance of this distributed object associated with the peer index `rank` in this distributed object’s team. The result is encapsulated in the returned `future`. This call is equivalent to

```cpp
rpc(team()[rank],
    [](dist_object<T> &obj) { return *obj; },
    *this)
```

`UPC++ progress level: internal`

```cpp
template<typename T>
struct dist_id<T>;
```

C++ Concepts: `DefaultConstructible`, `TriviallyCopyable`, `StandardLayoutType`, `EqualityComparable`, `LessThanComparable`, `hashable`

`UPC++ Concepts: DefinitelyTriviallySerializable`

```cpp
template<typename T>
dist_id<T>::dist_id();
```

Initializes this name to be an invalid ID.

`UPC++ progress level: none`
```cpp
template<typename T>
future<dist_object<T>>& dist_id<T>::when_here() const;

Precondition: This name must be a valid ID. The current rank’s dist_object<T> instance associated with this name must not have been destroyed. The calling thread must have the master persona.
Retrieves a future representing when the current rank constructs the dist_object<T> corresponding to this name.

UPC++ progress level: none

```
Chapter 14

Non-Contiguous One-Sided Communication

14.1 Overview

UPC++ provides functions to perform one-sided communications similar to \texttt{rget} and \texttt{rput} which are dedicated to handle data stored in non-contiguous locations. These functions are denoted with a suffix added to the type of operation, in increasing order of specialization:

\{\texttt{rput},\texttt{rget}\}_\{irregular, regular, strided\}

The most general variant of the API, \{\texttt{rput},\texttt{rget}\}_irregular, accept iterators over an array or collection of \texttt{std::pair} (or \texttt{std::tuple}) that contain a local or global pointer to a memory location in the first member while the second member contains the size of the contiguous chunk of memory to be transferred. This variant is capable of expressing non-contiguous RMA of arbitrary shape, but pays the highest overhead in metadata to payload ratio.

The next set of functions, \{\texttt{rput},\texttt{rget}\}_regular, operates over contiguous elements of identical size on each side of the transfer, and only requires the caller to provide an array or collection of base pointers to each element.

Finally, the most specialized set of functions, \{\texttt{rput},\texttt{rget}\}_strided, provide an interface for expressing translational and transposing copies between arbitrary rectangular sections of densely stored N-dimensional arrays. This specialized pattern requires the least metadata, which is constant in size for a given dimensionality. An example of such a transfer is depicted in Figure 14.1.
14.2 API Reference

14.2.1 Requirements on Iterators

An iterator used with a UPC++ operation in this section must adhere to the following requirements:

- It must satisfy the Iterator and EqualityComparable C++ concepts.
- Calling std::distance on the iterator must not invalidate it.

14.2.2 Irregular Put

```
template <typename SrcIter, typename DestIter,
          typename Completions = decltype(operation_cx::as_future())>
RType rput_irregular(
    SrcIter src_runs_begin, SrcIter src_runs_end,
    DestIter dest_runs_begin, DestIter dest_runs_end,
    Completions cxs=Completions{});
```

**Preconditions:**

SrcIter and DestIter both satisfy the iterator requirements above.

std::get<0>(*std::declval<SrcIter>()) has a return type convertible to T * const*, for some DefinitelyTriviallySerializable type T.
std::get<1>(*std::declval<SrcIter>()) has a return type convertible to std::size_t.

std::get<0>(*std::declval<DestIter>()) has the return type global_ptr<T>, for the same type T as with SrcIter.

std::get<1>(*std::declval<DestIter>()) has a return type convertible to std::size_t.

All destination addresses must be global_ptr<T>’s referencing memory with affinity to the same rank.

The length of the expanded address sequence (the sum over the run lengths) must be the same for the source and destination sequences.

For some type T, takes a sequence of source addresses of T const* and a sequence of destination addresses of global_ptr<T> and does the corresponding puts from each source address to the destination address of the same sequence position.

Address sequences are encoded in run-length form as sequences of runs, where each run is a pair consisting of a starting address plus the number of consecutive elements of type T beginning at that address.

As an example of valid types for individual runs, SrcIter could be an iterator over elements of type std::pair<T const*, std::size_t>, and DestIter an iterator over std::pair<global_ptr<T>, std::size_t>. Variations replacing std::pair with std::tuple or size_t with other primitive integral types are also valid.

