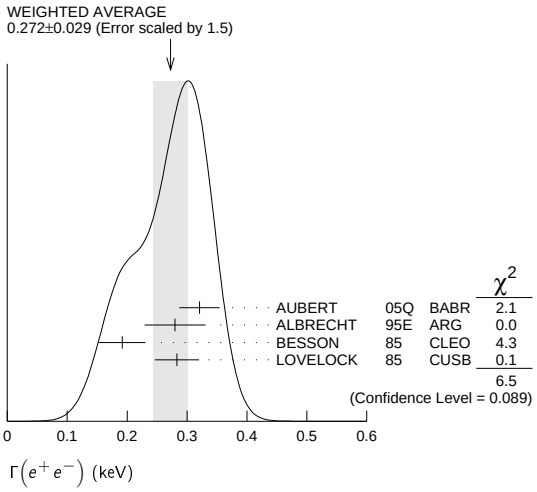
[3] Using LEYAOUANC 77 parametrization of $\Gamma(s)$.



$\Upsilon(4S)$ BRANCHING RATIOS

$B\overline{B}$ DECAYS

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the B^+/B^0 lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

$\Gamma(B^+B^-)/\Gamma_{total}$ Γ_2/Γ

VALUE	DOCUMENT ID
0.514±0.006 OUR EVALUATION	Assuming B($\Upsilon(4S) \to B\overline{B}$) = 1

$I^G(J^P) = ?^+(1^+)$

OMITTED FROM SUMMARY TABLE

Observed by BONDAR 12 in $\Upsilon(5S)$ decays to $\Upsilon(nS)\pi^+\pi^-$ (n = 1, 2, 3) and $h_b(mP)\pi^+\pi^-$ (m = 1, 2). $J^P = 1^+$ is favored from angular analyses.

10845 ±20	[6] LOVELOCK	85	CUSB	$e^+e^- \to$ hadrons

[1] In a model where a flat non-resonant $b\overline{b}$-continuum is incoherently added to a second flat component interfering with two Breit-Wigner resonances. Systematic uncertainties not estimated.
[2] The parameters of the $\Upsilon(11020)$ are fixed to those in AUBERT 09E.
[3] In a model where a flat nonresonant $\Upsilon(1S,2S,3S)\pi^+\pi^-$ continuum interferes with a single Breit-Wigner resonance.
[4] In a model where a non-resonant $b\overline{b}$-continuum represented by a threshold function at $\sqrt{s}=2m_B$ is incoherently added to a flat component interfering with two Breit-Wigner resonances. Not independent of other AUBERT 09E results. Systematic uncertainties not estimated.
[5] Assuming four Gaussians with radiative tails and a single step in R.
[6] In a coupled-channel model with three resonances and a smooth step in R.

$0.721^{+0.039}_{-0.038}\pm0.050$	711	DRUTSKOY	10	BELL	$\Upsilon(5S)\to B^+X$

[13] Not independent of DRUTSKOY 10 values for $\Upsilon(5S)\to B^{\pm,0}$ anything.
[14] Using measurements or limits from AQUINES 06.
[15] Assuming isospin conservation.
[16] Supersedes DRUTSKOY 07.
[17] Supersedes ARTUSO 05B. Combining inclusive ϕ, D_s, and B measurements. Using $B(D_s^+\to\phi\pi^+)=4.4\pm0.6\%$ from PDG 06.
[18] Using $B(D_s^+\to\phi\pi^+)=(4.4\pm0.6)\%$ from PDG 06.
[19] Uses a model-dependent estimate $B(B_s\to D_sX)=(92\pm11)\%$.
[20] Supersedes LOUVOT 09.
[21] With $N(B_s^{(*)}\overline{B}_s^{(*)})=(7.11\pm1.30)\times10^6$.
[22] The ratios $N(B_s^*\overline{B}_s^*)$ / $N(B_s^{(*)}\overline{B}_s^{(*)})$ and $N(B_s^*\overline{B}_s^0)$ / $N(B_s^{(*)}\overline{B}_s^{(*)})$ are measured with a correlation coefficient of -0.72.
[23] From a measurement of $\sigma(e^+e^-\to B_s^*\overline{B}_s^*)$ / $\sigma(e^+e^-\to B_s^{(*)}\overline{B}_s^{(*)})$ at $\sqrt{s}=10.86$ GeV.
[24] Assuming that the observed events are solely due to the $\Upsilon(5S)$ resonance.
[25] ARTUSO 05B reports $[\Gamma(\Upsilon(10860)\to D_s\text{ anything + c.c.})/\Gamma_{\text{total}}]\times[B(D_s^+\to\phi\pi^+)]=0.0198\pm0.0019\pm0.0038$ which we divide by our best value $B(D_s^+\to\phi\pi^+)=(4.5\pm0.4)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<2 × 10^{-5}		[7] HUGHES	92	RVUE	

[5] HORI 01, HORI 03, HORI 06, and HORI 11 use the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 99 (see above) to get their results. Their results are not independent of the HORI 01, HORI 03, HORI 06, and HORI 11 values for $|m_p-m_{\overline{p}}|/m_p$, above.

[6] TORII 99 uses the more-precisely-known constraint on the $\overline{p}$ charge-to-mass ratio of GABRIELSE 95 (see above) to get this result. This is not independent of the TORII 99 value for $|m_p-m_{\overline{p}}|/m_p$, above.

[7] HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.

$|q_p + q_e|/e$

See BRESSI 11 for a summary of experiments on the neutrality of matter.
See also "n CHARGE" in the neutron Listings.

VALUE	DOCUMENT ID		COMMENT
<1 × 10^{-21}	[8] BRESSI	11	Neutrality of SF_6
• • • We do not use the following data for averages, fits, limits, etc. • • •			
<3.2 × 10^{-20}	[9] SENGUPTA	00	binary pulsar
<0.8 × 10^{-21}	MARINELLI	84	Magnetic levitation
<1.0 × 10^{-21}	[8] DYLLA	73	Neutrality of SF_6

[8] BRESSI 11 uses the method of DYLLA 73 but finds serious errors in that experiment that greatly reduce its accuracy. The BRESSI 11 limit assumes that $n \rightarrow p e^- \nu_e$ conserves charge. Thus the limit applies equally to the charge of the neutron.

[9] SENGUPTA 00 uses the difference between the observed rate of of rotational energy loss by the binary pulsar PSR B1913+16 and the rate predicted by general relativity to set this limit. See the paper for assumptions.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
11.7 ±0.8 ±0.7	[17] BARANOV	01	RVUE	Global average
12.5 ±0.6 ±0.9	MACGIBBON	95	CNTR	γp Compton scattering
9.8 ±0.4 ±1.1	HALLIN	93	CNTR	γp Compton scattering
$10.62 ^{+1.25}_{-1.19} ^{+1.07}_{-1.03}$	ZIEGER	92	CNTR	γp Compton scattering
10.9 ±2.2 ±1.3	[18] FEDERSPIEL	91	CNTR	γp Compton scattering

[13] BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_N = (13.0 \pm 1.9 ^{+3.9}_{-1.5}) \times 10^{-4}$ fm^3 and $\beta_N = (-1.8 \pm 1.9 ^{+2.1}_{-0.9}) \times 10^{-4}$ fm^3.

[14] BLANPIED 01 gives $\alpha_p + \beta_p$ and $\alpha_p - \beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.

[15] This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4}$ fm^3. See the paper for a discussion.

[16] MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.

[17] BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

[18] FEDERSPIEL 91 obtains for the (static) electric polarizability α_p, defined in terms of the induced electric dipole moment by $\mathbf{D} = 4\pi\epsilon_0\alpha_p\mathbf{E}$, the value $(7.0 \pm 2.2 \pm 1.3) \times 10^{-4}$ fm^3.

p MAGNETIC POLARIZABILITY β_p

The electric and magnetic polarizabilities are subject to a dispersion sum-rule constraint $\overline{\alpha} + \overline{\beta} = (14.2 \pm 0.5) \times 10^{-4}$ fm^3. Errors here are anticorrelated with those on $\overline{\alpha}_p$ due to this constraint.

VALUE (10^{-4} fm^3)	DOCUMENT ID		TECN	COMMENT

[19] BEANE 03 uses effective field theory and low-energy γp and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_N = (13.0 \pm 1.9 ^{+3.9}_{-1.5}) \times 10^{-4}$ fm^3 and $\beta_N = (-1.8 \pm 1.9 ^{+2.1}_{-0.9}) \times 10^{-4}$ fm^3.

[20] BLANPIED 01 gives $\alpha_p + \beta_p$ and $\alpha_p - \beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from the model.

[21] This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (re-evaluated) sum-rule constraint that $\alpha + \beta = (13.8 \pm 0.4) \times 10^{-4}$ fm^3. See the paper for a discussion.

[22] MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.

[23] BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

p CHARGE RADIUS

This is the rms electric charge radius, $\sqrt{\langle r_E^2 \rangle}$.

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is $r_p = 0.879(8)$ fm (BERNAUER 10). The CODATA 10 value (MOHR 12), obtained from the electronic results, is 0.8775(51). However, a measurement using muonic hydrogen finds $r_p = 0.84087(39)$ fm (ANTOGNINI 13), which is 13 times more precise and seven standard deviations (using the CODATA 10 error) from the electronic results.

Since POHL 10 (the first μp result), there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, and HILL 11.

Until the difference between the ep and μp values is understood, it does not make sense to average the values together. For the present, we give both values. It is up to workers in this field to solve this puzzle.

p MEAN LIFE

A test of baryon conservation. See the "p Partial Mean Lives" section below for limits for identified final states. The limits here are to "anything" or are for "disappearance" modes of a bound proton (p) or (n). See also the 3ν modes in the "Partial Mean Lives" section. Table 1 of BACK 03 is a nice summary.

[25] ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the s shell of ^{12}C.
[26] AHMED 04 looks for γ rays from the de-excitation of a residual ^{15}O* or ^{15}N* following the disappearance of a neutron or proton in ^{16}O.
[27] BACK 03 looks for decays of unstable nuclides left after N decays of parent ^{12}C, ^{13}C, ^{16}O nuclei. These are "invisible channel" limits.
[28] ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO data in AHMAD 02.
[29] AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.
[30] BERNABEI 00B looks for the decay of a $^{128}_{53}$I nucleus following the disappearance of a proton in the otherwise-stable $^{129}_{54}$Xe nucleus.
[31] EVANS 77 looks for the daughter nuclide ^{129}Xe from possible ^{130}Te decays in ancient Te ore samples.
[32] This mean-life limit has been obtained from a half-life limit by dividing the latter by ln(2) = 0.693.
[33] FLEROV 58 looks for the spontaneous fission of a ^{232}Th nucleus after the disappearance of one of its nucleons.

$\overline{p}$ MEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also "$\overline{p}$ Partial Mean Lives" after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is 7×10^5 years, for $\overline{p} \to e^- \gamma$. We advance only the exclusive-mode limits to our Summary Tables.

LIMIT (years)	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
$>8 \times 10^5$	90		[34] GEER	00D		$\overline{p}/p$ ratio, cosmic rays
>0.28			GABRIELSE	90	TRAP	Penning trap

$>1 \times 10^7$			GOLDEN	79	SPEC	$\overline{p}/p$ ratio, cosmic rays
$>3.7 \times 10^{-3}$			BREGMAN	78	CNTR	Storage ring

[34] GEER 00D uses agreement between a model of galactic $\overline{p}$ production and propagation and the observed $\overline{p}/p$ cosmic-ray spectrum to set this limit.

p DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

	Mode	Partial mean life (10^{30} years)	Confidence level
	Antilepton + meson

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p = proton, n = bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

>0.000012	90	5	9.7	BERGER	91B	FREJ	τ per iron nucleus

[74] ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of two neutrons from the s shell of ^{12}C.

[75] TRETYAK 04 uses data from an old Homestake-mine radiochemical experiment on limits for invisible decays of ^{39}K to ^{37}Ar.

[76] BACK 03 looks for decays of unstable nuclides left after NN decays of parent ^{12}C, ^{13}C, ^{16}O nuclei. These are "invisible channel" limits.

[77] BERNABEI 00B looks for the decay of a $^{127}_{54}$Xe nucleus following the disappearance of an nn pair in the otherwise-stable $^{129}_{54}$Xe nucleus. The limit here applies as well to $nn \to \nu_\mu\overline{\nu}_\mu$, $nn \to \nu_\tau\overline{\nu}_\tau$, or any "disappearance" mode.

$\tau(nn \to \nu_\mu\overline{\nu}_\mu)$ τ_{74}

See the proceeding data block. "Invisible modes" would include any multi-neutrino mode.

n

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ****

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Anyone interested in the neutron should look at these two new review articles: D. Dubbers and M.G. Schmidt, "The neutron and its role in cosmology and particle physics," Reviews of Modern Physics **83** 1111 (2011); and F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," Reviews of Modern Physics **83** 1173 (2011).

n MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

VALUE (u)	DOCUMENT ID		TECN	COMMENT

939.56564 ±0.00028 [3,4]	GREENE	86	SPEC	$np \to d\gamma$
939.5731 ±0.0027 [3]	COHEN	73	RVUE	1973 CODATA value

[1] We use the 1998 CODATA u-to-MeV conversion factor (see the heading above) to get this mass in MeV from the much more precisely measured KESSLER 99 value of 1.00866491637 ± 0.00000000082 u.

[2] The mass is known much more precisely in u: m = 1.0086649235 ± 0.0000000023 u. We use the 1986 CODATA conversion factor to get the mass in MeV.

[3] These determinations are not independent of the $m_n - m_p$ measurements below.

[4] The mass is known much more precisely in u: m = 1.008664919 ± 0.000000014 u.

$\overline{n}$ MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
939.485±0.051	59	[5] CRESTI	86	HBC	$\overline{p}p \to \overline{n}n$

[5] This is a corrected result (see the erratum). The error is statistical. The maximum systematic error is 0.029 MeV.

$(m_n - m_{\overline{n}})/\, m_n$

A test of CPT invariance. Calculated from the n and $\overline{n}$ masses, above.

1.293429 ±0.000036	COHEN	73	RVUE	1973 CODATA value

[6] The 2010 CODATA mass difference in u is $m_n - m_p$ = 1.388 449 19(45) × $10^{-3}u$.

[7] Calculated by us from the MOHR 08 ratio m_n/m_p = 1.00137841918(46). In u, $m_n - m_p$ = 1.38844920(46) × 10^{-3} u.

