[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] $\overline{D}^{**}$ represents an excited state with mass $2.2 < M < 2.8$ GeV/c^2.

[c] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[d] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

[e] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[f] This decay refers to the coherent sum of resonant and nonresonant $J^P = 0^+$ $K\pi$ components with $1.60 < m_{K\pi} < 2.15$ GeV/c^2.

[g] $X(214)$ is a hypothetical particle of mass 214 MeV/c^2 reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

[i] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.

[j] Here S and P are the hypothetical scalar and pseudoscalar particles with masses of 2.5 GeV/c^2 and 214.3 MeV/c^2, respectively.

CONSTRAINED FIT INFORMATION

An overall fit to 28 branching ratios uses 68 measurements and one constraint to determine 19 parameters. The overall fit has a $\chi^2 = 44.0$ for 50 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

10.9 ±0.7 ±1.1	ATHANAS	94	CLE2	Sup. by ARTUSO 97

[1] URQUIJO 07 report a measurement of (9.80 ± 0.29 ± 0.21)% for the partial branching fraction of $B\to e\nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B\to e\nu_e X$ branching fraction.

[2] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+\to e^+\nu_e X)$ / $B(B^0\to e^+\nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

[3] ARTUSO 97 uses partial reconstruction of $B\to D^*\ell\nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96B (0.1049 ± 0.0017 ± 0.0043).

[4] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of $B(B^+\to e^+\nu_e X)/B(B^0\to e^+\nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

$\Gamma(e^+\nu_e X_c)/\Gamma_{\rm total}$ Γ_2/Γ

VALUE (units 10^{-2})	DOCUMENT ID		TECN	COMMENT
10.08±0.30±0.22	[1] URQUIJO	07	BELL	$e^+e^-\to\Upsilon(4S)$

[1] Measure the independent B^+ and B^0 partial branching fractions with electron threshold energies of 0.4 GeV.

$\Gamma(D^-\ell^+\nu_\ell)/\Gamma_{\rm total}$ Γ_4/Γ

ℓ denotes e or μ, not the sum.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. [1] Uses a fully reconstructed B meson as a tag on the recoil side.
[2] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[3] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.
[4] ATHANAS 97 uses missing energy and missing momentum to reconstruct neutrino.
[5] FULTON 91 assumes assuming equal production of B^0 and B^+ at the $\Upsilon(4S)$ and uses Mark III D and D^* branching ratios.
[6] ALBRECHT 89J reports 0.018 ± 0.006 ± 0.005. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$).

[1] Uses fully reconstructed $D^{*-}\ell^+\nu$ events ($\ell = e$ or μ).
[2] Uses a fully reconstructed B meson as a tag on the recoil side.
[3] Measured using fully reconstructed D^* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2 = 1.191 \pm 0.048 \pm 0.028$, $R_1(1) = 1.429 \pm 0.061 \pm 0.044$, and $R_2(1) = 0.827 \pm 0.038 \pm 0.022$.
[4] Measured using fully reconstructed D^* sample.
[5] Uses the combined fit of both $B^0 \to D^*(2010)^-\ell\nu$ and $B^+ \to \overline{D}(2007)^0\ell\nu$ samples.
[6] ABREU 01H measured using about 5000 partial reconstructed D^* sample.
[7] ABBIENDI 00Q assumes the fraction B($b \to B^0$)= $(39.7^{+1.8}_{-2.2})$%. This result is an average of two methods using exclusive and partial D^* reconstruction.
[8] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and D^* and D branching fractions.
[9] Combines with previous partial reconstructed D^* measurement.
[10] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[11] The results are based on the same analysis and data sample reported in ADAM 03.
[12] ACKERSTAFF 97G assumes fraction (B^+) = fraction (B^0) = (37.8±2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.
[13] ABREU 96P result is the average of two methods using exclusive and partial D^* reconstruction.
[14] BARISH 95 use B($D^0 \to K^-\pi^+$) = (3.91 ± 0.08 ± 0.17)% and B($D^{*+} \to D^0\pi^+$) = (68.1 ± 1.0 ± 1.3)%.
[15] BUSKULIC 95N assumes fraction (B^+) = fraction (B^0) = 38.2 ± 1.3 ± 2.2% and τ_{B^0} = 1.58 ± 0.06 ps. $\Gamma(D^{*-}\ell^+\nu_\ell)$/total = [5.18 − 0.13(fraction(B^0)−38.2)−1.5(τ_{B^0} − 1.58)]%.
[16] ALBRECHT 94 assumes B($D^{*+} \to D^0\pi^+$) = 68.1 ± 1.0 ± 1.3%. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.
[17] ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). We have taken their average e and μ value. They also obtain $\alpha = 2*\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{AF} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}|$ = 0.036–0.045 depending on model assumptions.
[18] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.
[19] ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.
[20] The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45. or $\alpha = 0.7 \pm 0.9$.
[21] ALBRECHT 89J is ALBRECHT 87J value rescaled using B($D^*(2010)^- \to D^0\pi^-$) = 0.57 ± 0.04 ± 0.04. Superseded by ALBRECHT 93.
[22] We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \to K^-\pi^+$). The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.
[23] ALBRECHT 87J assume μ-e universality, the B($\Upsilon(4S) \to B^0\overline{B}^0$) = 0.45, the B($D^0 \to K^-\pi^+$) = (0.042 ± 0.004 ± 0.004), and the B($D^*(2010)^- \to D^0\pi^-$) = 0.49 ± 0.08. Superseded by ALBRECHT 89J.

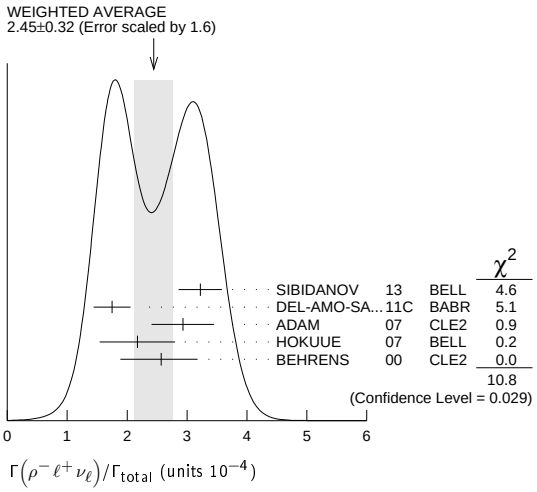
<4.1	90	[10] BEAN	93B	CLE2	$e^+e^- \to \Upsilon(4S)$

[1] The signal events are tagged by a second B meson reconstructed in the fully hadronic decays.
[2] B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.
[3] The B^0 and B^+ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the $\Upsilon(4S)$.
[4] The signal events are tagged by a second B meson reconstructed in the semileptonic mode $B \to D^{(*)}\ell\nu_\ell$.
[5] Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors $^{+0.33}_{-0.46} \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.
[6] ATHAR 03 reports systematic errors $^{+0.47}_{-0.50} \pm 0.41 \pm 0.01$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.
[7] Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.
[8] BEHRENS 00 reports $^{+0.35}_{-0.40} \pm 0.50$, where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^-\ell^+\nu) = 2\Gamma(B^+ \to \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \to \omega\ell^+\nu)$. No evidence for $\omega\ell\nu$ is reported.
[9] ALEXANDER 96T reports $^{+0.5}_{-0.7} \pm 0.5$ where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^-\ell^+\nu) = 2\Gamma(B^+ \to \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \to \omega\ell^+\nu)$. No evidence for $\omega\ell\nu$ is reported.
[10] BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0\ell^+\nu_\ell)$ and $\Gamma(\omega\ell^+\nu_\ell)$ with this result, they obtain a limit $<(1.6\text{–}2.7) \times 10^{-4}$ at 90% CL for $B^+ \to (\omega \text{or } \rho^0)\ell^+\nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08\text{–}0.13$ at 90% CL is derived as well.



$\Gamma(\pi^-\ell^+\nu_\ell)/\Gamma_{total}$ Γ_{17}/Γ

[1] The signal events are tagged by a second B meson reconstructed in the fully hadronic decays.

[2] Uses loose neutrino reconstruction technique. Assumes $B(\Upsilon(4S) \to B^+B^-) = (51.6 \pm 0.6)\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = (48.4 \pm 0.6)\%$.

[3] Reports also a branching fraction value $B(B^0 \to \pi^-\ell^+\nu) = (1.45 \pm 0.04 \pm 0.06) \times 10^{-4}$ from the decays of B^+ and B^0 that are combined using the isospin symmetry relation.

[4] Using the isospin symmetry relation, B^+ and B^0 branching fractions are combined.

[5] The B^0 and B^+ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the $\Upsilon(4S)$.

[6] Also report the rate for $q^2 > 16$ GeV^2 of $(0.41 \pm 0.08 \pm 0.04) \times 10^{-4}$ from which they obtain $|V_{ub}| = 3.6 \pm 0.4 \pm 0.2^{+0.6}_{-0.4}$ (last error is from theory).

[7] The signal events are tagged by a second B meson reconstructed in the semileptonic mode $B \to D^{(*)}\ell\nu_\ell$.

[8] The analysis uses events in which the signal B decays are reconstructed with an innovative loose neutrino reconstruction technique.

[9] The signals are tagged by a second B meson reconstructed in a semileptonic or hadronic decay. The B^0 and B^+ results are combined assuming the isospin symmetry.

[10] B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.

[11] ATHAR 03 reports systematic errors $0.11 \pm 0.01 \pm 0.07$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.

[12] ALEXANDER 96T gives systematic errors $\pm 0.3 \pm 0.2$ where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: $\Gamma(B^0 \to \pi^-\ell^+\nu) = 2 \times \Gamma(B^+ \to \pi^0\ell^+\nu)$.

$3.1 \pm 1.3 \pm 1.0$	7	[5] ALBRECHT	88K	ARG	$e^+e^- \to \Upsilon(4S)$

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[2] Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.

[3] AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of B^0 and B^+, which is not included here.

[4] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[5] ALBRECHT 88K assumes $B^0\overline{B}^0$:B^+B^- production ratio is 45:55. Superseded by ALBRECHT 90J which assumes 50:50.

[6] BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

[7] AUBERT,B 04O reports $[\Gamma(B^0 \to D^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \to K^0_S\pi^+)] = (42.7 \pm 2.1 \pm 2.2) \times 10^{-6}$ which we divide by our best value $B(D^+ \to K^0_S\pi^+) = (1.47 \pm 0.07) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[8] ALAM 94 reports $[\Gamma(B^0 \to D^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \to K^-2\pi^+)] = (0.265 \pm 0.032 \pm 0.023) \times 10^{-3}$ which we divide by our best value $B(D^+ \to K^-2\pi^+) = (9.13 \pm 0.19) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

700 ± 500		5	[5] BEHRENDS	83	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[2] No assumption about the intermediate mechanism is made in the analysis.
[3] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D. The product branching fraction into $D_0^*(2340)\pi$ followed by $D_0^*(2340) \to D^0\pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \to D^0\pi$ is < 0.0004 at 90% CL.
[4] BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%. $B(D^0 \to K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.
[5] Corrected by us using assumptions: $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 50\%$. The product branching ratio is $B(B^0 \to \overline{D}^0\pi^+\pi^-)B(\overline{D}^0 \to K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[2] AUBERT,BE 06J reports $[\Gamma(B^0 \to D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] / [B(B^0 \to D^-\pi^+)] = 0.99 \pm 0.11 \pm 0.08$ which we multiply by our best value $B(B^0 \to D^-\pi^+) = (2.68 \pm 0.13) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
[3] Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.
[4] BRANDENBURG 98 assume equal production of B^+ and B^0 at $\Upsilon(4S)$ and use the D^* reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of $B(D^* \to D\pi)$.
[5] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-2\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.
[6] BORTOLETTO 92 reports $(4.0 \pm 1.0 \pm 0.7) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.
[7] ALBRECHT 90J reports $(2.8 \pm 0.9 \pm 0.6) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.
[8] BEBEK 87 reports $(2.8^{+1.5+1.0}_{-1.2-0.6}) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.
[9] Assumes $B(Z \to b\overline{b}) = 0.217$ and 38% B_d production fraction.
[10] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.
[11] ALBRECHT 86F uses pseudomass that is independent of D^0 and D^+ branching ratios.
[12] Assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

0.081 ±0.029 $^{+0.059}_{-0.024}$	19	[6] CHEN	85	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] Assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$ resonance. The second error combines the systematic and theoretical uncertainties in quadrature. CSORNA 03 includes data used in ALAM 94. A full angular fit to three complex helicity amplitudes is performed.
[2] BORTOLETTO 92 reports $0.019 \pm 0.008 \pm 0.011$ from a measurement of $[\Gamma(B^0 \to D^*(2010)^-\rho^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.
[3] ALBRECHT 90J reports $0.007 \pm 0.003 \pm 0.003$ from a measurement of $[\Gamma(B^0 \to D^*(2010)^-\rho^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.
[4] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-2\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.
[5] This decay is nearly completely longitudinally polarized, $\Gamma_L/\Gamma = (93 \pm 5 \pm 5)\%$, as expected from the factorization hypothesis (ROSNER 90). The nonresonant $\pi^+\pi^0$ contribution under the ρ^+ is less than 9% at 90% CL.
[6] Uses $B(D^* \to D^0\pi^+) = 0.6 \pm 0.15$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.4$. Does not depend on D branching ratios.

0.012 ±0.007	3	[6] BORTOLETTO	90	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] ZUPANC 07 reports $(7.5 \pm 0.2 \pm 1.1) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to D^-D_s^+)/\Gamma_{total}] \times [B(D_s^+ \to \phi\pi^+)]$ assuming $B(D_s^+ \to \phi\pi^+) = (4.4 \pm 0.6) \times 10^{-2}$, which we rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[2] AUBERT 06N reports $(0.64 \pm 0.13 \pm 0.10) \times 10^{-2}$ from a measurement of $[\Gamma(B^0 \to D^-D_s^+)/\Gamma_{total}] \times [B(D_s^+ \to \phi\pi^+)]$ assuming $B(D_s^+ \to \phi\pi^+) = 0.0462 \pm 0.0062$, which we rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[3] GIBAUT 96 reports $0.0087 \pm 0.0024 \pm 0.0020$ from a measurement of $[\Gamma(B^0 \to D^-D_s^+)/\Gamma_{total}] \times [B(D_s^+ \to \phi\pi^+)]$ assuming $B(D_s^+ \to \phi\pi^+) = 0.035$, which we rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[4] ALBRECHT 92G reports $0.017 \pm 0.013 \pm 0.006$ from a measurement of $[\Gamma(B^0 \to D^-D_s^+)/\Gamma_{total}] \times [B(D_s^+ \to \phi\pi^+)]$ assuming $B(D_s^+ \to \phi\pi^+) = 0.027$, which we rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ branching ratios, e.g., $B(D^+ \to K^-2\pi^+) = 7.7 \pm 1.0\%$.

[5] BORTOLETTO 92 reports $0.0080 \pm 0.0045 \pm 0.0030$ from a measurement of $[\Gamma(B^0 \to D^-D_s^+)/\Gamma_{total}] \times [B(D_s^+ \to \phi\pi^+)]$ assuming $B(D_s^+ \to \phi\pi^+) = 0.030 \pm 0.011$, which we rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[6] BORTOLETTO 90 assume $B(D_s \to \phi\pi^+) = 2\%$. Superseded by BORTOLETTO 92.

[1] AUBERT 07AV reports $[\Gamma(B^0 \to J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \to p\overline{p})] = (2.82^{+0.30+0.36}_{-0.28-0.35}) \times 10^{-6}$ which we divide by our best value $B(J/\psi(1S) \to p\overline{p}) = (2.120 \pm 0.029) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[2] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[3] ABE 98O reports $[B(B^0 \to J/\psi(1S)K^*(892)^0)]/[B(B^+ \to J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \to J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[4] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[5] BORTOLETTO 92 reports $(1.1 \pm 0.5 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \to e^+e^-)]$ assuming $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[6] ALBRECHT 90J reports $(1.1 \pm 0.5 \pm 0.2) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \to e^+e^-)]$ assuming $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[7] BEBEK 87 reports $(3.5 \pm 1.6 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \to J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \to e^+e^-)]$ assuming $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.971 \pm 0.032) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

[8] ABE 96H assumes that $B(B^+ \to J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$.

[9] The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[10] ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$ making the neutral decay a CP eigenstate when the K^{*0} decays through $K_S^0\pi^0$.

[11] ALBAJAR 91E assumes B_d^0 production fraction of 36%.

[12] ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

[13] ALAM 86 assumes $B^\pm/B^0$ ratio is 60/40. The observation of the decay $B^+ \to J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

$\Gamma(J/\psi(1S)K^*(892)^0)/\Gamma(J/\psi(1S)K^0)$ $\Gamma_{171}/\Gamma_{169}$

<21	90	[4] ALAM	94	CLE2	$e^+e^-\to\ \Upsilon(4S)$

[1] Uses $\chi_{c1,2}\to J/\psi\gamma$. Assumes B($\Upsilon(4S)\to B^+B^-$) = (51.6±0.6)% and B($\Upsilon(4S)\to B^0\overline{B}^0$) = (48.4 ± 0.6)%.

[2] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[3] AUBERT 02 reports $(4.8\pm1.4\pm0.9)\times10^{-4}$ from a measurement of $[\Gamma(B^0\to\chi_{c1}K^*(892)^0)/\Gamma_{total}]\times[B(\chi_{c1}(1P)\to\gamma J/\psi(1S))]$ assuming $B(\chi_{c1}(1P)\to\gamma J/\psi(1S))=0.273\pm0.016$, which we rescale to our best value $B(\chi_{c1}(1P)\to\gamma J/\psi(1S))=(33.9\pm1.2)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[4] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

$\Gamma(\chi_{c1}K^*(892)^0)/\Gamma(J/\psi(1S)K^*(892)^0)$ $\Gamma_{224}/\Gamma_{171}$

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[2] ABE 00C assumes $B(Z\to b\overline{b})=(21.7\pm0.1)\%$ and the B fractions $f_{B^0}=f_{B^+}=(39.7^{+1.8}_{-2.2})\%$ and $f_{B_s}=(10.5^{+1.8}_{-2.2})\%$.

[3] ADAM 96D assumes $f_{B^0}=f_{B^-}=0.39$ and $f_{B_s}=0.12$. Contributions from B^0 and B_s decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral B mesons.

[4] BUSKULIC 96V assumes PDG 96 production fractions for B^0, B^+, B_s, b baryons.

[5] Assumes a B^0, B^- production fraction of 0.39 and a B_s production fraction of 0.12. Contributions from B^0 and B_s^0 decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral B mesons.

[6] Assumes $B(Z\to b\overline{b})=0.217$ and B_d^0 (B_s^0) fraction 39.5% (12%).

[7] BATTLE 93 assumes equal production of $B^0\overline{B}^0$ and B^+B^- at $\Upsilon(4S)$.

[8] Assumes the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$.

$\Gamma(K^+\pi^-)/\Gamma(K^0\pi^0)$ $\Gamma_{227}/\Gamma_{228}$

[1] DUH 13 reports also for the same data $B(B^0 \to K^+K^-) < 0.20\times10^{-6}$ at 90% CL.
[2] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[3] AAIJ 12AR reports $[\Gamma(B^0 \to K^+K^-)/\Gamma_{total}] / [B(B_s^0 \to K^+K^-)] / [\Gamma(\overline{b} \to B_s^0)/\Gamma(\overline{b} \to B^0)] = 0.018^{+0.008}_{-0.007} \pm 0.009$ which we multiply by our best values $B(B_s^0 \to K^+K^-) = (2.49 \pm 0.17)\times10^{-5}$, $\Gamma(\overline{b} \to B_s^0)/\Gamma(\overline{b} \to B^0) = 0.261 \pm 0.015$. Our first error is their experiment's error and our second error is the systematic error from using our best values.
[4] Reported a central value of $(0.23 \pm 0.10 \pm 0.10)\times10^{-6}$ using $B(B^0 \to K^+\pi^-) = (19.4 \pm 0.6)\times10^{-6}$.
[5] Obtains this result from $B(K^+K^-)/B(K^+\pi^-) = 0.020 \pm 0.008 \pm 0.006$, assuming $B(B^0 \to K^+\pi^-) = (19.4 \pm 0.6)\times10^{-6}$.
[6] ABULENCIA,A 06D obtains this from $\Gamma(K^+K^-)/\Gamma(K^+\pi^-) < 0.10$ at 90% CL, assuming $B(B^0 \to K^+\pi^-) = (18.9 \pm 0.7)\times10^{-6}$.
[7] ABE 00C assumes $B(Z \to b\overline{b})$=(21.7 ± 0.1)% and the B fractions $f_{B^0}=f_{B^+}=(39.7^{+1.8}_{-2.2})$% and $f_{B_s}=(10.5^{+1.8}_{-2.2})$%.
[8] ADAM 96D assumes $f_{B^0} = f_{B^-} = 0.39$ and $f_{B_s} = 0.12$. Contributions from B^0 and B_s decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral B mesons.
[9] BUSKULIC 96V assumes PDG 96 production fractions for B^0, B^+, B_s, b baryons.
[10] Assumes a B^0, B^- production fraction of 0.39 and a B_s production fraction of 0.12. Contributions from B^0 and B_s^0 decays cannot be separated. Limits are given for the weighted average of the decay rates for the two neutral B mesons.

<21	90	[6] FU	97	CLE2	$e^+e^-\to\Upsilon(4S)$

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[2] AUBERT 08BN reports $(1.89\pm0.21\pm0.49)\times10^{-5}$ from a measurement of $[\Gamma(B^0\to\overline{\Lambda}_c^- p)/\Gamma_{total}]\times[B(\Lambda_c^+\to pK^-\pi^+)]$ assuming $B(\Lambda_c^+\to pK^-\pi^+)=(5.0\pm1.3)\times10^{-2}$.
[3] The second error for GABYSHEV 03 includes the systematic and the error of $\Lambda_c\to\overline{p}K^+\pi^-$ decay branching fraction.
[4] Uses the value for $\Lambda_c\to pK^-\pi^+$ branching ratio (5.0 ± 1.3)%.
[5] DYTMAN 02 measurement uses $B(\Lambda_c^-\to\overline{p}K^+\pi^-)=5.0\pm1.3$%. The second error includes the systematic and the uncertainty of the branching ratio.
[6] FU 97 uses PDG 96 values of Λ_c branching ratio.

[1] Reports also a limit of $< 7.4 \times 10^{-10}$ at 95% CL. Uses normalization modes $B^+ \to J/\psi K^+ \to \mu^+\mu^- K^+$ and $B^0 \to K^+\pi^-$.
[2] Uses $B(B^+ \to J/\psi K^+ \to \mu^+\mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$ and $B(B^0 \to K^+\pi^-) = (1.94 \pm 0.06) \times 10^{-5}$ for normalization.
[3] Uses normalization mode $B(B^+ \to J/\psi K^+) = (10.22 \pm 0.35) \times 10^{-4}$.
[4] Uses $B(B^+ \to J/\psi K^+ \to \mu^+\mu^- K^+) = (6.0 \pm 0.2) \times 10^{-5}$ for normalization.
[5] Uses $B(B^+ \to J/\psi K^+ \to \mu^+\mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$.
[6] Uses B production ratio $f(\overline{b} \to B^+)/f(\overline{b} \to B_s^0) = 3.71 \pm 0.47$ and three normalization modes.
[7] Uses $B(B^+ \to J/\psi K^+)\, B(J/\psi \to \mu^+\mu^-) = (5.94 \pm 0.21) \times 10^{-5}$.
[8] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[9] Uses $B(B^+ \to J/\psi K^+)\, B(J/\psi \to \mu^+\mu^-) = (5.88 \pm 0.26) \times 10^{-5}$.
[10] Assumes production cross-section $\sigma(B_s)/\sigma(B^+) = 0.100/0.391$ and the CDF measured value of $\sigma(B^+) = 3.6 \pm 0.6\ \mu$b.
[11] ABE 98 assumes production of $\sigma(B^0) = \sigma(B^+)$ and $\sigma(B_s)/\sigma(B^0) = 1/3$. They normalize to their measured $\sigma(B^0, p_T(B) > 6, |y| < 1.0) = 2.39 \pm 0.32 \pm 0.44\ \mu$b.
[12] ACCIARRI 97B assume PDG 96 production fractions for B^+, B^0, B_s, and Λ_b.
[13] ABE 96L assumes equal B^0 and B^+ production. They normalize to their measured $\sigma(B^+, p_T(B) > 6\ \text{GeV}/c, |y| < 1) = 2.39 \pm 0.54\ \mu$b.
[14] B^0 and B_s^0 are not separated.
[15] Obtained from unseparated B^0 and B_s^0 measurement by assuming a B^0:B_s^0 ratio 2:1.
[16] AVERY 89B reports $< 5 \times 10^{-3}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%.
[17] ALBRECHT 87D reports $< 5 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 45% to $B^0\overline{B}^0$. We rescale to 50%.
[18] AVERY 87 reports $< 9 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 40% to $B^0\overline{B}^0$. We rescale to 50%.

POLARIZATION IN B DECAYS

Revised December 2013 by A. V. Gritsan (Johns Hopkins University) and J. G. Smith (University of Colorado at Boulder).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the B decays and the CP-violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor B meson decays, while more details about the theory and experimental results in B decays can be found in a separate mini-review [1] in this *Review*.

Figure 1 illustrates angular observables in an example of the sequential process $ab \to X \to P_1P_2 \to (p_{11}p_{12})(p_{21}p_{22})$ [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle X, such as B meson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment of the particles in the decay chain. The analyzer of the B-daughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent (*e.g.*, $\rho \to 2\pi$) [3], and for three-body decays as the normal to the decay plane (*e.g.*, $\omega \to 3\pi$) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes $A_{\lambda_1\lambda_2}$, corresponding to the X-daughter helicity states λ_i.

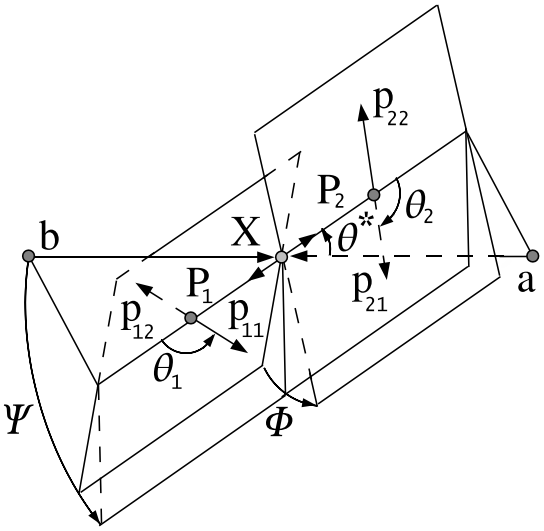

Figure 1: Definition of the production and helicity angles in the sequential process $ab \to X \to P_1P_2 \to (p_{11}p_{12})(p_{21}p_{22})$. The three helicity angles include θ_1 and θ_2, defined in the rest frame of the two daughters P_1 and P_2, and Φ, defined in the X frame as the angle between the two decay planes. The two production angles θ^* and Ψ are defined in the X frame, where Ψ is the angle between the production plane and the average of the two decay planes.

In the case of a spin-zero B-meson decay, its daughter helicities are constrained to $\lambda_1 = \lambda_2 = \lambda$. Therefore we simplify amplitude notation as A_λ. Moreover, most B-decay polarization analyses are limited to the case when the spin of one of the B-meson daughters is 1. In that case, there are only three independent amplitudes corresponding to $\lambda = 0$ or ±1 [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes $A_{\parallel,\perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$. The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner d functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the B-meson daughters and of their decay products, and can be found in the literature [6,7]. The differential decay rate would involve six real quantities α_i, including interference terms,

$$\frac{d\Gamma}{\Gamma\, d\cos\theta_1\, d\cos\theta_2\, d\Phi} = \sum_i \alpha_i \;\; f_i(\cos\theta_1,\, \cos\theta_2,\, \Phi)\,, \qquad (1)$$

where each $f_i(\cos\theta_1, \cos\theta_2, \Phi)$ has unique angular dependence specific to particle quantum numbers, and the α_i parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\Sigma|A_\lambda|^2} = f_L\,, \qquad (2)$$

$$\alpha_2 = \frac{|A_\parallel|^2 + |A_\perp|^2}{\Sigma|A_\lambda|^2} = (1 - f_L)\,, \qquad (3)$$

$$\alpha_3 = \frac{|A_\parallel|^2 - |A_\perp|^2}{\Sigma|A_\lambda|^2} = (1 - f_L - 2\,f_\perp)\,, \qquad (4)$$

$$\alpha_4 = \frac{\Im m(A_\perp A_\parallel^*)}{\Sigma|A_\lambda|^2} = \sqrt{f_\perp(1-f_L-f_\perp)}\,\sin(\phi_\perp-\phi_\parallel)\,, \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_\parallel A_0^*)}{\Sigma|A_\lambda|^2} = \sqrt{f_L\,(1-f_L-f_\perp)}\,\cos(\phi_\parallel)\,, \quad (6)$$

$$\alpha_6 = \frac{\Im m(A_\perp A_0^*)}{\Sigma|A_\lambda|^2} = \sqrt{f_\perp\,f_L}\,\sin(\phi_\perp)\,, \quad (7)$$

where the amplitudes have been expressed with the help of polarization parameters f_L, $f_\perp$, $\phi_\parallel$, and $\phi_\perp$ defined in Table 1. Note that the terms proportional to $\Re e(A_\perp A_\parallel^*)$, $\Im m(A_\parallel A_0^*)$, and $\Re e(A_\perp A_0^*)$ are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a B-meson daughter, see Ref. 7.

Table 1: Rate, polarization, and *CP*-asymmetry parameters defined for the B-meson decays to mesons with non-zero spin. Numerical examples are shown for the 2013 HFAG average of the $B^0 \to \varphi K^*(892)^0$ decay obtained from BABAR [8] and Belle [9] measurements. The first six parameters are defined under the assumption of no *CP* violation in decay, while they are averaged between the $\overline{B}$ and B parameters in general. The last six parameters involve differences between the $\overline{B}$ and B meson decay parameters. The phase convention δ_0 is chosen with respect to a single A_{00} amplitude from a reference B decay mode, which is $B^0 \to \varphi K_0^*(1430)^0$ for numerical results.

parameter	definition	average
$\mathcal{B}$	$\Gamma/\Gamma_{\rm total}$	$(9.8 \pm 0.6) \times 10^{-6}$
f_L	$\lvert A_0\rvert^2/\Sigma\lvert A_\lambda\rvert^2$	0.497 ± 0.025
$f_\perp$	$\lvert A_\perp\rvert^2/\Sigma\lvert A_\lambda\rvert^2$	0.228 ± 0.021
$\phi_\parallel - \pi$	$\arg(A_\parallel/A_0) - \pi$	-0.86 ± 0.09
$\phi_\perp - \pi$	$\arg(A_\perp/A_0) - \pi$	-0.78 ± 0.09
$\delta_0 - \pi$	$\arg(A_{00}/A_0) - \pi$	-0.26 ± 0.10
A_{CP}	$(\bar\Gamma - \Gamma)/(\bar\Gamma + \Gamma)$	0.00 ± 0.04
A_{CP}^0	$(\bar f_L - f_L)/(\bar f_L + f_L)$	-0.01 ± 0.05
$A_{CP}^\perp$	$(\bar f_\perp - f_\perp)/(\bar f_\perp + f_\perp)$	-0.11 ± 0.09
$\Delta\phi_\parallel$	$(\bar\phi_\parallel - \phi_\parallel)/2$	$+0.06 \pm 0.08$
$\Delta\phi_\perp$	$(\bar\phi_\perp - \phi_\perp - \pi)/2$	$+0.10 \pm 0.09$
$\Delta\delta_0$	$(\bar\delta_0 - \delta_0)/2$	$+0.13 \pm 0.08$

Overall, six real parameters describe three complex amplitudes A_0, $A_\parallel$, and $A_\perp$. These could be chosen to be the four polarization parameters f_L, $f_\perp$, $\phi_\parallel$, and $\phi_\perp$, one overall size normalization, such as decay rate Γ, or branching fraction $\mathcal{B}$, and one overall phase δ_0. The phase convention is arbitrary for an isolated B decay mode. However, for several B decays, the relative phase could produce meaningful and observable effects through interference with other B decays with the same final states, such as for $B \to VK_J^*$ with $J = 0, 1, 2, 3, 4, ...$ The phase could be referenced to the single $B \to VK_0^*$ amplitude A_{00} in such a case, as shown in Table 1. Here V stands for any spin-one vector meson.