The source sequence iterators must remain valid, and the underlying addresses and source memory contents must not be modified until source completion is signaled. Only after source completion is signaled can the source address sequences and memory be reclaimed by the application.

The destination sequence iterators must remain valid until source completion is signaled.

The destination memory regions must be completely disjoint and must not overlap with any source memory regions, otherwise behavior is undefined. Source regions are permitted to overlap with each other.

**Completions:**

- **Source:** Indicates that the source sequence iterators and underlying memory, as well as the destination sequence iterators, are no longer in use by UPC++ and may be reclaimed by the user.
• **Remote:** Indicates completion of the transfer of all values.

• **Operation:** Indicates completion of all aspects of the operation: the transfer and remote stores are complete.

*C++ memory ordering:* The reads of the sources will have a *happens-before* relationship with the source-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment). The writes to the destinations will have a *happens-before* relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment) and remote-completion actions (RPC enlistment). For LPC and RPC completions, all evaluations *sequenced-before* this call will have a *happens-before* relationship with the execution of the completion function.

**UPC++ progress level:** `internal`

### 14.2.3 Irregular Get

```cpp
template<typename SrcIter, typename DestIter, typename Completions = decltype(operation_cx::as_future())>
RType rget_irregular(
    SrcIter src_runs_begin, SrcIter src_runs_end,
    DestIter dest_runs_begin, DestIter dest_runs_end,
    Completions cxs = Completions{});
```

**Preconditions:**

- `SrcIter` and `DestIter` both satisfy the iterator requirements above.
- `std::get<0>(*std::declval<SrcIter>())` has the type `global_ptr<T>` for some DefinitelyTriviallySerializable type `T`.
- `std::get<1>(*std::declval<SrcIter>())` has a type that is convertible to `std::size_t`.
- `std::get<0>(*std::declval<DestIter>())` has the type `T*`, for the same type `T` as with `SrcIter`.
- `std::get<1>(*std::declval<DestIter>())` has a type that is convertible to `std::size_t`.

All source addresses must be `global_ptr<T>`’s referencing memory with affinity to the same rank.

The length of the expanded address sequence (the sum over the run lengths) must be the same for the source and destination sequences.
For some type T, takes a sequence of source addresses of `global_ptr<T>` and a sequence of destination addresses of T* and does the corresponding gets from each source address to the destination address of the same sequence position.

Address sequences are encoded in run-length form as sequences of runs, where each run is a pair consisting of a starting address plus the number of consecutive elements of type T beginning at that address.

As an example of valid types for individual runs, `DestIter` could be an iterator over elements of type `std::pair<T*, std::size_t>`, and `SrcIter` an iterator over `std::pair<global_ptr<T>, std::size_t>`. Variations replacing `std::pair` with `std::tuple` or `size_t` with other primitive integral types are also valid.

The source sequence iterators must remain valid, and the underlying addresses and memory contents must not be modified until operation completion is signaled. Only after operation completion is signaled can the address sequences and source memory be reclaimed by the application.

The destination sequence iterators must remain valid until operation completion is signaled.

The destination memory regions must be completely disjoint and must not overlap with any source memory regions, otherwise behavior is undefined. Source regions are permitted to overlap with each other.

**Completions:**

- **Operation**: Indicates completion of all aspects of the operation: the transfer and local stores are complete.

**C++ memory ordering**: The reads of the sources and writes to the destinations will have a happens-before relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment). For LPC completions, all evaluations sequenced-before this call will have a happens-before relationship with the execution of the completion function.