[8] Calculated by us from the MOHR 05 ratio m_n/m_p = 1.00137841870 ± 0.00000000058. In u, $m_n - m_p$ = (1.3884487 ± 0.0000006) × 10^{-3} u.

[9] Calculated by us from the MOHR 99 ratio m_n/m_p = 1.00137841887 ± 0.00000000058. In u, $m_n - m_p$ = (1.3884489 ± 0.0000006) × 10^{-3} u.

[10] Calculated by us from the COHEN 87 ratio m_n/m_p = 1.001378404 ± 0.000000009. In u, $m_n - m_p$ = 0.001388434 ± 0.000000009 u.

n MEAN LIFE

Limits on lifetimes for *bound* neutrons are given in the section "p PARTIAL MEAN LIVES."

The mean life of the neutron, 878.5 ± 0.8 s, obtained by SEREBROV 05 (for a more detailed account, see SEREBROV 08A; and for comments on the systematic error for this result, see STEYERL 10) was so far from our average of seven other measurements, 885.7 ± 0.8 s, that it made no sense to include it in our average. Thus our 2006, 2008, and 2010 *Reviews* stayed with 885.7 ± 0.8 s; but we noted that in light of SEREBROV 05 our value should be regarded as suspect until further experiments clarified matters.

However, after our 2010 *Review*, PICHLMAIER 10 obtained a mean life of 880.7 ± 1.8 s, and we averaged the best seven results to get 881.5 ± 1.5 s for our 2011 off-year web update. Since then, ARZUMANOV 12, responding to comments of SEREBROV 10B, recalculated the systematic corrections to its 2000 measurement (ARZUMANOV 00) and lowered its value from 885.4 ± 0.9 ± 0.4 s to 881.6 ± 0.8 ± 1.9 s. And STEYERL 12 reanalyzed systematic corrections to MAMPE 89 and lowered its value from 887.6 ± 3.0 to 882.5 ± 1.4 ± 1.5 s. Thus the trend is definitely toward a shorter lifetime.

There seems little better to do than to again average the best seven measurements. The result, 880.3 ± 1.1 s (including a scale factor of 1.9), is 5.4 seconds lower than the value we gave in 2010—a drop of 6.8 old and 4.9 new standard deviations.

For a full review of all matters concerning the neutron lifetime, see F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," Reviews of Modern Physics **83** 1173 (2011). In particular, there is a full discussion of the experimental methods and results; and an average lifetime is obtained making several different selections of those results. (The revised ARZUMANOV 12 mean life was not yet available.)

[11] YUE 13 differs from NICO 05 in that a different and better method was used to measure the neutron density in the fiducial volume. This shifted the lifetime by +1.4 seconds and reduced the previously largest source of systematic uncertainty by a factor of five.

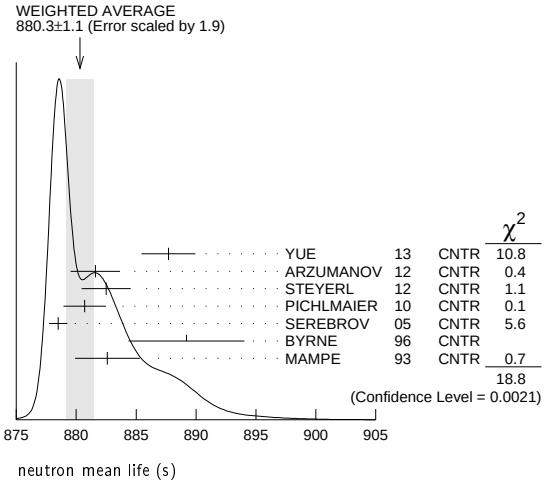
[12] ARZUMANOV 12 reanalyzes its systematic corrections in ARZUMANOV 00 and obtains this corrected value.

[13] STEYERL 12 is a detailed reanalysis of neutron storage loss corrections to the raw data of MAMPE 89, and it replaces that value.

[14] IGNATOVICH 95 calls into question some of the corrections and averaging procedures used by MAMPE 93. The response, BONDARENKO 96, denies the validity of the criticisms.

[15] The NESVIZHEVSKII 92 measurement has been withdrawn by A. Serebrov.

[16] The BYRNE 80 measurement has been withdrawn (J. Byrne, private communication, 1990).



n MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the Λ Listings.

[18] LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

[19] This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the results of these two experiments has been criticized by LAMOREAUX 00.

n MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron, $\langle r_n^2 \rangle$, is related to the neutron-electron scattering length b_{ne} by $\langle r_n^2 \rangle = 3(m_e a_0/m_n) b_{ne}$, where m_e and m_n are the masses of the electron and neutron, and a_0 is the Bohr radius. Numerically, $\langle r_n^2 \rangle = 86.34\, b_{ne}$, if we use a_0 for a nucleus with infinite mass.

LIMIT ON $n\overline{n}$ OSCILLATIONS

Mean Time for $n\overline{n}$ Transition in Vacuum

A test of ΔB=2 baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 89 discuss the theoretical motivations for looking for $n\overline{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for $n \to \overline{n}$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

[35] NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition ^{71}Ga → ^{71}Ge+neutrals rather than to solar-neutrino reactions.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[f_1(q^2)\gamma_\lambda + i\, f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5 q_\lambda \right] B_i \ . \quad (1)$$

Here B_i and $\overline{B}_f$ are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1, f_2, g_1, and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V, and g_1 reduces to the axial-vector coupling constant g_A. The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an $e^\pm$ is emitted, and gives a very small correction, which can be estimated by PCAC [4], for $\mu^\pm$ modes. Recoil effects

include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f} \ , \tag{2}$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2, it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |\, g_A/g_V \,| \, e^{i\phi_{AV}} \ . \tag{3}$$

The presence of a "triple correlation" term in the transition probability, proportional to $\mathrm{Im}(g_A/g_V)$ and of the form

$$\boldsymbol{\sigma}_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \tag{4}$$

for initial baryon polarization or

$$\boldsymbol{\sigma}_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu) \tag{5}$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F \, m_\pi^2 \cdot \overline{B}_f \, (A - B\gamma_5) \, B_i \ , \tag{6}$$

where A and B are constants [1]. The transition rate is proportional to

$$\begin{aligned} R = 1 &+ \gamma \, \widehat{\boldsymbol{\omega}}_f \cdot \widehat{\boldsymbol{\omega}}_i + (1-\gamma)(\widehat{\boldsymbol{\omega}}_f \cdot \widehat{\mathbf{n}})(\widehat{\boldsymbol{\omega}}_i \cdot \widehat{\mathbf{n}}) \\ &+ \alpha(\widehat{\boldsymbol{\omega}}_f \cdot \widehat{\mathbf{n}} + \widehat{\boldsymbol{\omega}}_i \cdot \widehat{\mathbf{n}}) + \beta \widehat{\mathbf{n}} \cdot (\widehat{\boldsymbol{\omega}}_f \times \widehat{\boldsymbol{\omega}}_i) \ , \end{aligned} \tag{7}$$

where $\widehat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\widehat{\boldsymbol{\omega}}_i$ and $\widehat{\boldsymbol{\omega}}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α, β, and γ are defined as

$$\begin{aligned} \alpha &= 2\,\mathrm{Re}(s^* p)/(\,|\,s\,|^2 + |\,p\,|^2) \ , \\ \beta &= 2\,\mathrm{Im}(s^* p)/(\,|\,s\,|^2 + |\,p\,|^2) \ , \\ \gamma &= (\,|\,s\,|^2 - |\,p\,|^2)/(\,|\,s\,|^2 + |\,p\,|^2) \ , \end{aligned} \tag{8}$$

where $s = A$ and $p = |\,\mathbf{p}_f\,| B/(E_f + m_f)$; here E_f and $\mathbf{p}_f$ are the energy and momentum of the final baryon. The parameters α, β, and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 \ . \tag{9}$$

If the hyperon polarization is $\mathbf{P}_Y$, the polarization $\mathbf{P}_B$ of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \widehat{\mathbf{n}})\widehat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \widehat{\mathbf{n}}) + \gamma \widehat{\mathbf{n}} \times (\mathbf{P}_Y \times \widehat{\mathbf{n}})}{1 + \alpha \mathbf{P}_Y \cdot \widehat{\mathbf{n}}} \ . \tag{10}$$

Here $\mathbf{P}_B$ is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\widehat{\mathbf{n}}$ from the hyperon rest frame, in which $\widehat{\mathbf{n}}$ and $\mathbf{P}_Y$ are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\phi \ . \tag{11}$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α, ϕ, and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |\,s\,| \, e^{i\delta_s} \text{ and } p = |\,p\,| \, e^{i\delta_p} \ , \tag{12}$$

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2\,|\,s\,|\,|\,p\,|}{|\,s\,|^2 + |\,p\,|^2} \sin(\delta_s - \delta_p) \ . \tag{13}$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

See also the note on "Radiative Hyperon Decays" in the Ξ^0 Listings in this *Review*.

$n \to p e^- \bar{\nu}_e$ DECAY PARAMETERS

See the above "Note on Baryon Decay Parameters." For discussions of recent results, see the references cited at the beginning of the section on the neutron mean life. For discussions of the values of the weak coupling constants g_A and g_V obtained using the neutron lifetime and asymmetry parameter A, comparisons with other methods of obtaining these constants, and implications for particle physics and for astrophysics, see DUBBERS 91 and WOOLCOCK 91. For tests of the $V-A$ theory of neutron decay, see EROZOLIMSKII 91B, MOSTOVOI 96, NICO 05, SEVERIJNS 06, and ABELE 08.

$\lambda \equiv g_A / g_V$

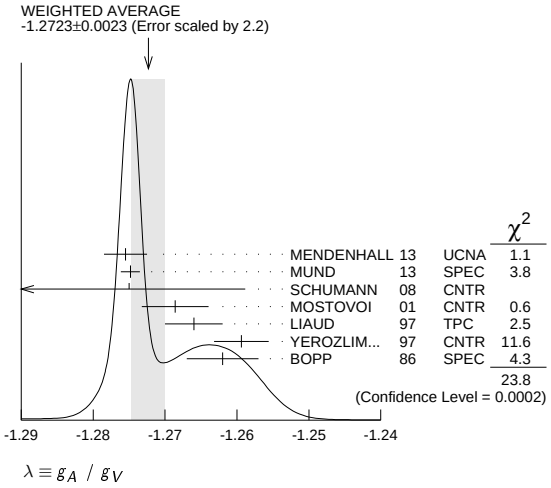
[36] MENDENHALL 13 gets $A = -0.11954 \pm 0.00055 \pm 0.00098$ and $\lambda = -1.2756 \pm 0.0030$. We quote the nearly identical values that include the earlier UCNA measurement (PLASTER 12), with a correction to that result.
[37] This MUND 13 value includes earlier PERKEO II measurements (ABELE 02 and ABELE 97D).
[38] MOSTOVOI 01 measures the two *P*-odd correlations *A* and *B*, or rather *SA* and *SB*, where *S* is the *n* polarization, in free neutron decay.
[39] YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.
[40] This PLASTER 12 value is identical with that given in LIU 10, but the experiment is now described in detail.
[41] This is the combined result of ABELE 02 and ABELE 97D.
[42] These experiments measure the absolute value of g_A/g_V only.
[43] KROHN 75 includes events of CHRISTENSEN 70.
[44] KROPF 74 reviews all data through 1972.



$\lambda \equiv g_A / g_V$

e^- ASYMMETRY PARAMETER *A*

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model, *A* is related to $\lambda \equiv g_A/g_V$ by $A = -2\lambda(\lambda+1)/(1+3\lambda^2)$; this assumes that g_A and g_V are real.

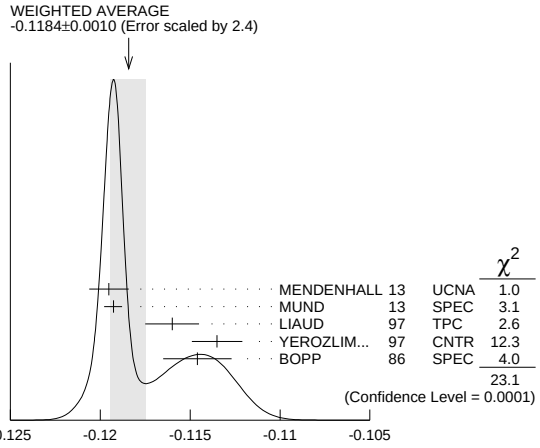
[45] MENDENHALL 13 gets $A = -0.11954 \pm 0.00055 \pm 0.00098$ and $\lambda = -1.2756 \pm 0.0030$. We quote the nearly identical values that include the earlier UCNA measurement (PLASTER 12), with a correction to that result.
[46] This MUND 13 value includes earlier PERKEO II measurements (ABELE 02 and ABELE 97D), with a correction to those results.
[47] YEROZOLIMSKY 97 makes a correction to the EROZOLIMSKII 91 value.
[48] This PLASTER 12 value is identical with that given in LIU 10, but the experiment is now described in detail.
[49] This is the combined result of ABELE 02 and ABELE 97D.
[50] MOSTOVOI 01 calculates this from its measurement of $\lambda = g_A/g_V$ above.
[51] These results are not corrected for radiative effects and weak magnetism, but the corrections are small compared to the errors.



e^- asymmetry parameter *A*

$\bar{\nu}_e$ ASYMMETRY PARAMETER *B*

This is the neutron-spin antineutrino-momentum correlation coefficient. In the Standard Model, *B* is related to $\lambda \equiv g_A/g_V$ by $B = 2\lambda(\lambda-1)/(1+3\lambda^2)$; this assumes that g_A and g_V are real.

VALUE	DOCUMENT ID		TECN	COMMENT

0.9876±0.0004	[52] MOSTOVOI	01	CNTR	Inferred

[52] MOSTOVOI 01 calculates this from its measurement of $\lambda = g_A/g_V$ above.

PROTON ASYMMETRY PARAMETER *C*

Describes the correlation between the neutron spin and the proton momentum. In the Standard Model, *C* is related to $\lambda \equiv g_A/g_V$ by $C = -x_c(A+B) = x_c\, 4\lambda/(1+3\lambda^2)$, where $x_c = 0.27484$ is a kinematic factor; this assumes that g_A and g_V are real.