Moreover, *CP* violation can be tested in the angular distribution of the decay as the difference between the B and $\overline{B}$. Each of the six real parameters describing the three complex amplitudes would have a counterpart *CP*-asymmetry term, corresponding to three direct-*CP* asymmetries in three amplitudes, and three *CP*-violating phase differences, equivalent to the phase measurements from the mixing-induced *CP* asymmetries in the time evolution of B-decays [1]. In Table 1 and Ref. 10, these are chosen to be the direct-*CP* asymmetries in the overall decay rate $\mathcal{A}_{CP}$, in the f_L fraction $\mathcal{A}_{CP}^0$, and in the $f_\perp$ fraction $\mathcal{A}_{CP}^\perp$, and three weak phase differences:

$$\Delta\phi_\parallel = \frac{1}{2}\arg(\bar A_\parallel A_0/A_\parallel \bar A_0)\,, \quad (8)$$

$$\Delta\phi_\perp = \frac{1}{2}\arg(\bar A_\perp A_0/A_\perp \bar A_0) - \frac{\pi}{2}\,, \quad (9)$$

$$\Delta\delta_0 = \frac{1}{2}\arg(\bar A_{00} A_0/A_{00} \bar A_0)\,. \quad (10)$$

The $\frac{\pi}{2}$ term in Eq. (9) reflects the fact that $A_\perp$ and $\bar A_\perp$ differ in phase by π if *CP* is conserved. The two parameters $\Delta\phi_\parallel$ and $\Delta\phi_\perp$ are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [11]. The *CP*-violating phase difference in the reference decay mode [10] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2}\arg(A_{00}/\bar A_{00})\,. \quad (11)$$

This can be measured only together with the mixing-induced phase difference for some of the neutral B-meson decays similar to other mixing-induced *CP* asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define δ_0 and $\Delta\delta_0$ parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta\phi_0 = \frac{1}{2}\arg(A_0/\bar A_0)\,. \quad (12)$$

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the $\Delta\phi_0$ and B-mixing phases. Examples include measurements of $\beta = \phi_1$ with $B \to J/\psi K^*$ and $\alpha = \phi_2$ with $B \to \rho\rho$.

Most of the B decays that arise from tree-level $b \to c$ transitions have the amplitude hierarchy $|A_0| > |A_+| > |A_-|$ which is expected from analyses based on quark-helicity conservation [12]. The larger the mass of the vector-meson daughters, the weaker the inequality. The B meson decays to heavy vector particles with charm, such as $B \to J/\psi K^*$, $\psi(2S)K^*$, $\chi_{c1}K^*$, $D^*\rho$, D^*K^*, D^*D^*, and $D^*D_s^*$, show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ($A_{\pm 1}$), in agreement with the factorization prediction. The detailed amplitude analysis of the $B \to J/\psi K^*$ decays has been performed by the BABAR [13], Belle [14], CDF [15], CLEO [16], and D0 [17] collaborations. Most analyses are performed under the assumption of the absence of

direct *CP* violation. The parameter values are given in the particle listing of this *Review*. The difference between the strong phases $\phi_\parallel$ and $\phi_\perp$ deviates significantly from zero. The recent measurements [13,14] of *CP*-violating terms similar to those in $B \to \varphi K^*$ [10] shown in Table 1 are consistent with zero.

In addition, the mixing-induced *CP*-violating asymmetry is measured in the $B^0 \to J/\psi K^{*0}$ decay [1,13,14] where angular analysis allows one to separate *CP*-eigenstate amplitudes. This allows one to resolve the sign ambiguity of the $\cos 2\beta$ ($\cos 2\phi_1$) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases $\phi_\parallel$ and $\phi_\perp$, as discussed below. The BABAR experiment used a method based on the dependence on the $K\pi$ invariant mass of the interference between the *S*- and *P*-waves to resolve the discrete ambiguity in the determination of the strong phases $(\phi_\parallel, \phi_\perp)$ in $B \to J/\psi K^*$ decays [13]. The result is in agreement with the amplitude hierarchy expectation [12]. The CDF [18], D0 [19], and LHCb [20] experiments have studied the $B_s^0 \to J/\psi\varphi$ decay and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy $|A_0| \gg |A_+| \gg |A_-|$ was expected in B decays to light vector particles in both penguin transitions [21,22] and tree-level transitions [12]. There is confirmation by the BABAR and Belle experiments of predominantly longitudinal polarization in the tree-level $b \to u$ transition, such as $B^0 \to \rho^+\rho^-$ [23], $B^+ \to \rho^0\rho^+$ [24], and $B^+ \to \omega\rho^+$ [25]; this is consistent with the analysis of the quark helicity conservation [12]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current B samples, and limits on the transverse amplitude fraction are obtained. The fraction of transverse polarization is large in decays to heavier mesons such as $B^0 \to a_1(1260)^+ a_1(1260)^-$ [26]. Only limits have been set for $B^0 \to \omega\rho^0, \omega\omega$ [25]; there is some evidence for $B^0 \to \rho^0\rho^0$ [27] decays. The small values for these branching fractions indicates that $b \to d$ penguin pollution is small in the charmless, strangeless vector-vector B decays.

The interest in the polarization and *CP*-asymmetry measurements in penguin transition, such as $b \to s$ decays $B \to \varphi K^*$, ρK^*, ωK^*, or $B_s^0 \to \varphi\varphi$, and $b \to d$ decay $B \to K^*\bar{K}^*$, is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for $B \to \varphi K^*$ have been measured by the BABAR and Belle experiments [10,9,28,29]. The fractions of longitudinal polarization are $f_L = 0.50 \pm 0.05$ for the $B^+ \to \varphi K^{*+}$ decay and $f_L = 0.497 \pm 0.025$ for the $B^0 \to \varphi K^{*0}$ decay. These indicate significant departure from the naive expectation of predominant longitudinal polarization, suggesting other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [30] or QCD rescattering [31], or from physics beyond the Standard Model [32]. The complete set of twelve amplitude parameters measured in the $B^0 \to \varphi K^{*0}$ decay is given in Table 1. Several other parameters could be constructed from the above twelve parameters, as suggested in Ref. 33.

The discrete ambiguity in the phase $(\phi_\parallel, \phi_\perp, \Delta\phi_\parallel, \Delta\phi_\perp)$ measurements has been resolved by BABAR in favor of $|A_+| \gg |A_-|$ through interference between the *S*- and *P*-waves of $K\pi$. The search for vector-tensor and vector-axialvector $B \to \varphi K_J^{(*)}$ decays with $J = 1, 2, 3, 4$ revealed a large fraction of longitudinal polarization in the decay $B \to \varphi K_2^*(1430)$ with $f_L = 0.90^{+0.06}_{-0.07}$ [10,34], but large contribution of transverse amplitude in $B \to \varphi K_1(1270)$ with $f_L = 0.46^{+0.13}_{-0.15}$ [35].

Like $B \to \varphi K^*$, the decays $B \to \rho K^*$ and $B \to \omega K^*$ may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in $B^+ \to \rho^0 K^{*0}$, $B^+ \to \rho^+ K^{*0}$ [36] and in both vector-vector and vector-tensor final states of $B \to \omega K_J^*$ [25] reveal a large fraction of transverse polarization, indicating an anomaly similar to $B \to \varphi K^*$ except for a different pattern in vector-tensor final states. A large transverse polarization is also observed in the $B_s^0 \to \varphi\varphi$ decay by CDF [37] and LHCb [38], $B_s^0 \to K^{*0}\bar{K}^{*0}$ decays by LHCb [39], and $B_s^0 \to \varphi K^{*0}$ decays by LHCb [40]. At the same time, first measurement of the polarization in the $b \to d$ penguin decays $B \to K^*\bar{K}^*$ indicates a large fraction of longitudinal polarization [41]. The polarization pattern in penguin-dominated B-meson decays is not fully understood [30,31,32].

The three-body semileptonic B-meson decays, such as $B \to V\ell_1\ell_2$, share many features with the two-body $B \to VV$ decays. Their differential decay width can be parameterized with the two helicity angles defined in the V and $(\ell_1\ell_2)$ frames and with the azimuthal angle, as defined in Fig. 1. However, since the $(\ell_1\ell_2)$ pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass $m_{\ell\ell}$ spectrum. The polarization measurements as a function of $m_{\ell\ell}$ provide complementary information on physics beyond the Standard Model, as discussed for $B \to K^*\ell^+\ell^-$ decay in Ref. 42. The current data in this mode has been analyzed by the BABAR, Belle, and CDF, LHCb, and CMS experiments [43].

The examples of the angular distributions and observables in $B \to K^*\ell^+\ell^-$ are discussed in Ref. 42. Typically two angular observables have been measured in this decay in certain ranges of the dilepton mass $m_{\ell\ell}$ [43]. One parameter is the fraction of longitudinal polarization F_L, which is determined by the K^* angular distribution and is similar to f_L defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair A_{FB}, which is the asymmetry of the decay rate with positive and negative values of $\cos\theta_1$.

In summary, there has been considerable recent interest in the polarization measurements of B-meson decays because they reveal both weak- and strong-interaction dynamics [30–32,44]. New measurements will further elucidate the pattern of spin alignment measurements in rare B decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the B-decay amplitudes.

POLARIZATION IN B^0 DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ($\|$) or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

Γ_L/Γ in $B^0 \to J/\psi(1S)K^*(892)^0$

[1] AAIJ 13AT obtains $\Gamma_\|/\Gamma = 0.227 \pm 0.004 \pm 0.011$. The relation $1 = (\Gamma_L + \Gamma_\perp + \Gamma_\|)/\Gamma$ is used to obtain Γ_L/Γ.

[2] Measured the angular and lifetime parameters for the time-dependent angular untagged decays $B^0_d \to J/\psi K^{*0}$ and $B^0_s \to J/\psi\phi$.

[3] Obtained by combining the B^0 and B^+ modes.

[4] AFFOLDER 00N measurements are based on 190 B^0 candidates obtained from a data sample of 89 pb^{-1}. The P-wave fraction is found to be $0.13^{+0.12}_{-0.09} \pm 0.06$.

[5] JESSOP 97 is the average over a mixture of B^0 and B^+ decays. The P-wave fraction is found to be $0.16 \pm 0.08 \pm 0.04$.

[6] Averaged over an admixture of B^0 and B^+ decays.

[7] Averaged over an admixture of B^0 and B^+ decays and the P wave fraction is $(19 \pm 2 \pm 3)\%$.

[8] Averaged over an admixture of B^0 and B^- decays and the P wave fraction is $(16.0 \pm 3.2 \pm 1.4) \times 10^{-2}$.

B^0–$\overline{B}^0$ MIXING

Updated April 2014 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral B^0–$\overline{B}^0$ meson systems, B^0_d–$\overline{B}^0_d$ and B^0_s–$\overline{B}^0_s$ (generically denoted B^0_q–$\overline{B}^0_q$, $q = s, d$), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{\rm L,H}\rangle = p|B^0_q\rangle \pm q|\overline{B}^0_q\rangle\,, \tag{1}$$

have a mass difference $\Delta m_q = m_{\rm H} - m_{\rm L} > 0$, and a total decay width difference $\Delta\Gamma_q = \Gamma_{\rm L} - \Gamma_{\rm H}$. In the absence of CP violation in the mixing, $|q/p| = 1$, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta\Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B^0_q\rangle$ or $|\overline{B}^0_q\rangle$ state at $t = 0$ is given by

$$|B^0_q(t)\rangle = g_+(t)\,|B^0_q\rangle + \frac{q}{p}\,g_-(t)\,|\overline{B}^0_q\rangle\,, \tag{2}$$

$$|\overline{B}^0_q(t)\rangle = g_+(t)\,|\overline{B}^0_q\rangle + \frac{p}{q}g_-(t)\,|B^0_q\rangle\,, \tag{3}$$

which means that the flavor states remain unchanged (+) or oscillate into each other (−) with time-dependent probabilities proportional to

$$|g_\pm(t)|^2 = \frac{e^{-\Gamma_q t}}{2}\left[\cosh\left(\frac{\Delta\Gamma_q}{2}\,t\right) \pm \cos(\Delta m_q\,t)\right]\,, \tag{4}$$

where $\Gamma_q = (\Gamma_{\rm H} + \Gamma_{\rm L})/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2\,dt/(\int |g_-(t)|^2\,dt + \int |g_+(t)|^2\,dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2+1)}\,, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}\,, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}\,. \tag{5}$$

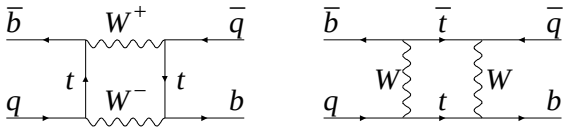

Figure 1: Dominant box diagrams for the $B^0_q \to \overline{B}^0_q$ transitions ($q = d$ or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B^0_q \to \overline{B}^0_q$ and $\overline{B}^0_q \to B^0_q$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for K^0–$\overline{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2}\,S_0(m_t^2/m_W^2)\,(V_{tq}^* V_{tb})^2\,, \tag{6}$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta'_B m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb}\;\mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2\;\mathcal{O}\left(\frac{m_c^4}{m_b^4}\right)\right]\,, \tag{7}$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i; m_{B_q}, f_{B_q} and B_{B_q} are the B^0_q mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784\,x_t^{0.76}$ [4], and V_{ij} are the elements of the CKM matrix [5]. The QCD corrections η_B and η'_B are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right)\,, \tag{8}$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the K^0–$\overline{K}^0$ system, the heavy state is expected to have a smaller decay width than that of the light state: $\Gamma_{\rm H} < \Gamma_{\rm L}$. Hence, $\Delta\Gamma = \Gamma_{\rm L} - \Gamma_{\rm H}$ is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2}\frac{m_b^2}{m_W^2}\frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \tag{9}$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right|\sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right)\,. \tag{10}$$

Therefore, considering both Eqs. (8) and (9), the CP-violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \mathrm{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \tag{11}$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the B^0_d–$\overline{B}^0_d$ system and $\lesssim \mathcal{O}(10^{-4})$ for the B^0_s–$\overline{B}^0_s$ system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the B^0_d–$\overline{B}^0_d$ and B^0_s–$\overline{B}^0_s$ systems. Calculations [7] yield $\sim 5\times10^{-3}$ with a $\sim 20\%$ uncertainty. Given the published experimental knowledge [8] on the mixing parameter x_q

$$\begin{cases} x_d = 0.774 \pm 0.006 & (B^0_d\text{–}\overline{B}^0_d \text{ system}) \\ x_s = 26.85 \pm 0.13 & (B^0_s\text{–}\overline{B}^0_s \text{ system}) \end{cases}\,, \tag{12}$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger ($\sim 10\%$). These width differences are caused by the existence of final states to which both the B^0_q and $\overline{B}^0_q$ mesons can decay. Such decays

involve $b \to c\bar{c}q$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$.

A complete set of Standard Model predictions for all mixing parameters in both the B^0_d–$\overline{B}{}^0_d$ and B^0_s–$\overline{B}{}^0_s$ systems can be found in Ref. 7.

Experimental issues and methods for oscillation analyses

Time-integrated measurements of B^0–$\overline{B}{}^0$ mixing were published for the first time in 1987 by UA1 [9] and ARGUS [10], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\overline{b}$ pairs. Such analyses cannot easily separate the contributions from the different b-hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B^0_d and charged B_u mesons are produced) is in principle best suited to measure χ_d.

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies Δm_d and Δm_s, from the proper time distributions of B^0_d or B^0_s candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the B^0_s–$\overline{B}{}^0_s$ system, where the large value of x_s implies maximal mixing, *i.e.*, $\chi_s \simeq 1/2$. In such analyses, the B^0_d or B^0_s mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \to \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron, LHC), the proper time $t = \dfrac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the B momentum p. At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \to \Upsilon(4S) \to B^0_d\overline{B}{}^0_d$ events with a boost $\beta\gamma$ ($= 0.425$, 0.55), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \dfrac{\Delta z}{\beta\gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance $\mathcal{S}$ of a B^0_d or B^0_s oscillation signal can be approximated as [11]

$$\mathcal{S} \approx \sqrt{N/2}\, f_{\rm sig}\, (1-2\eta)\, e^{-(\Delta m\, \sigma_t)^2/2}\,, \qquad (13)$$

where N is the number of selected and tagged candidates, $f_{\rm sig}$ is the fraction of signal in that sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity $\mathcal{S}$ decreases very quickly as Δm increases; this dependence is controlled by σ_t, which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \dfrac{m_B}{\langle p\rangle}\sigma_L \oplus t\dfrac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.04–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f, degrade $\mathcal{S}$ by a total factor $(1-2\eta) = (1-2\eta_i)(1-2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \to \ell^-$ decays; the largest contribution to η_f is then due to $\overline{b} \to \overline{c} \to \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B^0_d or D^-_s from B^0_s), or that of a kaon hypothesized to come from a $b \to c \to s$ decay [12], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jet-charge [13] and charge-dipole [14,15] methods. At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag the initial charge of the $\overline{b}$ quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the sign of a charged pion or kaon from the primary vertex is correlated with the production state of the B^0_d or B^0_s if that particle is a decay product of a B^{**} state or the first in the fragmentation chain [16,17]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \to \ell^-$ or of a kaon from $b \to c \to s$ can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \to b\overline{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [14]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [17,18], or even 22% at SLD [14] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency $Q = \epsilon D^2 = \epsilon(1-2\eta)^2$, where ϵ is the tagging efficiency, in the range $23-31\%$. The equivalent figure achieved by CDF during Tevatron Run I was $\sim 3.5\%$ [19], reflecting the fact that tagging is more difficult at hadron colliders. The CDF and DØ analyses of Tevatron Run II data reached $\epsilon D^2 = (1.8 \pm 0.1)\%$ [20] and $(2.5 \pm 0.2)\%$ [21] for opposite-side tagging, while same-side kaon tagging (for B^0_s analyses) contributed an additional $3.7-4.8\%$ at CDF [20], and pushed the combined performance to $(4.7 \pm 0.5)\%$ at DØ [22]. LHCb, operating in the forward region at the LHC where the environment is different in terms of track multiplicity and b-hadron production kinematics, has reported $\epsilon D^2 = (2.10 \pm 0.25)\%$ [23] for opposite-side tagging and $(1.5 \pm 0.4)\%$ [24] for same-side kaon tagging, with a combined figure of $(3.8 \pm 0.7)\%$ [24].

At B factories, the flavor of a B^0_d meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P-wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by

Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the "initial state" tag of a B can be taken as the final-state tag of the other B. Effective tagging efficiencies Q of 30% are achieved by BaBar and Belle [25], using different techniques including $b \to \ell^-$ and $b \to c \to s$ tags. It is worth noting that, in this case, mixing of the other B (*i.e.*, the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

Before the experimental observation of a decay-width difference, oscillation analyses typically neglected $\Delta\Gamma$ in Eq. (4), and described the physics with the functions $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm are usually extracted from the data using a maximum likelihood fit.

Δm_d and $\Delta\Gamma_d$ measurements

Many B^0_d–$\overline{B}{}^0_d$ oscillations analyses have been published [26] by the ALEPH [27], DELPHI [15,28], L3 [29], OPAL [30,31] BaBar [32], Belle [33], CDF [16], DØ [21], and LHCb [34–36] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at LEP and Tevatron have remarkably similar precision. Their average is compatible with the recent and more precise measurements from the asymmetric B factories and the LHC. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b-hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b-hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [15,16,21,27–36] and accounting for all identified correlations yields $\Delta m_d = 0.510 \pm 0.003(\text{stat}) \pm 0.002(\text{syst})$ ps^{-1} [8], a result dominated by the BaBar, Belle and LHCb.

On the other hand, ARGUS and CLEO have published time-integrated measurements [37–39], which average to $\chi_d = 0.182 \pm 0.015$. Following Ref. 39, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies published by DELPHI [15], BaBar [40], Belle [41], DØ [42] and LHCb [43] provide stronger constraints, which can be combined to yield [8]

$$\Delta\Gamma_d/\Gamma_d = 0.001 \pm 0.010\,. \tag{14}$$

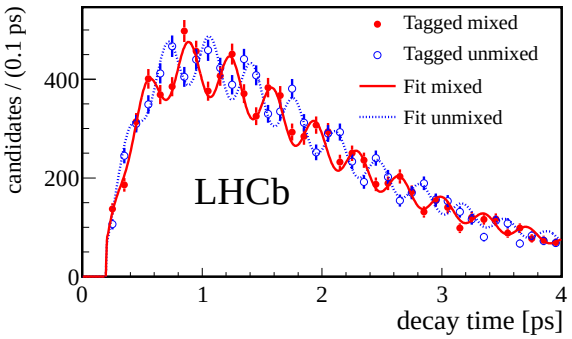

Figure 2: Proper time distribution of $B^0_s \to D^-_s\pi^+$ candidates tagged as mixed (red) or unmixed (blue) in the LHCb experiment, displaying B^0_s–$\overline{B}{}^0_s$ oscillations (from Ref. [46]) .

Assuming $\Delta\Gamma_d = 0$ and no CP violation in mixing, and using the measured B^0_d lifetime of 1.519 ± 0.005 ps, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.510 \pm 0.003 \text{ ps}^{-1} \tag{15}$$

or, equivalently,

$$\chi_d = 0.1874 \pm 0.0018\,. \tag{16}$$

This Δm_d value provides an estimate of $2|M_{12}|$, and can be used with Eq. (6) to extract $|V_{td}|$ within the Standard Model [44]. The main experimental uncertainties on the result come from m_t and Δm_d, but are completely negligible with respect to the uncertainty due to the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} = 216 \pm 15$ MeV [45] obtained from unquenched lattice QCD calculations.

Δm_s and $\Delta\Gamma_s$ measurements

After many years of intense search at LEP and SLC, B^0_s–$\overline{B}{}^0_s$ oscillations were first observed in 2006 by CDF using 1 fb^{-1} of Tevatron Run II data [20]. More recently LHCb observed B^0_s–$\overline{B}{}^0_s$ oscillations independently with $B^0_s \to D^-_s\pi^+$ [34,46], $B^0_s \to D^-_s\mu^+\nu$X [36] and even $B^0_s \to J/\psi K^+K^-$ [47] decays, using 1 fb^{-1} of data collected at the LHC until the end of 2011. Taking systematic correlations into account, the average of all published measurements of Δm_s [20,34,36,46,47] is

$$\Delta m_s = 17.761 \pm 0.021(\text{stat}) \pm 0.007(\text{syst}) \text{ ps}^{-1}\,, \tag{17}$$

dominated by LHCb (see Fig. 2) and still statistically limited.

The information on $|V_{ts}|$ obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the B^0_d case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}}\,\xi^2\left|\frac{V_{ts}}{V_{td}}\right|^2\,, \tag{18}$$

where $\xi = (f_{B_s}\sqrt{B_{B_s}})/(f_{B_d}\sqrt{B_{B_d}}) = 1.268 \pm 0.063$ is an SU(3) flavor-symmetry breaking factor obtained from unquenched

lattice QCD calculations [45]. Using the measurements of Eqs. (15) and (17), one can extract

$$\left|\frac{V_{td}}{V_{ts}}\right| = 0.2166 \pm 0.0007(\text{exp}) \pm 0.0108(\text{lattice})\,, \qquad (19)$$

in good agreement with (but much more precise than) the value obtained from the ratio of the $b \to d\gamma$ and $b \to s\gamma$ transition rates observed at the B factories [44].

The CKM matrix can be constrained using experimental results on observables such as Δm_d, Δm_s, $|V_{ub}/V_{cb}|$, ϵ_K, and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [44,48,49]. The constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (18). We also note that the measured value of Δm_s is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on Δm_s is used, *e.g.*, 17.4 ± 1.1 ps^{-1} [48] or $16.5\,^{+1.8}_{-1.4}$ ps^{-1} [49].

Information on $\Delta\Gamma_s$ can be obtained from the study of the proper time distribution of untagged B_s^0 samples [50]. In the case of an inclusive B_s^0 selection [51], or a flavor-specific (semileptonic or hadronic) B_s^0 decay selection [18,52,53], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_{\rm L,H} = \Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the effective lifetime of untagged B_s^0 candidates decaying to pure CP eigenstates; measurements exist for $B_s^0 \to K^+K^-$ [54], $B_s^0 \to D_s^+D_s^-$ [53], $B_s^0 \to J/\psi f_0(980)$ [55], $B_s^0 \to J/\psi\pi^+\pi^-$ [47] and $B_s^0 \to J/\psi K_{\rm S}^0$ [56]. The extraction of $1/\Gamma_s$ and $\Delta\Gamma_s$ from such measurements, discussed in detail in Ref. [57], requires additional information in the form of theoretical assumptions or external inputs on weak phases and hadronic parameters. In what follows, the effective lifetimes from the above decays to pure CP eigenstates will be assumed to be dominated by a single weak phase.

The best sensitivity to $1/\Gamma_s$ and $\Delta\Gamma_s$ is achieved by the time-dependent measurements of the $B_s^0 \to J/\psi\phi$ (or more generally $B_s^0 \to J/\psi K^+K^-$) decay rates performed at CDF [58], DØ [59], ATLAS [60], and LHCb [47], where the CP-even and CP-odd amplitudes are separated statistically through a full angular analysis. The LHCb collaboration analyzes the $B_s^0 \to J/\psi K^+K^-$ decay considering that the K^+K^- system can be in a P-wave or S-wave state, and measures the dependence of the strong phase difference between the P-wave and S-wave amplitudes as a function of the K^+K^- invariant mass [47,61]; this allows the unambiguous determination of the sign of $\Delta\Gamma_s$, which is found to be positive. All these studies use both untagged and tagged B_s^0 candidates and are optimized for the measurement of the CP-violating phase ϕ_s, defined as the weak phase difference between the B_s^0–$\overline{B}_s^0$ mixing amplitude and the $b \to c\bar{c}s$ decay amplitude. As reported further below, the central value of the current experimental average of ϕ_s is zero. Assuming no CP violation (*i.e.*, $\phi_s = 0$) a combination [8] of the published $B_s^0 \to J/\psi\phi$, $J/\psi K^+K^-$ analyses [47,58–60] and of the effective lifetime measurements with flavor-specific [18,52,53] and pure CP [47,53–56] final states yields

$$\Delta\Gamma_s = +0.091 \pm 0.008 \text{ ps}^{-1} \quad \text{and} \quad 1/\Gamma_s = 1.512 \pm 0.007 \text{ ps}\,, \qquad (20)$$

or, equivalently,

$$1/\Gamma_{\rm L} = 1.414 \pm 0.010 \text{ ps} \quad \text{and} \quad 1/\Gamma_{\rm H} = 1.624 \pm 0.014 \text{ ps}\,, \qquad (21)$$

in good agreement with the Standard Model prediction $\Delta\Gamma_s = 0.087 \pm 0.021$ ps^{-1} [7].

Independent estimates of $\Delta\Gamma_s/\Gamma_s$ obtained from measurements of the $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ branching fractions are not included in the average, since they are based on the questionable [7] assumption that these decays account for all CP-even final states.

Average b-hadron mixing probability and b-hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions f_u, f_d, f_s, and $f_{\rm baryon}$, defined as the fractions of B_u, B_d^0, B_s^0, and b-baryons in an unbiased sample of weakly decaying b hadrons produced in high-energy collisions. Indeed, time-integrated mixing analyses using lepton pairs from $b\bar{b}$ events at high energy measure the quantity

$$\overline{\chi} = f'_d\,\chi_d + f'_s\,\chi_s\,, \qquad (22)$$

where f'_d and f'_s are the fractions of B_d^0 and B_s^0 hadrons in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q\tau_b)$ $(q = s, d)$, where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements performed at LEP [62] and Tevatron [63–65], together with the χ_d average of Eq. (16) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s = 0.499311 \pm 0.000007$ from Eqs. (5), (17) and (20)), provide constraints on the fractions f_d and f_s. In what follows, we use the preliminary $\overline{\chi}$ result from CDF [64] instead of the published one [63]. Averages based on published data only can be found in the full listings of this *Review*.

The LEP experiments have measured $\mathcal{B}(\bar{b} \to B_s^0) \times \mathcal{B}(B_s^0 \to D_s^-\ell^+\nu_\ell X)$ [66], $\mathcal{B}(b \to \Lambda_b^0) \times \mathcal{B}(\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell X)$ [67], and $\mathcal{B}(b \to \Xi_b^-) \times \mathcal{B}(\Xi_b^- \to \Xi^-\ell^-\overline{\nu}_\ell X)$ [68] from partially reconstructed final states including a lepton, $f_{\rm baryon}$ from protons identified in b events [69], and the production rate of charged b hadrons [70]. The b-hadron fraction ratios measured at CDF are based on double semileptonic $K^*\mu\mu$ and $\phi\mu\mu$ final states [71] and lepton-charm final states [72]; in addition CDF and DØ have both measured strange b-baryon production [73]. On the

other hand, fraction ratios have been studied by LHCb using fully reconstructed hadronic B_s^0 and B_d^0 decays [74], as well as semileptonic decays [75]. Both CDF and LHCb observe that the ratio $f_{\Lambda_b^0}/(f_u + f_d)$ decreases with the transverse momentum of the lepton+charm system, indicating that the b-hadron fractions are not the same in different environments. We therefore provide sets of fractions separately for LEP and Tevatron (and no complete set for LHCb, where strange b-baryon production has not been measured yet). A combination of all the available information under the constraints $f_u = f_d$, $f_u + f_d + f_s + f_{\rm baryon} = 1$, and Eq. (22), yields the averages shown in Table 1.

Table 1: $\overline{\chi}$ and b-hadron fractions (see text).

	in Z decays [8]	at Tevatron [8]	at LHCb [74]
$\overline{\chi}$	0.1259 ± 0.0042	0.127 ± 0.008	
$f_u = f_d$	0.404 ± 0.009	0.330 ± 0.030	
f_s	0.103 ± 0.009	0.103 ± 0.012	
$f_{\rm baryon}$	0.089 ± 0.015	0.237 ± 0.067	
f_s/f_d	0.254 ± 0.025	0.311 ± 0.037	0.256 ± 0.020

CP-violation studies

Evidence for CP violation in B_q^0–$\overline{B}_q^0$ mixing has been searched for, both with flavor-specific and inclusive B_q^0 decays, in samples where the initial flavor state is tagged, usually with a lepton from the other b-hadron in the event. In the case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\rm SL}^q = \frac{N(\overline{B}_q^0(t) \to \ell^+\nu_\ell X) - N(B_q^0(t) \to \ell^-\overline{\nu}_\ell X)}{N(\overline{B}_q^0(t) \to \ell^+\nu_\ell X) + N(B_q^0(t) \to \ell^-\overline{\nu}_\ell X)} \simeq 1 - |q/p|_q^2 \tag{23}$$

has been measured either in time-integrated analyses at CLEO [39,76], CDF [77], DØ [42,78,79] and LHCb [80], or in time-dependent analyses at LEP [31,81], BaBar [40,82] and Belle [83]. In the inclusive case, also investigated at LEP [81,84], no final-state tag is used, and the asymmetry [85]

$$\frac{N(B_q^0(t) \to \text{all}) - N(\overline{B}_q^0(t) \to \text{all})}{N(B_q^0(t) \to \text{all}) + N(\overline{B}_q^0(t) \to \text{all})} \simeq \mathcal{A}_{\rm SL}^q \left[\frac{x_q}{2}\sin(\Delta m_q\, t) - \sin^2\left(\frac{\Delta m_q\, t}{2}\right)\right] \tag{24}$$

must be measured as a function of the proper time to extract information on CP violation.