**UPC++ progress level**: `internal`

### 14.2.4 Regular Put

```cpp
template< typename SrcIter , typename DestIter ,
          typename Completions = decltype (operation_cx::as_future())>
RType rput_regular(
    SrcIter src_runs_begin , SrcIter src_runs_end ,
...
std::size_t src_run_length,
DestIter dest_runs_begin, DestIter dest_runs_end,
std::size_t dest_run_length,
Completions cxs=Completions{};

Preconditions:

SrcIter and DestIter both satisfy the iterator requirements above.
*std::declval<SrcIter>() has a type convertible to T const*, for some
DefinitelyTriviallySerializable type T.
*std::declval<DestIter>() has the type global_ptr<T>, for the same
type T as with SrcIter.

All destination addresses must be global_ptr<T>’s referencing memory
with affinity to the same rank.
The length of the two sequences delimited by (src_runs_begin,
src_runs_end) and (dest_runs_begin, dest_runs_end) multiplied by
src_run_length and dest_run_length, respectively, must be the same.

This call has the same semantics as rput_irregular with the exception that,
for each sequence, all run lengths are the same and are factored out of the
sequences into two extra parameters src_run_length and dest_run_length,
which express the number of consecutive elements of type T in units of element
count. Thus the iterated elements are no longer pairs, but just pointers.
The source sequence iterators must remain valid, and the underlying addresses
and source memory contents must not be modified until source completion
is signaled. Only after source completion is signaled can the source address
sequences and memory be reclaimed by the application.
The destination sequence iterators must remain valid until source completion
is signaled.

Completions:

- **Source:** Indicates that the source sequence iterators and underlying mem-
  ory, as well as the destination sequence iterators, are no longer in use by
  UPC++ and may be reclaimed by the user.
- **Remote:** Indicates completion of the transfer of all values.
- **Operation:** Indicates completion of all aspects of the operation: the trans-
  fer and remote stores are complete.

**C++ memory ordering:** The reads of the sources will have a happens-before
relationship with the source-completion notification actions (future readying,
promise fulfillment, or persona LPC enlistment). The writes to the destinations
will have a happens-before relationship with the operation-completion notifica-
tion actions (future readying, promise fulfillment, or persona LPC enlistment)
and remote-completion actions (RPC enlistment). For LPC and RPC com-
pletions, all evaluations sequenced-before this call will have a happens-before
relationship with the execution of the completion function.

UPC++ progress level: internal

14.2.5 Regular Get

```cpp
template<
typename SrcIter,
typename DestIter,
typename Completions = decltype(operation_cx::as_future())>
RType rget_regular(
  SrcIter src_runs_begin, SrcIter src_runs_end,
  std::size_t src_run_length,
  DestIter dest_runs_begin, DestIter dest_runs_end,
  std::size_t dest_run_length,
  Completions cxs=Completions{});

Preconditions:

  SrcIter and DestIter both satisfy the iterator requirements above.
  *std::declval<DestIter>() has a type convertible to T*, for some Def-
  initelyTriviallySerializable type T.
  *std::declval<SrcIter>() has the type global_ptr<T>, for the same
  type T as with DestIter.
  All source addresses must be global_ptr<T>’s referencing memory with
  affinity to the same rank.
  The length of the two sequences delimited by (src_runs_begin,
  src_runs_end) and (dest_runs_begin, dest_runs_end) multiplied by
  src_run_length and dest_run_length, respectively, must be the same.

This call has the same semantics as rget_irregular with the exception that,
for each sequence, all run lengths are the same and are factored out of the
sequences into two extra parameters src_run_length and dest_run_length,
which express the number of consecutive elements of type T in units of element
count. Thus, the iterated elements are no longer pairs, but just pointers.

The source sequence iterators must remain valid, and the underlying addresses
and memory contents must not be modified until operation completion is sig-
naled. Only after operation completion is signaled can the address sequences
and source memory be reclaimed by the application.
```
CHAPTER 14. NON-CONTIGUOUS ONE-SIDED COMMUNICATION

The destination sequence iterators must remain valid until operation completion is signaled.

Completions:

- **Operation**: Indicates completion of all aspects of the operation: the transfer and local stores are complete.

**C++ memory ordering**: The reads of the sources and writes to the destinations will have a *happens-before* relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment). For LPC completions, all evaluations *sequenced-before* this call will have a *happens-before* relationship with the execution of the completion function.

**UPC++ progress level**: *internal*

### 14.2.6 Strided Put

```cpp
template <std::size_t Dim, typename T, 
    typename Completions=decltype(operation_cx::as_future())>
RType rput_strided(
    T const *src_base, 
    std::ptrdiff_t const *src_strides, 
    global_ptr<T> dest_base, 
    std::ptrdiff_t const *dest_strides, 
    std::size_t const *extents, 
    Completions cxs=Completions{});
```