VALUE	DOCUMENT ID		TECN	COMMENT
−0.2377±0.0010±0.0024	SCHUMANN	08	CNTR	Cold *n*, polarized

e-$\bar{\nu}_e$ ANGULAR CORRELATION COEFFICIENT *a*

For a review of past experiments and plans for future measurements of the *a* parameter, see WIETFELDT 05. In the Standard Model, *a* is related to $\lambda \equiv g_A/g_V$ by $a = (1-\lambda^2)/(1+3\lambda^2)$; this assumes that g_A and g_V are real.

−0.1045±0.0014	[53]	MOSTOVOI	01	CNTR	Inferred

[53] MOSTOVOI 01 calculates this from its measurement of $\lambda=g_A/g_V$ above.

ϕ_{AV}, PHASE OF g_A RELATIVE TO g_V

Time reversal invariance requires this to be 0 or 180°. This is related to D given in the next data block and $\lambda \equiv g_A/g_V$ by $\sin(\phi_{AV}) \equiv D(1+3\lambda^2)/2|\lambda|$; this assumes that g_A and g_V are real.

−27 ±50	[55] EROZOLIM...	74	CNTR	Cold n, polarized
−11 ±17	STEINBERG	74	CNTR	Cold n, polarized

[55] EROZOLIMSKII 78 says asymmetric proton losses and nonuniform beam polarization may give a systematic error up to 30×10^{-4}, thus increasing the EROZOLIMSKII 74 error to 50×10^{-4}. STEINBERG 74 and STEINBERG 76 estimate these systematic errors to be insignificant in their experiment.

TRIPLE CORRELATION COEFFICIENT R

Another test of time-reversal invariance. R measures the polarization of the electron in the direction perpendicular to the plane defined by the neutron spin and the electron momentum. $R = 0$ for T invariance.

VALUE	DOCUMENT ID		TECN	COMMENT
+0.004±0.012±0.005	[56] KOZELA	12	CNTR	Mott polarimeter
• • • We do not use the following data for averages, fits, limits, etc. • • •

N AND Δ RESONANCES

Revised Sept. 2013 by V. Burkert (Jefferson Lab), E. Klempt (University of Bonn), M.R. Pennington (Jefferson Lab), L. Tiator (University of Mainz), and R.L. Workman (George Washington University).

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The Breit-Wigner masses and widths, the pole positions, and the elasticities of the N and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller πN reaction data sets to get ηN, $K\Lambda$, and $K\Sigma$ branching fractions (see the Listings for references). Other branching fractions come from analyses of $\pi N \to \pi\pi N$ data.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to tell us much about the properties of baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in recent reviews [6,7].

II. Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic πN scattering, it was common to label resonances with the incoming partial wave $L_{2I,2J}$, as in $\Delta(1232)P_{33}$ and $N(1680)F_{15}$. However, most recent information has come from γN experiments. Therefore, we have replaced $L_{2I,2J}$ with the spin-parity J^P of the state, as in $\Delta(1232)3/2^+$ and $N(1680)5/2^+$; this name gives intrinsic properties of the resonance that are independent of the specific particles and reactions used to study them. This applies equally to all baryons, including Ξ resonances and charm baryons that are not produced in formation experiments. We do not, however, attach the mass or spin-parity to the names of the ground-state ("stable") baryons $N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \cdots$.

III. Using the *N* and Δ listings

Tables 1 and 2 list all the N and Δ entries in the Baryon Listings and give our evaluation of the overall status, the status from $\pi N \to \pi N$ scattering data and from photoproduction experiments, and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We long ago omitted from the Listings information from old analyses, prior to KH80 and CMB80, which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [8].

As a rule, we award an overall status **** or *** only to those resonances which are derived from analyses of data sets that include precision differential cross sections and polarization observables, and are confirmed by independent analyses. All other signals are given ** or * status. We do not consider new results that are not accompanied by proper error evaluation. The following criteria are guidelines for future error analysis.

1. Uncertainties in resonance parameters: The publication must have a detailed discussion on how the uncertainties of parameters were estimated and why the author(s) believe that they approximately represent real uncertainties. This requires that the error estimates go beyond the simple fit error as e.g. given by MINUIT, and the robustness of the results must be demonstrated.

2. Fit quality: Concrete measures for the fit quality must be provided. The reduced global χ^2 value of the fit, while useful, is insufficient. Other possibilities include quoting variations of local χ^2 value in kinematic regions where evidence for new states or significantly improved information on resonance parameters is claimed.

3. Weight factors in observables: Analyses often use weight factors for certain data sets to either increase or reduce their impact on the results. This has been particularly important when polarization observables are involved, which usually are very sensitive to amplitude interferences but often have much poorer statistics than differential cross section data. To evaluate sensitivities, the resulting resonance parameters should be checked against variations of the specific weight factors.

In future, we intend to give – for **** and *** resonances – statistical *averages* and not only *our estimates*. This requires carefully determined statistical and systematic errors. The errors in Arndt 06 and Shrestha 12 in the Listings below are statistical errors only. They will hence not be used to define *averages* but may serve to establish the star ratings and to define *our estimates* of particle properties.

IV. Properties of resonances

Resonances are defined by poles of the S-matrix, whether in scattering, production or decay matrix elements. These are

poles in the complex plane in s, as discussed in the new review on *Resonances*. As traditional we quote here the pole positions in the complex energy $w = \sqrt{s}$ plane. Crucially, the position of the pole of the S-matrix is independent of the process, and the production and decay properties factorize. This is the rationale for listing the pole position first for each resonance.

Table 1. The status of the N resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

					Status as seen in —						
Particle	J^P	Status overall	πN	γN	$N\eta$	$N\sigma$	$N\omega$	ΛK	ΣK	$N\rho$	$\Delta\pi$

**** Existence is certain, and properties are at least fairly well explored.
*** Existence is very likely but further confirmation of quantum numbers and branching fractions is required.
** Evidence of existence is only fair.
* Evidence of existence is poor.

These key properties of the S-matrix pole are in contrast to other quantities related to resonance phenomena, such as Breit-Wigner parameters or any K-matrix pole. Thus, Breit-Wigner parameters depend on the formalism used such as angular-momentum barrier factors, or cut-off parameters, and the assumed or modeled background. However, the accurate determination of pole parameters from the analysis of data on the real energy axis is not necessarily simple, or even straightforward. It requires the implementation of the correct analytic structure of the relevant (often coupled) channels. The example in the meson sector of the σ-pole highlights the need to incorporate right and left hand cut analyticity (and their relation imposed by crossing symmetry) into a dispersive analysis to obtain a robust determination of the pole position, for a very short-lived state close to the lowest threshold. The development of general methods that are simpler to implement in the baryon sector is a research problem of current interest, often exploiting techniques introduced long ago when the experimental data were far poorer than those presently available for reactions like $\gamma N \to \pi N$ [9]. No consensus yet exists for the use of any particular method, beyond the need to incorporate the general properties mentioned here and discussed more fully in the review of *Resonances*. This is an area we expect to be able to update in the next issue of the RPP.

To repeat: pole parameters appear first in the listings, then the Breit-Wigner mass and width parameters. Then we give "pole related quantities" like residues and phases of hadronic transition amplitudes and helicity amplitudes. Branching ratios and photoproduction amplitudes follow.

Table 2. The status of the Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

					Status as seen in —

V. Photoproduction

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn, Grenoble, and Mainz, and at the national laboratories Jefferson Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables for the photoproduction of pseudoscalar mesons provide a data set that is nearly a "complete experiment," one that fully constrains the four complex amplitudes describing the spin-structure of the reaction [11]. A large number of photoproduction reactions has been studied.

In pseudo-scalar meson photoproduction, the four independent helicity amplitudes can be expressed in terms of the four

CGLN [12] amplitudes allowed by Lorentz and gauge invariance. These amplitudes can be expanded in a series of electric and magnetic multipoles. Except for J=1/2, one electric and one magnetic mulipole contributes to each J^P combination.

For a given state, these two amplitudes determine the resonance photo-decay helicity amplitudes $A_{1/2}$ and $A_{3/2}$. As described below, this resonance extraction has been carried out either assuming a Breit-Wigner resonance or at the pole.

If a Breit-Wigner parametrization is used, the $N\gamma$ partial width, Γ_γ, is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k_{\rm BW}^2}{\pi}\frac{2m_N}{(2J+1)m_{\rm BW}}\left(|A_{1/2}|^2+|A_{3/2}|^2\right) \ . \qquad (1)$$

Here m_N and $m_{\rm BW}$ are the nucleon and resonance masses, J is the resonance spin, and $k_{\rm BW}$ is the photon c.m. decay momentum. Most earlier analyses have quoted these real quantities $A_{1/2}$ and $A_{3/2}$.

More recent studies have quoted related complex quantities, evaluated at the T-matrix pole. These complex helicity amplitudes, $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$, can be cast onto the form

$$\tilde{A}_h = \sqrt{\frac{\pi(2J+1)w_{\rm pole}}{m_N k_{\rm pole}^2}}\frac{Res(T_h(\gamma N\to N\,b))}{\sqrt{Res(T\,(N\,b\to N\,b))}} \qquad (2)$$

where the residues (Res) are evaluated at the pole position, $w_{\rm pole}$, and $k_{\rm pole}^2=(w_{\rm pole}^2-m_N^2)^2/4w_{\rm pole}^2$ [13]. For Breit-Wigner amplitudes, $w_{\rm pole}=m_{\rm BW}$ and $\tilde{A}_h=A_h$. Similar relations for the photo- and electrocouplings at the pole position can be found in [14,15].

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent measurements. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization $P_\perp$, $P_\odot$ and $\vec{T}$, respectively); the recoil polarization of the outgoing baryon $\vec{R}$ can be measured. The experiments can be divided into three classes: (1) the beam and target are polarized (BT); (2) the beam is polarized and the recoil baryon polarization is measured (BR); (3) the target is polarized and the recoil polarization is measured (TR). Different sign conventions are used in the literature, as summarized in [16].

One of the best studied reactions is $\gamma p\to\Lambda K^+$. Published data include differential cross sections, the beam asymmetry Σ, the target asymmetry T, the recoil polarization P, and the BR double-polarization variables C_x', C_z', O_x', and O_z'. For the photoproduction of pions and etas, off proton and neutron targets, differential cross sections, single- and double-polarization asymmetries have been measured, mainly for pions.

VI. Electroproduction

Electro-production of mesons provides information on the internal structure of resonances. The helicity amplitudes are functions of the (squared) momentum transfer $Q^2=-(e-e')^2$, where e and e' are the 4-momenta of the incident and scattered electron, and a third amplitude, $S_{1/2}$, measures the resonance response to the longitudinal component of the virtual photon. Most data stem from the reactions $e^-p\to e^-\,n\pi^+$ and $e^-p\to e^-\,p\pi^0$ but also the reactions $e^-p\to e^-\,p\eta$, $e^-p\to e^-\,p\pi^+\pi^-$, and $e^-p\to e^-\,\Lambda(\Sigma^0)K^+$ have been studied. The data and their interpretation are reviewed in Refs. [18,19].

The transition to the $\Delta(1232)3/2^+$ is often quantified in terms of the magnetic dipole transition moment M_{1+} (or the magnetic transition form factor $G_{M,Ash}^*(Q^2)$) [20], and the electric and scalar quadrupole transition moments E_{1+} and S_{1+}. Fig. 1 shows the strength of the $p\to\Delta^+$ transition plotted versus the photon virtuality Q^2. At $Q^2=0$, M_{1+} dominates the resonance transition strength. The two amplitudes E_{1+} and S_{1+} imply a quadrupole deformation of the transition to the lowest excited state. The magnitude of $R_{EM}=E_{1+}/M_{1+}$ remains nearly constant, while the magnitude of $R_{SM}=S_{1+}/M_{1+}$ increases rapidly up to 25% at the highest Q^2 value. Dynamical models assign most of the quadrupole strength in the $p\Delta^+$ transition to the effect of a meson cloud around the bare Δ states.

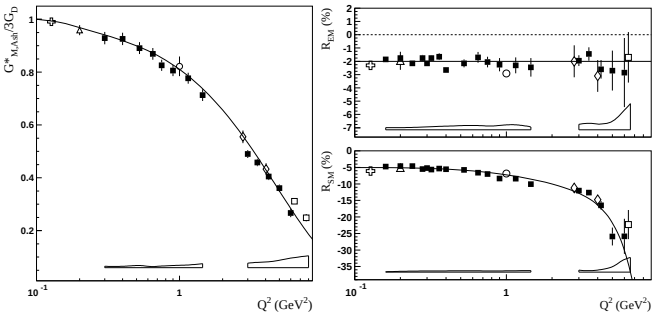

Figure 1: Left: The magnetic transition form factor for the $\gamma^*p\to\Delta^+(1232)$ transition versus the photon virtuality Q^2. Right: The electric and scalar quadrupole rations R_{EM} and R_{SM}. The different symbols are results from different experiments at JLab (squares, diamonds, circle) and MAMI (triangle, cross). The boxes near the horizontal axis indicate model uncertainties of the squares. Curves to guide the eyes. The figures are kindly provided by V. Burkert, JLab.

Fig. 2 shows the transverse and scalar helicity amplitudes for the $N(1440)1/2^+$, $N(1520)3/2^-$, and $N(1535)1/2^-$ resonances from JLab [18]. Similar results have been achieved at Mainz [19]. For the states $N(1440)1/2^+$ and $N(1520)3/2^-$, helicity amplitudes and $\pi\Delta$ and ρp decays were determined at JLab in an analysis of $\pi^+\pi^-p$ electroproduction [21]. The data show distinctly different Q^2 dependencies that indicate different internal structures.