The DØ collaboration measures a like-sign dimuon charge asymmetry in semileptonic b decays that deviates by $2.8\,\sigma$ from the tiny Standard Model prediction and concludes, from a more refined analysis in bins of muon impact parameters, that the overall discrepancy is at the level of $3.6\,\sigma$ [42]. In all other cases, asymmetries compatible with zero (and the Standard Model [7]) have been found, with a precision limited by the available statistics. Several of the analyses at high energy don't disentangle the B_d^0 and B_s^0 contributions, and either quote a mean asymmetry or a measurement of $\mathcal{A}_{\rm SL}^d$ assuming $\mathcal{A}_{\rm SL}^s = 0$: we no longer include these in the average. An exception is the latest dimuon DØ analysis [42], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of $\mathcal{A}_{\rm SL}^d$ and $\mathcal{A}_{\rm SL}^s$ are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of the measurements of Refs. [39,40,42,76,78–80,82,83] and obtain [8]

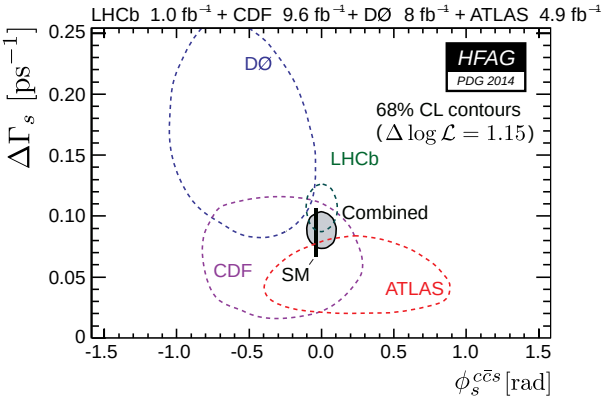

Figure 3: 68% CL contours in the $(\phi_s, \Delta\Gamma_s)$ plane, showing the measurements from CDF [58], DØ [59], ATLAS [60] and LHCb [47], with their combination [8]. The thin rectangle represents the Standard Model predictions of ϕ_s [49] and $\Delta\Gamma_s$ [7].

$$\mathcal{A}_{\rm SL}^d = -0.0009 \pm 0.0021\,, \quad \text{or} \quad |q/p|_d = 1.0005 \pm 0.0011\,, \tag{25}$$

$$\mathcal{A}_{\rm SL}^s = -0.0077 \pm 0.0042\,, \quad \text{or} \quad |q/p|_s = 1.0039 \pm 0.0021\,, \tag{26}$$

with a correlation coefficient of -0.19 between $\mathcal{A}_{\rm SL}^d$ and $\mathcal{A}_{\rm SL}^s$. These results show no evidence of CP violation and don't constrain yet the Standard Model.

CP violation induced by B_s^0–$\overline{B}_s^0$ mixing in $b \to c\bar{c}s$ decays has been a field of very active study in the past few years. In addition to the previously mentioned $B_s^0 \to J/\psi\phi$ and $B_s^0 \to J/\psi K^+K^-$ studies, the decay mode $B_s^0 \to J/\psi\pi^+\pi^-$ (including $B_s^0 \to J/\psi f_0(980)$) has also been analyzed by LHCb to measure ϕ_s [47], without the need for an angular analysis since the $J/\psi\pi^+\pi^-$ final state has been shown to be (very close to) a pure CP-odd state [86]. A two-dimensional fit [8] of all published analyses [47,58–60] in the $(\phi_s, \Delta\Gamma_s)$ plane, shown on Fig. 3, yields

$$\phi_s = 0.00 \pm 0.07\,. \tag{27}$$

This is consistent with the Standard Model prediction for ϕ_s, which is equal to $-2\beta_s = -2\arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)) = -0.0363\,^{+0.0016}_{-0.0015}$ [49], assuming negligible Penguin pollution.

Summary

B^0–$\overline{B}^0$ mixing has been and still is a field of intense study. While relatively little experimental progress was achieved in the B_d^0 sector during the past years, impressive new B_s^0

results became available from CDF, DØ and LHCb. The mass difference in the B_s^0–$\overline{B}_s^0$ system is now known to a relative precision of 0.12%, which is significantly better than that in the B_d^0–$\overline{B}_d^0$ system (0.68%). The non-zero decay width difference in the B_s^0–$\overline{B}_s^0$ system is now established, with a relative difference of $\Delta\Gamma_s/\Gamma_s = (13.8 \pm 1.2)\%$. Its sign has been determined: the heavy state of the B_s^0–$\overline{B}_s^0$ system lives longer than the light state. In contrast, the relative decay width difference in the B_d^0–$\overline{B}_d^0$ system, $\Delta\Gamma_d/\Gamma_d = (0.1 \pm 1.0)\%$, is still consistent with zero. CP violation in mixing has not been observed yet, with precisions on the semileptonic asymmetries below 0.5%. An impressive progress has been achieved in the measurement of the mixing-induced phase ϕ_s in B_s^0 decays proceeding through the $b \to c\bar{c}s$ transition, with a Gaussian uncertainty reaching the 0.07 radian level. Despite these significant improvements, all observations remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are expected in the future, especially from LHCb in the B_s^0 sector, with promising prospects for the investigation of the CP-violating phase $\arg(-M_{12}/\Gamma_{12})$ and an expected uncertainty on ϕ_s of ~ 0.03 radian by the time of the next edition of this *Review*.

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprize about) New Physics.

B^0-$\overline{B}^0$ MIXING PARAMETERS

For a discussion of B^0-$\overline{B}^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated B^0-$\overline{B}^0$ mixing probability that a produced $B^0(\overline{B}^0)$ decays as a $\overline{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L})\,\tau_{B^0}\ ,$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B^0_H}+\Gamma_{B^0_L})}$.

χ_d

This B^0-$\overline{B}^0$ mixing parameter is the probability (integrated over time) that a produced B^0 (or $\overline{B}^0$) decays as a $\overline{B}^0$ (or B^0), e.g. for inclusive lepton decays

$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0)) / \Gamma(B^0 \to \ell^\pm X)$

$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0)) / \Gamma(\overline{B}^0 \to \ell^\pm X)$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\overline{b}d)$ or $B^0_s(\overline{b}s)$. They are listed in the $B^\pm/B^0/B^0_s$/b-baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}^0$ fraction and about the ratio of the $B^\pm$ and B^0 semileptonic branching ratios (usually that it equals one).

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements, includes χ_d calculated from Δm_{B^0} and τ_{B^0}.

[1] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.

[2] ALBRECHT 94 reports r=0.194 ± 0.062 ± 0.054. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

[3] BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016^{+0.033}_{-0.028}$.

[4] ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14)$ (f_{+-}/f_0).

[5] Uses $D^{*+}K^\pm$ correlations.

[6] Uses $(D^{*+}\ell^-)\,K^\pm$ correlations.

[7] These experiments see a combination of B_s and B_d mesons.

[8] ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures r=0.21 ± 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.

[9] BEAN 87B measured $r <$ 0.24; we converted to χ.

[10] Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If $B^0/B^\pm$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from $r <$ 0.30 to $r <$ 0.37. We converted this limit to χ.

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

Δm_{B^0} is a measure of 2π times the B^0-$\overline{B}^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

[1] Measured using $B^0 \to D^-\pi^+$ and $B^0 \to J/\psi K^*(892)^0$ decays.

[2] Measured using $B^0 \to D^-\pi^+$.

[3] Uses opposite-side flavor-tagging with $B \to D^{(*)}\mu\nu_\mu X$ events.

[4] Measured using a simultaneous fit of the B^0 lifetime and $\overline{B}^0B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \to D^{*-}\ell\nu$ decays.

[5] Measurement performed using a combined fit of CP-violation, mixing and lifetimes.

[6] Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

[7] HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$ and CPT violation parameters in B^0-$\overline{B}^0$ mixing.

[8] ZHENG 03 data analyzed using partially reconstructed $\overline{B}^0 \to D^{*-}\pi^+$ decay and a flavor tag based on the charge of the lepton from the accompanying B decay.
[9] Uses a tagged sample of fully-reconstructed neutral B decays at $\Upsilon(4S)$.
[10] Measured based on the time evolution of dilepton events in $\Upsilon(4S)$ decays.
[11] Data analyzed using partially reconstructed $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}$ decay and a combination of flavor tags from the rest of the event.
[12] Uses di-muon events.
[13] Uses jet-charge and lepton-flavor tagging.
[14] Uses $\ell^- D^{*+} -\ell$ events.
[15] Uses π-B in the same side.
[16] Uses ℓ-ℓ.
[17] Uses ℓ-$Q_{\rm hem}$.
[18] Uses ℓ-ℓ with impact parameters.
[19] Uses $D^{*\pm}$-$Q_{\rm hem}$.
[20] Uses $\pi_s^{\pm}$ ℓ-$Q_{\rm hem}$.
[21] Uses $D^{*\pm}$-$\ell/Q_{\rm hem}$.
[22] Uses $D^{*\pm}$ ℓ-$Q_{\rm hem}$.
[23] Uses $D^{*\pm}$-ℓ.
[24] AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed $B^0 \to D^*(2010)^-\ell\nu$ and simultaneously measures the lifetime and oscillation frequency.
[25] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 02I.
[26] Uses a tagged sample of B^0 decays reconstructed in the mode $B^0 \to D^*\ell\nu$.
[27] Uses a tagged sample of fully-reconstructed hadronic B^0 decays at $\Upsilon(4S)$.
[28] ACCIARRI 98D combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, and ℓ-ℓ with impact parameters.
[29] ABREU 97N combines results from $D^{*\pm}$-$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, $\pi_s^{\pm}$ ℓ-$Q_{\rm hem}$, and ℓ-ℓ.
[30] ACKERSTAFF 97V combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, D^*-ℓ, and $D^{*\pm}$-$Q_{\rm hem}$.
[31] BUSKULIC 97D combines results from $D^{*\pm}$-$\ell/Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, and ℓ-ℓ.
[32] ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.
[33] ALEXANDER 96V combines results from $D^{*\pm}$-ℓ and $D^{*\pm}$ ℓ-$Q_{\rm hem}$.
[34] AKERS 95J combines results from charge measurement, $D^{*\pm}$ ℓ-$Q_{\rm hem}$ and ℓ-ℓ.

$x_d = \Delta m_{B^0}/\Gamma_{B^0}$

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes χ_d measured at $\Upsilon(4S)$.

VALUE	DOCUMENT ID
0.774±0.006 OUR EVALUATION	First
0.774±0.006 OUR EVALUATION	Second

Re(λ_{CP} / $|\lambda_{CP}|$) Re(z)

The λ_{CP} characterizes B^0 and $\overline{B}^0$ decays to states of charmonium plus K^0_L. Parameter z is used to describe CPT violation in mixing, see the review on "CP Violation" in the reviews section.

[2] Assuming $\Delta\Gamma = 0$, the result becomes Im(z) = −0.0037 ± 0.0046.
[3] Corresponds to 90% confidence range [−0.028, 0.104].
[4] Measured using inclusive dilepton events from B^0 decay.

CP VIOLATION PARAMETERS

Re(ϵ_{B^0})/(1+$|\epsilon_{B^0}|^2$)

CP impurity in B^0_d system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{cp}, the time-dependent asymmetry of inclusive B^0 and $\overline{B}^0$ decays.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no CP violation in B_S mixing.

The first "OUR EVALUATION", also provided by the HFAG, uses the measurements from B-factories only.

< 45	[15] BARTELT	93	CLE2	$e^+e^- \to \Upsilon(4S)$

[1] ABAZOV 14 uses the dimuon charge asymmetry with different impact parameters from which it reports $A^d_{SL} = (-0.62 \pm 0.42) \times 10^{-2}$.
[2] Uses $B^0 \to D^{*-}X\ell^+\nu_\ell$ and a kaon-tagged sample which yields measurement of A^d_{SL} = (0.06±0.17$^{+0.38}_{-0.32}$)%, corresponding to $\Delta_{CP} = 1-|q/p| = (0.29\pm0.84^{+1.88}_{-1.61})\times10^{-3}$.
[3] ABAZOV 12AC uses $B^0 \to D^-\mu^+X$ and $B^0 \to D^*(2010)^-\mu^+X$ decays without initial state flavor tagging which yields measurement of $A^d_{SL} = (6.8 \pm 4.5 \pm 1.4) \times 10^{-3}$.
[4] AUBERT 06T reports $|q/p|-1=(-0.8\pm2.7\pm1.9)\times10^{-3}$. We convert to $(1-|q/p|^2)/4$.
[5] Uses the charge asymmetry in like-sign dilepton events and reports $|q/p| = 1.0005 \pm 0.0040 \pm 0.0043$.
[6] AUBERT 02K uses the charge asymmetry in like-sign dilepton events.
[7] BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive B^0_d decays.
[8] JAFFE 01 finds $a_{\ell\ell} = 0.013 \pm 0.050 \pm 0.005$ and combines with the previous BEHRENS 00B independent measurement.
[9] Data analyzed using the time-dependent asymmetry of inclusive B^0 decay. The production flavor of B^0 mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.
[10] ACKERSTAFF 97U assumes CPT and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and $Q_{\rm hem}$ tags. If CPT is not invoked, Re(ϵ_B) = −0.006 ± 0.010 ± 0.006 is found. The indirect CPT violation parameter is determined to Im(δB) = −0.020 ± 0.016 ± 0.006.
[11] ABAZOV 11U uses the dimuon charge asymmetry with different impact parameters from which it reports $A^d_{SL} = (-1.2 \pm 5.2) \times 10^{-3}$.
[12] Uses the dimuon charge asymmetry.
[13] AUBERT 04C reports $|q/p| = 1.029\pm0.013\pm0.011$ and we converted it to (1- $|q/p|^2$)/4.
[14] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.
[15] BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $|{\rm Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2|$.

$A_{T/CP}$

$A_{T/CP}$ is defined as

$$\frac{P(\overline{B}^0 \to B^0) - P(B^0 \to \overline{B}^0)}{P(\overline{B}^0 \to B^0) + P(B^0 \to \overline{B}^0)},$$

the CPT invariant asymmetry between the oscillation probabilities P($\overline{B}^0 \to B^0$) and P($B^0 \to \overline{B}^0$).

VALUE	DOCUMENT ID		TECN	COMMENT
0.005±0.012±0.014	[1] AUBERT	02K	BABR	$e^+e^- \to \Upsilon(4S)$

[1] AUBERT 02K uses the charge asymmetry in like-sign dilepton events.

$A_{CP}(B^0 \to D^*(2010)^+ D^-)$

A_{CP} is defined as

$$\frac{B(\overline{B}^0 \to \overline{f}) - B(B^0 \to f)}{B(\overline{B}^0 \to \overline{f}) + B(B^0 \to f)},$$

the CP-violation charge asymmetry of exclusive B^0 and $\overline{B}^0$ decay.

[1] Measurement based on $B^0 \to J/\psi K^0_S$, $B^0 \to \psi(2S) K^0_S$, $B^0 \to J/\psi K^0_L$, and $B^0 \to \chi_{c1}(1P) K^0_S$ decays.
[2] SATO 12 uses 121 fb^{-1} data collected on $\Upsilon(5S)$ resonance. Uses the "$B-\pi$ tagging" where $B\pi^+$ and $B\pi^-$ tagged $J/\psi K^0_S$ events are compared.
[3] Uses Dalitz plot analysis of $B^0 \to K^0\pi^+\pi^-$ decays and the first of two equivalent solutions.
[4] Measurement based on $B^0 \to c\overline{c}K^{(*)0}$ decays.
[5] Measurement in which the J/ψ decays to hadrons or to muons that do not satisfy the standard identification criteria.
[6] AFFOLDER 00C uses about 400 $B^0 \to J/\psi(1S) K^0_S$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
[7] BARATE 00Q uses 23 candidates for $B^0 \to J/\psi(1S) K^0_S$ decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the B^0 production flavor.
[8] ACKERSTAFF 98Z uses 24 candidates for $B^0_d \to J/\psi(1S) K^0_S$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B^0_d production flavor.
[9] Based on $B^0 \to \psi(2S) K^0_S$ decays.
[10] Measurement based on 152×10^6 $B\overline{B}$ pairs.
[11] Measurement based on 227×10^6 $B\overline{B}$ pairs.
[12] ABE 02U result is based on the same analysis and data sample reported in ABE 01G.
[13] ABE 02Z result is based on 85×10^6 $B\overline{B}$ pairs.
[14] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.
[15] AUBERT 02P result is based on 88×10^6 $B\overline{B}$ pairs.
[16] First observation of CP violation in B^0 meson system.
[17] ABE 98U uses 198 ± 17 $B^0_d \to J/\psi(1S) K^0$ events. The production flavor of B^0 was determined using the same side tagging technique.

[1] Obtained using the time dependent analysis of $B^0 \to a_1(1260)^\pm\pi^\mp$ and branching fraction measurements of $B \to a_1(1260)K$ and $B \to K_1\pi$.

[2] Based on the favored $B \to \rho\rho$ isospin method.

[3] Obtained using isospin relation and selecting a solution closest to the CKM best fit average; the 90% CL allowed interval is $59^\circ < \phi_2\ (\equiv\alpha) < 115^\circ$.

[4] The angle $\alpha_{\rm eff}$ is obtained using the measured CP parameters of $B^0 \to a_1(1260)^\pm\pi^\mp$ and choosing one of the four solutions that is compatible with the result of SM-based fits.

[5] Obtained using isospin relation and selecting a solution closest to the CKM best fit average; 90% CL allowed interval is $79^\circ < \alpha < 123^\circ$.

[6] Obtained from the measured CP parameters of the longitudinal polarization by selecting the solution closest to the CKM best fit central value of $\alpha = 95^\circ$ – 98°.

T and CPT VIOLATION PARAMETERS

Measured values of the T-, CP-, and CPT-asymmetry parameters, defined as the differences in $S^\pm_{\alpha,\beta}$ and $C^\pm_{\alpha,\beta}$ between symmetry-transformed transitions. The indices $\alpha = \ell^+$, ℓ^- and $\beta = K^0_S$, K^0_L stand for reconstructed the flavor final state and the CP final states from $\Upsilon(4S)$ decay. The sign $\pm$ indicates whether the decay to the flavor final state α occurs before or after the decay to the CP final state.

$B^\pm/B^0$ ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ *anything*, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level
	Semileptonic and leptonic modes			
Γ_1	$e^+\nu_e$ anything	[a]	(10.86 ± 0.16) %	
Γ_2	$\overline{p}e^+\nu_e$ anything		< 5.9	$\times 10^{-4}$ CL=90%

[a] These values are model dependent.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d] This is a B($B^0 \to D^{*-}\ell^+\nu_\ell$) value.

[e] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[f] The value is for the sum of the charge states or particle/antiparticle states indicated.

[g] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[h] $X(3915)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.

[i] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

$B^{\pm}/B^0$ ADMIXTURE BRANCHING RATIOS

$\Gamma(e^+\nu_e \text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

These branching fraction values are model dependent.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

0.132 ±0.008 ±0.014	[14] KLOPFEN...	83B	CUSB	Direct e at $\Upsilon(4S)$	

[1] URQUIJO 07 report a measurement of (10.07 ± 0.18 ± 0.21)% for the partial branching fraction of $B \to e\nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B \to e\nu_e X$ branching fraction.

[2] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \to e^+\nu_e X) / B(B^0 \to e^+\nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

[3] Uses charge and angular correlations in $\Upsilon(4S)$ events with a high-momentum lepton and an additional electron.

[4] ALBRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[5] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of $B(B^+ \to e^+\nu_e X)/B(B^0 \to e^+\nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

[6] The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

[7] Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

[8] Uses the high-momentum lepton tag method. They also report $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$.

[9] Uses the high-momentum lepton tag method. ABE 02Y also reports $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$. The second error is due to uncertainties of theoretical inputs.

[10] BARISH 96B analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[11] YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

[12] ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

[13] Using data above $p(e) = 2.4$ GeV, WACHS 89 determine $\sigma(B \to e\nu\text{up})/\sigma(B \to e\nu\text{charm}) < 0.065$ at 90% CL.

[14] Ratio $\sigma(b \to e\nu\text{up})/\sigma(b \to e\nu\text{charm}) < 0.055$ at CL = 90%.

[1] Measures several partial branching fractions in different phase space regions. The most precise result on the full branching fraction is obtained in the region for lepton momentum in B rest frame $p_\ell^* > 1$ GeV/c, where the measured partial branching fraction is $\Delta B = (1.80 \pm 0.13 \pm 0.15) \times 10^{-3}$. The acceptance in that region is reported in a private communication by the Authors to be 0.894. The corresponding $|V_{ub}|$ from the BLNP method is $(4.28 \pm 0.15 \pm 0.18 \pm 0.19) \times 10^{-3}$, where the last uncertainty comes from theoretical prediction.

[2] Obtained from the partial rate $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$ for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.

[3] Determined from the partial rate $\Delta B = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$ measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV^2, and calculated acceptance 0.174 in that region. The V_{ub} is measured as $(4.41 \pm 0.30^{+0.65}_{-0.47} \pm 0.28) \times 10^{-3}$.

[4] Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The V_{ub} is found to be $(5.08 \pm 0.47^{+0.49}_{-0.48}) \times 10^{-3}$.

[5] BORNHEIM 02 uses the observed yield of leptons from semileptonic B decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on $B \to X_s\gamma$. The V_{ub} is found to be $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$.

[6] Uses a multivariate analysis method and requires lepton momentum in the B rest frame, $p_l^{*B} > 1.0$ GeV/c.

[7] Measures several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass $M_X < 1.55$ GeV/c^2, and is $\Delta B = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$. The corresponding $|V_{ub}|$ from the BLNP method is $(4.27 \pm 0.16 \pm 0.13 \pm 0.30) \times 10^{-3}$, where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.

[8] Used BaBar measurement of Semileptonic branching fraction $B(B \to X \ell \nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$ to convert the ratio of rates to branching fraction.

[9] The third error includes the systematics and theoretical errors summed in quadrature.

$\Gamma(X_u \ell^+ \nu_\ell)/\Gamma(\ell^+ \nu_\ell \text{anything})$ Γ_{24}/Γ_4

ℓ denotes e or μ, not the sum. These experiments measure this ratio in very limited momentum intervals.

<5.5	90		KLOPFEN...	83B	CUSB	Direct e at $\Upsilon(4S)$

[1] The third error includes the systematics and theoretical errors summed in quadrature.

[2] ALBRECHT 94C find $\Gamma(b \to c)/\Gamma(b \to \text{all}) = 0.99 \pm 0.02 \pm 0.04$.

[3] BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \to u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008, respectively.

[4] ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

[5] ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$–2.6 GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.

[6] FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$–2.6 GeV signaling the presence of the $b \to u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \to c\ell\nu) = 10.2 \pm 0.2 \pm 0.7\%$.

[7] The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

[1] GIBBONS 97B reports $B(B \to D^*(2010)^+\text{anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$ using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[2] ALBRECHT 96D reports $B(B \to D^*(2010)^+\text{anything})$ 0.196 ± 0.019 using CLEO measured $B(D^*(2010)^+ \to D^0\pi^+) = 0.681 \pm 0.01 \pm 0.013$, $B(D^0 \to K^-\pi^+) = 0.0401 \pm 0.0014$, $B(D^0 \to K^-\pi^+\pi^+\pi^-) = 0.081 \pm 0.005$., We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[3] BORTOLETTO 92 reports $B(B \to D^*(2010)^+\text{anything}) = 0.25 \pm 0.03 \pm 0.04$ using MARK II $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$ and $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.008$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[4] ALBRECHT 91H reports 0.348 ± 0.060 ± 0.035 from a measurement of $[\Gamma(B \to D^*(2010)^{\pm}\text{anything})/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \to D^0\pi^+)]$ assuming $B(D^*(2010)^+ \to D^0\pi^+) = 0.55 \pm 0.04$, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+) = 0.0371 \pm 0.0025$.

[5] BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \to K^-\pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. The product branching ratio for $B(B \to D^*(2010)^+)\, B(D^*(2010)^+ \to D^0\pi^+)$ is 0.13 ± 0.02 ± 0.012. Superseded by BORTOLETTO 92.

[6] $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.006$ and $B(D^{*+} \to D^0\pi^+) = 0.6^{+0.08}_{-0.15}$. The product branching fraction is $B(B \to D^{*+}X)\cdot B(D^{*+} \to \pi^+D^0)\cdot B(D^0 \to K^-\pi^+) = (68 \pm 15 \pm 9) \times 10^{-4}$.

[1] AUBERT 03F also reports the momentum distribution and helicity of $J/\psi\to\ell^{+}\ell^{-}$ in the $\Upsilon(4S)$ center-of-mass frame.

[2] MASCHMANN 90 reports $(1.12\pm0.33\pm0.25)\times10^{-2}$ from a measurement of $[\Gamma(B\to J/\psi(1S)\text{anything})/\Gamma_{total}]\times[B(J/\psi(1S)\to e^+e^-)]$ assuming $B(J/\psi(1S)\to e^+e^-)=0.069\pm0.009$, which we rescale to our best value $B(J/\psi(1S)\to e^+e^-)=(5.971\pm0.032)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[3] ALBRECHT 87D reports $(1.07\pm0.16\pm0.22)\times10^{-2}$ from a measurement of $[\Gamma(B\to J/\psi(1S)\text{anything})/\Gamma_{total}]\times[B(J/\psi(1S)\to e^+e^-)]$ assuming $B(J/\psi(1S)\to e^+e^-)=0.069\pm0.009$, which we rescale to our best value $B(J/\psi(1S)\to e^+e^-)=(5.971\pm0.032)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. ALBRECHT 87D find the branching ratio for J/ψ not from $\psi(2S)$ to be 0.0081 ± 0.0023.

[4] ALAM 86 reports $(1.09\pm0.16\pm0.21)\times10^{-2}$ from a measurement of $[\Gamma(B\to J/\psi(1S)\text{anything})/\Gamma_{total}]\times[B(J/\psi(1S)\to\mu^+\mu^-)]$ assuming $B(J/\psi(1S)\to\mu^+\mu^-)=0.074\pm0.012$, which we rescale to our best value $B(J/\psi(1S)\to\mu^+\mu^-)=(5.961\pm0.033)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[5] BALEST 95B reports $(1.12\pm0.04\pm0.06)\times10^{-2}$ from a measurement of $[\Gamma(B\to J/\psi(1S)\text{anything})/\Gamma_{total}]\times[B(J/\psi(1S)\to e^+e^-)]$ assuming $B(J/\psi(1S)\to e^+e^-)=0.0599\pm0.0025$, which we rescale to our best value $B(J/\psi(1S)\to e^+e^-)=(5.971\pm0.032)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. They measure $J/\psi(1S)\to e^+e^-$ and $\mu^+\mu^-$ and use PDG 1994 values for the branching fractions. The rescaling is the same for either mode so we use e^+e^-.

[6] Statistical and systematic errors were added in quadrature. ALBRECHT 85H also report a CL = 90% limit of 0.007 for $B\to J/\psi(1S)+X$ where $m_X<1$ GeV.

[7] Dimuon and dielectron events used.

$\Gamma(J/\psi(1S)(\text{direct})\text{anything})/\Gamma_{total}$ Γ_{48}/Γ

[1] AUBERT 03F also reports the helicity of $J/\psi\to\ell^{+}\ell^{-}$ produced directly in B decay.

[2] Also reports the measurement of $J/\psi\to\ell^{+}\ell^{-}$ polarization produced directly from B decay.

[3] BALEST 95B assume PDG 1994 values for sub mode branching ratios. $J/\psi(1S)$ mesons are reconstructed in $J/\psi(1S)\to e^+e^-$ and $J/\psi(1S)\to\mu^+\mu^-$. The $B\to J/\psi(1S)X$ branching ratio contains $J/\psi(1S)$ mesons directly from B decays and also from feeddown through $\psi(2S)\to J/\psi(1S)$, $\chi_{c1}(1P)\to J/\psi(1S)$, or $\chi_{c2}(1P)\to J/\psi(1S)$. Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the $B\to J/\psi(1S)$ (direct) X branching ratio.

seen	[3] GIANNINI	82	CUSB	$e^+e^- \to \Upsilon(4S)$

[1] ALBRECHT 93I value is not independent of the sum of $B \to K^+$ anything and $B \to K^-$ anything ALBRECHT 94C values.

[2] Assuming $\Upsilon(4S) \to B\overline{B}$, a total of $3.38 \pm 0.34 \pm 0.68$ kaons per $\Upsilon(4S)$ decay is found (the second error is systematic). In the context of the standard B-decay model, this leads to a value for (b-quark $\to$ c-quark)/(b-quark $\to$ all) of $1.09 \pm 0.33 \pm 0.13$.

[3] GIANNINI 82 at CESR-CUSB observed 1.58 ± 0.35 K^0 per hadronic event much higher than 0.82 ± 0.10 below threshold. Consistent with predominant $b \to c$X decay.

[1] We correct it to $E_\gamma>1.6$ GeV using the method of BUCHMULLER 06 (average of three theoretical models).

[2] Reports $(3.29\pm0.19\pm0.48)\times10^{-4}$ for $E_\gamma>1.9$ GeV.

[3] Reports $(3.21\pm0.15\pm0.29\pm0.08)\times10^{-4}$ for $1.8<E_\gamma<2.8$ GeV, where the last systematic uncertainty is for model dependency. Results with other cutoffs are also reported.

[4] The measurement reported is $(3.45\pm0.15\pm0.40)\times10^{-4}$ for $E_\gamma>1.7$ GeV.

[5] Uses a fully reconstructed B meson as a tag on the recoil side. The measurement reported is $(3.66\pm0.85\pm0.60)\times10^{-4}$ for $E_\gamma>1.9$ GeV.

[6] ABE 01F reports their systematic errors $(\pm0.42^{+0.50}_{-0.54})\times10^{-4}$, where the second error is due to the theoretical uncertainty. We combine them in quadrature.

[7] The measurement reported is $(3.21\pm0.43^{+0.32}_{-0.29})\times10^{-4}$ for $E_\gamma>2.0$ GeV.

[8] Measured using sums of seven exclusive final states $B\to X_{d(s)}\gamma$ where $X_{d(s)}$ is a nonstrange (strange) charmless hadronic system in mass range 0.5–2.0 GeV/c^2.

[9] Measured using sums of seven exclusive final states $B\to X_{d(s)}\gamma$ where $X_{d(s)}$ is a nonstrange (strange) charmless hadronic system in mass range 0.6–1.8 GeV/c^2.

[10] The measurement reported is $(3.67\pm0.29\pm0.45)\times10^{-4}$ for $E_\gamma>1.9$ GeV.

[11] The measurement reported is $(3.27\pm0.18^{+0.55}_{-0.42})\times10^{-4}$ for $E_\gamma>1.9$ GeV.

[12] The measurement reported is $(3.55\pm0.32\pm0.32)\times10^{-4}$ for $E_\gamma>1.8$ GeV.

• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.08		2	[2] ALBRECHT	95D	ARG	$e^+e^-\to\Upsilon(4S)$

[1] COAN 98 uses D-ℓ correlation.

[2] ALBRECHT 95D use full reconstruction of one B decay as tag. Two candidate events for charmless B decay can be interpreted as either $b\to s$gluon or $b\to u$ transition. If interpreted as $b\to s$gluon they find a branching ratio of ~0.026 or the upper limit quoted above. Result is highly model dependent.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
$6.2\pm1.6^{+1.3}_{-2.0}$	[3] BROWDER	98	CLE2	$e^+e^-\to\Upsilon(4S)$

[1] AUBERT,B 04F reports branching ratio $B\to\eta' X_s$ for high momentum η' between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. X_s represents a recoil system consisting of a kaon and zero to four pions.

[2] BONVICINI 03 observed a signal of 61.2 ± 13.9 events in $B\to\eta' X_{nc}$ production for high momentum η' between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. The X_{nc} denotes "charmless" hadronic states recoiling against η'. The second error combines systematic and background subtraction uncertainties in quadrature.

[3] BROWDER 98 observed a signal of 39.0 ± 11.6 events in high momentum $B\to\eta' X_s$ production between 2.0 and 2.7 GeV/c. The branching fraction is based on the interpretation of $b\to sg$, where the last error includes additional uncertainties due to the color-suppressed $b\to$ backgrounds.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.064±0.008±0.008		[2] CRAWFORD	92	CLEO	$e^+e^- \to \Upsilon(4S)$
0.14 ±0.09		[3] ALBRECHT	88E	ARG	$e^+e^- \to \Upsilon(4S)$
<0.112	90	[4] ALAM	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] AUBERT 07C reports 0.045 ± 0.003 ± 0.012 from a measurement of $[\Gamma(B \to \Lambda_c^+ / \overline{\Lambda}_c^-\text{ anything})/\Gamma_{\text{total}}] \times [B(\Lambda_c^+ \to p K^-\pi^+)]$ assuming $B(\Lambda_c^+ \to p K^-\pi^+) = (5.0 \pm 1.3) \times 10^{-2}$.
[2] CRAWFORD 92 result derived from lepton baryon correlations. Assumes all charmed baryons in B^0 and $B^{\pm}$ decay are Λ_c.
[3] ALBRECHT 88E measured $B(B \to \Lambda_c^+ X)\cdot B(\Lambda_c^+ \to p K^-\pi^+) = (0.30 \pm 0.12 \pm 0.06)\%$ and used $B(\Lambda_c^+ \to p K^-\pi^+) = (2.2 \pm 1.0)\%$ from ABRAMS 80 to obtain above number.
[4] Assuming all baryons result from charmed baryons, ALAM 86 conclude the branching fraction is 7.4 ± 2.9%. The limit given above is model independent.

0.076±0.014	[2] ALBRECHT	89K	ARG	$e^+e^- \to \Upsilon(4S)$

[1] ALBRECHT 92O result is from simultaneous analysis of p and Λ yields, $p\overline{p}$ and $\Lambda\overline{p}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89K.
[2] ALBRECHT 89K obtain this result by adding their their measurements $(5.5 \pm 1.6)\%$ for direct protons and $(4.2 \pm 0.5 \pm 0.6)\%$ for inclusive Λ production. They then assume $(5.5 \pm 1.6)\%$ for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain $(7.6 \pm 1.4)\%$.

<17	90	[5] ANDERSON	01B	CLE2	$e^+e^-\to\Upsilon(4S)$	

[1] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[2] Assumes all four $B\to K\ell^+\ell^-$ modes having equal partial widths in the fit.
[3] Assumes equal production rate for charge and neutral B meson pairs, isospin invariance, lepton universality for $B\to K\ell^+\ell^-$, and $B(B\to K^*(892)\mu^+\mu^-)=1.33$. The second error is total systematic uncertainties including model dependence.
[4] Assumes lepton universality.
[5] The result is for di-lepton masses above 0.5 GeV.

$\Gamma(K^*(892)\ell^+\ell^-)/\Gamma_{total}$ Γ_{130}/Γ

Test for $\Delta B=1$ weak neutral current. Allowed by higher-order electroweak interactions.

VALUE	DOCUMENT ID		TECN	COMMENT
$-0.13\pm0.04^{+0.02}_{-0.03}$	[1] NISHIMURA	10	BELL	$e^+e^- \to \Upsilon(4S)$

[1] Uses $B \to \eta X_s$ with $0.4 < m_{X_s} < 2.6$ GeV/c^2.

POLARIZATION IN B DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ($\|$) or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

LEPTON FORWARD-BACKWARD ASYMMETRY IN $B \to K^{(*)}\ell^+\ell^-$ DECAY

The forward-backward angular asymmetry of the lepton pair in $B \to K^{(*)}\ell^+\ell^-$ decay is defined as

$$A_{FB}(s) = \frac{N(cos\theta>0)-N(cos\theta<0)}{N(cos\theta>0)+N(cos\theta<0)},$$

where $s=q^2/m_B^2$, and θ is the angle of the lepton with respect to the flight direction of the B meson, measured in the dilepton rest frame. In addition, the fraction of longitudinal polarization F_L of the K^* and F_S, the relative contribution from scalar and pseudoscalar penguin amplitudes in $B \to K\ell^+\ell^-$, can be measured from the angular distribution of its decay products.

A_{FB}($B \to K^*\ell^+\ell^-$) ($q^2 > 0.1$ GeV$^2/c^4$)

ISOSPIN ASYMMETRY

Δ_{0-} is defined as

$$\frac{\Gamma(B^0 \to f_d) - \Gamma(B^+ \to f_u)}{\Gamma(B^0 \to f) + \Gamma(B^+ \to f)},$$

the isospin asymmetry of inclusive neutral and charged B decay.

$\Delta_{0-}(B(B \to X_s\gamma))$

VALUE	DOCUMENT ID		TECN	COMMENT

$B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE

$B^{\pm}/B^0/B^0_s/b$-baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

[1] Measurement performed using an inclusive reconstruction and B flavor identification technique.
[2] Measured using inclusive $J/\psi(1S) \to \mu^+\mu^-$ vertex.
[3] ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.
[4] ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.
[5] BUSKULIC 96F analyzed using 3D impact parameter.
[6] ABE,K 95B uses an inclusive topological technique.
[7] ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
[8] ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.
[9] BUSKULIC 93O analyzed using dipole method.
[10] Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
[11] From proper time distribution of $b \to J/\psi(1S)$ anything.
[12] ABE 93J analyzed using $J/\psi(1S) \to \mu\mu$ vertices.
[13] ABREU 93D data analyzed using $D/D^*\ell$anything event vertices.
[14] ABREU 93G data analyzed using charged and neutral vertices.
[15] ACTON 93C analysed using $D/D^*\ell$anything event vertices.
[16] ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
[17] ACTON 92 is combined result of muon and electron impact parameter analyses.
[18] BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.
[19] BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.
[20] Using $Z \to e^+$X or μ^+X, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
[21] Using $Z \to J/\psi(1S)$X, $J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
[22] Using $Z \to e$X or μX, DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
[23] HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
[24] LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUNSCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
[25] We have combined an overall scale error of 15% in quadrature with the systematic error of ±0.7 to obtain ±2.1 systematic error.
[26] Statistical and systematic errors were combined by BROM 87.

[1] Data analyzed using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

$\overline{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LHC, LEP, Tevatron, S$p\overline{p}$S) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings. The production fractions in b-hadronic Z decay or $p\overline{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$B(\overline{b} \to B^+) = B(\overline{b} \to B^0)$$
$$B(\overline{b} \to B^+) + B(\overline{b} \to B^0) + B(\overline{b} \to B^0_s) + B(b \to b\text{-baryon}) = 100\ \%.$$

The correlation coefficients between production fractions are also reported:

$cor(B^0_s, b\text{-baryon}) = -0.291$
$cor(B^0_s, B^{\pm}{=}B^0) = -0.083$
$cor(b\text{-baryon}, B^{\pm}{=}B^0) = -0.929.$

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b \to \overline{B}^0)$, $Br(b \to \overline{B}^0)$). We use our own branching fraction notation here, $B(\overline{b} \to B^0)$.

Note these production fractions are b-hadronization fractions, not the conventional branching fractions of b-quark to a B-hadron, which may have

considerable dependence on the initial and final state kinematic and production environment.

0.21 ±0.036 $^{+0.038}_{-0.030}$	[5] ABE	99P	CDF	$\overline{p}p$ at 1.8 TeV

[1] Measured using b-hadron semileptonic decays and assuming isospin symmetry.

[2] AAIJ 11F measured $f_s/f_d = 0.253 \pm 0.017 \pm 0.017 \pm 0.020$, where the errors are statistical, systematic, and theoretical. We divide their value by 2. Our second error combines systematic and theoretical uncertainties.

[3] AALTONEN 08N reports $[\Gamma(\overline{b} \to B_s^0)/\left[\Gamma(\overline{b} \to B^+) + \Gamma(\overline{b} \to B^0)\right]] \times [\mathrm{B}(D_s^+ \to \phi\pi^+)] = (5.76 \pm 0.18^{+0.45}_{-0.42}) \times 10^{-3}$ which we divide by our best value $\mathrm{B}(D_s^+ \to \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[4] AFFOLDER 00E uses several electron-charm final states in $b \to ce^-\mathrm{X}$.

[5] ABE 99P uses the numbers of $K^*(892)^0$, $K^*(892)^+$, and $\phi(1020)$ events produced in association with the double semileptonic decays $b \to c\mu^-\mathrm{X}$ with $c \to s\mu^+\mathrm{X}$.

$0.114\ \pm0.003\ \pm0.004$	[8] BUSKULIC	94G	ALEP	$e^+e^-\to Z$
$0.100\ \pm0.007\ \pm0.007$	[9] ABREU	93C	DLPH	$e^+e^-\to Z$
$0.105\ \pm0.006\ \pm0.005$	[10] AKERS	93B	OPAL	Repl. by ABBIENDI 00E

[1] Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

[2] The experimental systematic and model uncertainties are combined in quadrature.

[3] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z\to b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

[4] ACCIARRI 00 result obtained from a combined fit of $R_b=\Gamma(Z\to b\overline{b})/\Gamma(Z\to\text{hadrons})$ and $B(b\to\ell\nu X)$, using double-tagging method.

[5] ACCIARRI 96C result obtained by a fit to the single lepton spectrum.

[6] Assumes Standard Model value for R_B.

[7] ABREU 95D give systematic errors ±0.0019 (model) and 0.0012 (R_C). We combine these in quadrature.

[8] BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T, but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ±0.0026 and is included in the systematic error.

[9] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.

[10] AKERS 93B analysis performed using single and dilepton events.

[1] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z\to b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

[2] ACCIARRI 96C result obtained by a fit to the single lepton spectrum.

[3] Assumes Standard Model value for R_B.

[4] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.

[5] ADEVA 91C measure the average $B(b\to eX)$ branching ratio using single and double tagged b enhanced Z events. Combining e and μ results, they obtain $0.113\pm0.010\pm0.006$. Constraining the initial number of b quarks by the Standard Model prediction (378 ± 3 MeV) for the decay of the Z into $b\overline{b}$, the electron result gives $0.112\pm0.004\pm0.008$. They obtain $0.119\pm0.003\pm0.006$ when e and μ results are combined. Used to measure the $b\overline{b}$ width itself, this electron result gives 370 ± 12 ± 24 MeV and combined with the muon result gives 385 ± 7 ± 22 MeV.

[6] ABE 93E experiment also measures forward-backward asymmetries and fragmentation functions for b and c.

[7] AKERS 93B analysis performed using single and dilepton events.

χ_b AT HIGH ENERGY

For a discussion of B-$\overline{B}$ mixing, see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings.

χ_b is the average B-$\overline{B}$ mixing parameter at high-energy $\chi_b = f'_d\chi_d + f'_s\chi_s$ where f'_d and f'_s are the fractions of B^0 and B_s^0 hadrons in an unbiased sample of semileptonic b-hadron decays.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

[1] Uses the dimuon charge asymmetry. Averaged over the mix of b-flavored hadrons.
[2] Measurement performed using events containing a dimuon or an e/μ pair.
[3] The average B mixing parameter is determined simultaneously with b and c forward-backward asymmetries in the fit.
[4] The experimental systematic and model uncertainties are combined in quadrature.
[5] ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A_{FB}^b in $Z \to b\overline{b}$ events containing prompt leptons.
[6] This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.
[7] BUSKULIC 94G data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[8] BUSKULIC 92B uses a jet charge technique combined with electrons and muons.
[9] ABE 91G measurement of χ is done with $e\mu$ and ee events.
[10] ALBAJAR 91D measurement of χ is done with dimuons.
[11] Uses di-muon events.
[12] ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \to Z \to b\overline{b}$ and $c\overline{c}$.
[13] UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.
[14] ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi} = f_d\chi_d + 0.9 f_s\chi_s$.
[15] This ABREU 94J result combines $\ell\ell$, $\Lambda\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{\chi} = f_d\chi_d + 0.96 f_s\chi_s$.
[16] ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
[17] ABREU 93C data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[18] AKERS 93B analysis performed using dilepton events.
[19] ACTON 92C uses electrons and muons. Superseded by AKERS 93B.
[20] ADEVA 92C uses electrons and muons.
[21] DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.
[22] ADEVA 90P measurement uses ee, $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.
[23] These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.
[24] The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
[25] ALBAJAR 87C measured $\chi = (\overline{B}^0 \to B^0 \to \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.
[26] Limit is average probability for hadron containing B quark to produce a positive lepton.

CP VIOLATION PARAMETERS in semileptonic b-hadron decays.

Re(ϵ_b) / (1 + $|\epsilon_b|^2$)

CP impurity in semileptonic b-hadron decays.

VALUE (units 10^{-3})	DOCUMENT ID		TECN	COMMENT
1.24±0.38±0.18	[1] ABAZOV	14	D0	$p\overline{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
−1.97±0.43±0.23	[2] ABAZOV	11U	D0	Repl. by ABAZOV 14
−2.39±0.63±0.37	[3] ABAZOV	10H	D0	Repl. by ABAZOV 11U

[1] ABAZOV 14 reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-4.96 \pm 1.53 \pm 0.72) \times 10^{-3}$ in semileptonic b-hadron decays.
[2] ABAZOV 11U reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-7.87 \pm 1.72 \pm 0.93) \times 10^{-3}$ in semileptonic b-hadron decays.
[3] ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$ in semileptonic b-hadron decays. Using the measured production ratio of B_d^0 and B_s^0, and the asymmetry of B_d^0 $A_{SL}^d = (-4.7 \pm 4.6) \times 10^{-3}$ measured from B-factories, they obtain the asymmetry for B_s^0 as $A_{SL}^s = (-14.6 \pm 7.5) \times 10^{-3}$.

B-HADRON PRODUCTION FRACTIONS IN HADRONIC Z DECAY

The production fractions of b-hadrons in hadronic Z decays have been calculated using the best values of mean lives, mixing parameters and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see http://www.slac.stanford.edu/xorg/hfag/).

The values reported below assume:

$f(\overline{b} \to B^+) = f(\overline{b} \to B^0)$

$f(\overline{b} \to B^+) + f(\overline{b} \to B^0) + f(\overline{b} \to B_s^0) + f(b \to b\text{-baryon}) = 1$

The values are:

$f(\overline{b} \to B^+) = f(\overline{b} \to B^0) = 0.404 \pm 0.009$

$f(\overline{b} \to B_s^0) = 0.103 \pm 0.009$

$f(b \to b\text{-baryon}) = 0.089 \pm 0.015$

and their correlation coefficients are:

$cor(B_s^0, b\text{-baryon}) = +0.052$

$cor(B_s^0, B^+ = B^0) = -0.534$

$cor(b\text{-baryon}, B^+ = B^0) = -0.872$

as obtained using a time-integrated mixing parameter $\overline{\chi} = 0.1259 \pm 0.0042$ given by a fit to heavy quark quantities with asymmetries removed (see the note "The Z boson").

B-HADRON PRODUCTION FRACTIONS IN $p\overline{p}$ COLLISIONS AT Tevatron

The production fractions for b-hadrons in $p\overline{p}$ collisions at the Tevatron have been calculated from the best values of mean lifetimes, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see http://www.slac.stanford.edu/xorg/hfag/).

The values reported below assume:

$f(\overline{b} \to B^+) = f(\overline{b} \to B^0)$

$f(\overline{b} \to B^+) + f(\overline{b} \to B^0) + f(\overline{b} \to B_s^0) + f(b \to b\text{-baryon}) = 1$

The values are:

$f(\overline{b} \to B^+) = f(\overline{b} \to B^0) = 0.339 \pm 0.031$

$f(\overline{b} \to B_s^0) = 0.111 \pm 0.014$

$f(b \to b\text{-baryon}) = 0.212 \pm 0.069$

and their correlation coefficients are:

$cor(B_s^0, b\text{-baryon}) = -0.581$

$cor(B_s^0, B^+ = B^0) = +0.425$

$cor(b\text{-baryon}, B^+ = B^0) = -0.984$

as obtained with the Tevatron average of time-integrated mixing parameter $\overline{\chi} = 0.147 \pm 0.011$.

V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

SEMILEPTONIC B MESON DECAYS AND THE DETERMINATION OF V_{cb} AND V_{ub}

Updated February 2014 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

INTRODUCTION

Semileptonic B meson decay amplitudes allow determinations of $|V_{ub}|$ and $|V_{cb}|$ which are assumed to be largely free from any impact of non-standard model physics, since they are dominated by the standard-model W boson exchange. A charged Higgs boson, present in many models of new physics, will couple to the mass of the lepton and hence it will have practically no impact in decays into e and μ. However, decays to tau leptons, which are also discussed in this review, provide sensitivity to these models.

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$, making its determination a high priority of the heavy-flavor physics program.

The semileptonic transitions $b \to c\ell\overline{\nu}_\ell$ and $b \to u\ell\overline{\nu}_\ell$ (where ℓ refers to an electron or muon) each provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. Recent measurements and calculations are reflected in the values quoted in this article, which is an update of the previous review [1]. The leptonic decay $B^- \to \tau\overline{\nu}$ can also be used to extract $|V_{ub}|$; we do not use this information at present since none of the current experimental measurements has reached the significance level of an observation.

The theory underlying the determination of $|V_{qb}|$ is mature, in particular for $|V_{cb}|$. Most of the theoretical approaches use the fact that the mass m_b of the b quark is large compared to the scale $\Lambda_{\rm QCD}$ that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of Λ/m_b, where $\Lambda \sim 500 - 700$ MeV is a hadronic scale of the order of $\Lambda_{\rm QCD}$, based on effective-field-theory methods described in a separate RPP mini-review.

The large data samples available at the B factories enable analyses where one B meson from an $\Upsilon(4S)$ decay is fully reconstructed, allowing a recoiling semileptonic B decay to be studied with high purity. Improved knowledge of $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays allows partial rates for $\overline{B} \to X_u\ell\overline{\nu}_\ell$ transitions to be measured in regions previously considered inaccessible, increasing the acceptance for $\overline{B} \to X_u\ell\overline{\nu}_\ell$ transitions and reducing theoretical uncertainties.

Experimental measurements of the exclusive $\overline{B} \to \pi\ell\overline{\nu}_\ell$ decay are quite precise, and recent improvements in the theoretical calculation of the form factor normalization have enabled

a determination of $|V_{ub}|$ from this decay with an uncertainty below 10%.

The decays $\overline{B} \to D^{(*)}\tau\overline{\nu}_\ell$ provide sensitivity to possible non-universalities in the couplings to the third generation leptons that are present at tree level in models involving new charged mediators. The constraints on these models are weak at present, and the enhanced decay rates seen in recent measurements of these decay modes, if they turn out to be robust, are an indication of new physics.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [2].

DETERMINATION OF $|V_{cb}|$

Summary: The determination of $|V_{cb}|$ from $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays has a relative precision of about 2%, with the main uncertainty coming from knowledge of the form factor near the maximum momentum transfer to the leptons. The $\overline{B} \to D\ell\overline{\nu}_\ell$ decay provides a determination with an uncertainty of 5%.

Inclusive decays provide a determination of $|V_{cb}|$ with a relative uncertainty of about 2%. The limitations arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are marginally consistent with each other:

$$|V_{cb}| = (42.2 \pm 0.7) \times 10^{-3} \text{ (inclusive)} \quad (1)$$

$$|V_{cb}| = (39.5 \pm 0.8) \times 10^{-3} \text{ (exclusive);} \quad (2)$$

as a result, their combination should be treated with caution. An average of these determinations has $p(\chi^2) = 0.01$, so we scale the error by $\sqrt{\chi^2/1} = 2.6$ to find

$$|V_{cb}| = (41.1 \pm 1.3) \times 10^{-3} \ . \quad (3)$$

$|V_{cb}|$ from exclusive decays

Exclusive determinations of $|V_{cb}|$ are based on a study of semileptonic B decays into the ground state charmed mesons D and D^*. The main uncertainties in this approach stem from our ignorance of the form factors describing the $B \to D$ and $B \to D^*$ transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [3], which depends on the product of the four-velocities v and v' of the initial and final-state hadrons.

The extraction of $|V_{cb}|$ is based on the distribution of the variable $w \equiv v \cdot v'$, which corresponds to the energy of the final state $D^{(*)}$ meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [3,4] predicts the normalization of the rate at $w = 1$, the point of maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation of the measured spectrum to $w = 1$. This extrapolation relies on a parametrization of the form factor, as explained below.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point $w = 1$. The framework for this is "Heavy Quark Effective Theory", which is discussed in a separate mini-review. The corrections to the HQS prediction are due to finite quark masses and are essentially of the order $\Lambda_{\rm QCD}/m_c$. Form factors that are normalized due to HQS are protected against linear corrections of this order and hence the corrections are here of order $\Lambda^2_{\rm QCD}/m_c^2$ due to Luke's Theorem [5], which is an application of the Ademollo-Gatto theorem [6] to heavy quarks. For the form factors that vanish in the infinite mass limit the corrections are in general linear in $\Lambda_{\rm QCD}/m_c$, and thus we have, using the definitions as in Eq. (2.84) of Ref. 7

$$\begin{aligned} h_i(1) &= 1 + \mathcal{O}(\Lambda^2_{\rm QCD}/m_c^2) && \text{for } i = +, V, A_1, A_3 \ , \\ h_i(1) &= \mathcal{O}(\Lambda_{\rm QCD}/m_c) && \text{for } i = -, A_2 \ . \end{aligned} \quad (4)$$

In addition to these corrections, there are perturbatively calculable radiative corrections from hard gluons and photons, which will be discussed in the relevant sections.

$\overline{B} \to D^*\ell\overline{\nu}_\ell$

The decay rate for $\overline{B} \to D^*\ell\overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D^*\ell\overline{\nu}_\ell) = \frac{G_F^2 m_B^5}{48\pi^3}|V_{cb}|^2(w^2-1)^{1/2}P(w)(\eta_{\rm ew}\mathcal{F}(w))^2, \quad (5)$$

where $P(w)$ is a phase space factor,

$$P(w) = r^3(1-r)^2(w+1)^2\left(1 + \frac{4w}{w+1}\frac{1-2rw+r^2}{(1-r)^2}\right).$$

with $r = m_{D^*}/m_B$. The form factor $\mathcal{F}(w)$ is dominated by the axial vector form factor h_{A_1} as $w \to 1$. Furthermore, $\eta_{\rm ew} = 1.007$ accounts for the electroweak corrections to the four-fermion operator mediating the semileptonic decay [8]. In the infinite-mass limit, the HQS normalization gives $\mathcal{F}(1) = 1$.

The form factor $\mathcal{F}(w)$ must be parametrized to perform an extrapolation to the zero-recoil point. A frequently used one-parameter form motivated by analyticity and unitarity is [9,10]

$$\begin{aligned} h_{\rm A1}(w) = \eta_{\rm A}&\left[1 + \delta_{1/m^2} + \cdots\right] \\ &\left[1 - 8\rho^2_{\rm A1}z + (53\rho^2_{\rm A1} - 15)z^2 - (231\rho^2_{\rm A1} - 91)z^3\right] \end{aligned} \quad (6)$$

with $z = (\sqrt{w+1} - \sqrt{2})/(\sqrt{w+1} + \sqrt{2})$ originating from a conformal transformation. The parameter $\rho^2_{\rm A1}$ is the slope of the form factor at $w = 1$. The factor $\eta_{\rm A}$ is the QCD short-distance radiative correction [11] to the form factor

$$\eta_{\rm A} = 0.960 \pm 0.007, \quad (7)$$

and δ_{1/m^2} comes from non-perturbative $1/m^2$ corrections.

Precise lattice determinations of the $B \to D^{(*)}$ form factors naturally build in heavy-quark symmetries, so all uncertainties scale with the deviation of the form factor from unity. Unquenched calculations, i.e. calculations with realistic sea quarks, obtain quite precise predictions of the form factors; the relevant calculations for the form factor $\mathcal{F}(\omega)$ in Refs. [12,13] quote a total uncertainty at the 2% level. The main contributions to this uncertainty are from the chiral extrapolation from

the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and from discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings.

Including effects from finite quark masses to calculate the deviation of $\mathcal{F}(1)$ from unity, the current lattice prediction is

$$\mathcal{F}(1) = 0.902 \pm 0.017, \quad (8)$$

where the factor $\eta_{\rm ew}$ has been divided out from the value quoted in Ref. 14 and the errors have been added in quadrature. The leading uncertainties are due to heavy-quark discretization and chiral extrapolation errors.

Non-lattice estimates based on sum rules for the form factor tend to yield lower values for $\mathcal{F}(1)$ [15,16,17]. Omitting the contributions from excited states, the sum rules indicate that $\mathcal{F}(1) < 0.93$. Including an estimate for the contribution of the excited states yields $\mathcal{F}(1) = 0.86 \pm 0.01 \pm 0.02$ [17,18] where the second uncertainty originates from the estimate for the excited states.

Many experiments [19–27] have measured the differential rate as a function of w. These measurements are input to a four-dimensional fit [28] for $\mathcal{F}(1)|V_{cb}|$, $\rho^2_{A_1}$ and the form factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$. The leading sources of uncertainty on $\mathcal{F}(1)\,|V_{cb}|$ are due to detection efficiencies and $D^{(*)}$ decay branching fractions, while for $\rho^2_{A_1}$ the uncertainties in R_1 and R_2 still dominate. Recent BABAR measurements, one using $\overline{B}^0 \to D^{*0}\ell\overline{\nu}_\ell$ decays [25] and the other using a global fit to $\overline{B} \to D\ell\overline{\nu}_\ell X$ decays [26] are completely insensitive to uncertainties related to the reconstruction of the charged pion from $D^* \to D\pi$ decays; both measurements agree with the average given below.

The fit gives [29] $\eta_{\rm ew}\mathcal{F}(1)\,|V_{cb}| = (35.85 \pm 0.45) \times 10^{-3}$ with a p-value of 0.15. Along with the lattice value given above for $\mathcal{F}(1)$ this yields

$$|V_{cb}| = (39.48 \pm 0.50_{\rm exp} \pm 0.74_{\rm theo}) \times 10^{-3}\ (\overline{B} \to D^*\ell\overline{\nu}_\ell,\ \text{LQCD}). \quad (9)$$

The value of $\mathcal{F}(1)$ obtained from QCD sum rules results in a larger value for $|V_{cb}|$:

$$|V_{cb}| = (41.4 \pm 0.5_{\rm exp} \pm 1.0_{\rm theo}) \times 10^{-3}\ (\overline{B} \to D^*\ell\overline{\nu}_\ell,\ \text{SR}). \quad (10)$$

$\overline{B} \to D\ell\overline{\nu}_\ell$

The differential rate for $\overline{B} \to D\ell\overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D\ell\overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3}|V_{cb}|^2(m_B + m_D)^2 m_D^3 (w^2-1)^{3/2}(\eta_{\rm ew}\mathcal{G}(w))^2. \quad (11)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (12)$$

where h_+ is normalized to unity in the infinite-mass limit due to HQS and h_- vanishes in the heavy-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D}\frac{\Lambda_{\rm QCD}}{m_c}\right) \quad (13)$$

and the corrections to the HQET predictions are parametrically larger than was the case for $\overline{B} \to D^*\ell\overline{\nu}_\ell$.

In order to get a more precise prediction for the form factor $\mathcal{G}(1)$ the heavy-quark expansion can be supplemented by additional assumptions. It has been argued in Ref. 30 that in a limit in which the kinetic energy μ_π^2 is equal to the chromomagnetic moment μ_G^2 (these quantities are discussed below in more detail) one may obtain the value

$$\mathcal{G}(1) = 1.04 \pm 0.01_{\rm power} \pm 0.01_{\rm pert}. \quad (14)$$

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case $\overline{B} \to D^*\ell\overline{\nu}_\ell$ is irrelevant. These unquenched calculations quote a value (preliminary, from 2005) [31]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016. \quad (15)$$

Recent, yet unpublished results indicate that the updated lattice value for $\mathcal{G}(1)$ will become slightly smaller, making it better compatible with Eq. (14).

Recent measurements of $\overline{B} \to D\ell\overline{\nu}_\ell$ [26,32] are consistent with earlier measurements [19,33,34] but are significantly more precise. The average of these inputs [29] gives $\eta_{\rm ew}\mathcal{G}(1)|V_{cb}| = (42.5 \pm 1.6) \times 10^{-3}$. Using the value from Eq. (15) for $\mathcal{G}(1)$, accounting for the electroweak correction and conservatively adding the theory uncertainties linearly gives

$$|V_{cb}| = (39.3 \pm 1.4 \pm 1.3) \times 10^{-3}\quad (\overline{B} \to D\ell\overline{\nu}_\ell,\ \text{LQCD}), \quad (16)$$

where the first uncertainty is from experiment and the second from theory.

Using the non-lattice estimate from Eq. (14) one finds $|V_{cb}| = (40.6 \pm 1.5 \pm 0.8) \times 10^{-3}$.

Measuring the differential rate at $w = 1$ is more difficult in $\overline{B} \to D\ell\overline{\nu}_\ell$ decays than in $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays, since the rate is smaller and the background from mis-reconstructed $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays is significant; this is reflected in the larger experimental uncertainty. The B factories study decays recoiling against fully reconstructed B mesons or perform a global fit to $\bar{B} \to D(X)\ell\nu$ decays. Theoretical input on the shape of the w spectrum in $\overline{B} \to D\ell\overline{\nu}_\ell$ is valuable, as precise measurements of the total rate are easier; recent measurements [26,32] of $\mathcal{B}(\overline{B} \to D\ell\overline{\nu}_\ell)$ have uncertainties of $\sim 5\%$.

The determinations from $\overline{B} \to D^*\ell\overline{\nu}_\ell$ and $\overline{B} \to D\ell\overline{\nu}_\ell$ decays are consistent, and their uncertainties are largely uncorrelated. Averaging the two lattice-based results quoted above gives

$$|V_{cb}| = (39.5 \pm 0.8) \times 10^{-3}\quad (\text{exclusive}). \quad (17)$$

$|V_{cb}|$ from inclusive decays

At present the most precise determination of $|V_{cb}|$ comes from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive

semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE) [35,36]. Details of this can be found in the separate mini-review on Effective Theories. The validity of the OPE is proven in the deep Euclidean region for the momenta (which is satisfied, *e.g.*, in deep inelastic scattering), but its application to heavy-quark decays requires a continuation to time-like momenta $p_B^2 = M_B^2$, where possible contributions that are exponentially damped in the Euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of parton-hadron duality, and any violation of this assumption would imply the presence of terms which do not appear in the $1/m_b$ expansion [37]. However, fits of the HQE predictions to the data show no evidence for such terms and hence for duality violations. Thus duality or, equivalently, the validity of the OPE, is assumed in the analysis.