```cpp
template <std::size_t Dim, typename T, 
    typename Completions=decltype(operation_cx::as_future())>
RType rput_strided(
    T const *src_base, 
    std::array<std::ptrdiff_t,Dim> const &src_strides, 
    global_ptr<T> dest_base, 
    std::array<std::ptrdiff_t,Dim> const &dest_strides, 
    std::array<std::size_t,Dim> const &extents, 
    Completions cxs=Completions{});
```

**Precondition**: T must be a DefinitelyTriviallySerializable type. All source addresses and destination global pointers must reference valid objects of type T. Each element src_strides[i], dest_strides[i], and extents[i] must be valid objects of their respective pointed-to type for all 0 <= i < Dim.
If Dim == 0, src_strides, dest_strides, and extents are ignored, and the
data movement performed is equivalent to rput(src_base, dest_base, 1).
Otherwise, performs the semantic equivalent of many put’s of type T. Let
the index space be the set of integer vectors of dimension Dim contained in
the bounding box with the inclusive lower bound at the all-zero origin, and
the exclusive upper bound equal to extents. For each index vector index in
this index space, a put will be executed with source and destination addresses
computed according to the following pseudo-code, where dotprod is the vector
dot product and pointer arithmetic is done in units of bytes (not elements of
T):

```
src_address = src_base + dotprod(index, src_strides)
dest_address = dest_base + dotprod(index, dest_strides)
```

Note this implies the elements of the src_strides and dest_strides arrays
are expressed in units of bytes.

The destination memory regions must be completely disjoint and must not over-
lap with any source memory regions, otherwise behavior is undefined. Source
regions are permitted to overlap with each other.

The elements of type T residing in the source addresses must remain valid and
unmodified until source completion is signaled.

The contents of the src_strides, dest_strides, and extents arrays are con-
sumed synchronously before the call returns.

**Completions:**

- **Source:** Indicates that the source memory is no longer in use by UPC++
  and may be reclaimed by the user.
- **Remote:** Indicates completion of the transfer of all values.
- **Operation:** Indicates completion of all aspects of the operation: the trans-
  fer and remote stores are complete.

**C++ memory ordering:** The reads of the sources will have a happens-before
relationship with the source-completion notification actions (future readying,
promise fulfillment, or persona LPC enlistment). The writes to the destinations
will have a happens-before relationship with the operation-completion notifica-
tion actions (future readying, promise fulfillment, or persona LPC enlistment)
and remote-completion actions (RPC enlistment). For LPC and RPC com-
pletions, all evaluations sequenced-before this call will have a happens-before
relationship with the execution of the completion function.

**UPC++ progress level:** internal
14.2.7 Strided Get

```cpp
template< std::size_t Dim , typename T ,
          typename Completions = decltype( operation_cx::as_future() ) >
RType rget_strided(
    global_ptr<T> src_base ,
    std::ptrdiff_t const * src_strides ,
    T * dest_base ,
    std::ptrdiff_t const * dest_strides ,
    std::size_t const * extents ,
    Completions cxs = Completions{ });
```