The $N(1520)3/2^-$ helicity amplitudes reveal the dominance of its three-quark nature: the $A_{3/2}$ amplitude is large at the photon point and decreases rapidly $\sim Q^{-5}$ with increasing Q^2;

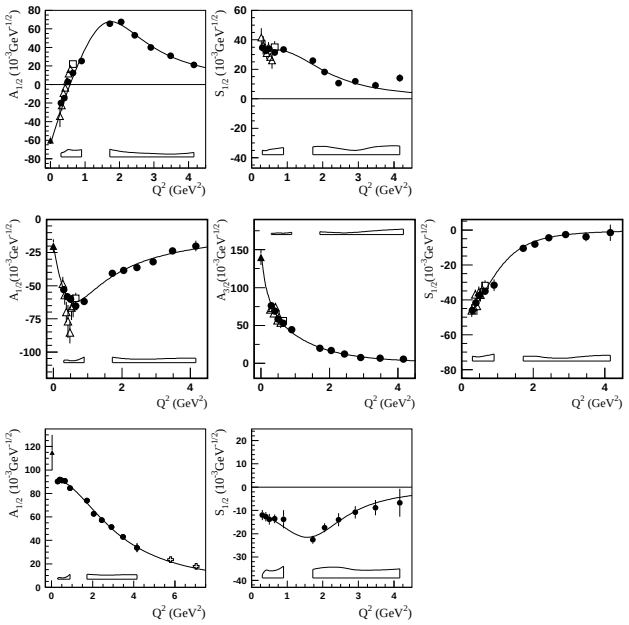

Figure 2: Transverse and scalar (longitudinal) helicity amplitudes for $\gamma p \to N(1440)1/2^+$ (top), $\gamma p \to N(1520)3/2^-$ (center), and $\gamma p \to N(1535)1/2^-$ (bottom) as extracted from the JLab/CLAS data in $n\pi^+$ production (full circles), in $p\pi^+\pi^-$ (open triangles), combined single and double pion production (open squares). The solid triangle is the PDG 2013 value at $Q^2 = 0$. The open boxes are the model uncertainties of the full circles. The figures are kindly provided by V. Burkert, JLab.

$A_{1/2}$ is small at the photon point, increases rapidly with Q^2 and then falls off with $\sim Q^{-3}$. Quantitative agreement with the data is, however, achieved only when meson cloud effects are included.

At high Q^2, both amplitudes for $N(1440)1/2^+$ are qualitatively described by light front quark models [22]: at short distances the resonance behaves as expected from a radial excitation of the nucleon. On the other hand, $A_{1/2}$ changes sign at about $0.6\,\mathrm{GeV}^2$. This remarkable behavior has not been observed before for any nucleon form factor or transition amplitude. Obviously, an important change in the structure occurs when the resonance is probed as a function of Q^2.

The Q^2 dependence of $A_{1/2}$ of the $N(1535)1/2^-$ resonance exhibits the expected $\sim Q^{-3}$ dependence, except for small Q^2 values where meson cloud effects set in.

VII. Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. The GWU group maintains a nearly complete database covering reactions from πN and KN elastic scattering to $\gamma N \to N\pi$, $N\eta$, and $N\eta'$. It is presently the only group determining πN elastic amplitudes from scattering data in sliced energy bins. Given the high-precision of photoproduction data already or soon to be collected, the spectrum of N and Δ resonances will in the near future be better known.

Fits to the data are performed by various groups with the aim to understand the reaction dynamics and to identify N and Δ resonances. For practical reasons, approximations have to be made. We mention several analyses here: (1) The Mainz unitary isobar model [23] focusses on the correct treatment of the low-energy domain. Resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. This model also obtains resonance transition form factors and helicity amplitudes from electroproduction [19]. (2) For $N\pi$ electroproduction, the Yerevan/JLab group uses both the unitary isobar model and the dispersion relation approach developed in [22]. A phenomenological model was developed to extract resonance couplings and partial decay widths from exclusive $\pi^+\pi^- p$ electroproduction [21]. (3) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian - providing a microscopical description of the background - (Giessen [24,25]) or from phenomenology (Bonn-Gatchina [26]) . (4.) Several groups (EBAC-Jlab [27,28], ANL-Osaka [29], Dubna-Mainz-Taipeh [30], Bonn-Jülich [31,32,33], Valencia [34]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. Several other groups have made important contributions. The Giessen group pioneered multichannel analyses of large data sets on pion- and photo-induced reactions [24,25]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in Ref. [26].

N(1440) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] ARNDT 06 also finds a second-sheet pole with real part = 1388 MeV, −2 × imaginary part = 165 MeV, and residue with modulus 86 MeV and phase = −46 degrees.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] ARNDT 04 also finds a second-sheet pole with real part = 1385 MeV, −2 × imaginary part = 166 MeV, and residue with modulus 82 MeV and phase = −51°.

[6] ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV, −2×imaginary part = 210 MeV, and residue with modulus 92 MeV and phase = −54°.

[7] ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, $-2\times$ imaginary part = 256 MeV, and residue = $(78-153i)$ MeV.
[8] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[9] LONGACRE 77 considers this coupling to be well determined.
[10] WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

$N(1520)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	55–65 %
Γ_2	$N\eta$	$(2.3\pm0.4)\times10^{-3}$
Γ_3	$N\pi\pi$	20–30 %
Γ_4	$\Delta\pi$	15–25 %
Γ_5	$\Delta(1232)\pi$, S-wave	10–20 %
Γ_6	$\Delta(1232)\pi$, D-wave	10–15 %
Γ_7	$N\rho$	15–25 %
Γ_8	$N\rho$, S=3/2, S-wave	(9.0±1.0) %
Γ_9	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	<8 %
Γ_{10}	$p\gamma$	0.31–0.52 %
Γ_{11}	$p\gamma$, helicity=1/2	0.01–0.02 %
Γ_{12}	$p\gamma$, helicity=3/2	0.30–0.50 %
Γ_{13}	$n\gamma$	0.30–0.53 %
Γ_{14}	$n\gamma$, helicity=1/2	0.04–0.10 %
Γ_{15}	$n\gamma$, helicity=3/2	0.25–0.45 %

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1520)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] LONGACRE 77 considers this coupling to be well determined.

[6] MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The *ratio* of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2} = -2.5 \pm 0.5 \pm 0.4$.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$(\Gamma_i\Gamma_f)^{1/2}/\Gamma_{total}$ in $N\pi \to N(1535) \to \Delta(1232)\pi$, D-wave $(\Gamma_1\Gamma_5)^{1/2}/\Gamma$

$N(1535)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] KRUSCHE 97 fits with the mass fixed at 1544 MeV.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.

[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[7] The best value ARMSTRONG 99B obtains is $\simeq 0.55$; this assumes S_{11} dominance in the reaction $p(e, e'p)\ \eta$ at $Q^2 = 4\ (\mathrm{GeV}/c)^2$.

[8] This STAROSTIN 03 value is an estimate made using simplest assumptions.

[9] BENMERROUCHE 91 uses an effective Lagrangian approach to analyze η photoproduction data.

[10] This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(20\pm15)°$.

[11] This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(20\pm20)°$.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1650)$ FOOTNOTES

[1] ARNDT 95 finds two distinct states.
[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[5] ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
[6] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[7] LONGACRE 77 considers this coupling to be well determined.
[8] This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(25\pm20)^\circ$.
[9] This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(30\pm25)^\circ$.

$N(1675)$ DECAY MODES

The following branching fractions are our estimates, not fits or averages.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\pi$	35–45 %
Γ_2	$N\eta$	(0 ± 7) × 10^{-3}
Γ_3	ΛK	<1 %
Γ_4	ΣK	
Γ_5	$N\pi\pi$	50–60 %
Γ_6	$\Delta\pi$	50–60 %
Γ_7	$\Delta(1232)\pi$, D-wave	(50 ±15) %
Γ_8	$\Delta(1232)\pi$, G-wave	
Γ_9	$N\rho$	< 1–3 %
Γ_{10}	$N\rho$, S=1/2, D-wave	(0.0 ± 1.0) %
Γ_{11}	$N\rho$, S=3/2, D-wave	(1.0 ± 1.0) %
Γ_{12}	$N\rho$, S=3/2, G-wave	
Γ_{13}	$N(\pi\pi)^{I=0}_{S\text{-wave}}$	(7.0 ± 3.0) %
Γ_{14}	$p\gamma$	0–0.02 %
Γ_{15}	$p\gamma$, helicity=1/2	0–0.01 %
Γ_{16}	$p\gamma$, helicity=3/2	0–0.01 %
Γ_{17}	$n\gamma$	0–0.15 %
Γ_{18}	$n\gamma$, helicity=1/2	0–0.05 %
Γ_{19}	$n\gamma$, helicity=3/2	0–0.10 %

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1675)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] SAXON 80 finds the coupling phase is near 90°.

[6] LONGACRE 77 considers this coupling to be well determined.

Note: Signs of couplings from $\pi N \rightarrow N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$N(1680)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[5] LONGACRE 77 considers this coupling to be well determined.

$N(1685)$ $?^?$

$I(J^P) = \frac{1}{2}(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

There is a small literature (which we do not try to cover) on this possible narrow state. See KUZNETSOV 11A, MART 11, and the other papers for further references. This state does not gain status by being a sought-after member of a baryon anti-decuplet.

$N(1700)$ $3/2^-$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics (generic for all A,B,E,G) **G33** 1 (2006).

The various partial-wave analyses do not agree very well.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

$N(1700)$ FOOTNOTES

[1] The two BAKER 77 entries are from an IPWA using the Barrelet-zero method and from a conventional energy-dependent analysis.
[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[6] The overall phase of BAKER 78 couplings has been changed to agree with previous conventions.
[7] The range given is from the four best solutions.

$N(1710)$ FOOTNOTES

[1] BATINIC 10 finds evidence for a second P_{11} state with all parameters except for the phase of the pole residue very similar to the parameters we give here.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$N(1720)$ FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$N(1860)$ $5/2^+$

$I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a $J^P = 5/2^+$ state with a mass above 1800 MeV was filed under a two-star $N(2000)$. There is now some evidence from ANISOVICH 12A for two $5/2^+$ states in this region, so we have split the older data (according to mass) between two two-star $5/2^+$ states, an $N(1860)$ and an $N(2000)$.

$N(1875)$ $3/2^-$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

Before the 2012 *Review*, all the evidence for a $J^P = 3/2^-$ state with a mass above 1800 MeV was filed under a two-star $N(2080)$. There is now evidence from ANISOVICH 12A for two $3/2^-$ states in this region, so we have split the older data (according to mass) between a three-star $N(1875)$ and a two-star $N(2120)$.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

$N(1875)$ FOOTNOTES

[1] CUTKOSKY 80 finds a lower mass D_{13} resonance, as well as one in this region. Both are listed here.

[2] The range given for DEANS 75 is from the four best solutions. Disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.

OMITTED FROM SUMMARY TABLE

Before our 2012 *Review*, this state appeared in our Listings as the $N(2090)$. Any structure in the S_{11} wave above 1800 MeV is listed here. A few early results that are now obsolete have been omitted.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

$N(1895)$ FOOTNOTES

[1] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[2] This ANISOVICH 12A value is the complex helicity amplitude at the pole position.

$N(1990)\ 7/2^+$

$I(J^P) = \frac{1}{2}(\frac{7}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics (generic for all A,B,E,G) **G33** 1 (2006).

The various analyses do not agree very well with one another.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

$N(2000)\ 5/2^+$

$I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a $J^P = 5/2^+$ state with a mass above 1800 MeV was filed under a two-star $N(2000)$. There is now some evidence from ANISOVICH 12A for two $5/2^+$ states in this region, so we have split the older data (according to mass) between two two-star $5/2^+$ states, an $N(1860)$ and an $N(2000)$.

$N(2120)$ $3/2^-$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a $J^P = 3/2^-$ state with a mass above 1800 MeV was filed under a two-star $N(2080)$. There is now evidence from ANISOVICH 12A for two $3/2^-$ states in this region, so we have split the older data (according to mass) between a three-star $N(1875)$ and a two-star $N(2120)$.

$N(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an $N(3245)$, an $N(3690)$, and an $N(3755)$, each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an $N(3030)$, deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 $L_{1,15}$ state below.

[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[3] The second (lower) value of HANSTEIN 96 here goes with the second (higher) value of the real part in the preceding data block.

[5] This ARNDT 97 value is very sensitive to the database being fitted. The result is from a fit to the full pion photoproduction database, apart from the BLANPIED 97 cross-section measurements.

Δ(1232) MAGNETIC MOMENTS

Δ(1232)++ MAGNETIC MOMENT

The values are extracted from UCLA and SIN data on $\pi^+ p$ bremsstrahlung using a variety of different theoretical approximations and methods. Our estimate is *only* a rough guess of the range we expect the moment to lie within.

Δ(1600) 3/2+

$I(J^P) = \frac{3}{2}(\frac{3}{2}^+)$ Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics (generic for all A,B,E,G) **G33** 1 (2006).

The various analyses are not in good agreement.

Δ(1600) FOOTNOTES

[1] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[5] The range given is from the four best solutions. DEANS 75 disagrees with $\pi^+ p \to \Sigma^+ K^+$ data of WINNIK 77 around 1920 MeV.
[6] LONGACRE 77 considers this coupling to be well determined.
[7] WADA 84 is inconsistent with other analyses — see the Note on N and Δ Resonances.

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

$\Delta(1620)$ FOOTNOTES

[1] CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] LONGACRE 77 considers this coupling to be well determined.

Δ(1700) FOOTNOTES

[1] Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[4] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[5] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

[6] LONGACRE 77 considers this coupling to be well determined.

Δ(1750) FOOTNOTES

[1] CHEW 80 reports four resonances in the P_{31} wave — see also the Δ(1910). Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] ARNDT 04 gives no corresponding Breit-Wigner parameters for this state, because the mass so obtained is about 500 MeV higher than that suggested by the position of the pole.

Δ(1900) FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
[2] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
[3] This ANISOVICH 12A value is the complex helicity amplitude at the pole position.

$\Delta(1905)$ FOOTNOTES

[1] ANISOVICH 10 finds an alternate solution for this resonance. The only statistically significant differences are in the Breit-Wigner mass and γp couplings.

[2] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[4] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

Δ(1910) FOOTNOTES

[1] CHEW 80 reports four resonances in the P_{31} wave — see also the Δ(1750). Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

[2] LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[3] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

Δ(1930) FOOTNOTES

[1] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

0.4 ± 0.1	ANISOVICH	12A	DPWA	Multichannel

Note: Signs of couplings from $\pi N \to N\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the Δ(1620) S_{31} coupling to $\Delta(1232)\pi$.

$(\Gamma_i\Gamma_f)^{1/2}/\Gamma_{total}$ in $N\pi \to \Delta(1950) \to \Delta(1232)\pi$, F-wave — $(\Gamma_1\Gamma_5)^{1/2}/\Gamma$

Δ(1950) FOOTNOTES

[1] From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

[2] See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

[3] LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

$\Delta(\sim 3000$ Region) Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic cross-section measurements. The $\Delta(2850)$ has been resolved into the $\Delta(2750)$ $I_{3,13}$ and $\Delta(2950)$ $K_{3,15}$. The $\Delta(3230)$ is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

[1] We assume CPT invariance: this is the $\overline{\Lambda}$ mass as measured by HARTOUNI 94. See below for the fractional mass difference, testing CPT.
[2] The SCHMIDT 65 masses have been reevaluated using our April 1973 proton and $K^\pm$ and $\pi^\pm$ masses. P. Schmidt, private communication (1974).
[3] The mass has been raised 35 keV to take into account a 46 keV increase in the proton mass and an 11 keV decrease in the $\pi^\pm$ mass (note added Reviews of Modern Physics **39** 1 (1967)).