The OPE result for the total rate can be written schematically (the details of the expression can be found, *e.g.*, in Ref. 38) as

$$\begin{aligned}\Gamma =& |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu)(1+A_{\rm ew})\times \\ & \left[z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left(\frac{\alpha_s(\mu)}{\pi}\right)^2 z_0^{(2)}(r) + \cdots \right. \\ & + \frac{\mu_\pi^2}{m_b^2}\left(z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \cdots \right) \\ & + \frac{\mu_G^2}{m_b^2}\left(y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \cdots \right) \\ & + \frac{\rho_{\rm D}^3}{m_b^3}\left(z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \cdots \right) \\ & \left. + \frac{\rho_{\rm LS}^3}{m_b^3}\left(y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \cdots \right) + ... \right] \end{aligned} \quad (18)$$

where $\eta_{\rm ew} = 1 + A_{\rm ew}$ denotes the electroweak corrections, r is the ratio m_c/m_b and the y_i and z_i are functions which appear in the perturbative expansion of the different orders of the heavy mass expansion. A similar expansion can be set up for moments of the distributions of charged-lepton energy, hadronic invariant mass and hadronic energy.

This expression is known up to order $1/m_b^5$, where the terms of order $1/m_b^n$ with $n > 2$ have been computed only at tree level [39–42]. The leading term is the parton model, which is known completely to order α_s and α_s^2 [43–45], and the terms of order $\alpha_s^{n+1}\beta_0^n$ (where β_0 is the first coefficient of the QCD β function, $\beta_0 = (33-2n_f)/3$) have been included by the usual BLM procedure [38,46,47]. Furthermore, the corrections of order $\alpha_s\mu_\pi^2/m_b^2$ have been computed [48,49].

Starting at order $1/m_b^3$ contributions with an infrared sensitivity to the charm mass m_c appear [41,50,51]. At order $1/m_b^3$ this "intrinsic charm" contribution is a $\log(m_c)$ in the coefficient of the Darwin term ρ_D^3. At higher orders, terms such as $1/m_b^3 \times 1/m_c^2$ and $\alpha_s(m_c)1/m_b^3 \times 1/m_c$ appear, which are comparable in size to the contributions of order $1/m_b^4$

The HQE parameters are given in terms of forward matrix elements; the parameters entering the expansion for orders up to $1/m_b^3$ are

$$\begin{aligned} \overline{\Lambda} &= M_B - m_b\,, \\ \mu_\pi^2 &= -\langle B|\overline{b}(iD_\perp)^2 b|B\rangle\,, \\ \mu_G^2 &= \langle B|\overline{b}(iD_\perp^\mu)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle\,, \\ \rho_{\rm D}^3 &= \langle B|\overline{b}(iD_{\perp\mu})(ivD)(iD_\perp^\nu) b|B\rangle\,, \\ \rho_{\rm LS}^3 &= \langle B|\overline{b}(iD_\perp^\mu)(ivD)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle. \end{aligned} \quad (19)$$

These parameters still depend on the heavy quark mass. Sometimes the infinite mass limits of these parameters $\overline{\Lambda} \to \overline{\Lambda}_{\rm HQET}$, $\mu_\pi^2 \to -\lambda_1$, $\mu_G^2 \to 3\lambda_2$, $\rho_D^3 \to \rho_1$ and $\rho_{LS}^3 \to 3\rho_2$, are used instead. The hadronic parameters of the orders $1/m_b^4$ and $1/m_b^5$ have been defined and estimated in Ref. 42 while the five hadronic parameters s_i of the order $1/m_b^4$ can be found in Ref. 40; these have not yet been included in the fits.

The rates and the spectra depend strongly on m_b (or equivalently on $\overline{\Lambda}$), This makes the discussion of renormalization issues mandatory, since the size of the QCD corrections is strongly correlated with the definitions used for the quark masses. Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of $|V_{cb}|$ in such a scheme impossible.

The solution to this problem is to choose an appropriate "short-distance" mass definition. Frequently used mass definitions are the kinetic scheme [15], or the 1S scheme [52]. Both of these schemes have been applied to semileptonic $b \to c$ transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the b quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the Υ system. The physical mass of the $\Upsilon(1S)$ contains non-perturbative contributions, which have been estimated in Ref. 53. These non-perturbative contributions are small; nevertheless, the best determination of the b quark mass in the 1S scheme is obtained from sum rules for $e^+e^- \to b\bar{b}$ [54].

Alternatively one may use a short-distance mass definition such as the $\overline{\rm MS}$ mass $m_b^{\overline{\rm MS}}(m_b)$. However, it has been argued that the scale m_b is unnaturally high for B decays, while for smaller scales $\mu \sim 1\,{\rm GeV}$ $m_b^{\overline{\rm MS}}(\mu)$ is under poor control. For this reason the so-called "kinetic mass" $m_b^{\rm kin}(\mu)$, has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [15].

Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays [55–63] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum ($0^{\rm th}$-$3^{\rm rd}$) and of the squared hadronic mass spectrum ($0^{\rm th}$-$2^{\rm nd}$) have statistical uncertainties that are roughly equal to

their systematic uncertainties. The sets of moments measured by each experiment have strong correlations; the full statistical and systematic correlation matrices are required to allow these to be used in a global fit. Measurements of photon energy moments ($0^{\rm th}$-$2^{\rm nd}$) in $B \to X_s\gamma$ decays [64–68] as a function of the minimum accepted photon energy are still primarily statistics limited.

Global fits to the full set of moments [63,65,69–72] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of m_b and m_c very accurately but leave the orthogonal combination poorly determined [73]; additional input is required to allow a precise determination of m_b. This additional information can come from the radiative $B \to X_s\gamma$ moments, which provide complementary information on m_b and μ_π^2, or from precise determinations of the charm quark mass [74,75]. The values obtained in the kinetic scheme fits [71] with these two constraints are consistent. Based on the charm quark mass constraint [76], $m_c^{\overline{\rm MS}}(3\,{\rm GeV}) = 0.986 \pm 0.013\,{\rm GeV}$, a recent analysis [77] obtains

$$|V_{cb}| = (42.42 \pm 0.86) \times 10^{-3} \quad (20)$$
$$m_b^{\rm kin} = 4.541 \pm 0.023\,{\rm GeV} \quad (21)$$
$$\mu_\pi^2({\rm kin}) = 0.414 \pm 0.078\,{\rm GeV}^2, \quad (22)$$

where the error on $|V_{cb}|$ includes experimental and theoretical uncertainties.

Theoretical uncertainties are estimated and included in performing the fits. Similar values for the parameters are obtained with a variety of assumptions about the theoretical uncertainties and their correlations. The χ^2/dof is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated. While one could obtain a satisfactory fit with smaller uncertainties, this would make the use of the extracted values for the HQE parameters in other processes unsafe. In any case, the low χ^2 shows no evidence for duality violations at a significant level. The mass in the $\overline{\rm MS}$ scheme corresponding to Eq. (21) is $m_b^{\overline{\rm MS}} = 4.17 \pm 0.04\,{\rm GeV}$, which can be compared with a recent value obtained using relativistic sum rules [76], $m_b^{\overline{\rm MS}} = 4.163 \pm 0.016\,{\rm GeV}$, and provides a non-trivial cross-check.

A fit in the 1S scheme [72] to the measured moments gives

$$|V_{cb}| = (41.96 \pm 0.45 \pm 0.07) \times 10^{-3} \quad (23)$$
$$m_b^{\rm 1S} = 4.691 \pm 0.037\,{\rm GeV} \quad (24)$$
$$\lambda_1({\rm 1S}) = -0.362 \pm 0.067\,{\rm GeV}^2, \quad (25)$$

where the last error on $|V_{cb}|$ is due to the uncertainties in the B meson lifetimes. This fit uses semileptonic and radiative moments and constrains the chromomagnetic operator using the mass difference between the pseudoscalar and vector mesons (for both B abd D); however, the fit does not include the constraint on m_c nor the full NNLO corrections.

The fits in the two renormalization schemes give consistent results for $|V_{cb}|$ and, after translation to a common renormalization scheme, for m_b and μ_π^2. We take the arithmetic average of the $|V_{cb}|$ values and of the quoted uncertainties to find

$$|V_{cb}| = (42.2 \pm 0.7) \times 10^{-3}\ ({\rm inclusive}). \quad (26)$$

The precision of the global fit results can be further improved by calculating higher order perturbative corrections to the coefficients of the HQE parameters, in particular the still missing $\alpha_s\mu_G^2$ corrections, which are presently only known for $B \to X_s\gamma$ [78]. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

Determination of $|V_{ub}|$

Summary: The determination of $|V_{ub}|$ is the focus of significant experimental and theoretical work. The determinations based on inclusive semileptonic decays using different calculational ansätze are consistent. The largest parametric uncertainty comes from the error on m_b. The best determinations of $|V_{ub}|$ from $\overline{B} \to \pi\ell\overline{\nu}_\ell$ decays come from combined fits to theory and experimental data as a function of q^2; the precision is limited by the form factor normalization.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.41 \pm 0.15\ ^{+\ 0.15}_{-\ 0.17}) \times 10^{-3} \quad ({\rm inclusive}), \quad (27)$$
$$|V_{ub}| = (3.28 \pm 0.29) \times 10^{-3} \quad ({\rm exclusive}). \quad (28)$$

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. Given the marginal agreement between the inclusive and exclusive values their combination should be treated with caution. To combine these values, the inclusive and exclusive values are weighted by their relative errors and the uncertainties are treated as normally distributed. The resulting average has $p(\chi^2) = 0.01$, so we scale the error by $\sqrt{\chi^2/1} = 2.7$ to find

$$|V_{ub}| = (4.13 \pm 0.49) \times 10^{-3}. \quad (29)$$

Given the poor consistency between the two determinations, this average should be treated with caution.

$|V_{ub}|$ from inclusive decays

The theoretical description of inclusive $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays is based on the Heavy Quark Expansion, as for $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays, and leads to a predicted total decay rate with uncertainties below 5% [79,80]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored $\overline{B} \to X_c\ell\overline{\nu}_\ell$ transitions. Technically, the calculation of the partial decay rate in regions of phase space where $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays are suppressed requires the introduction of a non-perturbative distribution function, the "shape function" (SF) [81,82], whose form is unknown. The shape function becomes important when the light-cone momentum component $P_+ \equiv E_X - |P_X|$ is not large compared to Λ_{QCD}. This additional difficulty can be

addressed in two complementary ways. The leading shape function can either be measured in the radiative decay $\overline{B} \to X_s\gamma$, or be modeled with constraints on the 0^{th}-2^{nd} moments, and the results applied to the calculation of the $\overline{B} \to X_u\ell\overline{\nu}_\ell$ partial decay rate [83–85]; in such an approach the largest challenges are for the theory. Alternatively, measurements of $\overline{B} \to X_u\ell\overline{\nu}_\ell$ partial decay rates can be extended further into the $\overline{B} \to X_c\ell\overline{\nu}_\ell$-allowed region, enabling a simplified theoretical (pure HQE) treatment [86] but requiring precise experimental knowledge of the $\overline{B} \to X_c\ell\overline{\nu}_\ell$ background.

At leading order a single shape function appears, which is universal for all heavy-to-light transitions [81,82], and thus it can be measured in $\overline{B} \to X_s\gamma$ decays. However, at sub-leading order in $1/m_b$ several shape functions appear [87] rendering a simple comparison of semileptonic and radiative B decays impossible.

The form of the SFs cannot be calculated from first principles. Prescriptions that relate directly the partial rates for $\overline{B} \to X_s\gamma$ and $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays are available [88–91]; however, this approach is limited to the leading order in $1/m_b$.

Existing approaches have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments, which are given in terms of the HQE parameters $\overline{\Lambda} = M_B - m_b$ and μ_π^2, respectively. The relations between SF moments and the HQE parameters are known to second order in α_s [92]. As a result, measurements of HQE parameters from global fits to $\overline{B} \to X_c\ell\overline{\nu}_\ell$ and $\overline{B} \to X_s\gamma$ moments can be used to constrain the SF moments, as well as provide accurate values of m_b and other parameters for use in determining $|V_{ub}|$.

A recent development is to use appropriate basis functions to approximate the shape function, thereby also including the known short-distance contributions as well as the renormalization properties of the SF [93], in order to allow a global fit of all inclusive B meson decay data.

The calculations that are used for the fits performed by HFAG are documented in Refs. [83] (BLNP), [94] (GGOU), [95] (DGE) and [86] (BLL).

The triple diffential rate in the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (30)$$

is

$$\frac{d^3\Gamma}{dP_+\,dP_-\,dP_l} = \frac{G_F^2|V_{ub}|^2}{16\pi^2}(M_B - P_+) \quad (31)$$
$$\Big\{(P_- - P_l)(M_B - P_- + P_l - P_+)\mathcal{F}_1$$
$$+(M_B - P_-)(P_- - P_+)\mathcal{F}_2 + (P_- - P_l)(P_l - P_+)\mathcal{F}_3\Big\}.$$

The "structure functions" $\mathcal{F}_i$ can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion.

The BLNP [83] calculation uses these factorization theorems to write the $\mathcal{F}_i$ in terms of perturbatively calculable hard coefficients H and jet functions J, which are convolved with the (soft) light-cone distribution functions S, the shape functions of the B meson. The partial calculation of the $\mathcal{O}(\alpha_S^2)$ contributions in Ref. 96 has recently been completed [97]. However, the full calculation is not yet included in the fit.

The leading order term in the $1/m_b$ expansion of the $\mathcal{F}_i$ contains a single non-perturbative function and is calculated to subleading order in α_s, while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions which have been calculated only at tree level in the α_s expansion.

To extract the non-perturbative input one can study the photon energy spectrum in $B \to X_s\gamma$ [85]. This spectrum is known to a similar accuracy as the P_+ spectrum in $B \to X_u\ell\overline{\nu}_\ell$. Going to subleading order in the $1/m_b$ expansion requires the modeling of subleading SFs, a large variety of which were studied in Ref. 83.

A distinct approach (GGOU) [94] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite m_b and depend on the light-cone component k_+ of the b quark momentum and on the momentum transfer q^2 to the leptons. These functions include sub-leading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (31). Their k_+ moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. 83.

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the SF. It has been noted that the relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [83,85], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can also attempt to calculate the SF by using additional assumptions. One possible approach (DGE) is the so-called "dressed gluon exponentiation" [95], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large β_0 limit, where β_0 has been defined following Eq. (18).

While attempts to quantify the SF are important, the impact of uncertainties in the SF is significantly reduced in some recent measurements that cover a larger portion of the $\overline{B} \to X_u\ell\overline{\nu}_\ell$ phase space. Several measurements using a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass m_X as suggested in Ref. 98 have been made. Measurements of the electron spectrum in $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays have been made down to momenta of 1.9 GeV, where SF

uncertainties are not dominant; however, determining $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial rates in charm-dominated regions can bring in a strong dependence on the modeling of the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ spectrum, which is problematic. The measurements quoted below have used a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on $|V_{ub}|$.

Weak Annihilation [99,100,94] (WA) can in principle contribute significantly in the high-q^2 region accepted by measurements of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. Estimates based on semileptonic D_s decays [100,51,86] lead to a $\sim 2\%$ uncertainty on the total $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate from the $\Upsilon(4S)$. The q^2 spectrum of the WA contribution is not well known, but from the OPE it is expected to contribute predominantly at high q^2. More recent investigations [51,101,102] indicate that WA is a small effect, but may become a significant source of uncertainty for $|V_{ub}|$ measurements that only accept a small fraction of the full $\overline{B} \to X_u \ell \overline{\nu}_\ell$ phase space. Model-dependent limits on WA were determined in Ref. 103, where the CLEO data were fitted to combinations of WA models and a spectator $\overline{B} \to X_u \ell \overline{\nu}_\ell$ component and background. More direct experimental constraints [104] on WA have been made by comparing the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decay rates of charged and neutral B mesons, although these constraints are not sensitive to the isoscalar contribution to WA.

Measurements

We summarize the measurements used in the determination of $|V_{ub}|$ below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [105–108] will not be further considered in this review.

Inclusive electron momentum measurements [109–111] reconstruct a single charged electron to determine a partial decay rate for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ near the kinematic endpoint. This results in a high $\mathcal{O}(50\%)$ selection efficiency and only modest sensitivity to the modeling of detector response. The decay rate can be cleanly extracted for $E_e > 2.3\,\text{GeV}$, but this is deep in the SF region, where theoretical uncertainties are large. Measurements down to 2.0 or 1.9 GeV have a low ($< 1/10$) signal-to-background (S/B) ratio. The inclusive electron momentum spectrum from $B\overline{B}$ events, after subtraction of the $e^+e^- \to q\overline{q}$ continuum background, is fitted to a model $\overline{B} \to X_u \ell \overline{\nu}_\ell$ spectrum and several components ($D\ell\overline{\nu}_\ell$, $D^*\ell\overline{\nu}_\ell$, ...) of the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background; the dominant uncertainties are related to this subtraction and modelling. The resulting $|V_{ub}|$ values for various E_e cuts are given in Table 1.

An untagged "neutrino reconstruction" measurement [112] from BABAR uses a combination [113] of a high-energy electron with a measurement of the missing momentum vector. This allows a much higher S/B~ 0.7 at the same E_e cut and a $\mathcal{O}(5\%)$ selection efficiency, but at the cost of a smaller accepted phase space for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum. The corresponding values for $|V_{ub}|$ are given in Table 1.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [114–118]. The experiments can fully reconstruct a "tag" B candidate in about 0.5% (0.3%) of B^+B^- ($B^0\overline{B}^0$) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B and the remaining particles are assigned to the X_u system. The full set of kinematic properties (E_ℓ, m_X, q^2, *etc.*) are available for studying the semileptonically decaying B, making possible selections that accept up to 90% of the full $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected or mis-measured particles from $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decay (e.g., K_L^0 and additional neutrinos) remain an important source of uncertainty. Measurements with the largest kinematic acceptance (i.e. $E_\ell > 1\,\text{GeV}$) lead to the smallest theoretical and overall uncertainties on $|V_{ub}|$.

BABAR [114] and BELLE [115,116] have measured partial rates with cuts on m_X, m_X and q^2, P_+ and E_ℓ based on large samples of $B\overline{B}$ events; the corresponding $|V_{ub}|$ values are given in Table 1. In each case the experimental systematics have significant contributions from the modeling of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ and $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons.

Determination of $|V_{ub}|$

The determination of $|V_{ub}|$ from the measured partial rates requires input from theory. The BLNP, GGOU and DGE calculations described previously are used to determine $|V_{ub}|$ from all measured partial $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rates; the values [28] are given in Table 1. The HFAG averages quoted here are based on the following m_b values: $m_b^{SF} = 4.588 \pm 0.025$ GeV for BLNP, $m_b^{\rm kin} = 4.560 \pm 0.023$ GeV for GGOU, and $m_b^{\overline{MS}} = 4.194 \pm 0.043$ GeV for DGE. The $m_b^{\rm kin}$ value is determined in a global fit to moments in the kinetic scheme; this value is translated into m_b^{SF} and $m_b^{\overline{MS}}$ at fixed order in α_s. These input values are based on an earlier determination of $m_b^{\rm kin}$ than is quoted in equation Eq. (21); using the latest value would increase the $|V_{ub}|$ averages by 1-2%.

As an illustration of the relative sizes of the uncertainties entering $|V_{ub}|$ we give the error breakdown for the GGOU average: statistical—2.0%; experimental—1.7%; $\overline{B} \to X_c \ell \overline{\nu}_\ell$ modeling—1.3%; $\overline{B} \to X_u \ell \overline{\nu}_\ell$ modeling—1.9%; HQE parameters —1.9%; higher-order corrections—1.4%; q^2 modeling—1.3%; Weak Annihilation—$^{+0}_{-1.9}$%; SF form—0.2%. The uncertainty on m_b dominates the uncertainty on $|V_{ub}|$ from HQE parameters, but no longer dominates the overall uncertainty.

The correlations amongst the multiple BABAR recoil-based measurements [114] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments.

Table 1: $|V_{ub}|$ (in units of 10^{-5}) from inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing f_u (0.19 to 0.90); those below the horizontal bar are based on recoil methods.

Ref.	cut	BLNP	GGOU	DGE
[109]	$E_e > 2.1$	$419 \pm 49 \,^{+\,26}_{-\,34}$	$393 \pm 46 \,^{+\,22}_{-\,29}$	$382 \pm 45 \,^{+\,23}_{-\,26}$
[112]	E_e-q^2	$466 \pm 31 \,^{+\,31}_{-\,36}$	not available	$432 \pm 29 \,^{+\,24}_{-\,29}$
[111]	$E_e > 2.0$	$448 \pm 25 \,^{+\,27}_{-\,28}$	$429 \pm 24 \,^{+\,18}_{-\,24}$	$428 \pm 24 \,^{+\,22}_{-\,24}$
[110]	$E_e > 1.9$	$488 \pm 45 \,^{+\,24}_{-\,27}$	$475 \pm 44 \,^{+\,17}_{-\,22}$	$479 \pm 44 \,^{+\,21}_{-\,24}$
[114]	m_X-q^2	$425 \pm 23 \,^{+\,23}_{-\,25}$	$417 \pm 22 \,^{+\,22}_{-\,25}$	$419 \pm 22 \,^{+\,18}_{-\,19}$
[114]	P_+	$402 \pm 25 \,^{+\,24}_{-\,23}$	$375 \pm 23 \,^{+\,30}_{-\,32}$	$410 \pm 25 \,^{+\,37}_{-\,28}$
[114]	m_X	$397 \pm 22 \,^{+\,20}_{-\,20}$	$394 \pm 22 \,^{+\,16}_{-\,17}$	$416 \pm 23 \,^{+\,26}_{-\,22}$
[114]	$E_e > 1$	$428 \pm 24 \,^{+\,18}_{-\,20}$	$435 \pm 24 \,^{+\,09}_{-\,10}$	$440 \pm 24 \,^{+\,12}_{-\,13}$
[116]	$E_e > 1$	$447 \pm 27 \,^{+\,19}_{-\,21}$	$454 \pm 27 \,^{+\,10}_{-\,11}$	$460 \pm 27 \,^{+\,11}_{-\,13}$
		$440 \pm 15 \,^{+\,19}_{-\,21}$	$439 \pm 15 \,^{+\,12}_{-\,14}$	$445 \pm 15 \,^{+\,15}_{-\,16}$

The theoretical calculations produce very similar results for $|V_{ub}|$; the standard deviation of the theory predictions for the endpoint rate is 4.6%, for the m_X-q^2 rate is 2.2%, and for the $E_e > 1\,\mathrm{GeV}$ rate is 0.8%. The $|V_{ub}|$ values do not show a marked trend versus the kinematic acceptance, f_u, for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. The p-values of the averages are in the range 34-44%, indicating that the ratios of calculated partial widths in the different phase space regions are in good agreement with ratios of measured partial branching fractions.

All calculations yield compatible $|V_{ub}|$ values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.41 \pm 0.15_{\rm exp}\,{}^{+0.15}_{-0.17\,\rm theo}) \times 10^{-3} \quad \text{(inclusive)}. \qquad (32)$$

Hadronization uncertainties also impact the $|V_{ub}|$ determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (*e.g.* $\overline{B} \to \pi \ell \overline{\nu}_\ell$); this must be added to the simulated $\overline{B} \to X_u \ell \overline{\nu}_\ell$ event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables (q^2, E_ℓ, m_X) averaged over the sample, but these prescriptions are not unique. The resulting uncertainties have been estimated to be $\sim$ 1-2% on $|V_{ub}|$.

A separate class of analyses follows the strategy discussed in Refs. [88–91], where integrals of differential distributions in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays are compared with corresponding integrals in $\overline{B} \to X_s \gamma$ decays to extract $|V_{ub}|$, thereby eliminating the need to model the leading shape function. A study [117] using the measured BABAR electron spectrum in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays provides $|V_{ub}|$ determinations using all available "SF-free" calculations; the resulting $|V_{ub}|$ values have total uncertainties of $\sim 12\%$ and are compatible with the average quoted above.

The BLL [98] calculation can be used for measurements [115,118,119] with cuts on m_X and q^2. Using the same HQE parameter input as above yields a $|V_{ub}|$ value of $(4.62 \pm 0.20 \pm 0.29) \times 10^{-3}$, which is about 7% higher than the values obtained from the calculations used in Table 1 for these same measurements.

Status and outlook

At present, as indicated by the average given above, the uncertainty on $|V_{ub}|$ from inclusive decays is at the 5% level. The uncertainty on m_b was discussed in detail above. The uncertainties quoted in the calculations due to matching scales, higher order corrections, etc., are at the few percent level on $|V_{ub}|$. While these uncertainties are inherently difficult to quantify, the calculations take different approaches and yet yield similar estimates. The recent calculation of the full NNLO contributions in Ref. 97 indicates, that the NNLO terms are indeed dominated by the contributions of the order $\alpha_s^2\beta_0$, which are included in both the GGOU and DGE fits. To this end, the sizeable shift of V_{ub} in the BLNP approach induced by including the partial $\mathcal{O}(\alpha_s^2)$ corrections computed in [96] seems to be an artifact.

Experimental uncertainties have been assessed independently by BaBar and Belle. An important common source of uncertainty comes from the modelling of hadronization in inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. Better measurements of these exclusive decays, as in Ref. 120, are helpful in this regard, as would improved knowledge of the main $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays.

$|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\overline{B} \to \pi \ell \overline{\nu}_\ell$, as it is the most promising mode for both experiment and theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [121–127].

$\overline{B} \to \pi \ell \overline{\nu}_\ell$ form factor calculations

The relevant form factors for the decay $\overline{B} \to \pi \ell \overline{\nu}_\ell$ are usually defined as

$$\langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = \qquad (33)$$
$$f_+(q^2) \left[p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu$$

in terms of which the rate becomes (in the limit $m_\ell \to 0$)

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2, \qquad (34)$$

where p_π is the pion momentum in the B meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD (LQCD) and light-cone sum rules (LCSR). The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer q^2 to the leptons, while light-cone sum rules provide information near $q^2 = 0$. Interpolations between these two regions can be constrained by unitarity and analyticity.

Unquenched simulations, i.e. where quark loop effects are fully incorporated, have become quite common, and the commonly used results based on these simulations for the $\overline{B} \to \pi\ell\overline{\nu}_\ell$ form factors have been obtained by the Fermilab/MILC collaboration [128] and the HPQCD collaboration [129]. The two calculations differ in the way the b quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy-quark method; they agree within the quoted errors.

The extrapolation to small values of q^2 can be performed by using analyticity and unitarity bounds. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [130], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in the variable

$$z = \frac{\sqrt{t_+ - t_-} - \sqrt{t_+ - q^2}}{\sqrt{t_+ - t_-} + \sqrt{t_+ - q^2}}$$

where $t_\pm = (M_B \pm m_\pi)^2$. The use of lattice data in combination with a data point at small q^2 from SCET or sum rules provides a stringent constraint on the shape of the form factor [131]. The form factor parametrization given in Ref. 131 has been applied to the extraction of $|V_{ub}|$ from $B \to \pi\ell\bar{\nu}_\ell$ using lattice data in Ref. 128.

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the $\sim 10\%$ level on $|V_{ub}|$ and need to be reduced. Reduction of errors to the $\sim$ 5-6% level for $|V_{ub}|$ will be feasible within the next few years, with the inclusion of numerical data at lighter pion masses and finer lattice spacings, as well as possibly two-loop or nonperturbative matching between lattice and continuum heavy-to-light current operators.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), where the heavy mass limit has been discussed from the point of view of SCET in Ref. 132. The sum-rule approach provides an approximation for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 <\sim 12$ GeV^2. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B, which usually is obtained by replacing f_B by its two-point QCD (SVZ) sum rule [133] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/(f_B)$. The LCSR for $f_B f_+$ is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b-quark mass. The resulting expressions actually comprise a triple expansion: in the twist t of the operators near the light-cone, in α_s, and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

There are multiple sources of uncertainties in the LCSR calculation, which are discussed in Refs. [134,135]. Currently, a total uncertainty slightly larger than 10% on $|V_{ub}|$ is extracted from a LCSR calculation of

$$\Delta\zeta(0, q^2_{max}) = \frac{G_F^2}{24\pi^3} \int_0^{q^2_{max}} dq^2\, p_\pi^3 |f_+(q^2)|^2$$
$$= \frac{1}{|V_{ub}|^2 \tau_{B_0}} \int_0^{q^2_{max}} dq^2 \frac{d\mathcal{B}(B \to \pi\ell\nu)}{dq^2} \qquad (35)$$

which gives [136]

$$\Delta\zeta(0, 12\,\mathrm{GeV}^2) = 4.59^{+1.00}_{-0.85}\,\mathrm{ps}^{-1}. \qquad (36)$$

The recent calculation of two loop contributions to the LCQCD sum rules [137] only yields a small effect.

It is interesting to note that the results from LQCD extrapolate smoothly onto the LCSR results when employing the parametrizations based on conformal mappings [131,138]. This increases confidence in the theoretical predictions for the rate of $\overline{B} \to \pi\ell\overline{\nu}_\ell$.

$\overline{B} \to \pi\ell\overline{\nu}_\ell$ measurements

The $\overline{B} \to \pi\ell\overline{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels (S/B $<$ 1) and make slightly more restrictive kinematic cuts, but have adequate statistics to measure the q^2 dependence of the form factor.

CLEO has analyzed $\overline{B} \to \pi\ell\overline{\nu}_\ell$ and $\overline{B} \to \rho\ell\overline{\nu}_\ell$ using an untagged analysis [125]. Similar analyses have been done at BABAR [126,127] and BELLE [139]. The leading systematic uncertainties in the untagged $\overline{B} \to \pi\ell\overline{\nu}_\ell$ analyses are associated with modeling the missing momentum reconstruction, with backgrounds from $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays and $e^+e^- \to q\overline{q}$ continuum events, and with varying the form factor for the $\overline{B} \to \rho\ell\overline{\nu}_\ell$ decay. The values obtained for the full and partial branching fractions [28] are listed in Table 2 above the horizontal line. These BABAR and BELLE measurements provide the differential $\overline{B} \to \pi\ell\overline{\nu}_\ell$ rate versus q^2, shown in Fig. 1, which is used in the determination of $|V_{ub}|$ discussed below.

Table 2: Total and partial branching fractions for $\overline{B}^0 \to \pi^+\ell^-\overline{\nu}_\ell$. B-tagged analyses are indicated (SL *for semileptonic*, had *for hadronic*). The uncertainties are from statistics and systematics. Measurements of $\mathcal{B}(B^- \to \pi^0\ell^-\overline{\nu}_\ell)$ have been multiplied by a factor $2\tau_{B^0}/\tau_{B^+}$ to obtain the values below.