```cpp
template< std::size_t Dim , typename T ,
          typename Completions = decltype( operation_cx::as_future() ) >
RType rget_strided(
    global_ptr<T> src_base ,
    std::array< std::ptrdiff_t , Dim > const & src_strides ,
    T * dest_base ,
    std::array< std::ptrdiff_t , Dim > const & dest_strides ,
    std::array< std::size_t , Dim > const & extents ,
    Completions cxs = Completions{ });
```

**Precondition:** T must be a DefinitelyTriviallySerializable type. All source global pointers and destination addresses must reference valid objects of type T. Each element src_strides[i], dest_strides[i], and extents[i] must be valid objects of their respective pointed-to type for all 0 <= i < Dim.

If Dim == 0, src_strides, dest_strides, and extents are ignored, and the data movement performed is equivalent to rget(src_base, dest_base, 1).

Otherwise, performs the reverse direction of rput_strided where now the source memory is remote and the destination is local.

The destination memory regions must be completely disjoint and must not overlap with any source memory regions, otherwise behavior is undefined. Source regions are permitted to overlap with each other.

The elements of type T residing in the source addresses must remain valid and unmodified until operation completion is signaled.

The contents of the src_strides, dest_strides, and extents arrays are consumed synchronously before the call returns.

**Completions:**
• **Operation**: Indicates completion of all aspects of the operation: the transfer and local stores are complete.

**C++ memory ordering**: The reads of the sources and writes to the destinations will have a *happens-before* relationship with the operation-completion notification actions (future readying, promise fulfillment, or persona LPC enlistment). For LPC completions, all evaluations *sequenced-before* this call will have a *happens-before* relationship with the execution of the completion function.

**UPC++ progress level**: *internal*
Chapter 15

Memory Kinds

The memory kinds interface enables the programmer to identify regions of memory requiring different access methods or having different performance properties, and subsequently rely on the UPC++ communication services to perform transfers among such regions (both local and remote) in a manner transparent to the programmer. With GPU devices, HBM, scratch-pad memories, NVRAM and various types of storage-class and fabric-attached memory technologies featured in vendors’ public road maps, UPC++ must be prepared to deal efficiently with data transfers among all the memory technologies in any given system.

Since memory kinds will be implemented in Year 2, we defer detailed discussion until next year.
Appendix A

Notes for Implementers

The following are possible implementations of template metaprogramming utilities for UPC++ features.

A.1  future_element_t and future_element Moved_t

```cpp
template<int I, typename T>
struct future_element; // undefined

template<int I, typename T, typename ...U>
struct future_element<I, future<T, U...>> {
    typedef typename future_element<I -1 , future<U ...>>::type type;
    typedef typename future_element<I -1 , future<U ...>>::moved_type
        moved_type;
};

template<typename T, typename ...U>
struct future_element<0, future<T, U...>> {
    typedef T type;
    typedef T&& moved_type;
};

template<int I>
struct future_element<I, future<> >> {
    typedef void type;
    typedef void moved_type;
};
```
APPENDIX A. NOTES FOR IMPLEMENTERS

1 template<int I, typename T>
2 using future_element_t = typename future_element<I, T>::type;
3
4 template<int I, typename T>
5 using future_element_moved_t =
6      typename future_element<I, T>::moved_type;

A.2 future<T...>::when_all

Utility types:

9 template<template<typename ...Us> class T, typename A, typename B>
10 struct concat_type; // undefined
11
12 template<template<typename ...Us> class T,
13 typename ...As, typename... Bs>
14 struct concat_type<T, T<As...>, T<Bs...> > {
15      typedef T<As..., Bs...> type;
16    };
17
18 template<template<typename ...Us> class T,
19 typename A, typename... Bs>
20 struct concat_element_types {
21      typedef typename concat_element_types<T, Bs...>::type rest;
22      typedef typename concat_type<T, A, rest>::type type;
23    };
24
25 template<template<typename ...Us> class T, typename A>
26 struct concat_element_types<T, A> {
27      typedef A type;
28    };
29
30 template<template<typename ...Us> class T, typename ...U>
31 using concat_element_types_t =
32      typename concat_element_types<T, U...>::type;

Declaration of future<T...>::when_all:

33 template<typename ...Futures>
34 concat_element_types_t<future, Futures...> when_all(Futures... fs);
A.3 to_future

Utility types:

```cpp
template<typename T>
struct future_type {
    typedef future<T> type;
};

template<typename ...T>
struct future_type<future<T...>> {
    typedef future<T...> type;
};

template<> 
struct future_type<void> {
    typedef future<> type;
};

template<typename T>
using future_type_t = typename future_type<T>::type;
```

Declaration of to_future:

```cpp
template<typename T>
future_type_t<T> to_future(T future_or_value);
```

A.4 future_invoke_result_t

C++11-compliant implementation:

```cpp
template<typename Func, typename... ArgTypes>
using future_invoke_result_t = 
    future_type_t<typename std::result_of<Func(ArgTypes...)>::type>;
```

C++17-compliant implementation:

```cpp
template<typename Func, typename... ArgTypes>
using future_invoke_result_t = 
   future_type_t<std::invoke_result_t<Func, ArgTypes...>>;
```