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured p, n, and Λ moments as input. In this model, the moments are [1]

$$\mu_p = (4\mu_u - \mu_d)/3 \qquad \mu_n = (4\mu_d - \mu_u)/3$$
$$\mu_{\Sigma^+} = (4\mu_u - \mu_s)/3 \qquad \mu_{\Sigma^-} = (4\mu_d - \mu_s)/3$$
$$\mu_{\Xi^0} = (4\mu_s - \mu_u)/3 \qquad \mu_{\Xi^-} = (4\mu_s - \mu_d)/3$$
$$\mu_\Lambda = \mu_s \qquad \mu_{\Sigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3$$
$$\mu_{\Omega^-} = 3\mu_s$$

and the $\Sigma^0 \to \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3}\,.$$

The quark moments that result from this model are $\mu_u = +1.852\,\mu_N$, $\mu_d = -0.972\,\mu_N$, and $\mu_s = -0.613\,\mu_N$. The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu = q\hbar/2m$, are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 10.5$ for 16 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[10] CHAUVAT 85 actually gives $\alpha_+(\overline{\Lambda})/\alpha_-(\Lambda) = -1.04 \pm 0.29$. Assumes polarization is same in $\overline{p}p \to \overline{\Lambda}X$ and $pp \to \Lambda X$. Tests of this assumption, based on *C*-invariance and fragmentation, are satisfied by the data.

g_A / g_V FOR $\Lambda \to pe^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. The measurements all assume that the form factor $g_2 = 0$. See also the footnote on DWORKIN 90.

[11] The tabulated result assumes the weak-magnetism coupling $w \equiv g_W(0)/g_V(0)$ to be 0.97, as given by the CVC hypothesis and as assumed by the other listed measurements. However, DWORKIN 90 *measures* w to be 0.15 ± 0.30, and then $g_A/g_V = -0.731 \pm 0.016$.

[12] This experiment measures only the absolute value of g_A/g_V.

Λ REFERENCES

We have omitted some papers that have been superseded by later experiments. See our earlier editions.

Λ AND Σ RESONANCES

Introduction: Since our last edition, there have been a few measurements of properties of the lowest Λ and Σ resonances—mostly of masses and widths. But the field remains at a standstill. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1, the amplitude for $K^- p \to \overline{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \to \Lambda\pi$ and $\overline{K}N \to \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or − sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the Λ(1520), the Λ(1820), and the Σ(1775), there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

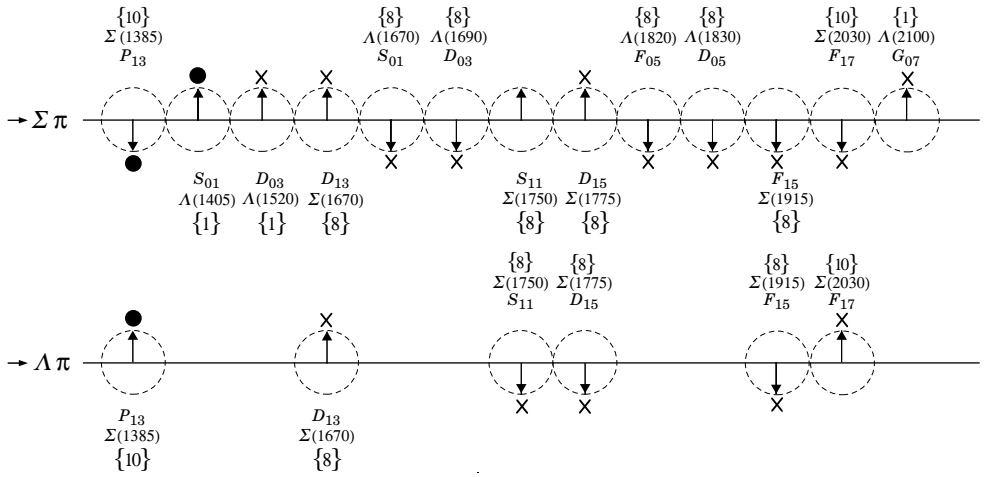

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \to \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a •, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

Particle	J^P	Overall status	Status as seen in — $N\overline{K}$	$\Lambda\pi$	$\Sigma\pi$	Other channels

Σ(3170)		*				multi-body

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The Σ(1385) and Λ(1405) of course lie below the $\overline{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case of Λ(1520) and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the Σ(1670).

Λ(1405) 1/2−

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ****

The nature of the Λ(1405) has been a puzzle for decades: three-quark state or hybrid; two poles or one. We cannot here survey the rather extensive literature. See, for example, CIEPLY 10, KISSLINGER 11, SEKIHARA 11, and SHEVCHENKO 12A for discussions and earlier references.

It seems to be the universal opinion of the chiral-unitary community that there are two poles in the 1400-MeV region. ZYCHOR 08 presents experimental evidence against the two-pole model, but this is disputed by GENG 07A. See also REVAI 09, which finds little basis for choosing between one- and two-pole models; and IKEDA 12, which favors the two-pole model.

A single, ordinary three-quark Λ(1405) fits nicely into a $J^P = 1/2^-$ SU(4) $\overline{4}$ multiplet, whose other members are the $\Lambda_c(2595)^+$, $\Xi_c(2790)^+$, and $\Xi_c(2790)^0$; see Fig. 1 of our note on "Charmed Baryons."

$\Lambda(1405)$ FOOTNOTES

[1] DALITZ 91 fits the HEMINGWAY 85 data.
[2] THOMAS 73 data is fit by CHAO 73 (see next section).
[3] The KIMURA 00 values are from fits A and B from a coupled-channel potential model using low-energy $\overline{K}N$ and $\Sigma\pi$ data, kaonic-hydrogen x-ray measurements, and our $\Lambda(1405)$ mass and width. The results bear mainly on the *nature* of the $\Lambda(1405)$: three-quark state or $\overline{K}N$ bound state.
[4] The MARTIN 81 fit includes the $K^\pm p$ forward scattering amplitudes and the dispersion relations they must satisfy.
[5] See also the accompanying paper of THOMAS 73.
[6] Data of SAKITT 65 are used in the fit by KITTEL 66.
[7] An asymmetric shape, with $\Gamma/2 = 41$ MeV below resonance, 14 MeV above.

$\Lambda(1520)$ $3/2^-$

$I(J^P) = 0(\frac{3}{2}^-)$ Status: ****

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel resonance.

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters **111B** 1 (1982).

Production and formation experiments agree quite well, so they are listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 28 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 18.9$ for 23 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.041±0.005	CHAN	72	HBC	$K^-p \rightarrow \Lambda\pi\pi$

$\Gamma(\Sigma(1385)\pi(\rightarrow \Lambda\pi\pi))/\Gamma(\Lambda\pi\pi)$ — Γ_5/Γ_3

The $\Lambda\pi\pi$ mode is largely due to $\Sigma(1385)\pi$. Only the values of $(\Sigma(1385)\pi)\ /\ (\Lambda 2\pi)$ given by MAST 73B and CORDEN 75 are based on real 3-body partial-wave analyses. The discrepancy between the two results is essentially due to the different hypotheses made concerning the shape of the $(\pi\pi)_{S\text{-wave}}$ state.

$\Lambda(1670)$ FOOTNOTES

[1] GARCIA-RECIO 03 gives pole, not Breit-Wigner, parameters, but the narrow width of the $\Lambda(1670)$ means there will be little difference.

[2] MARTIN 77 obtains identical resonance parameters from a T-matrix pole and from a Breit-Wigner fit.

$\Lambda(1690)$ DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	20–30 %
Γ_2	$\Sigma\pi$	20–40 %
Γ_3	$\Lambda\pi\pi$	∼ 25 %
Γ_4	$\Sigma\pi\pi$	∼ 20 %
Γ_5	$\Lambda\eta$	
Γ_6	$\Sigma(1385)\pi$, S-wave	

The above branching fractions are our estimates, not fits or averages.

$\Lambda(1690)$ BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

$\Lambda(1690)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another D_{03} Λ at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

[2] BARTLEY 68 uses only cross-section data. The enhancement is not seen by PREVOST 71.

Λ(1820) 5/2+

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ****

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

Λ(1820) FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] There is a suggestion of a bump, enough to be consistent with what is expected from $\Sigma(1385) \rightarrow \Sigma\pi$ decay.
[3] The published sign has been changed to be in accord with the baryon-first convention.

Λ(2000) $I(J^P) = 0(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

ZHANG 13A claims a $J^P = 1/2^-$ state.

We list here all the ambiguous resonance possibilities with a mass around 2 GeV. The proposed quantum numbers are D_3 (BARBARO-GALTIERI 70 in $\Sigma\pi$), D_3+F_5, P_3+D_5, or P_1+D_3 (BRANDSTETTER 72 in $\Lambda\omega$), and S_1 (CAMERON 78B in $N\overline{K}^*$). The first two of the above analyses should now be considered obsolete. See also NAKKASYAN 75.

Λ(2020) 7/2+ $I(J^P) = 0(\frac{7}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new K^-n angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

$I(J^P) = 0(\frac{7}{2}^-)$ Status: ****

Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters **170B** 1 (1986).

Λ(2100) FOOTNOTES

[1] The NAKKASYAN 75 values are from the two best solutions found. Each has the Λ(2100) and one additional resonance (P_3 or F_5).
[2] Note that the three for BACCARI 77 entries are for three different waves.
[3] The published sign has been changed to be in accord with the baryon-first convention. The upper limit on the G_3 wave is 0.03.

Λ(2325) 3/2⁻

$I(J^P) = 0(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P = 3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $K^- p \to \Lambda\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^- p \to \overline{K}N$ data, and finds $J^P = 3/2^-$ or $3/2^+$. They again prefer $J^P = 3/2^-$, but only on the basis of model-dependent considerations.

Λ(2350) 9/2⁺

$I(J^P) = 0(\frac{9}{2}^+)$ Status: ***

DAUM 68 favors $J^P = 7/2^-$ or $9/2^+$. BRICMAN 70 favors $9/2^+$. LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find $9/2^+$ in energy-dependent partial-wave analyses of $\overline{K}N \to \Sigma\pi$, $\Lambda\omega$, and $N\overline{K}$.

0.83 ±0.032	1300	[4] CHANG	66	HBC	

[3] This is a measurement of the $\overline{\Sigma}^-$ lifetime. Here we assume CPT invariance; see below for the fractional Σ^+-$\overline{\Sigma}^-$ lifetime difference obtained by BARBOSA 00.

[4] We have increased the CHANG 66 error of 0.018; see our 1970 edition, Reviews of Modern Physics **42** 87 (1970).

$(\tau_{\Sigma^+} - \tau_{\overline{\Sigma}^-}) / \tau_{\Sigma^+}$

A test of CPT invariance.

VALUE	DOCUMENT ID		TECN	COMMENT
$(-6\pm12)\times10^{-4}$	BARBOSA	00	E761	hyperons, 375 GeV

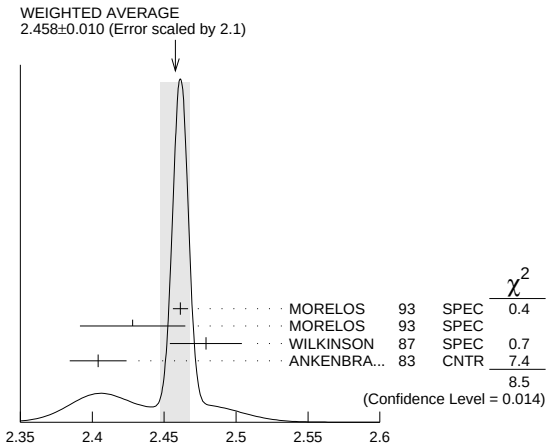
Σ^+ MAGNETIC MOMENT

See the "Note on Baryon Magnetic Moments" in the Λ Listings. Measurements with an error $\geq 0.1\ \mu_N$ have been omitted.

VALUE (μ_N)	EVTS	DOCUMENT ID		TECN	COMMENT
2.458 ±0.010 OUR AVERAGE Error includes scale factor of 2.1. See the ideogram below.					
2.4613±0.0034±0.0040	250k	MORELOS	93	SPEC	pCu 800 GeV
2.428 ±0.036 ±0.007	12k	[5] MORELOS	93	SPEC	pCu 800 GeV
2.479 ±0.012 ±0.022	137k	WILKINSON	87	SPEC	pBe 400 GeV
2.4040±0.0198	44k	[6] ANKENBRA...	83	CNTR	pCu 400 GeV

[5] We assume CPT invariance: this is (minus) the $\overline{\Sigma}^-$ magnetic moment as measured by MORELOS 93. See below for the moment difference testing CPT.

[6] ANKENBRANDT 83 gives the value 2.38 ± 0.02μ_N. MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.



$(\mu_{\Sigma^+} + \mu_{\overline{\Sigma}^-}) / \mu_{\Sigma^+}$

A test of CPT invariance.

VALUE	DOCUMENT ID		TECN	COMMENT
0.014±0.015	[7] MORELOS	93	SPEC	pCu 800 GeV

[7] This is our calculation from the MORELOS 93 measurements of the Σ^+ and $\overline{\Sigma}^-$ magnetic moments given above. The statistical error on $\mu_{\overline{\Sigma}^-}$ dominates the error here.

Σ^+ DECAY MODES

	Mode		Fraction (Γ_i/Γ)		Confidence level
Γ_1	$p\pi^0$		(51.57±0.30) %

Γ_9	$p\mu^+\mu^-$	$S1$	(9 $^{+9}_{-8}$)	$\times10^{-8}$	

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.7$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Σ^0

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ****

COURANT 63 and ALFF 65, using $\Sigma^0 \to \Lambda e^+ e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that $J = 1/2$ and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \to \Lambda$ transition magnetic moment come (see below), strongly support $J = 1/2$.

Σ^0 MASS

The fit uses Σ^+, Σ^0, Σ^-, and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0-Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma\Lambda}/\mu_N)^2\ \tau = 1.92951 \times 10^{-19}$ s (see DEVLIN 86).