	$\mathcal{B}\times10^4$	$\mathcal{B}(q^2>16)\times10^4$
CLEO π^+,π^0 [125]	$1.38\pm0.15\pm0.11$	$0.41\pm0.08\pm0.04$
BABAR π^+,π^0 [126]	$1.41\pm0.05\pm0.08$	$0.32\pm0.02\pm0.03$

BABAR had π^+ [142]	$1.07\pm0.27\pm0.19$	$0.65\pm0.20\pm0.13$
BABAR had π^0 [142]	$1.52\pm0.41\pm0.30$	$0.48\pm0.22\pm0.12$
Average	$1.45\pm0.02\pm0.04$	$0.38\pm0.01\pm0.01$

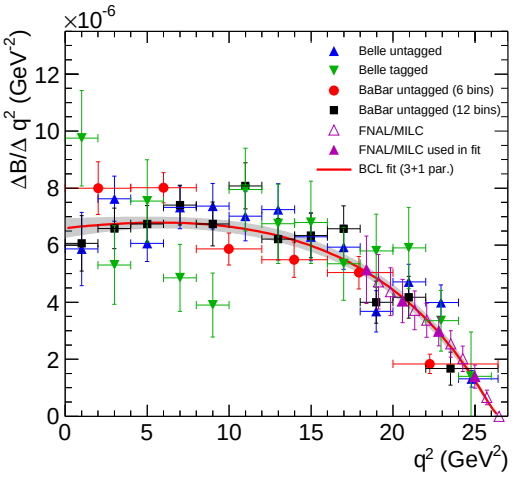

Figure 1: The untagged measurements of the differential $\overline{B} \to \pi\ell\overline{\nu}_\ell$ branching fraction versus q^2 that are used together with lattice calculations in the determination of $|V_{ub}|$.

Analyses [140,141] based on reconstructing a B in the $\overline{D}^{(*)}\ell^+\nu_\ell$ decay mode and looking for a $\overline{B} \to \pi\ell\overline{\nu}_\ell$ or $\overline{B} \to \rho\ell\overline{\nu}_\ell$ decay amongst the remaining particles in the event make use of the fact that the B and $\overline{B}$ are back-to-back in the $\Upsilon(4S)$ frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. 143. BABAR [141] and [120] have also used their samples of B mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2. The averages take account of correlations and common systematic uncertainties, and have $p(\chi^2) > 0.5$ in each case.

$|V_{ub}|$ can be obtained from the average $\overline{B} \to \pi\ell\overline{\nu}_\ell$ branching fraction and the measured q^2 spectrum. Using the average [28] of partial branching fractions in the $q^2 < 12\,\mathrm{GeV}^2$ region, $(0.81\pm0.02\pm0.02)\times10^{-4}$, along with an LCSR calculation of the theoretical rate [136] gives

$$|V_{ub}| = (3.41\pm0.06_{\rm exp}{}^{+0.37}_{-0.32\ \rm theo})\times10^{-3} \quad (\mathrm{LCSR}, q^2<12\,\mathrm{GeV}^2). \tag{37}$$

Fits to the measured q^2 spectrum using a theoretically motivated parameterization (e.g. "BCL" from Ref. 138) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. Recent determinations [28,128] of $|V_{ub}|$ from $\overline{B} \to \pi\ell\overline{\nu}_\ell$ decays have used simultaneous fits (see also Ref. 144) to the experimental partial rate and lattice points versus q^2. A fit [28] to the untagged measurements incorporates the full statistical and systematic uncertainties in the measured spectrum and uses four lattice points in the region $q^2 > 16\,\mathrm{GeV}^2$, taking into account their correlations. The fit, shown in Fig. 1, has $p(\chi^2) = 2.2\%$. If the tagged measurements, which are less consistent in the $q^2 < 8\,\mathrm{GeV}^2$ region, are included, the fit gives $p(\chi^2) < 0.01\%$. We quote the result from the untagged measurements and add the difference (0.09×10^{-3}) between the $|V_{ub}|$ values from the two fits as an additional uncertainty to find

$$|V_{ub}| = (3.28\pm0.29)\times10^{-3} \quad \text{(exclusive)}. \tag{38}$$

The largest contributions to the uncertainty come from lattice systematic and statistical errors, which will be further improved in the future.

$\overline{B} \to D^{(*)}\tau\overline{\nu}_\ell$

Summary: Semileptonic decays to third-generation leptons provide sensitivity to non-standard model amplitudes, such as from a charged Higgs boson [145]. The ratios of branching fractions of semileptonic decays involving tau leptons to those involving e/μ, $\mathcal{R}_{D^{(*)}} \equiv \mathcal{B}(\overline{B} \to \mathcal{D}^{(*)}\tau\overline{\nu}_\ell)/\mathcal{B}(\overline{B} \to \mathcal{D}^{(*)}\ell\overline{\nu}_\ell)$, are predicted with good precision in the standard model: [146]

$$\mathcal{R}_D^{\rm SM} = 0.297\pm0.017$$
$$\mathcal{R}_{D^*}^{\rm SM} = 0.252\pm0.003. \tag{39}$$

Measurements [146–150] of these ratios yield higher values; using B-tagged measurements only we find

$$\mathcal{R}_D^{\rm meas} = 0.462\pm0.067$$
$$\mathcal{R}_{D^*}^{\rm meas} = 0.341\pm0.029 \tag{40}$$

These values exceed standard model predictions by 2.4σ and 3.0σ, respectively. A variety of new physics models have been proposed [145,151–154] to explain this excess. The potential impact of any new physics in this decay mode on the $|V_{ub}|$ and $|V_{cb}|$ results given above is expected to be negligible.

Sensitivity of $\overline{B} \to D^{(*)}\tau\overline{\nu}_\ell$ to additional amplitudes

In addition to the helicity amplitudes present for decays to $e\overline{\nu}_e$ and $\mu\overline{\nu}_\mu$, decays proceeding through $\tau\overline{\nu}_\tau$ include a scalar amplitude H_s. The differential decay rate is given by [155]

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2\,|V_{cb}|^2\,|\mathbf{p}^*_{D^{(*)}}|q^2}{96\pi^3 m_B^2}\left(1-\frac{m_\tau^2}{q^2}\right)^2 \left[(|H_+|^2+|H_-|^2+|H_0|^2)\left(1+\frac{m_\tau^2}{2q^2}\right)+\frac{3m_\tau^2}{2q^2}|H_s|^2\right], \quad (41)$$

where $|\mathbf{p}^*_{D^{(*)}}|$ is the 3-momentum of the $D^{(*)}$ in the $\bar{B}$ rest frame and the helicity amplitudes depend on q^2. All four helicity amplitudes contribute to $\overline{B} \to D^*\tau\overline{\nu}_\ell$, while only H_0 and H_s contribute to $\overline{B} \to D\tau\overline{\nu}_\ell$; as a result, new physics contributions tend to produce larger effects in the latter mode. The use of the ratios of decay rates, $\mathcal{R}_{D^{(*)}}$, allows a partial cancellation of uncertainties in standard model form factors, and reduces the impact of many experimental uncertainties.

The (semi)-leptonic B decays into a τ lepton provide a stringent test of the two-Higgs doublet model of type II (2HDMII), i.e. where the two Higgs doublets couple separately to up- and down-type quarks. This is also of relevance for Supersymmetry, since this corresponds to the Higgs sector of any commonly used supersymmetric model. These models involve additional charged scalar particles, which contribute at tree level to the (semi)-leptonic B decays into a τ. The distinct feature of the 2HDMII is that the contributions of the charged scalars scale as $m_\tau^2/m_{H^+}^2$, since the couplings to the charged Higgs particles are proportional to the mass of the lepton. As a consequence, one may expect visible effects in decays into a τ, but only small effects for decays into e and μ.

As discussed in the next section, the observations cannot be fitted to the expectations from the 2HDMII. To this end one has to extend the analysis to other models, where the scaling of the new contributions with the lepton mass is different.

Measurement of $\mathcal{R}_{D^{(*)}}$

The $\overline{B} \to D^{(*)}\tau\overline{\nu}_\ell$ decays have been studied at the $\Upsilon(4S)$ resonance, where the experimental signature consists of a D or D^* meson, an electron or muon from the decay $\tau \to \ell\nu_\tau\overline{\nu}_\ell$, a fully-reconstructed hadronic decay of the second B meson in the event and multiple missing neutrinos. The signal decays are separated from $\overline{B} \to D^{(*)}\ell\overline{\nu}_\ell$ decays using the measured missing mass squared; decays with only a single missing neutrino peak sharply at zero in this variable, while the signal is spread out to positive values. Background from $\overline{B} \to D^{**}\ell\overline{\nu}_\ell$ decays with one or more unreconstructed particles is harder to separate from signal.

Measurements from BELLE [147–149] and BABAR [150,146] have consistently resulted in values for $\mathcal{R}_D$ and $\mathcal{R}_{D^*}$ that exceed standard model predictions. The largest uncertainty is statistical; leading sources of systematic uncertainty include the modelling of semileptonic decays to charm final states with masses above m_{D^*} and the modelling of the selection efficiency for signal events. The first two BELLE measurements were untagged and are subject to larger systematic uncertainties. We choose to average the tagged measurements [149,146], and take the systematic uncertainties of the BELLE measurements to have a 50% correlation with each other and a 25% correlation with the BABAR measurements to find the values quoted in Eq. (40). If we include the untagged measurements (assuming 50%/25% correlation in systematic errors with other BELLE/BABAR measurements) we find $\mathcal{R}_D^{\rm meas} = 0.427 \pm 0.060$ and $\mathcal{R}_{D^*}^{\rm meas} = 0.345 \pm 0.028$. Some improvement should be possible with existing B-factory data sets.

Table 3 lists the inputs used in calculating the averages quoted here. Where the ratios $\mathcal{R}_{D^{(*)}}$ were not directly measured, the branching fractions used to obtain these results were $\mathcal{B}(\overline{B}^0 \to D^{*+}\ell\overline{\nu}_\ell) = 0.0495 \pm 0.0011$ and $\mathcal{B}(\overline{B}^0 \to D^{+}\ell\overline{\nu}_\ell) = 0.0213 \pm 0.0010$, with the corresponding B^- branching fractions obtained by multiplying by the lifetime ratio $\tau_{B^+}/\tau_{B^0} = 1.079 \pm 0.007$.

Table 3: Measurements of $\mathcal{R}_D$ and $\mathcal{R}_{D^*}$ times 10^2.

	$\mathcal{R}_D$	$\mathcal{R}_{D^*}$
BABAR [146] all B, tag	$44.0 \pm 5.8 \pm 4.2$	$33.2 \pm 2.4 \pm 1.8$
BELLE [149] B^+, tag	$70 \pm 19 \pm 10$	$47 \pm 11 \pm 7$
BELLE [149] B^0, tag	$48 \pm 21 \pm 6$	$48 \pm 13 \pm 5$
BELLE [147] B^+, no tag	$34 \pm 10 \pm 5$	$40 \pm 5 \pm 5$
BELLE [148] B^0, no tag		$41 \pm 8 \pm 7$

The tension between the SM prediction and the measurements at the level of 2.4σ and 3.0σ lead to various speculations on possible new physics contributions. It is striking that an interpretation in terms of the 2HDMII seems to be ruled out by the data. Fig. 2 shows that the interpretation of the deviation of $\mathcal{R}_D$ in terms of the 2HDMII requires vastly different values of the relevant parameter $\tan\beta/m_{H^+}$ than for $\mathcal{R}_{D^*}$, excluding this possibility.

A more general approach has been formulated in [153] on the basis of an effective field theory consideration. Assuming lepton-flavour universality (LFU) violating operators of dimension six and eight the observed values can be fitted to the coefficients of these operators. Although a detailed analysis along these lines requires to have more data on related decays (such as $B \to \pi\tau\nu$), there are indications that the tension in $\mathcal{R}_{D^{(*)}}$ cannot be explained by a minimally flavor-violating scenario with only left-handed interactions; a better fit is obtained once right-handed and scalar currents are involved.

Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, where fits to moments of $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays provide precise values for $|V_{cb}|$ and, in conjunction with $B \to X_s\gamma$ decays or input on m_c, provide precise and consistent

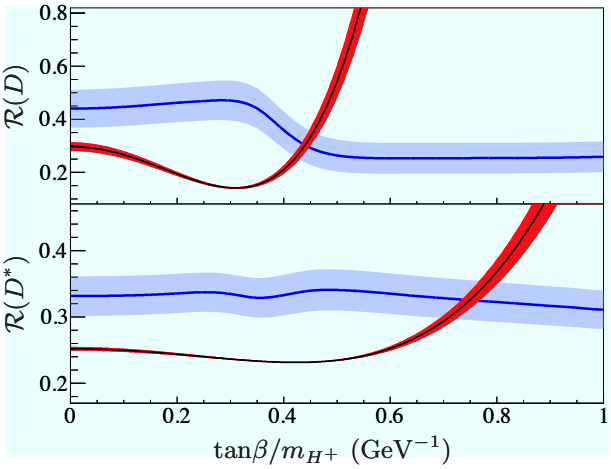

Figure 2: The $\mathcal{R}_{D^{(*)}}$ measured in Ref. 146 along with expectations in the 2HDMII as a function of $\tan\beta/m_{H^+}$.

values for m_b. The values from the inclusive and exclusive $|V_{cb}|$ determinations are marginally consistent.

Continued improvements in measurements of inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays, along with additional theoretical studies of higher order contributions and improved knowledge of m_b, have strengthened our determination of $|V_{ub}|$. Further progress in this area is possible, but will require better theoretical control over higher order terms, and improved experimental knowledge of the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background.

Progress in both $b \to u$ and $b \to c$ exclusive channels depends crucially on progress in lattice QCD calculations. Here the prospects are good, since unquenched calculations are now available for the semileptonic form factors discussed here, as well as for other hadronic weak matrix elements needed to obtain the elements and phase of the CKM matrix [156,157]. Projections for future uncertainties from lattice calculations can be found in Ref. 158.

The measurements of the $\overline{B} \to \pi \ell \overline{\nu}_\ell$ branching fraction have uncertainties below 4%, and the measured q^2 dependence is reasonably precise. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is essential.

The tension between the values for $|V_{ub}|$ obtained from inclusive and exclusive decays has persisted for many years, despite significant improvements in both theory and experiment for both methods. How to reconcile these results remains an intriguing puzzle.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with good precision allows a test of CKM unitarity in the most direct way, by comparing the length of the $|V_{ub}|$ side of the unitarity triangle with the measurement of $\sin(2\beta)$. This comparison of a "tree" process ($b \to u$) with a "loop-induced" process ($B^0 - \overline{B}^0$ mixing) provides sensitivity to possible contributions from new physics.

The observation of semileptonic decays into τ leptons has opened a new window to the physics of the third generation. The data indicate a tension between the data and the standard model prediction, which could be a hint to new physics. However, the most prominent and simplest candidate, the 2HDMII, cannot explain the current data. More general ansätze can fit the data, but do not lead to a deeper insight unless measurements of related processes (such as $B \to \pi\tau\bar{\nu}$) are available.

The authors would like to acknowledge helpful input from F. Bernlochner, P. Gambino and C. Schwanda.

V_{cb} MEASUREMENTS

For the discussion of V_{cb} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{cb}|$ can be determined by studying the rate of the semileptonic decay $B \to D^{(*)} \ell\nu$ as a function of the recoil kinematics of $D^{(*)}$ mesons. Taking advantage of theoretical constraints on the normalization and a linear ω dependence of the form factors ($F(\omega)$, $G(\omega)$) provided by Heavy Quark Effective Theory (HQET), the $|V_{cb}|\times F(\omega)$ and ρ^2 (a^2) can be simultaneously extracted from data, where ω is the scalar product of the two-meson four velocities, $F(1)$ is the form factor at zero recoil (ω=1) and ρ^2 is the slope, sometimes denoted as a^2. Using the theoretical input of $F(1)$, a value of $|V_{cb}|$ can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

$|V_{cb}| \times F(1)$ (from $B^0 \to D^{*-}\ell^+\nu$)

[1] Uses fully reconstructed $D^{*-}\ell^+\nu$ events ($\ell = e$ or μ).

[2] Obtained from a global fit to $B \to D^{(*)}\ell\nu_\ell$ events, with reconstructed $D^0\ell$ and $D^+\ell$ final states and $\rho^2 = 1.22 \pm 0.02 \pm 0.07$.

[3] Measured using the dependence of $B^- \to D^{*0}e^-\overline{\nu}_e$ decay differential rate and the form factor description by CAPRINI 98 with $\rho^2 = 1.16 \pm 0.06 \pm 0.08$.

[4] Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.32 \pm 0.15 \pm 0.33$.

[5] Average of the $B^0 \to D^*(2010)^-\ell^+\nu$ and $B^+ \to \overline{D}^*(2007))\ell^+\nu$ modes with $\rho^2 = 1.61 \pm 0.09 \pm 0.21$ and $f_{+-} = 0.521 \pm 0.012$.

[6] ABREU 01H measured using about 5000 partial reconstructed D^* sample with a ρ^2=1.34 ± 0.14 $^{+0.24}_{-0.22}$.

[7] ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples with a ρ^2=1.21 ± 0.12 ± 0.20. The statistical and systematic correlations between $|V_{cb}|\times F(1)$ and ρ^2 are 0.90 and 0.54 respectively.

[8] BUSKULIC 97: measured using exclusively reconstructed $D^{*\pm}$ with a a^2=0.31 ± 0.17 ± 0.08. The statistical correlation is 0.92.

[9] Measured using fully reconstructed D^* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2 = 1.191 \pm 0.048 \pm 0.028$, $R_1(1) = 1.429 \pm 0.061 \pm 0.044$, and $R_2(1) = 0.827 \pm 0.038 \pm 0.022$.

[10] Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.29 \pm 0.03 \pm 0.27$.

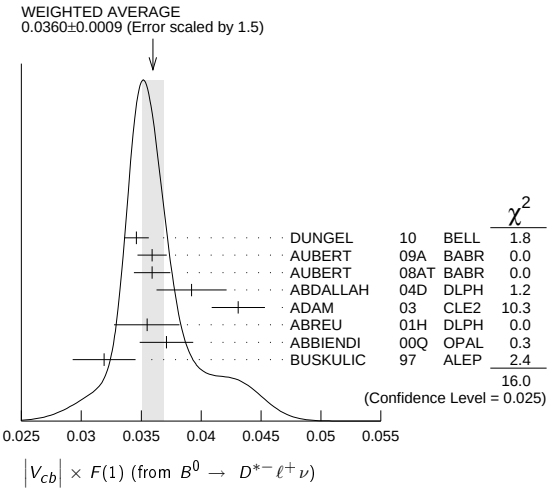
[11] Combines with previous partial reconstructed D^* measurement with a $\rho^2 = 1.39 \pm 0.10 \pm 0.33$.

[12] Measured using exclusive $B^0 \to D^*(892)^-e^+\nu$ decays with ρ^2= 1.35 ± 0.17 ± 0.19 and a correlation of 0.91.

[13] BRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.

[14] ABREU 96P: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples.

[15] BARISH 95: measured using both exclusive reconstructed $B^0 \to D^{*-}\ell^+\nu$ and $B^+ \to D^{*0}\ell^+\nu$ samples. They report their experiment's uncertainties ±0.0019 ± 0.0018 ± 0.0008, where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.



$|V_{cb}| \times G(1)$ (from $B \to D^-\ell^+\nu$)

[16] Obtained from a fit to the combined $B \to \overline{D}\ell^+\nu_\ell$ sample in which a hadronic decay of the second B meson is fully reconstructed and $\rho^2 = 1.20 \pm 0.09 \pm 0.04$.

[17] Obtained from a global fit to $B \to D^{(*)}\ell\nu_\ell$ events, with reconstructed $D^0\ell$ and $D^+\ell$ final states and $\rho^2 = 1.20 \pm 0.04 \pm 0.07$.

[18] Using the missing energy and momentum to extract kinematic information about the undetected neutrino in the $B^0 \to D^-\ell^+\nu$ decay.

[19] BARTELT 99: measured using both exclusive reconstructed $B^0 \to D^-\ell^+\nu$ and $B^+ \to D^0\ell^+\nu$ samples.

[20] BUSKULIC 97: measured using exclusively reconstructed $D^\pm$ with a a^2=−0.05 ± 0.53 ± 0.38. The statistical correlation is 0.99.

[21] ATHANAS 97: measured using both exclusive reconstructed $B^0 \to D^-\ell^+\nu$ and $B^+ \to D^0\ell^+\nu$ samples with a ρ^2=0.59 ± 0.22 ± 0.12 $^{+0.59}_{-0}$. They report their experiment's uncertainties ±0.0044 ± 0.0048 $^{+0.0053}_{-0.0012}$, where the first error is statistical, the second is systematic, and the third is the uncertainty due to the form factor model variations. We combine the last two in quadrature.

V_{ub} MEASUREMENTS

For the discussion of V_{ub} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{ub}|$ can be determined by studying the rate of the charmless semileptonic decay $b \to u\ell\nu$. The relevant branching ratio measurements based on exclusive and inclusive decays can be found in the B Listings, and are not repeated here.

5713± 2		[4] ACCIARRI	99N	L3	$e^+e^- \to Z$

[1] AFFOLDER 01F uses the reconstructed B meson through semileptonic decay channels. The fraction of light B mesons that are produced at L=1 B^{**} states is measured to be 0.28 ± 0.06 ± 0.03.
[2] BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\pi^\pm$ system. In the framework of heavy quark symmetry (HQS), they also measured the mass of B_2^* to be $5739^{+8}_{-11}{}^{+6}_{-4}$ MeV/c^2 and the relative production rate of $B(b \to B_2^* \to B^{(*)}\pi)/B(b \to B_{u,d})$ = $(31 \pm 9^{+6}_{-5})$%.
[3] Using $m_{B\pi} - m_B$ = 424 ± 4 ± 10 MeV.
[4] ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^{(*)}\pi^\pm$ system. In the framework of HQET, they measured the mass of B_1^* and B_2^* to be 5670±10±13 MeV and 5768±5±6 with the $B(b \to B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$. They also reported the evidence for the existence of an excited B-meson state or mixture of states in the region 5.9–6.0 GeV.

B_s^0 MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

The
First "OUR EVALUATION" is an average of 1 / [0.5 ($\Gamma_{B^0_{sL}} + \Gamma_{B^0_{sH}}$)].
The Second "OUR EVALUATION" is the average of $B_s \to D_s X$ data listed below.

1.27 ±0.33 ±0.08	[6] BARATE	00K	ALEP	$e^+e^- \to Z$

[1] Measured using $B_s^0 \to D_s^- D_s^+$. The effective lifetime is translated into a decay width of $\Gamma_L = 0.725 \pm 0.014 \pm 0.009$ ps^{-1}.

[2] Measured using decays $B_s^0 \to K^+K^-$.

[3] Uses the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays and assuming CP-violating angle $\beta_s(B^0 \to J/\psi\phi) = 0.02$.

[4] Obtained from $\Delta\Gamma_s$ and Γ_s fit with a correlation of 0.6.

[5] Measured using the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.

[6] Uses $\phi\phi$ correlations from $B_s^0 \to D_s^{(*)+} D_s^{(*)-}$.

$\Delta\Gamma_{B_s^0}/\Gamma_{B_s^0}$

$\Gamma_{B_s^0}$ and $\Delta\Gamma_{B_s^0}$ are the decay rate average and difference between two B_s^0 CP eigenstates (light − heavy).

"OUR EVALUATION" is an average of all available B_s flavor-specific lifetime measurements with the $\Delta\Gamma_{B_s^0}/\Gamma_s$ analyses performed by the Heavy Flavor Averaging Group (HFAG) as described in our "Review on B-$\overline{B}$ Mixing" in the B^0 Section of these Listings.

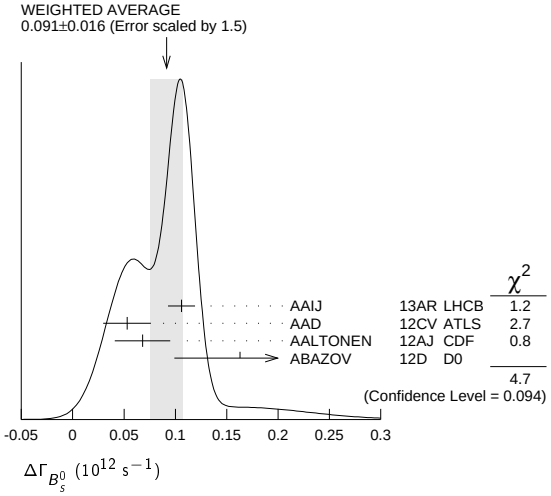
[1] AAIJ 13AR result comes from a combined fit to $B_s^0 \to J/\psi K^+K^-$ and $B_s^0 \to J/\psi\pi^+\pi^-$ data sets. Also reports $\Delta\Gamma_s = 0.100 \pm 0.016 \pm 0.003$ ps^{-1} from a fit to $B_s^0 \to J/\psi K^+K^-$ decays.
[2] Measured using the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.
[3] The error includes both statistical and systematic uncertainties.
[4] Measured using fully reconstructed $B_s \to J/\psi\phi$ decays.
[5] Uses the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays and assuming CP-violating angle $\beta_s(B^0 \to J/\psi\phi) = 0.02$.
[6] Measured the angular and lifetime parameters for the time-dependent angular untagged decays $B_d^0 \to J/\psi K^{*0}$ and $B_s^0 \to J/\psi\phi$.
[7] Measured using the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays and assuming CP-violating phase $\phi_s = 0$.
[8] Obtaines 90% CL interval $-0.06 < \Delta\Gamma_s < 0.30$.
[9] ABAZOV 07 reports $0.17 \pm 0.09 \pm 0.02$ with CP-violating phase ϕ_s as a free parameter.
[10] Combines D^0 measurements of time-dependent angular distributions in $B_s^0 \to J/\psi\phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.



$\Delta\Gamma_s^{CP}$ / Γ_s

Γ_s and $\Delta\Gamma_s^{CP}$ are the decay rate average and difference between even, $\Gamma_s^{CP-even}$, and odd, Γ_s^{CP-odd}, CP eigenstates.

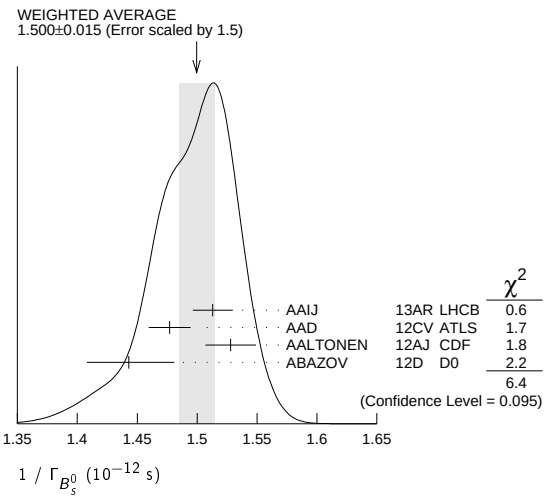
[1] AAIJ 13AR reports $\Gamma_s = 0.661 \pm 0.004 \pm 0.006$ ps^{-1} obtained from combined fit to $B_s^0 \to J/\psi K^+K^-$ and $B_s^0 \to J/\psi\pi^+\pi^-$ data sets. Also reports a separate measurement of $\Gamma_s = 0.663 \pm 0.005 \pm 0.006$ ps^{-1} from $B_s^0 \to J/\psi K^+K^-$ decays.
[2] AAD 12CV reports $\Gamma_{B_s^0} = 0.677 \pm 0.007 \pm 0.004$ ps^{-1} measured using a time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.
[3] Measured using the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.
[4] The error includes both statistical and systematic uncertainties.
[5] AAIJ 12D reports average deacy width of B_s^0, $\Gamma_{B_s^0} = 0.657 \pm 0.009 \pm 0.008$ ps^{-1} that we converted to $1/\Gamma_{B_s^0}$.



B_s^0 DECAY MODES

These branching fractions all scale with B($\overline{b} \to B_s^0$).

The branching fraction B($B_s^0 \to D_s^-\ell^+\nu_\ell$anything) is not a pure measurement since the measured product branching fraction B($\overline{b} \to B_s^0$) × B($B_s^0 \to D_s^-\ell^+\nu_\ell$anything) was used to determine B($\overline{b} \to B_s^0$), as described in the note on "B^0-$\overline{B}^0$ Mixing"

For inclusive branching fractions, *e.g.*, $B \to D^\pm$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

[a] Not a pure measurement. See note at head of B_s^0 Decay Modes.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

[c] Here S and P are the hypothetical scalar and pseudoscalar particles with masses of 2.5 GeV/c^2 and 214.3 MeV/c^2, respectively.

CONSTRAINED FIT INFORMATION

An overall fit to 10 branching ratios uses 18 measurements and one constraint to determine 7 parameters. The overall fit has a $\chi^2 = 5.6$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

B_s^0 BRANCHING RATIOS

$\Gamma(D_s^-\ \text{anything})/\Gamma_{\rm total}$ Γ_1/Γ

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.93±0.25 OUR AVERAGE					
0.91±0.18±0.41		[1] DRUTSKOY	07	BELL	$e^+e^- \to \Upsilon(4S)$
0.81±0.24±0.22	90	[2] BUSKULIC	96E	ALEP	$e^+e^- \to Z$
1.56±0.58±0.44	147	[3] ACTON	92N	OPAL	$e^+e^- \to Z$

[1] The extraction of this result takes into account the correlation between the measurements of $B(\Upsilon(5S) \to D_s X)$ and $B(\Upsilon(5S) \to D^0 X)$.

[2] BUSKULIC 96E separate $c\overline{c}$ and $b\overline{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\overline{b} \to W^+ \to D_s^+$ events, and obtain $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^-\ \text{anything}) = 0.088 \pm 0.020 \pm 0.020$ assuming $B(D_s \to \phi\pi) = (3.5 \pm 0.4)\times10^{-2}$ and PDG 1994 values for the relative partial widths to other D_s channels. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

[3] ACTON 92N assume that excess of 147 ± 48 D_s^0 events over that expected from B^0, B^+, and $c\overline{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $B(\overline{b} \to B_s^0) B(B_s^0 \to D_s^-\ \text{anything}) \times B(D_s^- \to \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1)\times10^{-3}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_s \to \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi\pi)$.

10.5±0.8 OUR AVERAGE				
10.6±0.5±0.7	[1] OSWALD	13	BELL	$e^+e^- \to \Upsilon(5S)$
$9.5\ ^{+2.5}_{-2.0}\ ^{+1.1}_{-1.9}$	[2] LEES	12A	BABR	e^+e^-

[1] The measurement corresponds to the average of the electron and muon branching fractions. OSWALD 13 also reports separate branching fractions for muons and electrons.

[2] The measurement corresponds to a branching fraction where the lepton originates from bottom decay and is the average between the electron and muon branching fractions. LEES 12A uses the correlation of the production of ϕ mesons in association with a lepton in e^+e^- data taken at center-of-mass energies between 10.54 and 11.2 GeV.

$\Gamma(D_s^-\ell^+\nu_\ell\ \text{anything})/\Gamma_{\rm total}$ Γ_3/Γ

The values and averages in this section serve only to show what values result if one assumes our $B(\overline{b} \to B_s^0)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(\overline{b} \to B_s^0)$ as described in the note on "Production and Decay of b-Flavored Hadrons."

B_s^0

[1] BUSKULIC 95O use $D_s\ell$ correlations. The measured product branching ratio is $B(\overline{b}\to B_s)\times B(B_s\to D_s^-\ell^+\nu_\ell \text{anything}) = (0.82\pm0.09^{+0.13}_{-0.14})\%$ assuming $B(D_s\to\phi\pi) = (3.5\pm0.4)\times10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $\Upsilon(4S)$ experiments this can be used to extract $B(\overline{b}\to B_s) = (11.0\pm1.2^{+2.5}_{-2.6})\%$. We evaluate using our current values $B(\overline{b}\to B_s^0) = 0.107\pm0.014$ and $B(D_s\to\phi\pi) = 0.036\pm0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b}\to B_s^0)$ and $B(D_s\to\phi\pi)$.

[2] ABREU 92M measured muons only and obtained product branching ratio $B(Z\to b\text{or }\overline{b})\times B(\overline{b}\to B_s)\times B(B_s\to D_s\mu^+\nu_\mu \text{anything})\times B(D_s\to\phi\pi) = (18\pm8)\times10^{-5}$. We evaluate using our current values $B(\overline{b}\to B_s^0) = 0.107\pm0.014$ and $B(D_s\to\phi\pi) = 0.036\pm0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b}\to B_s^0)$ and $B(D_s\to\phi\pi)$. We use $B(Z\to b\text{or }\overline{b}) = 2B(Z\to b\overline{b}) = 2\times(0.2212\pm0.0019)$.