Γ_5	$\Lambda e^-\overline{\nu}_e$	(5.73 ±0.27) × 10^{-5}

[a] See the Listings below for the pion momentum range used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 8.7$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

g_A/g_V FOR $\Sigma^- \to ne^-\overline{\nu}_e$

Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. What is actually listed is $|g_1/f_1 - 0.237 g_2/f_1|$. This reduces to $g_A/g_V \equiv g_1(0)/f_1(0)$ on making the usual assumption that $g_2 = 0$. See also the note on HSUEH 88.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.340±0.017 OUR AVERAGE					
+0.327±0.007±0.019	50k	[7] HSUEH	88	SPEC	Σ^- 250 GeV
+0.34 ±0.05	4456	[8] BOURQUIN	83C	SPEC	SPS hyperon beam
0.385±0.037	3507	[9] TANENBAUM	74	ASPK	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.29 ±0.07	25k	HSUEH	85	SPEC	See HSUEH 88
$0.17\ ^{+0.07}_{-0.09}$	519	DECAMP	77	ELEC	Hyperon beam

[7] The sign is, *with our conventions*, unambiguously positive. The value assumes, as usual, that $g_2 = 0$. If g_2 is included in the fit, than (with our sign convention) $g_2 = -0.56 \pm 0.37$, with a corresponding reduction of g_A/g_V to $+0.20 \pm 0.08$.

[8] BOURQUIN 83C favors the positive sign by at least 2.6 standard deviations.

[9] TANENBAUM 74 gives 0.435 ± 0.035, assuming no q^2 dependence in g_A and g_V. The listed result allows q^2 dependence, and is taken from HSUEH 88.

$f_2(0)/f_1(0)$ FOR $\Sigma^- \to ne^-\overline{\nu}_e$

The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

TRIPLE CORRELATION COEFFICIENT D for $\Sigma^- \to ne^-\overline{\nu}_e$

The coefficient D of the term $D\,\mathbf{P}\cdot(\hat{\mathbf{p}}_e\times\hat{\mathbf{p}}_\nu)$ in the $\Sigma^- \to ne^-\overline{\nu}$ decay angular distribution. A nonzero value would indicate a violation of time-reversal invariance.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.11±0.10	50k	HSUEH	88	SPEC	Σ^- 250 GeV

g_V/g_A FOR $\Sigma^- \to \Lambda e^-\overline{\nu}_e$

For the sign convention, see the "Note on Baryon Decay Parameters" in the neutron Listings. The value is predicted to be zero by conserved vector current theory. The values averaged assume CVC-SU(3) weak magnetism term.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.01 ±0.10 OUR AVERAGE Error includes scale factor of 1.5. See the ideogram below.

$\Sigma(1385)\ 3/2^+$

$I(J^P) = 1(\frac{3}{2}^+)$ Status: ****

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energy-independent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLMGREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P-wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

$\Sigma(1385)$ FOOTNOTES

[1] From fit to inclusive $\Lambda\pi$ spectrum.
[2] Includes data of HOLMGREN 77.
[3] The errors are statistical only. The resolution is not unfolded.
[4] The error is enlarged to $\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
[5] From a fit to $\Lambda\pi^0$ with the width fixed at 34 MeV.
[6] From fit to inclusive $\Lambda\pi^0$ spectrum with the width fixed at 40 MeV.
[7] Redundant with data in the mass Listings.
[8] Results from $\Lambda\pi^+\pi^-$ and $\Lambda\pi^+\pi^-\pi^0$ combined by us.
[9] The error is enlarged to $4\Gamma/\sqrt{N}$. See the note on the $K^*(892)$ mass in the 1984 edition.
[10] Consistent with +, 0, and − widths equal.
[11] KELLER 12 gives $\Gamma(\Sigma^+\gamma)/\Gamma(\Sigma^+\pi^0) = (11.95 \pm 2.21^{+0.53}_{-1.21})\%$, using 1/2 our total $\Sigma(1385) \to \Sigma\pi$ fraction for $\Sigma^+\pi^0$. We divide the KELLER 12 value by two.
[12] We calculate this from the MOLCHANOV 04 upper limit of 9.5 keV on the $\Sigma^-\gamma$ width.
[13] We calculate this from the ARIK 77 upper limit of 24 keV on the $\Sigma^-\gamma$ width.
[14] An extrapolation of the parametrized amplitude below threshold.

$\Sigma(1480)$ Bumps

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+ p \to (Y\pi)K^+$ at 1.7 GeV/c. Also, the Y polarization oscillates in the same region.

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \to \Lambda K$ decay. However, such an explanation for the $(\Sigma^+\pi^0)K^+$ channel in terms of $\Delta(1650) \to \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^- p \to \Lambda\pi^0$.

ENGELEN 80 performs a multichannel analysis of $K^- p \to p\overline{K}^0\pi^-$ at 4.2 GeV/c. They observe a 3.5 standard-deviation signal at 1480 MeV in $p\overline{K}^0$ which cannot be explained as a reflection of any competing channel.

PRAKHOV 04 sees no evidence for this or other light Σ resonances, aside from the $\Sigma(1385)$, in $K^- p \to \Lambda\pi^0\pi^0$.

ZYCHOR 06 finds peaks in $pp \to pK^+(\pi^\pm X^\mp)$ at p_{beam} = 3.65 GeV/c.

$\Sigma(1560)$ Bumps

$I(J^P) = 1(?^?)$ Status: **

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^-p \rightarrow (\Lambda/\Sigma)\pi K\overline{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^{\pm}$ from the reaction $pp \rightarrow \Lambda\pi^+\pi^-X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\overline{K}N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$I(J^P) = 1(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen in the isospin-1 $\overline{K}N$ cross section at BNL (LI 73, CARROLL 76) and in a partial-wave analysis of $K^-p \rightarrow \Lambda\pi^0$ for c.m. energies 1560–1600 MeV by LITCHFIELD 74. LITCHFIELD 74 finds $J^P = 3/2^-$. Not seen by ENGLER 78 or by CAMERON 78C (with larger statistics in $K^0_Lp \rightarrow \Lambda\pi^+$ and $\Sigma^0\pi^+$).

Neither OLMSTED 04 (in $K^-p \rightarrow \Lambda\pi^0$) nor PRAKHOV 04 (in $K^-p \rightarrow \Lambda\pi^0\pi^0$) see any evidence for this state.

Baryon Particle Listings

$\Sigma(1580)$, $\Sigma(1620)$, $\Sigma(1620)$ Production Experiments

$\Sigma(1580)$ FOOTNOTES

[1] CARROLL 76 sees a total-cross-section bump with $(J+1/2)\ \Gamma_{el}\ /\ \Gamma_{total} = 0.06$.

[2] The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\overline{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

$\Sigma(1620)$ Production Experiments

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the previous entry.

The results of CRENNELL 69B at 3.9 GeV/c are not confirmed by SABRE 70 at 3.0 GeV/c. However, at 4.5 GeV/c, AMMANN 70 sees a peak at 1642 MeV which on the basis of branching ratios they do not associate with the $\Sigma(1670)$. See MILLER 70 for a review of these conflicts.

THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma\pi/\Sigma\pi\pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^-p \to \pi^-\Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma\pi\pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma\pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13}. There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda\pi/\Sigma\pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

$\Sigma(1670)$ $3/2^-$

$I(J^P) = 1(\frac{3}{2}^-)$ Status: ****

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

Results from production experiments are listed separately in the next entry.

0.081±0.016	[6] CAMERON	77	DPWA	P-wave decay

$\Sigma(1670)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] Results are with and without an S_{11} $\Sigma(1620)$ in the fit.
[3] Ratio only for $\Sigma 2\pi$ system in $I = 1$, which cannot be $\Sigma(1385)$.
[4] SIMS 68 uses only cross-section data. Result used as upper limit only.
[5] Assuming the $\Lambda(1405)\pi$ cross-section bump is due only to $3/2^-$ resonance.
[6] The CAMERON 77 upper limit on F-wave decay is 0.03.

$\Sigma(1670)$ Bumps

$I(J^P) = 1(?^?)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to $\Sigma\pi$ and $\Lambda\pi$, the other to $\Lambda(1405)\pi$. See the note in front of the preceding entry.

$\Sigma(1690)$ FOOTNOTES (PRODUCTION EXPERIMENTS)

[1] From $\pi^+ p \rightarrow (\Lambda\pi^+) K^+$. $J > 1/2$ is not required by the data.
[2] From $\pi^+ p \rightarrow (\Lambda\pi^+)(K\pi)^+$. $J > 1/2$ is indicated, but large background precludes a definite conclusion.
[3] See the $\Sigma(1670)$ Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the $\Sigma(1690)$.
[4] This analysis, which is difficult and requires several assumptions and shows no unambiguous $\Sigma(1690)$ signal, suggests $J^P = 5/2^+$. Such a state would lead all previously known Y^* trajectories.

$\Sigma(1750)$ 1/2$^-$

$I(J^P) = 1(\frac{1}{2}^-)$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\overline{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74).

$\Sigma(1770)\ 1/2^+$

$I(J^P) = 1(\frac{1}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the $\Lambda\pi$ partial-wave amplitudes of this solution are in disagreement with amplitudes from most other $\Lambda\pi$ analyses. ZHANG 13A finds no evidence for this state.

$\Sigma(1770)$ FOOTNOTES

[1] Required to fit the isospin-1 total cross section of CARROLL 76 in the $\overline{K}N$ channel. The addition of new K^-p polarization and K^-n differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660)$ P_{11}.
[2] From solution 1 of BAILLON 75; not present in solution 2.
[3] Not required in KANE 74, which supersedes KANE 72.

$\Sigma(1775)$ DECAY MODES

	Mode	Fraction (Γ_i/Γ)
Γ_1	$N\overline{K}$	37–43%
Γ_2	$\Lambda\pi$	14–20%
Γ_3	$\Sigma\pi$	2–5%
Γ_4	$\Sigma(1385)\pi$	8–12%
Γ_5	$\Sigma(1385)\pi$, D-wave	
Γ_6	$\Lambda(1520)\pi$, P-wave	17–23%
Γ_7	$\Sigma\pi\pi$	
Γ_8	$\Delta(1232)\overline{K}$, D-wave	
Γ_9	$N\overline{K}^*(892)$, S=1/2	
Γ_{10}	$N\overline{K}^*(892)$, S=3/2, D-wave	

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 18 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 363.4$ for 14 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_2	−44			
x_3	−23	10		
x_4	−23	−32	−4	
x_6	−3	1	1	−84
	x_1	x_2	x_3	x_4

$\Sigma(1775)$ BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too small.

$\Sigma(1775)$ FOOTNOTES

[1] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[2] The CAMERON 78 upper limit on G-wave decay is 0.03.
[3] This rate combines P-wave- and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014. The published signs have been changed here to be in accord with the baryon-first convention.
[4] For about 3/4 of this, the $\Sigma\pi$ system has $I = 0$ and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has $I = 1$, which is about what is expected from the known $\Sigma(1775) \to \Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

$\Sigma(1915)$ FOOTNOTES

[1] The two entries for CORDEN 77C are from two different acceptable solutions.
[2] Preferred solution 3; see CORDEN 76 for other possibilities.
[3] The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
[4] The mass and width are fixed to the GOPAL 77 values due to the low elasticity.
[5] The published sign has been changed to be in accord with the baryon-first convention.

$I(J^P) = 1(\frac{7}{2}^+)$ Status: ****

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics **56** S1 (1984).

$\Sigma(2250)$

$I(J^P) = 1(?^?)$ Status: ***

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \to \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$\Sigma(3170)$ Bumps

$I(J^P) = 1(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^- p \rightarrow Y^{*+}\pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a $K^- p$ experiment in LASS at 11 GeV/c (ASTON 85B).

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 11 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 7.5$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[9] DAUBER 69 uses $\alpha_\Lambda = 0.647 \pm 0.020$.

[10] The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

RADIATIVE HYPERON DECAYS

Revised July 2011 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i \to B_f\gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q = 0$, $\Delta S = 1$ transition, the angular distribution of the direction $\hat{\mathbf{p}}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi}\,(1 + \alpha_\gamma\,\mathbf{P}_i\cdot\hat{\mathbf{p}})\ . \qquad (1)$$

Here $\mathbf{P}_i$ is the polarization of the decaying hyperon, and α_γ is the asymmetry parameter. In terms of the form factors $F_1(q^2)$, $F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_\lambda + iF_2(q^2)\sigma_{\lambda\mu}q^\mu + G(q^2)\gamma_\lambda\gamma_5\ ,$$

α_γ is

$$\alpha_\gamma = \frac{2\,\mathrm{Re}[G(0)F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2}\ , \qquad (2)$$

where $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = -\alpha_\gamma$ [1].

The angular distribution for the weak hadronic decay, $B_i \to B_f\pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_π. Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = +\alpha_\pi$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

$\Xi^0 \to \Lambda\gamma$ *decay*—The radiative decay $\Xi^0 \to \Lambda\gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \to p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_\Lambda = -\alpha_{\Xi\Lambda\gamma}$. Let α_- be the $\Lambda \to p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \to p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2}\,(1 - \alpha_{\Xi\Lambda\gamma}\,\alpha_-\cos\theta_{\Lambda p}) \qquad (3)$$

for the angular distribution of the proton in the Λ frame. Our current value, from the CERN NA48/1 experiment [4], is $\alpha_{\Xi\Lambda\gamma} = -0.704 \pm 0.019 \pm 0.064$.

$\Xi^0 \to \Sigma^0\gamma$ *decay*—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \to \Sigma^0\gamma$, $\Sigma^0 \to \Lambda\gamma$, $\Lambda \to p\pi^-$. Again, for an unpolarized Ξ^0, the longitudinal polarization of the Σ^0 will be $P_\Sigma = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \to \Lambda\gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ, as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity $+1/2$, the probability amplitudes for positive and negative spin states of the Σ^0 *along the* Λ *momentum* are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity $-1/2$, the amplitudes are interchanged. If the Σ^0 has longitudinal polarization P_Σ, the probabilities for Λ helicities $\pm1/2$ are therefore

$$p(\pm1/2) = \frac{1}{2}(1 \mp P_\Sigma)\cos^2(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_\Sigma)\sin^2(\theta_{\Sigma\Lambda}/2)\ , \qquad (4)$$

and the longitudinal polarization of the Λ is

$$P_\Lambda = -P_\Sigma \cos\theta_{\Sigma\Lambda} = +\alpha_{\Xi\Sigma\gamma} \cos\theta_{\Sigma\Lambda} \ . \qquad (5)$$

Using Eq. (1) for the $\Lambda \to p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \to \Lambda\gamma$, $\Lambda \to p\pi^-$ chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}\, d\cos\theta_{\Lambda p}} = \frac{N}{4}\left(1 + \alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda}\,\alpha_-\cos\theta_{\Lambda p}\right) . \qquad (6)$$

Our current average for $\alpha_{\Xi\Sigma\gamma}$ is -0.69 ± 0.06 [4,5].