[3] ACTON 92N is measured using $D_s\to\phi\pi^+$ and $K^*(892)^0K^+$ events. The product branching fraction measured is measured to be $B(\overline{b}\to B_s^0)B(B_s^0\to D_s^-\ell^+\nu_\ell \text{anything})\times B(D_s^-\to\phi\pi^-) = (3.9\pm1.1\pm0.8)\times10^{-4}$. We evaluate using our current values $B(\overline{b}\to B_s^0) = 0.107\pm0.014$ and $B(D_s\to\phi\pi) = 0.036\pm0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b}\to B_s^0)$ and $B(D_s\to\phi\pi)$.

[4] BUSKULIC 92E is measured using $D_s\to\phi\pi^+$ and $K^*(892)^0K^+$ events. They use $2.7\pm0.7\%$ for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be $B(\overline{b}\to B_s^0)B(B_s^0\to D_s^-\ell^+\nu_\ell \text{anything}) = 0.020\pm0.0055^{+0.005}_{-0.006}$. We evaluate using our current values $B(\overline{b}\to B_s^0) = 0.107\pm0.014$ and $B(D_s\to\phi\pi) = 0.036\pm0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b}\to B_s^0)$ and $B(D_s\to\phi\pi)$. Superseded by BUSKULIC 95O.

[1] Use $\Upsilon(5S) \to B_s^* \overline{B}_s^*$ decays assuming B($\Upsilon(5S) \to B_s^* \overline{B}_s^*$) = (17.1 ± 3.0)% and $\Gamma(\Upsilon(5S) \to B_s^* \overline{B}_s^*)$ / $\Gamma(\Upsilon(5S) \to B_s^{(*)} \overline{B}_s^{(*)})$ = (87.0 ± 1.7)%.

[2] AALTONEN 12C reports (f_s/f_d) (B($B_s^0 \to D_s^{*+} D_s^{*-}$) / B($B^0 \to D^- D_s^+$)) = 0.654 ± 0.072 ± 0.065. We multiply this result by our best value of B($B^0 \to D^- D_s^+$) = (7.2 ± 0.8) × 10^{-3} and divide by our best value of f_s/f_d, where 1/2 f_s/f_d = 0.131 ± 0.008. Our first quoted uncertainty is the combined experiment's uncertainty and our second is the systematic uncertainty from using out best values.

[3] Uses $\Upsilon(10860) \to B_s^* \overline{B}_s^*$ assuming B($\Upsilon(10860) \to B_s^{(*)} \overline{B}_s^{(*)}$) = (19.3 ± 2.9)% and $\Gamma(\Upsilon(10860) \to B_s^* \overline{B}_s^*)$ / $\Gamma(\Upsilon(10860) \to B_s^{(*)} \overline{B}_s^{(*)})$ = $(90.1^{+3.8}_{-4.0})$%.

$\Gamma(D_s^{(*)+} D_s^{(*)-})/\Gamma_{total}$ Γ_{21}/Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

POLARIZATION IN B_s^0 DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L), or both are transverse and parallel ($\|$), or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

B_s^0-$\overline{B}_s^0$ MIXING

For a discussion of B_s^0-$\overline{B}_s^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_s is a measure of the time-integrated B_s^0-$\overline{B}_s^0$ mixing probability that produced $B_s^0(\overline{B}_s^0)$ decays as a $\overline{B}_s^0(B_s^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_{sH}^0} - m_{B_{sL}^0})\,\tau_{B_s^0},$$

where H, L stand for heavy and light states of two B_s^0 CP eigenstates and $\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{sH}^0} + \Gamma_{B_{sL}^0})}$.

$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$

$\Delta m_{B_s^0}$ is a measure of 2π times the B_s^0-$\overline{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is provided by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

[1] Measured using $B_s^0 \to D_s^-\pi^+$ decays.
[2] Measured using $B_s^0 \to D_s^-\mu^+\nu_\mu X$ decays.
[3] Significance of oscillation signal is 5.4 σ. Also reports $|V_{td}\ /\ V_{ts}| = 0.2060 \pm 0.0007^{+0.0081}_{-0.0060}$.
[4] Measured using $B_s^0 \to D_s^-\pi^+$ and $D_s^-\pi^+\pi^-\pi^+$ decays.
[5] A likelihood scan over the oscillation frequency, Δm_s, gives a most probable value of 19 ps^{-1} and a range of $17 < \Delta m_s < 21$ (ps^{-1}) at 90% C.L. assuming Gaussian uncertainties. Also excludes $\Delta m_s < 14.8$ ps^{-1} at 95% C.L.
[6] Significance of oscillation signal is 0.2%. Also reported the value $|V_{td}\ /\ V_{ts}| = 0.208^{+0.001+0.008}_{-0.002-0.006}$.
[7] Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.
[8] Updates of D_s-lepton analysis.
[9] Combined results from all Delphi analyses.
[10] Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.
[11] ABE 03 uses the novel "charge dipole" technique to reconstruct separate secondary and tertiary vertices originating from the $B \to D$ decay chain. The analysis excludes $\Delta m_s < 4.9$ ps^{-1} and $7.9 < \Delta m_s < 10.3$ ps^{-1}.
[12] Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with D_s exclusively reconstructed; (3) inclusive semileptonic decays.
[13] ABE 02V uses exclusively reconstructed D_s^- mesons and excludes $\Delta m_s < 1.4$ ps^{-1} and $2.4 < \Delta m_s < 5.3$ ps^{-1} at 95%CL.
[14] Uses fully or partially reconstructed $D_s\ell$ vertices and a mixing tag as a flavor tagging.
[15] Replaced by ABDALLAH 04A. Uses $D_s^-\ell^+$, and $\phi\ell^+$ vertices, and a multi-variable discriminant as a flavor tagging.
[16] Uses inclusive D_s vertices and fully reconstructed B_s decays and a multi-variable discriminant as a flavor tagging.
[17] Uses ℓ-$Q_{\rm hem}$ and ℓ-ℓ.
[18] ABE 99D assumes $\tau_{B_s^0} = 1.55 \pm 0.05$ ps and $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$.
[19] ABE 99J uses ϕ ℓ-ℓ correlation.
[20] BARATE 99J uses combination of an inclusive lepton and D_s^--based analyses.
[21] BARATE 98C combines results from $D_s h$-$\ell/Q_{\rm hem}$, $D_s h$-K in the same side, $D_s\ell$-$\ell/Q_{\rm hem}$ and $D_s\ell$-K in the same side.
[22] Uses ℓ-$Q_{\rm hem}$.
[23] Uses ℓ-ℓ.
[24] ADAM 97 combines results from $D_s\ell$-$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, and ℓ-ℓ.
[25] BUSKULIC 96M uses D_s lepton correlations and lepton, kaon, and jet charge tags.
[26] BUSKULIC 95J uses ℓ-$Q_{\rm hem}$. They find $\Delta m_s > 5.6$ [> 6.1] for f_s=10% [12%]. We interpolate to our central value f_s=10.5%.

$x_s = \Delta m_{B_s^0}/\Gamma_{B_s^0}$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on $\Delta m_{B_s^0}$ and "OUR EVALUATION" of the B_s^0 mean lifetime.

Meson Particle Listings

B_s^0

[1] AAIJ 14D reports a measurement of time-integrated flavor-specific asymmetry in $B_s^0 \to \mu^+ D_s^- X$ decays $a_{sl}^s = (-0.06 \pm 0.50 \pm 0.36)\%$ which is approximately equal to $4 \times \mathrm{Re}(\epsilon_{B_s^0}) / (1 + |\epsilon_{B_s^0}|^2)$.

[2] ABAZOV 14 uses the dimuon charge asymmetry with different impact parameters from which it reports $A_{SL}^s = (-0.86 \pm 0.74) \times 10^{-2}$.

[3] ABAZOV 13 reports a measurement of time-integrated flavor-specific asymmetry in mixed semileptonic $B_s^0 \to \mu^+ D_s^- X$ decays $A_s^{SL} = (-1.12 \pm 0.74 \pm 0.17)\%$ which is approximately equal to $4 \times \mathrm{Re}(\epsilon_{B_s^0}) / (1 + |\epsilon_{B_s^0}|^2)$.

[4] ABAZOV 10E reports a measurement of flavor-specific asymmetry in $B_{(s)}^0 \to \mu^+ D_{(s)}^{*-} X$ decays with a decay-time analysis including initial-state flavor tagging, $A_{SL}^s = (-1.7 \pm 9.1^{+1.4}_{-1.5}) \times 10^{-3}$ which is approximately equal to $4 \times \mathrm{Re}(\epsilon_{B_s^0}) / (1 + |\epsilon_{B_s^0}|^2)$.

[5] ABAZOV 11U uses the dimuon charge asymmetry with different impact parameters from which it reports $A_{SL}^s = (-18.1 \pm 10.6) \times 10^{-3}$.

[6] ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$ in semileptonic b-hadron decays. Using the measured production ratio of B_d^0 and B_s^0, and the asymmetry of B_d^0 $A_{SL}^d = (-4.7 \pm 4.6) \times 10^{-3}$ measured from B-factories, they obtain the asymmetry for B_s^0.

[7] The first direct measurement of the time integrated flavor untagged charge asymmetry in semileptonic B_s^0 decays is reported as $2xA_{SL}^s(\text{untagged}) = A_{SL}^s = (2.45 \pm 1.93 \pm 0.35) \times 10^{-2}$.

[1] AAIJ 13AR reports $\phi_S = -2\beta_S = 0.01 \pm 0.07 \pm 0.01$ radians obtained from combined fit to $B_s^0 \to J/\psi K^+K^-$ and $B_s^0 \to J/\psi\pi^+\pi^-$ data sets. Also reports separate results of $\phi_S = 0.07 \pm 0.09 \pm 0.01$ radians from $B_s^0 \to J/\psi K^+K^-$ decays and $\phi_S = -0.14^{+0.17}_{-0.16} \pm 0.01$ radians from $B_s^0 \to J/\psi\pi^+\pi^-$ decays.

[2] AAD 12CV reports $\phi_s = -2\beta_S = 0.22 \pm 0.41 \pm 0.10$ rad. that was measured using a time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.

[3] AALTONEN 12AJ reports $-\pi/2 < \beta_S < -1.51$ or $-0.06 < \beta_S < 0.30$, or $1.26 < \beta_S < \pi/2$ at 68% CL. Measured using the time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.

[4] The error includes both statistical and systematic uncertainties.

[5] Measured using fully reconstructed $B_s \to J/\psi\phi$ decays.

[6] Reports ϕ_S which equals to $-2\beta_S$.

[7] Uses $B_s^0 \to \phi\phi$ mode, and reports the 68% CL interval of $\phi_S = -2\beta_S$ as $[-2.46, -0.76]$.

[8] Reports $\phi_S = -2\beta_S = -0.44 \pm 0.44 \pm 0.02$ that was measured using a time-dependent fit to $B_s^0 \to J/\psi f_0(980)$ decays.

[9] Reports $\phi_S = -2\beta_S = 0.15 \pm 0.18 \pm 0.06$ that was measured using a time-dependent angular analysis of $B_s^0 \to J/\psi\phi$ decays.

[10] Reports $\phi_S = -2\beta_S = -0.019^{+0.173+0.004}_{-0.174-0.003}$ radians which was measured using a time-dependent fit to $B_s^0 \to J/\psi\pi^+\pi^-$ decays, with the $\pi^+\pi^-$ mass within 775–1550 MeV. Searches for, but finds no evidence, for direct CP violation in $B_s^0 \to J/\psi\pi\pi$ decays.

[11] Reports $0.02 < \phi_S < 0.52$ or $1.08 < \phi_S < 1.55$ at 68% C.L. confidence regions in the two-dimensional space of ϕ_S and $\Delta\Gamma_{B_s^0}$ from $B_s^0 \to J/\psi\phi$ decays.

[12] Reports $0.32 < 2\beta_S < 2.82$ at 68% C.L. and confidence regions in the two-dimensional space of $2\beta_S$ and $\Delta\Gamma$ from the first measurement of $B_s^0 \to J/\psi\phi$ decays using flavor tagging. The probability of a deviation from SM prediction as large as the level of observed data is 15%.

[13] Reports $\phi_S = -2\beta_S$ and obtains 90% CL interval $-0.03 < \beta_S < 0.60$.

[14] The first direct measurement of the CP-violating mixing phase is reported from the time-dependent analysis of flavor untagged $B_s^0 \to J/\psi\phi$ decays.

[15] Combines D0 collaboration measurements of time-dependent angular distributions in $B_s^0 \to J/\psi\phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

$A_{CP}(B_s \to \pi^+K^-)$

A_{CP} is defined as

$$\frac{B(\overline{B}_s^0 \to f) - B(B_s^0 \to \overline{f})}{B(\overline{B}_s^0 \to f) + B(B_s^0 \to \overline{f})},$$

the CP-violation asymmetry of exclusive B_s^0 and $\overline{B}_s^0$ decay.

[1] AAIJ 13AS uses the $B_c^+ \to J/\psi D_s^+$.

[2] AAIJ 12AV uses the $B_c^+ \to J/\psi\pi^+$ mode and also measures the mass difference $M(B_c^+) - M(B^+) = 994.6 \pm 1.3 \pm 0.6$ MeV/c^2.

[3] Measured using a fully reconstructed decay mode of $B_c \to J/\psi\pi$.

[4] ABE 98M observed $20.4^{+6.2}_{-5.5}$ events in the $B_c^+ \to J/\psi(1s)\ell\nu_\ell$ with a significance of > 4.8 standard deviations. The mass value is estimated from $m(J/\psi(1S)\ell)$.

[5] ACKERSTAFF 98O observed 2 candidate events in the $B_c^+ \to J/\psi(1S)\pi^+$ channel with an estimated background of 0.63 ± 0.20 events.

$B_c^{\pm}$ MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

$\Gamma(J/\psi(1S)\ell^+\nu_\ell \text{anything})/\Gamma_{\text{total}} \times B(\overline{b} \to B_c)$ — $\Gamma_1/\Gamma \times B$

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$(5.2^{+2.4}_{-2.1}) \times 10^{-5}$		[9] ABE	98M	CDF	$p\overline{p}$ 1.8 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$< 1.6 \times 10^{-4}$	90	[10] ACKERSTAFF	98O	OPAL	$e^+e^- \to Z$
$< 1.9 \times 10^{-4}$	90	[11] ABREU	97E	DLPH	$e^+e^- \to Z$
$< 1.2 \times 10^{-4}$	90	[12] BARATE	97H	ALEP	$e^+e^- \to Z$

[9] ABE 98M result is derived from the measurement of $[\sigma(B_c)\times B(B_c \to J/\psi(1S)\ell\nu_\ell)] / [\sigma(B^+)\times B(B^+ \to J/\psi(1S)K^+)] = 0.132^{+0.041}_{-0.037}(\text{stat}) \pm 0.031(\text{sys})^{+0.032}_{-0.020}(\text{lifetime})$ by using PDG 98 values of $B(b \to B^+)$ and $B(B^+ \to J/\psi(1S)K^+)$.

[10] ACKERSTAFF 98O reports $B(Z \to B_c X)/B(Z \to q\overline{q})\times B(B_c \to J/\psi(1S)\ell\nu_\ell) < 6.95 \times 10^{-5}$ at 90%CL. We rescale to our PDG 98 values of $B(Z \to b\overline{b})$.

[11] ABREU 97E value listed is for an assumed $\tau_{B_c} = 0.4$ ps and improves to 1.6×10^{-4} for $\tau_{B_c} = 1.4$ ps.

[12] BARATE 97H reports $B(Z \to B_c X)/B(Z \to q\overline{q})\cdot B(B_c \to J/\psi(1S)\ell\nu_\ell) < 5.2\times 10^{-5}$ at 90%CL. We rescale to our PDG 96 values of $B(Z \to b\overline{b})$. A $B_c^+ \to J/\psi(1S)\mu^+\nu_\mu$ candidate event is found, compared to all the known background sources 2×10^{-3}, which gives $m_{B_c} = 5.96^{+0.25}_{-0.19}$ GeV and $\tau_{B_c} = 1.77 \pm 0.17$ ps.

$\Gamma(J/\psi(1S)\pi^+)/\Gamma_{\text{total}} \times B(\overline{b} \to B_c)$ — $\Gamma_2/\Gamma \times B$

POLARIZATION IN B_c^+ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ($\|$) or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

DEVELOPMENTS IN HEAVY QUARKONIUM SPECTROSCOPY

Updated March 2014 by S. Eidelman (Budker Inst. and Novosibirsk State Univ.), C. Hanhart (Forschungszentrum Jülich), B.K. Heltsley (Cornell Univ.), J.J. Hernandez-Rey (Univ. Valencia–CSIC), S. Navas (Univ. Granada), and C. Patrignani (Univ. Genova, INFN).

A golden age for heavy quarkonium physics dawned at the turn of this century, initiated by the confluence of exciting advances in quantum chromodynamics (QCD) and an explosion of related experimental activity. The subsequent broad spectrum of breakthroughs, surprises, and continuing puzzles had not been anticipated. In that period, the BESII program concluded only to give birth to BESIII; the B-factories and CLEO-c flourished; quarkonium production and polarization measurements at HERA and the Tevatron matured; and heavy-ion collisions at RHIC opened a window on the deconfinement regime. Recently also ATLAS, CMS and LHCb started to contribute to the field. For an extensive presentation of the status of heavy quarkonium physics, the reader is referred to several reviews [1–7], the last of which covers developments through the middle of 2010, and which supplies some tabular information and phrasing reproduced here (with kind permission, copyright 2011, Springer). This note focuses solely on experimental developments in heavy quarkonium spectroscopy, and in particular on those too recent to have been included in Ref. 7.

In this mini-review we display the newly discovered states, where "newly" is interpreted to include the period since 2003. In earlier versions of this write-up the particles were sorted according to an assumed *conventional* or *unconventional* nature with respect to the quark model. However, since this classification is not always unambiguous, we here follow Ref. [8] and sort

Table 1: New states below the open flavor thresholds in the $c\bar{c}$, $b\bar{c}$, and $b\bar{b}$ regions, ordered by mass. Masses m and widths Γ represent the weighted averages from the listed sources. Quoted uncertainties reflect quadrature summation from individual experiments. Ellipses (...) in the Process column indicate inclusively selected event topologies; *i.e.*, additional particles not required by the Experiments to be present. A question mark (?) indicates an unmeasured value. For each Experiment a citation is given, as well as the statistical significance ($\#\sigma$), or "(np)" for "not provided". The Year column gives the date of the first measurement cited. The Status column indicates that the state has been observed by at most one (NC!-needs confirmation) or at least two independent experiments with significance of $>5\sigma$ (OK). The state labelled $\chi_{c2}(2P)$ has previously been called $Z(3930)$. In the publication $X(3823)$ is called $\psi_2(1D)$, however, only the C–parity is measured; $J^P = 2^+$ are assigned from quark model. Adapted from [7] with kind permission, copyright (2011), Springer, and [8] with kind permission from the authors.

the states into three groups, namely states below (*cf.* Table 1), near (*cf.* Table 2) and above (*cf.* Table 3) the lowest open flavor thresholds.

Table 1 lists properties of newly observed heavy quarkonium states located below the lowest open flavor thresholds. Those are expected to be (at least prominently) conventional quarkonia. The h_c is the $^1P_1$ state of charmonium, singlet partner of the long-known χ_{cJ} triplet ^3P_J. The $\eta_c(2S)$ is the first excited state of the pseudoscalar ground state $\eta_c(1S)$, lying just below the mass of its vector counterpart, $\psi(2S)$. The ground state of bottomonium is the $\eta_b(1S)$, recently confirmed with a second observation of more than 5σ significance at Belle. In addition, in the same experiment strong evidence was collected for $\eta_b(2S)$ [29], but it still needs experimental confirmation at the 5σ level. The $\Upsilon(1D)$ is the lowest-lying D-wave triplet of the $b\bar{b}$ system. Both the $h_b(1P)$, the bottomonium counterpart of $h_c(1P)$, and the next excited state, $h_b(2P)$, were recently observed by Belle [31], as described further below, in dipion transitions from either the $\Upsilon(10860)$ or $Y_b(10888)$. In addition, Belle recently reported a measurement of $\psi_2(1D)$ which would be a $J^{PC} = 2^{+-}$ state [22]. While the negative C-parity is indeed established by the measurement, the assignment of $J = 2$ was done by matching to the closest quark model state. In the table this state is therefore simply called $X(3823)$, according to

Table 2: As in Table 1, but for new states near the first open flavor thresholds in the $c\bar{c}$ and $b\bar{b}$ regions, ordered by mass. For $X(3872)$, the values given are based only upon decays to $\pi^+\pi^- J/\psi$. Updated from [7] with kind permission, copyright (2011), Springer, and [8] with kind permission from the authors.

the PDG name convention. After the mass of the $\eta_b(1S)$ was shifted upwards by about 11 MeV based on a new Belle measurement [29], all states mentioned in this paragraph fit into their respective spectroscopies roughly where expected. Their exact masses, production mechanisms, and decay modes provide guidance to their descriptions within QCD.

There is a large number of newly discovered states both near and above the lowest open flavor thresholds. They are displayed in Table 2 and Table 3, respectively*; notice that just a few of them have been confirmed experimentally. With the possible exception of the tensor state located at 3930 MeV, neither can unambiguously be assigned a place in the hierarchy of charmonia or bottomonia nor has a universally accepted unconventional origin. The $X(3872)$ is widely studied, yet its interpretation demands additional experimental attention: after the quantum numbers were fixed at LHCb [54] the next experimental challenge will be a measurement of its line shape. The state originally dubbed $Z(3930)$ is now regarded by many as the first observed $2P$ state of χ_{cJ}, the $\chi_{c2}(2P)$. The scalar state at 3915 MeV is now called $\chi_{c0}(3915)$. It might be the first radial excitation of $\chi_{c0}(1P)$, but this interpretation is not generally accepted [100]. The $Y(4260)$ and $Y(4360)$ are vector states decaying to $\pi^+\pi^- J/\psi$ and $\pi^+\pi^-\psi(2S)$, respectively, yet, unlike most conventional vector charmonia, do not correspond to enhancements in the e^+e^- hadronic cross section.

Based on a full amplitude analysis of the $B^0 \to K^+\pi^-\psi(2S)$ decays, Belle determined the spin-parity of the $Z(4430)^{\pm}$** to be $J^P = 1^+$ [92]. Very recently this state as well as its quantum numbers were confirmed at LHCb [94] with much higher statistics. Improved values for mass and width from LHCb are consistent with earlier measurements; our new average is in Table 3; the experiment even reports a resonant behavior of the $Z(4430)^{\pm}$ amplitude. This state as well as $Z(4050)^{\pm}$ and $Z(4250)^{\pm}$ seen in $\pi^{\pm}\chi_{c1}$ are, however, not confirmed (nor excluded) by BaBar (see [93] for the $Z(4430)$ and [74] for the $Z(4050)^{\pm}$ and $Z(4250)^{\pm}$). Belle observes signals of significances 5.0σ, 5.0σ, and 6.4σ for $Z_1(4050)^+$, $Z_2(4250)^+$, and $Z(4430)^+$, respectively, whereas BABAR reports 1.1σ, 2.0σ, and 2.4σ effects, setting upper limits on product branching fractions that are not inconsistent with Belle's and LHCb's measured rates. For $Z_1(4050)^+$ and $Z_2(4250)^+$ the situation remains unresolved.

In addition to the three Z_c^+ discussed in the previous paragraph, in 2013 two more states named $Z_c(3900)^+$ and $Z_c(4020)^+$ were unearthed in the charmonium region. Note that in this write-up as well as the RPP listings we combined $Z_c(3900)^+$ (seen in $J/\psi\pi\pi$) and $Z_c(3885)^+$ (seen in $D\bar{D}^*$) as well as $Z_c(4020)^+$ (seen in $h_c\pi\pi$) and $Z_c(4025)^+$ (seen in $D^*\bar{D}^*$)

* For consistency with the literature, we preserve the use of X, Y and Z, contrary to the practice of the PDG, which exclusively uses X for unidentified states.

** There are currently various candidates for isotriplet states in the spectrum. For some of them both charged states are already established and sometimes there is also evidence for the neutral partner. We still chose to put the charge as superscript since it is an explicit marker of the exotic nature of the states.

Table 3: As in Table 1, but for new states above the first open flavor thresholds in the $c\bar{c}$ and $b\bar{b}$ regions, ordered by mass. $X(3945)$ and $Y(3940)$ have been subsumed under $X(3915)$ due to compatible properties. The quantum numbers of the state were measured at BaBar [65]. The state known as $Z(3930)$ appears as the $\chi_{c2}(2P)$ in Table 1. In some cases experiment still allows two J^{PC} values, in which case both appear. See also the reviews in [1–7]. into only two states due to their close proximity in mass. In various respects $Z_c(3900)^+$ and $Z_c(4020)^+$ seem to be the charmed partners of $Z_b(10610)^+$ and $Z_b(10650)^+$ as will be outlined below.

Although $\eta_c(2S)$ measurements began to converge towards a mass and a width some time ago, refinements are still in progress. In particular, Belle [15] has revisited its analysis of $B \to K\eta_c(2S)$, $\eta_c(2S) \to KK\pi$ decays with more data and methods that account for interference between the above decay chain, an equivalent one with the $\eta_c(1S)$ instead, and one with no intermediate resonance. The net effect of this interference is far from trivial; it shifts the apparent mass by $\sim$+10 MeV and blows up the apparent width by a factor of six. The updated $\eta_c(2S)$ mass and width are in better accordance with other measurements than the previous treatment [14], which did not include interference. Complementing this measurement in B-decay, BABAR [16] updated their previous [17] $\eta_c(2S)$ mass and width measurements in two-photon production, where interference effects, judging from studies of $\eta_c(1S)$, appear to be small. In combination, precision on the $\eta_c(2S)$ mass has improved dramatically.

The $Y(4140)$ observed in 2008 by CDF [75,76] was confirmed at CMS and D0 [79,80], however, a second structure related to $Y(4274)$ could not be established unambiguously. The two states were neither seen in B decays at Belle [77] and LHCb [78] nor in $\gamma\gamma$ collisions at Belle [87]. Thus the situation for $Y(4140)$ and $Y(4274)$ is still controversial.

New results on η_b, h_b, and Z_b^+ mostly come from Belle, all from analyses of 121.4 fb^{-1} of e^+e^- collision data collected near the peak of the $\Upsilon(10860)$ resonance. They all appear in the same types of decay chains: $\Upsilon(10860) \to \pi^- Z_b^+$, $Z_b^+ \to \pi^+(b\bar{b})$, and, when the $b\bar{b}$ forms an $h_b(1P)$, frequently decaying as $h_b(1P) \to \gamma\eta_b$.

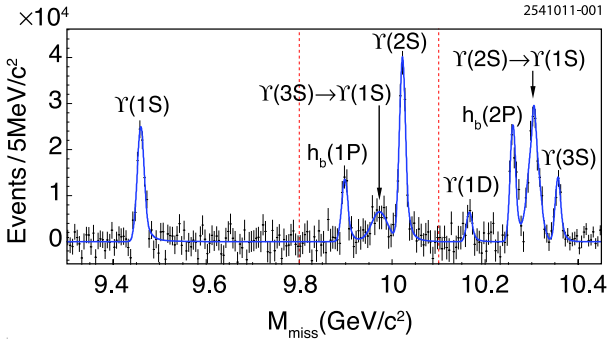

Figure 1: From Belle [31], the mass recoiling against $\pi^+\pi^-$ pairs, $M_{\rm miss}$, in e^+e^- collision data taken near the peak of the $\Upsilon(10860)$ (*points with error bars*). The smooth combinatoric and $K_S^0 \to \pi^+\pi^-$ background contributions have already been subtracted. The fit to the various labeled signal contributions overlaid (*curve*). Adapted from [31] with kind permission, copyright (2011) The American Physical Society.

The Belle h_b discovery analysis [31] selects hadronic events and searches for peaks in the mass recoiling against $\pi^+\pi^-$ pairs, the spectrum for which, after subtraction of smooth combinatoric and $K_S^0 \to \pi^+\pi^-$ backgrounds, appears in Fig. 1. Prominent and unmistakable $h_b(1P)$ and $h_b(2P)$ peaks are present. This search was directly inspired by a CLEO result [101], which found the surprisingly copious transitions $\psi(4160) \to \pi^+\pi^- h_c(1P)$ and an indication that $Y(4260) \to \pi^+\pi^- h_c(1P)$ occurs at a comparable rate as the signature mode, $Y(4260) \to \pi^+\pi^- J/\psi$. The presence of $\Upsilon(nS)$ peaks in Fig. 1 at rates two orders of magnitude larger than expected for transitions requiring a heavy-quark spin-flip, along with separate studies with exclusive decays $\Upsilon(nS) \to \mu^+\mu^-$, allow precise calibration of the $\pi^+\pi^-$ recoil mass spectrum and very accurate measurements of $h_b(1P)$ and $h_b(2P)$ masses. Both corresponding hyperfine splittings are consistent with zero within an uncertainty of about 1.5 MeV (lowered to ± 1.1 MeV for $h_b(1P)$ in Ref. [30]) .

Belle soon noticed that, for events in the peaks of Fig. 1, there seemed to be two intermediate charged states nearby. For example, Fig. 2 shows a Dalitz plot for events restricted to the $\Upsilon(2S)$ region of $\pi^+\pi^-$ recoil mass. The two bands observed in the maximum of the two $M[\pi^\pm\Upsilon(2S)]^2$ values also appear for $\Upsilon(1S)$, $\Upsilon(3S)$, $h_b(1P)$, and $h_b(2P)$ samples but not in the respective $[b\bar{b}]$ sidebands. Belle fits all subsamples to resonant plus non-resonant amplitudes, allowing for interference (notably, between $\pi^- Z_b^+$ and $\pi^+ Z_b^-$), and finds consistent pairs of Z_b^+ masses for all bottomonium transitions, and comparable strengths of the two states. A recent angular analysis assigned $J^P = 1^+$ for both Z_b^+ states [102], which must also have negative G-parity. Transitions through Z_b^+ to the $h_b(nP)$ saturate the observed $\pi^+\pi^- h_b(nP)$ cross sections. The two masses of Z_b^+ states are just a few MeV above the $B^*\bar{B}$ and $B^*\bar{B}^*$ thresholds, respectively. Still, they predominantly decay into these channels [64], regardless the small phase space, with branching fractions that exceed 80% and 70%, respectively, at 90% CL. This feature provides strong evidence for their molecular nature—note that the Z_b^+ states cannot be simple mesons because they are charged and have $b\bar{b}$ content.

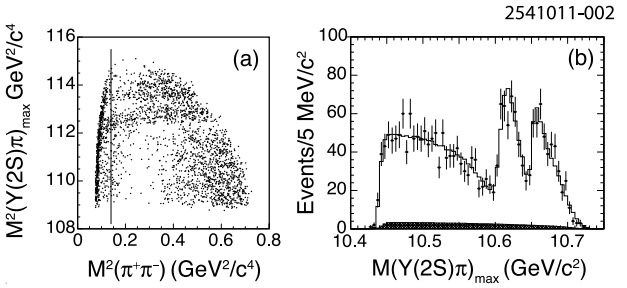

Figure 2: From Belle [62] e^+e^- collision data taken near the peak of the $\Upsilon(10860)$ for events with a $\pi^+\pi^-$-missing mass consistent with a $\Upsilon(nS)2$, (a) the maximum of the two possible single $\pi^\pm$-missing-mass-squared combinations vs. the $\pi^+\pi^-$-mass-squared; and (b) projection of the maximum of the two possible single $\pi^\pm$-missing-mass combinations (*points with error bars*) overlaid with a fit (*curve*). Events to the left of the vertical line in (a) are excluded from further analysis. The two horizontal stripes in (a) and two peaks in (b) correspond to the two Z_b^+ states. Adapted from [62] with kind permission, copyright (2011) The American Physical Society.