References

1. R.E. Behrends, Phys. Rev. **111**, 1691 (1958); see Eq. (7) or (8).
2. In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 50 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 1.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

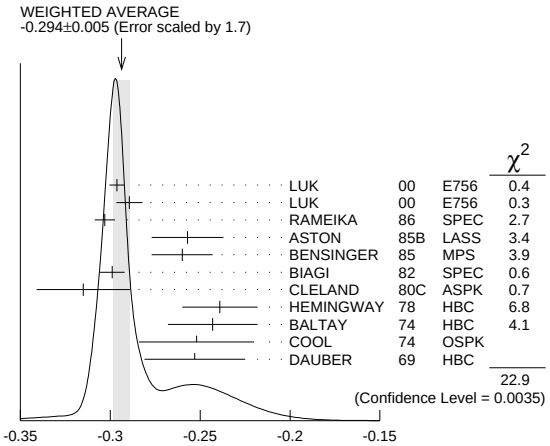
−0.253 ±0.028	2781	DAUBER	69	HBC	

[8] This LUK 00 value is for $\alpha(\overline{\Xi}^+)\ \alpha_+(\overline{\Lambda})$. We assume *CP* conservation here by including it in the average for $\alpha(\Xi^-)\ \alpha_-(\Lambda)$. But see the second data block below for the *CP* test.



α FOR $\Xi^-\to\Lambda\pi^-$

The above average, $\alpha(\Xi^-)\ \alpha_-(\Lambda) = -0.294 \pm 0.005$, where the error includes a scale factor of 1.7, divided by our current average $\alpha_-(\Lambda) = 0.642 \pm 0.013$, gives the following value for $\alpha(\Xi^-)$.

VALUE	DOCUMENT ID
−0.458±0.012 OUR EVALUATION	Error includes scale factor of 1.8.

$\frac{[\alpha(\Xi^-)\alpha_-(\Lambda)-\alpha(\overline{\Xi}^+)\alpha_+(\overline{\Lambda})]}{[\alpha(\Xi^-)\alpha_-(\Lambda)+\alpha(\overline{\Xi}^+)\alpha_+(\overline{\Lambda})]}$

This is zero if *CP* is conserved. The α's are the decay-asymmetry parameters for $\Xi^-\to\Lambda\pi^-$ and $\Lambda\to p\pi^-$ and for $\overline{\Xi}^+\to\overline{\Lambda}\pi^+$ and $\overline{\Lambda}\to\overline{p}\pi^+$.

54 ±30	356	[12] CARMONY	64B	HBC	

[9] From this result and α_Ξ, HUANG 04 gets $\beta_\Xi = -0.037 \pm 0.011 \pm 0.010$ and $\gamma_\Xi = 0.888 \pm 0.0004 \pm 0.006$. And the strong p–s phase difference for $\Lambda\pi^-$ scattering is $(4.6 \pm 1.4 \pm 1.2)^\circ$.

[10] From this result and α_Ξ, CHAKRAVORTY 03 obtains $\beta_\Xi = -0.025 \pm 0.042 \pm 0.006$ and $\gamma_\Xi = 0.889\pm0.001\pm0.007$. And the strong p–s phase difference for $\Lambda\pi^-$ scattering is $(3.17 \pm 5.28 \pm 0.73)^\circ$.

[11] BENSINGER 85 used $\alpha_\Lambda = 0.642 \pm 0.013$.

[12] The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

g_A / g_V FOR $\Xi^-\to\Lambda e^-\overline{\nu}_e$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.25±0.05	1992	[13] BOURQUIN	83	SPEC	SPS hyperon beam

[13] BOURQUIN 83 assumes that $g_2 = 0$. Also, the sign has been changed to agree with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μb), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on Ξ resonances has been added since our 1988 edition.

For a detailed earlier review, see Meadows [1].

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

Particle	J^P	Overall status	Status as seen in — $\Xi\pi$	ΛK	ΣK	$\Xi(1530)\pi$	Other channels
Ξ(1318)	1/2+	****					Decays weakly
Ξ(1530)	3/2+	****	****				
Ξ(1620)		*	*				
Ξ(1690)		***		***	**		
Ξ(1820)	3/2−	***	**	***	**	**	
Ξ(1950)		***	**	**		*	
Ξ(2030)		***		**	***		
Ξ(2120)		*		*			
Ξ(2250)		**					3-body decays
Ξ(2370)		**					3-body decays
Ξ(2500)		*		*	*		3-body decays

**** Existence is certain, and properties are at least fairly well explored.
*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, *etc.* are not well determined.
** Evidence of existence is only fair.
* Evidence of existence is poor.

Reference

Ξ(1530) 3/2+

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ****

This is the only Ξ resonance whose properties are all reasonably well known. Assuming that the Λ_c^+ has $J^P = 1/2^+$, AUBERT 08AK, in a study of $\Lambda_c^+ \to \Xi^-\pi^+K^+$, finds conclusively that the spin of the $\Xi(1530)^0$ is 3/2. In conjunction with SCHLEIN 63B and BUTTON-SHAFER 66, this proves also that the parity is +.

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$\Xi(1690)$

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

AUBERT 08AK, in a study of $\Lambda_c^+ \to \Xi^- \pi^+ K^+$, finds some evidence that the $\Xi(1690)$ has $J^P = 1/2^-$.

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma\overline{K}$ mass spectra in $K^- p \to (\Sigma\overline{K})K\pi$ at 4.2 GeV/c. The data from the $\Sigma\overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda\overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ.

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda\overline{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0\overline{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^-. The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 ± 300 events in the $\Xi^-\pi^+$ spectrum produced by 345 GeV/c Σ^--nucleus interactions.

$\Xi(1820)$ $3/2^-$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$ Status: ***

The clearest evidence is an 8-standard-deviation peak in ΛK^- seen by GAY 76C. TEODORO 78 favors $J = 3/2$, but cannot make a parity discrimination. BIAGI 87C is consistent with $J = 3/2$ and favors negative parity for this J value.

$\Xi(1820)$ MASS

We only average the measurements that appear to us to be most significant and best determined.

Ξ(1820) FOOTNOTES

[1] BIAGI 87 also sees weak signals in the in the $\Xi^-\pi^+\pi^-$ channel at 1782.6 ± 1.4 MeV (Γ = 6.0 ± 1.5 MeV) and 1831.9 ± 2.8 MeV (Γ = 9.6 ± 9.9 MeV).
[2] BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV.
[3] From a fit to inclusive $\Xi\pi$, $\Xi\pi\pi$, and ΛK^- spectra.
[4] From a fit to inclusive $\Xi\pi$ and $\Xi\pi\pi$ spectra only.
[5] Including $\Xi\pi\pi$.
[6] DAUBER 69 uses in part the same data as SMITH 65C.
[7] For the decay mode $\Xi^-\pi^+\pi^0$ only. This limit includes $\Xi(1530)\pi$.
[8] Or less. Upper limit for the 3-body decay.

Ξ(1950)

$I(J^P) = \frac{1}{2}(?^?)$ Status: ***

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a Ξ(1950) in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

Ξ(2030)

$I(J^P) = \frac{1}{2}(\geq \frac{5}{2}^?)$ Status: ***

The evidence for this state has been much improved by HEMINGWAY 77, who see an eight standard deviation enhancement in $\Sigma\overline{K}$ and a weaker coupling to $\Lambda\overline{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi\pi\pi$ (or $\Xi(1530)\pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma)\overline{K}\pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

Ξ(2120) FOOTNOTES

[1] CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\overline{\Lambda}K^+)$ X final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV.
[2] GAY 76C sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the $\Xi(2120)$ is real.

Ω BARYONS
($S = -3$, $I = 0$)

$\Omega^- = sss$

Ω^-

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ****

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out $J = 1/2$ and find consistency with $J = 3/2$. AUBERT,BE 06 finds from the decay angular distributions of $\Xi_c^0 \to \Omega^- K^+$ and $\Omega_c^0 \to \Omega^- K^+$ that $J = 3/2$; this depends on the spins of the Ξ_c^0 and Ω_c^0 being $J = 1/2$, their supposed values.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

1673.0 ±8.0	1	ABRAMS	64	HBC	$\to \Xi^-\pi^0$
1670.6 ±1.0	1	[2] FRY	55B	EMUL	
1615	1	[4] EISENBERG	54	EMUL	

[1] DIBIANCA 75 gives a mass for each event. We quote the average.

[2] The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler shift the K^- energy and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L.Alvarez, private communication 1973). We have calculated the error assuming that the orbital n is 4 or larger.

[3] Excluded from the average; the Ω^- lifetimes measured by the experiments differ significantly from other measurements.

[4] The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K^-\,\Xi$Ag.

$\overline{\Omega}^+$ MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them together.

Status: **

OMITTED FROM SUMMARY TABLE

A peak in the $\Omega^-\pi^+\pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS

Revised March 2012 by C.G. Wohl (LBNL).

There are 17 known charmed baryons, and four other candidates not well enough established to be promoted to the Summary Tables.* Fig. 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c differs from a Λ or a Σ only by the replacement of the s quark with a c quark. However, a Ξ or an Ω has more than one s quark, only *one* of which is changed to a c quark to make a Ξ_c or an Ω_c. Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ and Ω spectra.**

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells what charmed baryons to expect; this is essential, because few of the spin-parity values given in Fig. 1(a) have been measured. Rather, they have been assigned in accord with expectations of the theory. However, they are all very likely as shown (see below).

SU(4) multiplets—Baryons made from u, d, s, and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3\times3\times3 = 10+8_1+8_2+1$ for the subset of baryons made from just u, d, and s quarks, is $4\times4\times4 = 20+20'_1+20'_2+\bar{4}$. Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. Figure 2(b) shows the $20'$-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(c) shows the $\bar{4}$ multiplet, an inverted tetrahedron. One level up from the bottom level of each multiplet are the baryons with one c quark. All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet-Λ resonance calls for another $20'$- or 20- or $\bar{4}$-plet, respectively.

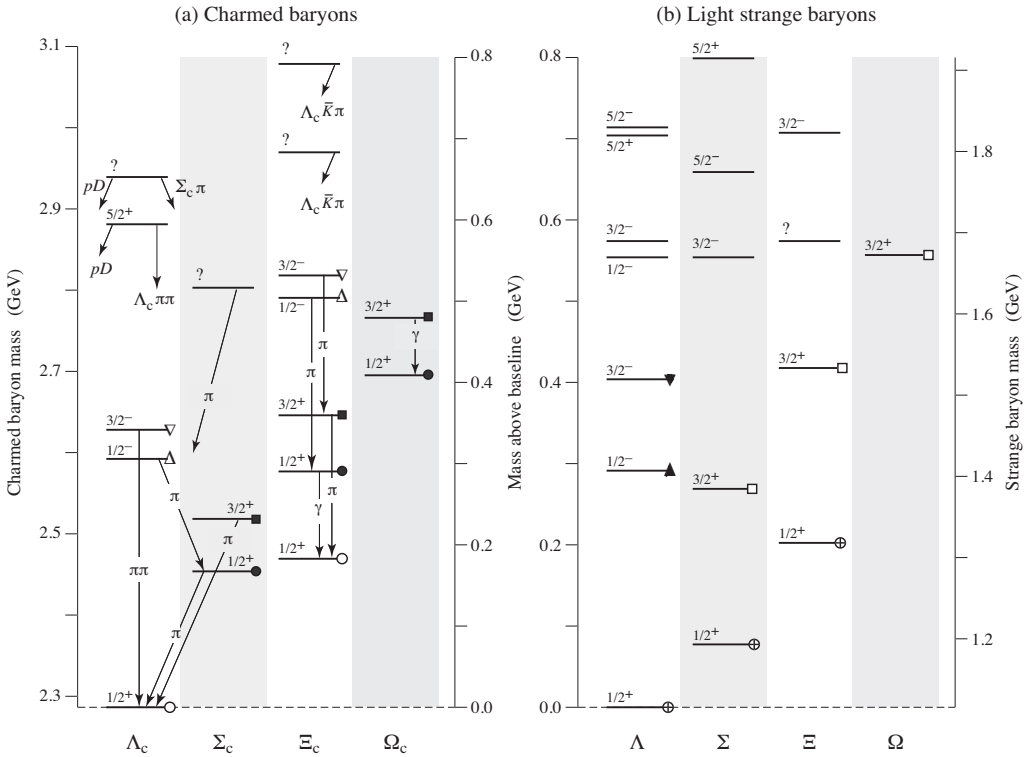

Fig. 1. (a) The known charmed baryons, and (b) the lightest "4-star" strange baryons. Note that there are two $J^P = 1/2^+$ Ξ_c states, and that the lightest Ω_c does not have $J = 3/2$. The $J^P = 1/2^+$ states, all tabbed with a circle, belong to the SU(4) multiplet that includes the nucleon; states with a circle with the same *fill* belong to the same SU(3) multiplet within that SU(4) multiplet. Similar remarks apply to the other states: same shape of tab, same SU(4) multiplet; same fill of that shape, same SU(3) multiplet. The $J^P = 1/2^-$ and $3/2^-$ states tabbed with triangles complete two SU(4) $\bar{4}$ multiplets.

The flavor symmetries shown in Fig. 2 are of course badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same $J^P = 1/2^+$ 20′-plet as the nucleon, a Λ_c, a Σ_c, *two* Ξ_c's, and an Ω_c. Note that this Ω_c has $J^P = 1/2^+$ and is not in the same SU(4) multiplet as the famous $J^P = 3/2^+$ Ω^-.

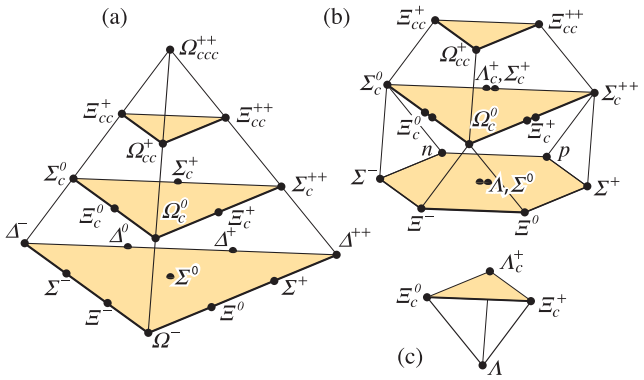

Figure 2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) decuplet on the lowest level. (b) The 20′-plet with an SU(3) octet on the lowest level. (c) The $\overline{4}$-plet. Note that here and in Fig. 3, but not in Fig. 1, each charge state is shown separately.