The third Belle result to follow from these data is the confirmation of the $\eta_b(1S)$ and measurement of the $h_b(1P) \to \gamma\eta_b(1S)$ branching fraction, expected to be several tens of percent. To accomplish this, events with the $\pi^+\pi^-$ recoil mass in the $h_b(1P)$ mass window and a radiative photon candidate are selected, and the $\pi^+\pi^-\gamma$ recoil mass queried for correlation with non-zero $h_b(1P)$ population in the $\pi^+\pi^-$ missing mass spectrum, as shown in Fig. 3. A clear peak is observed, corresponding to the $\eta_b(1S)$. A fit is performed to extract the $\eta_b(1S)$ mass, and determine its width and the branching fraction for $h_b(1P) \to \gamma\eta_b(1S)$ (the latter of which is $(49.8 \pm 6.8^{+10.9}_{-5.2})\%$) for the first time. The mass determination has comparable uncertainty and a larger central value (by 10 MeV, or 2.4σ) than the average of previous measurements, thereby reducing the new world average hyperfine splitting by nearly 5 MeV. An independent experimental confirmation of the shifted mass is very important to pursue.

The $\chi_{bJ}(nP)$ states have recently been observed at the LHC by ATLAS [35] and confirmed by D0 [36] for $n = 1, 2, 3$,

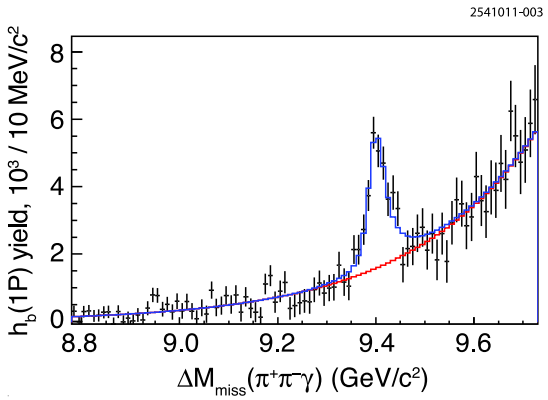

Figure 3: From Belle [30] e^+e^- collision data taken near the peak of the $\Upsilon(10860)$, the $h_b(1P)$ event yield vs. the mass recoiling against the $\pi^+\pi^-\gamma$ (corrected for misreconstructed $\pi^+\pi^-$), where the $h_b(1P)$ yield is obtained by fitting the mass recoiling against the $\pi^+\pi^-$ (*points with error bars*). The fit results (*solid histograms*) for signal plus background and background alone are superimposed. Adapted from [30] with kind permission, copyright (2011) The American Physical Society.

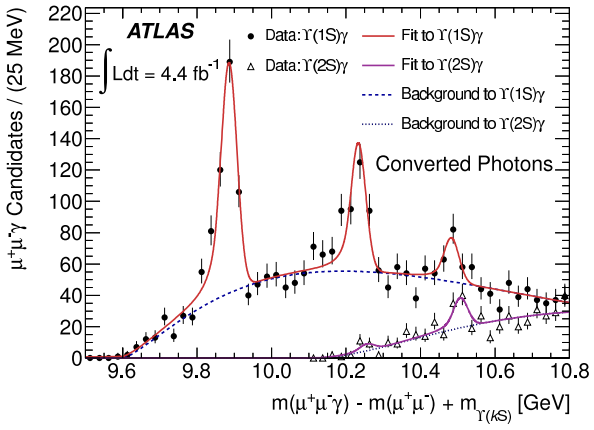

Figure 4: From ATLAS [35] pp collision data (*points with error bars*) taken at $\sqrt{s}$ = 7 TeV, the effective mass of $\chi_{bJ}(1P, 2P, 3P) \to \gamma\Upsilon(1S, 2S)$ candidates in which $\Upsilon(1S, 2S) \to \mu^+\mu^-$ and the photon is reconstructed as an e^+e^- conversion in the tracking system. Fits (*smooth curves*) show significant signals for each triplet (merged-J) on top of a smooth background. From [35] with kind permission, copyright (2012) The American Physical Society.

although in each case the three J states are not distinguished from one another. Events are sought which have both a photon and an $\Upsilon(1S, 2S) \to \mu^+\mu^-$ candidate which together form a mass in the χ_b region. Observation of all three J-merged peaks is seen with significance in excess of 6σ for both unconverted and converted photons. The mass plot for converted photons, which provide better mass resolution, is shown in Fig. 4. This marks the first observation of the $\chi_{bJ}(3P)$ triplet, quite near the expected mass.

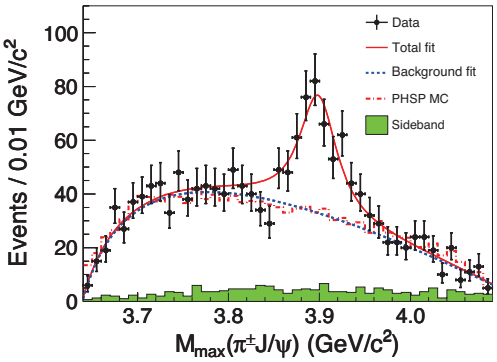

Figure 5: $J/\psi\pi$ invariant mass distributions from BES-III [56] e^+e^- collision data taken near the peak of the $Y(4260)$. Adapted from [56] with kind permission, copyright (2013) The American Physical Society.

In 2013 at BESIII [56] and shortly after at Belle [57] a charged state called $Z_c(3900)^+$ was found near the $D\bar{D}^*$ threshold—the corresponding spectrum from BESIII is shown in Fig. 5. In addition to confirming these findings, Ref. [58] also provided evidence for a neutral partner. A nearby signal was also seen in the $D\bar{D}^*$ channel [55] whose quantum numbers were fixed to 1^{+-}. The masses extracted from these experiments agree only within 2σ. However, since the extraction did not allow for an interference with the background and used Breit-Wigner line shapes, which is not justified near thresholds, there might be some additional systematic uncertainty in the mass values. Therefore in the RPP listings as well as Table 2 both structures appear under the name $Z_c(3900)^+$. Analogously, $Z_c(4020)^+$ (seen in in $h_c\pi\pi$ [59]) and $Z_c^+(4025)$ (seen in $D^*\bar{D}^*$ [60]) are listed as one state, $Z_c(4020)^+$. The Z_c^+ states show some remarkable similarities to the Z_b^+ states, e.g. they decay dominantly to the $D^{(*)}\bar{D}^*$ channels. However, current analyses suggest that the mass of especially the $Z_c(3900)^+$ might be somewhat above the $D\bar{D}^*$ threshold. If confirmed, this feature would clearly challenge a possible $D\bar{D}^*$–molecular interpretation.

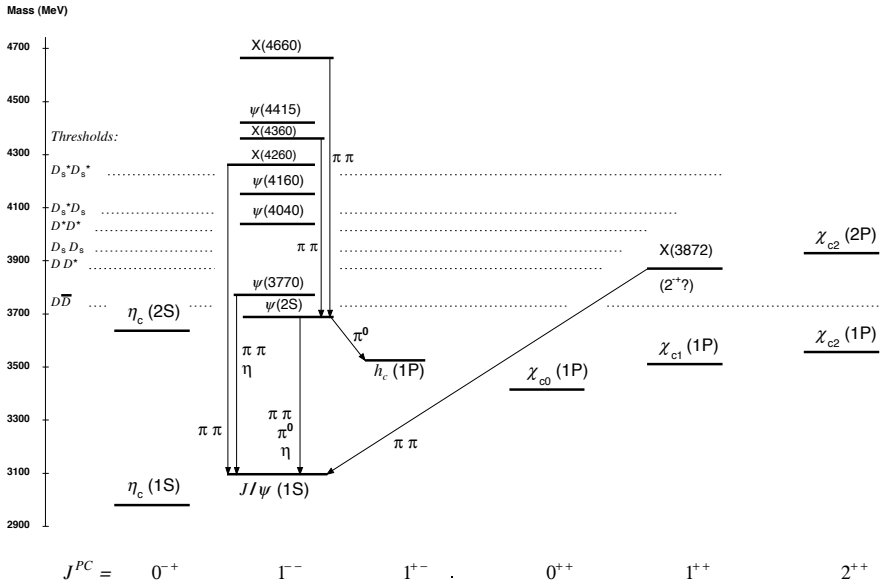
$c\overline{c}$ MESONS

THE CHARMONIUM SYSTEM



The level scheme of the $c\overline{c}$ states showing experimentally established states with solid lines. Singlet states are called η_c and h_c, triplet states ψ and χ_{cJ}, and unassigned charmonium-like states X. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. Only observed hadronic transitions are shown; the single photon transitions $\psi(nS) \to \gamma\eta_c(mP)$, $\psi(nS) \to \gamma\chi_{cJ}(mP)$, and $\chi_{cJ}(1P) \to \gamma J/\psi$ are omitted for clarity.

$\eta_c(1S)$

$I^G(J^{PC}) = 0^+(0^{-+})$

$\eta_c(1S)$ MASS

[1] From a simultaneous fit to six decay modes of the η_C.
[2] Accounts for interference with non-resonant continuum.
[3] With floating width.
[4] Taking into account interference with the non-resonant $J^P = 0^-$ amplitude.
[5] From a fit of the J/ψ recoil mass spectrum. Supersedes ABE,K 02 and ABE 04G.
[6] Using mass of $\psi(2S) = 3686.00$ MeV.
[7] Not independent from the measurements reported by LEES 10.
[8] MITCHELL 09 observes a significant asymmetry in the lineshapes of $\psi(2S) \to \gamma\eta_C$ and $J/\psi \to \gamma\eta_C$ transitions. If ignored, this asymmetry could lead to significant bias whenever the mass and width are measured in $\psi(2S)$ or J/ψ radiative decays.
[9] From the fit of the kaon momentum spectrum. Systematic errors not evaluated.
[10] Superseded by LEES 10.
[11] From a simultaneous fit of five decay modes of the η_C.
[12] Superseded by VINOKUROVA 11.
[13] Weighted average of the $\psi(2S)$ and $J/\psi(1S)$ samples. Using an η_C width of 13.2 MeV.
[14] Average of several decay modes. Using an η_C width of 13.2 MeV.
[15] Superseded by ASNER 04.
[16] Average of several decay modes.
[17] $\eta_C \to \phi\phi$.
[18] Mass adjusted by us to correspond to $J/\psi(1S)$ mass = 3097 MeV.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 8 combinations of partial widths obtained from integrated cross section, and 17 branching ratios uses 80 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 113.0$ for 69 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i\delta p_j\rangle/(\delta p_i\cdot\delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

3097.0 ±1		[4] BRANDELIK	79C	DASP	e^+e^-

[1] Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).
[2] Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the $\psi(2S)$ mass from AULCHENKO 03.
[3] Superseded by ARTAMONOV 00.
[4] From a simultaneous fit to e^+e^-, $\mu^+\mu^-$ and hadronic channels assuming $\Gamma(e^+e^-) = \Gamma(\mu^+\mu^-)$.

[a] For $E_\gamma > 100$ MeV.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

[c] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.

[d] See the "Note on the $\eta(1405)$" in the $\eta(1405)$ Particle Listings.

[e] For a narrow state A with mass less than 960 MeV.

[f] For a narrow scalar or pseudoscalar A^0 with mass 0.21–3.0 GeV.

[1] From $J/\psi \to \pi^+\pi^-\pi^0$ events directly.
[2] The quoted systematic error includes a contribution of 1.23% (added in quadrature) from the uncertainty on the number of J/ψ events.
[3] AUBERT 07AU reports $[\Gamma(J/\psi(1S) \to \pi^+\pi^-\pi^0)/\Gamma_{total}] \times [\Gamma(\psi(2S) \to J/\psi(1S)\pi^+\pi^-) \times \Gamma(\psi(2S) \to e^+e^-)/\Gamma_{total}] = (18.6\pm1.2\pm1.1)\times10^{-3}$ keV which we divide by our best value $\Gamma(\psi(2S) \to J/\psi(1S)\pi^+\pi^-) \times \Gamma(\psi(2S) \to e^+e^-)/\Gamma_{total} = 0.813 \pm 0.013$ keV. Our first error is their experiment's error and our second error is the systematic error from using our best value.
[4] From the ratio of $\Gamma(e^+e^-)\,B(\pi^+\pi^-\pi^0)$ and $\Gamma(e^+e^-)\,B(\mu^+\mu^-)$ (AUBERT 04).
[5] Mostly $\rho\pi$, see also $\rho\pi$ subsection.
[6] Obtained comparing the rates for $\pi^+\pi^-\pi^0$ and $\mu^+\mu^-$, using J/ψ events produced via $\psi(2S) \to \pi^+\pi^- J/\psi$ and with $B(J/\psi \to \mu^+\mu^-) = 5.88 \pm 0.10\%$.

BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Updated May 2012 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Genova)

Since 2002, the treatment of the branching ratios of the $\psi(2S)$ and $\chi_{c0,1,2}$ has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the *Review of Particle Physics* (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles Ref. 1,Ref. 2 as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles, $\psi(2S)$, χ_{c0}, χ_{c1}, and χ_{c2}, and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the $\chi_{c0,1,2}$ are measured independently of the $\psi(2S)$ radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 25 combinations of partial widths, 7 branching ratios, and 77 combinations of branching ratios. Of the latter 57 involve decays of more than one particle.

The overall fit uses 223 measurements to determine 49 parameters and has a χ^2 of 312.2 for 174 degrees of freedom.

The relatively high χ^2 of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No rescaling of errors has been applied.

In the listing we provide the correlation coefficients $< \delta x_i \delta x_j > / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the corresponding parameter x_i.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 238 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 339.7$ for 189 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\rm total}$.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 238 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 339.7$ for 189 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 238 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 339.7$ for 189 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left\langle \delta p_i \delta p_j \right\rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
3686.00 ± 0.10	413	[4] ZHOLENTZ 80	OLYA	e^+e^-

[1] From the scans in 2004 and 2006. ANASHIN 12 reports the value $3686.114 \pm 0.007 \pm 0.011^{+0.002}_{-0.012}$ MeV, where the third uncertainty is due to assumptions on the interference between the resonance and hadronic continuum. We combined the two systematic uncertainties.

[2] Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85).

[3] Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 93B, using the value for the $J/\psi(1S)$ mass from AULCHENKO 03.

[4] Superseded by ARTAMONOV 00.

$m_{\psi(2S)} - m_{J/\psi(1S)}$

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 238 measurements to determine 49 parameters. The overall fit has a $\chi^2 = 339.7$ for 189 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$.

$\psi(2S)$ Γ(i)$\Gamma(e^+e^-)/\Gamma$(total)

This combination of a partial width with the partial width into e^+e^- and with the total width is obtained from the integrated cross section into channel(i) in the e^+e^- annihilation. We list only data that have not been used to determine the partial width Γ(i) or the branching ratio Γ(i)/total.

20–130	95	EDWARDS	82C	CBAL	$e^+e^- \to \gamma X$

[1] ABLIKIM 12G reports $[\Gamma(\psi(2S) \to \gamma\eta_c(2S))/\Gamma_{\text{total}}] \times [B(\eta_c(2S) \to K\overline{K}\pi)] = (1.30 \pm 0.20 \pm 0.30) \times 10^{-5}$ which we divide by our best value $B(\eta_c(2S) \to K\overline{K}\pi) = (1.9 \pm 1.2) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[2] CRONIN-HENNESSY 10 reports $[\Gamma(\psi(2S) \to \gamma\eta_c(2S))/\Gamma_{\text{total}}] \times [B(\eta_c(2S) \to K\overline{K}\pi)] < 14.5 \times 10^{-6}$ which we divide by our best value $B(\eta_c(2S) \to K\overline{K}\pi) = 1.9 \times 10^{-2}$. This measurement assumes $\Gamma(\eta_c(2S)) = 14$ MeV. CRONIN-HENNESSY 10 gives the analytic dependence of limits on width.

$\psi(3770)$ DECAY MODES

In addition to the dominant decay mode to $D\overline{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 3 branching ratios uses 23 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 20.0$ for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta p_i\delta p_j\rangle/(\delta p_i\cdot\delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.96±0.07 OUR FIT Error includes scale factor of 1.3.				
1.3 ±0.2	RAPIDIS	77	LGW	e^+e^-

[16] Neglecting interference.
[17] Obtained by comparing a measurement of the total cross section (corrected in BESSON 10) with that of $D\overline{D}$ reported by CLEO in DOBBS 07.
[18] Using $\sigma^{obs} = 7.07 \pm 0.58$ nb and neglecting interference.
[19] Not independent of ABLIKIM 08B.
[20] From a measurement of $\sigma(e^+e^- \to D\overline{D})$ at $\sqrt{s} = 3773$ MeV, using the $\psi(3770)$ resonance parameters measured by ABLIKIM 06L.
[21] See ADLER 88C for older measurements of this quantity.

[22] Comparing cross sections at $\sqrt{s} = 3.773$ GeV and $\sqrt{s} = 3.671$ GeV, neglecting interference, and using $\sigma(\psi(3770) \to D\overline{D}) = 6.39 \pm 0.20$ nb.

[23] Assuming that interference effects between resonance and continuum can be neglected and using $\sigma^{obs}(e^+e^- \to \psi(3770)) = 7.15 \pm 0.38$ nb.

[24] Data suggest possible destructive interference with continuum.

[25] Using $\sigma(e^+e^- \to \psi(3770) \to \text{hadrons}) = (6.38 \pm 0.08^{+0.41}_{-0.30})$ nb from BESSON 06 and $B(K_S^0 \to \pi^+\pi^-) = 0.6895 \pm 0.0014$.

[26] Using $B(K_S^0 \to \pi^+\pi^-) = 0.6860 \pm 0.0027$.

[27] Using $\sigma_{tot}(e^+e^- \to \psi(3770)) = 7.9 \pm 0.6$ nb at the resonance.

[28] Using $\sigma^{obs} = 7.15 \pm 0.27 \pm 0.27$ nb and neglecting interference.

[29] Assuming that interference effects between resonance and continuum can be neglected.

X(3872)

$I^G(J^{PC}) = 0^+(1^{++})$

First observed by CHOI 03 in $B \to K\pi^+\pi^- J/\psi(1S)$ decays as a narrow peak in the invariant mass distribution of the $\pi^+\pi^- J/\psi(1S)$ final state. Isovector hypothesis excluded by AUBERT 05B and CHOI 11.

AAIJ 13Q perform a full five-dimensional amplitude analysis of the angular correlations between the decay products in $B^+ \to X(3872)K^+$ decays, where $X(3872) \to J/\psi\pi^+\pi^-$ and $J/\psi \to \mu^+\mu^-$, which unambiguously gives the $J^{PC} = 1^{++}$ assignment.

See our note on "Developments in Heavy Quarkonium Spectroscopy".

Meson Particle Listings

$X(3900)^{\pm}$, $X(3900)^0$, $\chi_{c0}(2P)$

$X(3900)^{\pm}$

$I(J^P) = ?(1^+)$

Seen as a peak in the invariant mass distribution of the $J/\psi\pi^{\pm}$ system by BES3 (ABLIKIM 13T) in $e^+e^- \to \pi^+\pi^- J/\psi$ at c.m. energy of 4.42 GeV and by radiative return from e^+e^- collisions at $\sqrt{s}$ from 9.46 to 10.86 GeV at BELLE (LIU 13B). Angular analysis of ABLIKIM 14A favors the $J^P = 1^+$ assignment. Needs confirmation.

$\psi(4040)$ DECAY MODES

Due to the complexity of the $c\overline{c}$ threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective $\sqrt{s}$ near this particle's central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in $\sqrt{s}$ or absence thereof. See mode listing(s) for details and references.

[9] Reanalysis of data presented in BAI 02C. From a global fit over the center-of-mass energy region 3.7–5.0 GeV covering the $\psi(3770)$, $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ resonances. Phase angle fixed in the fit to $\delta = (130 \pm 46)^\circ$.

[10] Reanalysis of data presented in BAI 00 and BAI 02C. From a global fit over the center-of-mass energy 3.8–4.8 GeV covering the $\psi(4040)$, $\psi(4160)$ and $\psi(4415)$ resonances and including interference effects. Four sets of solutions are obtained with the same fit quality, mass and total width, but with different e^+e^- partial widths. We quote only the range of values.

[11] From a fit to Crystal Ball (OSTERHELD 86) data.

[12] From a fit to BES (BAI 02C) data.

$\psi(4160)$ DECAY MODES

Due to the complexity of the $c\overline{c}$ threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective $\sqrt{s}$ near this particle's central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in $\sqrt{s}$ or absence thereof. See mode listing(s) for details and references.

$X(4260)$

$I^G(J^{PC}) = ?^?(1^{--})$

Seen in radiative return from e^+e^- collisions at $\sqrt{s} = 9.54$–10.58 GeV by AUBERT,B 05I, HE 06B, and YUAN 07, and in e^+e^- collisions at $\sqrt{s} \approx 4.26$ GeV by COAN 06. Possibly seen by AUBERT 06 in $B^- \to K^-\pi^+\pi^-J/\psi$. See also the mini-review under the $X(3872)$. (See the index for the page number.)

$\psi(4415)$ DECAY MODES

Due to the complexity of the $c\overline{c}$ threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective $\sqrt{s}$ near this particle's central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in $\sqrt{s}$ or absence thereof. See mode listing(s) for details and references.

$X(4430)^{\pm}$

$I(J^P) = ?(1^+)$

OMITTED FROM SUMMARY TABLE

Spin and parity assigment $J^P = 1^+$ is favored over 0^-, 1^-, 2^-, and 2^+ at the levels of 3.4 σ, 3.7 σ, 4.7 σ, and 5.1 σ, respectively, according to the four-dimensional amplitude analysis of CHILIKIN 13. Seen by CHOI 08 in $B \to K\pi^+\psi(2S)$ decays and confirmed by reanalysis of the same data sample in MIZUK 09. Not seen by AUBERT 09AA.

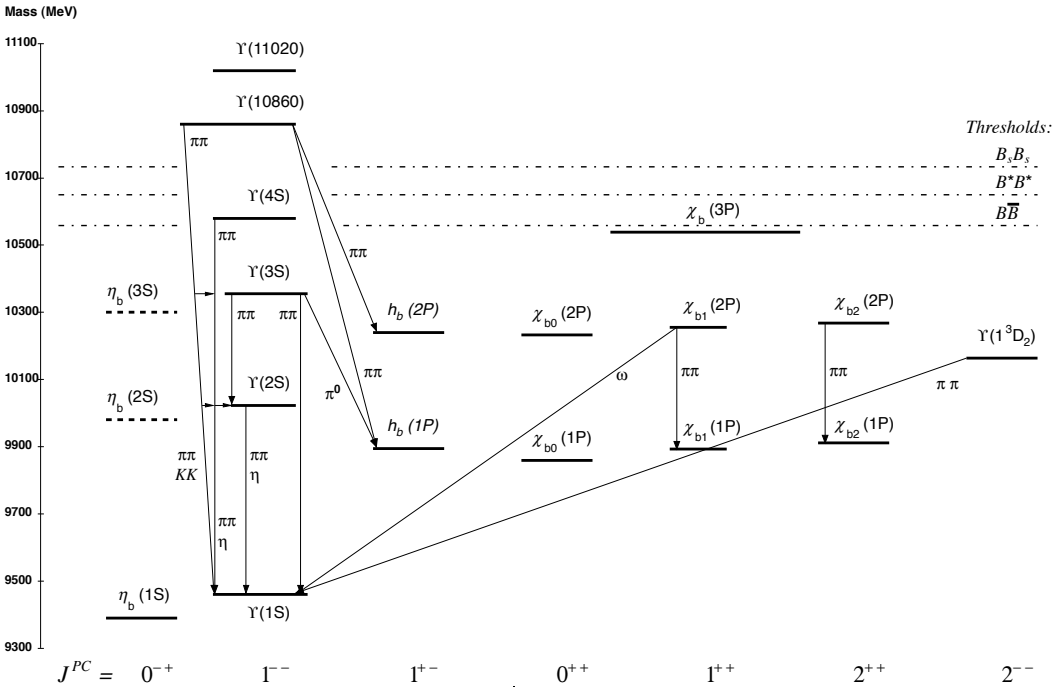
$b\bar{b}$ MESONS

THE BOTTOMONIUM SYSTEM



The level scheme of the $b\bar{b}$ states showing experimentally established states with solid lines. Singlet states are called η_b and h_b, triplet states Υ and χ_{bJ}. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. *E.g.*, $h_b(2P)$ means 2^1P_1 with $n = 2$, $L = 1$, $S = 0$, $J = 1$, $PC = +-$. The figure shows observed hadronic transitions. The single photon transitions $\Upsilon(nS) \to \gamma\eta_b(mS)$, $\Upsilon(nS) \to \gamma\chi_{bJ}(mP)$, and $\chi_{bJ}(nP) \to \gamma\Upsilon(mS)$ are omitted for clarity.

WIDTH DETERMINATIONS OF THE Υ STATES

As is the case for the $J/\psi(1S)$ and $\psi(2S)$, the full widths of the $b\bar{b}$ states $\Upsilon(1S)$, $\Upsilon(2S)$, and $\Upsilon(3S)$ are not directly measurable, since they are much narrower than the energy resolution of the e^+e^- storage rings where these states are produced. The common indirect method to determine Γ starts from

$$\Gamma = \Gamma_{\ell\ell}/B_{\ell\ell} \ , \tag{1}$$

where $\Gamma_{\ell\ell}$ is one leptonic partial width and $B_{\ell\ell}$ is the corresponding branching fraction ($\ell = e$, μ, or τ). One then assumes e-μ-τ universality and uses

$$\Gamma_{\ell\ell} = \Gamma_{ee}$$

$$B_{\ell\ell} = \text{average of } B_{ee},\ B_{\mu\mu}, \text{ and } B_{\tau\tau} \ . \tag{2}$$

The electronic partial width Γ_{ee} is also not directly measurable at e^+e^- storage rings, only in the combination $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$, where $\Gamma_{\rm had}$ is the hadronic partial width and

$$\Gamma_{\rm had} + 3\Gamma_{ee} = \Gamma \ . \tag{3}$$

This combination is obtained experimentally from the energy-integrated hadronic cross section

$$\int_{\text{resonance}} \sigma(e^+e^- \to \Upsilon \to \text{hadrons})dE$$

$$= \frac{6\pi^2}{M^2}\frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma}C_r = \frac{6\pi^2}{M^2}\frac{\Gamma^{(0)}_{ee}\Gamma_{\rm had}}{\Gamma}C^{(0)}_r \ , \tag{4}$$

where M is the Υ mass, and C_r and $C^{(0)}_r$ are radiative correction factors. C_r is used for obtaining Γ_{ee} as defined in Eq. (1), and contains corrections from all orders of QED for describing $(b\bar{b}) \to e^+e^-$. The lowest order QED value $\Gamma^{(0)}_{ee}$, relevant for comparison with potential-model calculations, is defined by the lowest order QED graph (Born term) alone, and is about 7% lower than Γ_{ee}.

The Listings give experimental results on B_{ee}, $B_{\mu\mu}$, $B_{\tau\tau}$, and $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$. The entries of the last quantity have been re-evaluated consistently using the correction procedure of KURAEV 85. The partial width Γ_{ee} is obtained from the average values for $\Gamma_{ee}\Gamma_{\rm had}/\Gamma$ and $B_{\ell\ell}$ using

$$\Gamma_{ee} = \frac{\Gamma_{ee}\Gamma_{\rm had}}{\Gamma(1 - 3B_{\ell\ell})} \ . \tag{5}$$

The total width Γ is then obtained from Eq. (1). We do not list Γ_{ee} and Γ values of individual experiments. The Γ_{ee} values in the Meson Summary Table are also those defined in Eq. (1).

$\eta_b(1S)$

$I^G(J^{PC}) = 0^+(0^{-+})$

OMITTED FROM SUMMARY TABLE

Quantum numbers shown are quark-model predictions. Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$.

3.4 ±0.4 ±0.4		GILES	83	CLEO	$e^+e^- \to \tau^+\tau^-$

[8] BESSON 07 reports [$\Gamma(\Upsilon(1S) \to \tau^+\tau^-)/\Gamma_{total}$] / [B($\Upsilon(1S) \to \mu^+\mu^-$)] = 1.02 ± 0.02 ± 0.05 which we multiply by our best value B($\Upsilon(1S) \to \mu^+\mu^-$) = (2.48 ± 0.05) × 10^{-2}. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[9] Using B($\Upsilon(1S) \to ee$) = B($\Upsilon(1S) \to \mu\mu$) = 0.0256; not used for width evaluations.

[25] BESSON 11 reports $(4.0 \pm 1.3 \pm 0.6) \times 10^{-5}$ from a measurement of $[\Gamma(\Upsilon(1S) \to \gamma f_2'(1525))/\Gamma_{\text{total}}] \times [B(f_2'(1525) \to K\overline{K})]$ assuming $B(f_2'(1525) \to K\overline{K}) = (88.8 \pm 3.1) \times 10^{-2}$, which we rescale to our best value $B(f_2'(1525) \to K\overline{K}) = (88.7 \pm 2.2) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. The result also assumes $B(K_S^0 \to \pi^+\pi^-) = (69.20 \pm 0.05)\%$ and $B(f_2'(1525) \to K\overline{K}) = 4\, B(f_2'(1525) \to K_S^0 K_S^0)$.

[26] Assuming $B(f_2'(1525) \to K\overline{K}) = 0.71$.

$\chi_{b0}(1P)$

$I^G(J^{PC}) = 0^+(0^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b1}(1P)$

$I^G(J^{PC}) = 0^+(1^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 1$ from SKWARNICKI 87.

$\chi_{b2}(1P)$

$I^G(J^{PC}) = 0^+(2^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(2S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$. $J = 2$ from SKWARNICKI 87.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 11.8 for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Upsilon(1D)$

$I^G(J^{PC}) = 0^-(2^{--})$

First observed by BONVICINI 04 in the decay to $\gamma\gamma\,\Upsilon(1S)$ and confirmed by DEL-AMO-SANCHEZ 10R in the decay to $\pi^+\pi^-\,\Upsilon(1S)$. Data consistent with $J^P = 2^-$. The states with $J = 1$ and 3 also possibly seen, but need confirmation.

$\chi_{b0}(2P)$

$I^G(J^{PC}) = 0^+(0^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

Meson Particle Listings

$\chi_{b1}(2P)$

$\chi_{b1}(2P)$

$I^G(J^{PC}) = 0^+(1^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

$\chi_{b2}(2P)$

$I^G(J^{PC}) = 0^+(2^{++})$
J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore $C = +$. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore $P = +$.

12±4±1	45	[24] ASNER	08A	CLEO	$\Upsilon(3S) \to \gamma 3\pi^+3\pi^-2\pi^0$

[24] ASNER 08A reports $[\Gamma(\chi_{b2}(2P) \to 3\pi^+3\pi^-2\pi^0)/\Gamma_{total}] \times [B(\Upsilon(3S) \to \gamma\chi_{b2}(2P))] = (159 \pm 33 \pm 43)\times10^{-6}$ which we divide by our best value $B(\Upsilon(3S) \to \gamma\chi_{b2}(2P)) = (13.1 \pm 1.6)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