Figure 3 shows in more detail the middle level of the 20′-plet of Fig. 2(b); it splits apart into two SU(3) multiplets, a $\bar{3}$ and a 6. The states of the $\bar{3}$ are antisymmetric under the interchange of the two light quarks (the u, d, and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\bar{3}$.

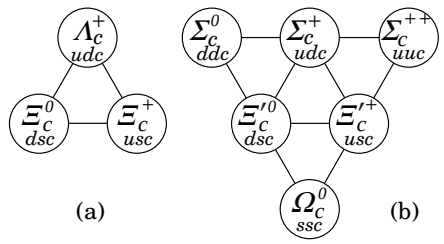

Figure 3: The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 2(b). The Λ_c and Ξ_c tabbed with open circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) $\overline{3}$-plet, as in (a) here. The Σ_c, Ξ_c, and Ω_c tabbed with closed circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) 6-plet, as in (b) here. Together the nine particles complete the charm = +1 level of a $J^P = 1/2^+$ SU(4) 20′-plet, as in Fig. 2(b).

The observed spectra—(1) The parity of the lightest Λ_c is defined to be positive (as are the parities of the p, n, and Λ); the limited evidence about its spin is consistent with $J = 1/2$. However, few of the J^P quantum numbers given in Fig. 1(a) have been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.† There are no surprises: the $J^P = 1/2^+$ states come first, then the $J^P = 3/2^+$ states ...

(2) There is, however, evidence that many of the J^P assignments in Fig. 1(a) must be correct. As is well known, the successive mass differences between the $J^P = 3/2^+$ particles, the $\Delta(1232)^-$, $\Sigma(1385)^-$, $\Xi(1535)^-$, and Ω^-, which lie along the lower left edge of the 20-plet in Fig. 2(a), should according to SU(3) be about equal; and indeed experimentally they nearly are. In the same way, the mass differences between the $J^P = 1/2^+$ $\Sigma_c(2455)^0$, $\Xi_c'^0$, and Ω_c^0,‡ the particles along the left edge of Fig. 3(b), should be about equal—assuming, of course, that they *do* all have the same J^P. The measured differences are 125.0 ± 2.9 MeV and 117.3 ± 3.4 MeV—not perfect, but close. Similarly, the mass differences between the presumed $J^P = 3/2^+$ $\Sigma_c(2520)^0$, $\Xi_c(2645)^0$, and $\Omega_c(2770)^0$ are 127.1 ± 0.8 MeV and 120.0 ± 2.1 MeV. In Fig. 1(a), these two sets of charm particles are tabbed with solid circles and solid squares.

(3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \to \Lambda_c^+ \pi\pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the "Q" is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s-wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P = 1/2^+$, makes $J^P = 1/2^-$ for the $\Lambda_c(2593)$.

Footnotes:

* The unpromoted states are a $\Lambda_c(2765)^+$, a $\Xi_c(2930)$, a $\Xi_c(3055)$, and a $\Xi_c(3123)$. There is also very weak evidence for a baryon with *two* c quarks, a Ξ_{cc}^+ at 3519 MeV. See the Particle Listings.

** For example, there are three Ω_c^0 states (properly symmetrized states of ssc, scs, and css) corresponding to each Ω^- (sss) state.

† This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.

‡ A reminder about the Particle Data Group naming scheme: A particle has its mass as part of its name if and only if it decays strongly. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c'.

Baryon Particle Listings

Λ_c^+

Λ_c^+ $I(J^P) = 0(\frac{1}{2}^+)$ Status: ****

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The quark content is udc. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with $J = 1/2$. Nobody doubts that the spin is indeed 1/2.

The only new measurements since our 2010 Review are of limits on rare or forbidden $\Lambda_c^+ \to p\ell^+\ell^-$ and $\overline{p}\ell^+\ell^+$ modes.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

Λ_c^+ MASS

Our value in 2004, 2284.9±0.6 MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes Σ_c–Λ_c^+ and Λ_c^{*+}–Λ_c^+ mass-difference measurements, but this doesn't affect the Λ_c^+ mass. The new (in 2006) Λ_c^+ mass simply pushes all those other masses higher.

[1] AUBERT,B 05S uses low-Q $\Lambda K_S^0 K^+$ and $\Sigma^0 K_S^0 K^+$ decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the Λ_c^+ mass.

Λ_c^+ MEAN LIFE

Measurements with an error $\geq 100 \times 10^{-15}$ s or with fewer than 20 events have been omitted from the Listings.

Λ_c^+ DECAY MODES

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of B($\Lambda_c^+ \to pK^-\pi^+$) in a Note at the beginning of the branching-ratio measurements, below. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

[a] See the note on "Λ_c^+ Branching Fractions" below.

[b] This branching fraction includes all the decay modes of the final-state resonance.

[c] An ℓ indicates an e or a μ mode, not a sum over these modes.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 33 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 15.5$ for 22 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Λ_c^+ BRANCHING FRACTIONS

Revised 2002 by P.R. Burchat (Stanford University).

Most Λ_c^+ branching fractions are measured relative to the decay mode $\Lambda_c^+ \to pK^-\pi^+$. However, there are no completely model-independent measurements of the absolute branching fraction for $\Lambda_c^+ \to pK^-\pi^+$. Here we describe the measurements that have been used to extract $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$, the model-dependence of the results, and the method we have used to average the results.

ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92) measure $\mathrm{B}(\overline{B} \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$ to be $(0.30 \pm 0.12 \pm 0.06)\%$ and $(0.273 \pm 0.051 \pm 0.039)\%$. Under the assumptions that decays of $\overline{B}$ mesons to baryons are dominated by $\overline{B} \to \Lambda_c^+ \mathrm{X}$ and that $\Lambda_c^+ \mathrm{X}$ final states other than $\Lambda_c^+ \overline{N} \mathrm{X}$ can be neglected, they also measure $\mathrm{B}(\overline{B} \to \Lambda_c^+ \mathrm{X})$ to be $(6.8 \pm 0.5 \pm 0.3)\%$ (ALBRECHT 92O) and $(6.4 \pm 0.8 \pm 0.8)\%$ (CRAWFORD 92). Combining these results, we get $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$. However, the assumption that $\overline{B}$ decay modes to baryons other than $\Lambda_c^+ \overline{N} \mathrm{X}$ are negligible is not on solid ground experimentally or theoretically [2]. Therefore, the branching fraction for $\Lambda_c^+ \to pK^-\pi^+$ given above may be low by some undetermined amount.

A second type of model-dependent determination of $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$ is based on measurements by ARGUS (ALBRECHT 91G) and CLEO (BERGFELD 94) of $\sigma(e^+e^- \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell) = (4.15 \pm 1.03 \pm 1.18)$ pb and $(4.77 \pm 0.25 \pm 0.66)$ pb. ARGUS (ALBRECHT 96E) and CLEO (AVERY 91) have also measured $\sigma(e^+e^- \to \Lambda_c^+ \mathrm{X}) \cdot \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)$. The weighted average is (11.2 ± 1.3) pb.

From these measurements, we extract $R \equiv \mathrm{B}(\Lambda_c^+ \to pK^-\pi^+)/\mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell) = 2.40 \pm 0.43$. We estimate the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction from the equation

$$\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = R\, f\, F\, \frac{\Gamma(D \to \mathrm{X} \ell^+ \nu_\ell)}{1 + |V_{cd}/V_{cs}|^2} \cdot \tau(\Lambda_c^+) \ , \quad (1)$$

where $f = \mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell)/\mathrm{B}(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)$ and $F = \Gamma(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)/\Gamma(D^0 \to X_s \ell^+ \nu_\ell)$. When we use $1 + |V_{cd}/V_{cs}|^2 = 1.05$ and the world averages $\Gamma(D \to \mathrm{X} \ell^+ \nu_\ell) = (0.166 \pm 0.006) \times 10^{12}\ \mathrm{s}^{-1}$ and $\tau(\Lambda_c^+) = (0.192 \pm 0.005) \times 10^{-12}$ s, we calculate $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot f\, F$. Theoretical estimates for f and F are near 1.0 with significant uncertainties.

So, we have two results with significant model-dependence: $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$ from $\overline{B}$ decays, and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4)\% \cdot f\, F$ from semileptonic Λ_c^+ decays. If we set $f\, F = 1.0$ in the second result, and assign an uncertainty of 30% to each result to account for the unknown model-dependence, we get the consistent results $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91 \pm 1.24)\%$ and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3 \pm 1.4 \pm 2.2)\%$. The weighted average of these two results is $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (5.0 \pm 1.3)\%$, where the uncertainty contains both the experimental uncertainty and the 30% estimate of model dependence in each result. We assigned the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction in our 2000 *Review* [1].

A third type of measurement of $B(\Lambda_c^+ \to pK^-\pi^+)$ has been published by CLEO (JAFFE 00). Under the assumption that a $\overline{D}$ meson and an antiproton in opposite hemispheres is evidence for a Λ_c^+ in the hemisphere of the $\overline{p}$, the fraction of such $\overline{D}\,\overline{p}$ events with a $\Lambda_c^+ \to pK^-\pi^+$ decay can be used to determine the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction. CLEO measures $B(\Lambda_c^+ \to pK^-\pi^+) = (5.0 \pm 1.3)\%$, which is coincidentally exactly the same value as our PDG 00 average given above. The quoted uncertainty includes significant contributions from model-dependent effects (*e.g.,* differences between the $\overline{p}$ momentum spectrum in events with a Λ_c^+ and $\overline{p}$ in the same hemisphere, and with a $\overline{D}$ and $\overline{p}$ in opposite hemispheres; extrapolation of the Λ_c^+ and $\overline{D}$ momentum spectrum below the minimum value used for rejecting B decay products; and our limited understanding of backgrounds such as $D\overline{D}N\overline{p}$ events).

We have chosen to continue to assign the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction (given as PDG 02 below). As was noted earlier, most of the other Λ_c^+ decay modes are measured relative to this mode.

New methods for measuring the Λ_c^+ absolute branching fractions have been proposed [2,3].

[2] JAFFE 00 assumes that a $\overline{D}$ meson and an antiproton in opposite hemispheres tags for a Λ_c^+ in the hemisphere of the $\overline{p}$. The fraction of such $\overline{D}\,\overline{p}$ events with a $\Lambda_c^+ \to pK^-\pi^+$ decay then gives the $pK^-\pi^+$ branching fraction. See the paper for assumptions, caveats, etc.

[3] To extract $\Gamma(pK^-\pi^+)/\Gamma_{total}$, we use $B(\overline{B} \to \Lambda_c^+ X)\cdot B(\Lambda_c^+ \to pK^-\pi^+) = (0.28 \pm 0.06)\%$, which is the average of measurements from ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92).

[4] ALBRECHT 92O measures $B(\overline{B} \to \Lambda_c^+ X) = (6.8 \pm 0.5 \pm 0.3)\%$.

[5] CRAWFORD 92 measures $B(\overline{B} \to \Lambda_c^+ X) = (6.4 \pm 0.8 \pm 0.8)\%$.

α FOR $\Lambda_c^+ \to \Lambda\pi^+$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.91±0.15 OUR AVERAGE					
−0.78±0.16±0.19		LINK	06A	FOCS	γ A, $\overline{E}_\gamma \approx$ 180 GeV
−0.94±0.21±0.12	414	[22] BISHAI	95	CLE2	$e^+e^- \approx \Upsilon(4S)$
−0.96±0.42		ALBRECHT	92	ARG	$e^+e^- \approx$ 10.4 GeV
−1.1 ±0.4	86	AVERY	90B	CLEO	$e^+e^- \approx$ 10.6 GeV

[22] BISHAI 95 actually gives $\alpha = -0.94^{+0.21}_{-0.06}{}^{+0.12}_{-0.06}$, chopping the errors at the physical limit −1.0. However, for $\alpha \approx -1.0$, some experiments should *get* unphysical values ($\alpha < -1.0$), and for averaging with other measurements such values (or errors that extend below −1.0) should *not* be chopped.

α FOR $\Lambda_c^+ \to \Sigma^+\pi^0$

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.45±0.31±0.06	89	BISHAI	95	CLE2	$e^+e^- \approx \Upsilon(4S)$

α FOR $\Lambda_c^+ \to \Lambda\ell^+\nu_\ell$

The experiments don't cover the complete (or same incomplete) $M(\Lambda\ell^+)$ range, but we average them together anyway.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.86±0.04 OUR AVERAGE					
−0.86±0.03±0.02	3201	[23] HINSON	05	CLEO	$e^+e^- \approx \Upsilon(4S)$
−0.91±0.42±0.25		[24] ALBRECHT	94B	ARG	$e^+e^- \approx$ 10 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$-0.82^{+0.09}_{-0.06}{}^{+0.06}_{-0.03}$	700	[25] CRAWFORD	95	CLE2	See HINSON 05
$-0.89^{+0.17}_{-0.11}{}^{+0.09}_{-0.05}$	350	[26] BERGFELD	94	CLE2	See CRAWFORD 95

[23] HINSON 05 measures the form-factor ratio $R \equiv f_2/f_1$ for $\Lambda_c^+ \to \Lambda e^+\nu_e$ events to be $-0.31 \pm 0.05 \pm 0.04$ and the pole mass to be $2.21 \pm 0.08 \pm 0.14$ GeV/c^2, and from these calculates α, averaged over q^2, where $\langle q^2\rangle = 0.67$ (GeV/c)^2.

[24] ALBRECHT 94B uses Λe^+ and $\Lambda\mu^+$ events in the mass range $1.85 < M(\Lambda\ell^+) < 2.20$ GeV.

[25] CRAWFORD 95 measures the form-factor ratio $R \equiv f_2/f_1$ for $\Lambda_c^+ \to \Lambda e^+\nu_e$ events to be $-0.25 \pm 0.14 \pm 0.08$ and from this calculates α, averaged over q^2, to be the above.

[26] BERGFELD 94 uses Λe^+ events.

Λ_c^+, $\overline{\Lambda}_c^-$ *CP*-VIOLATING DECAY ASYMMETRIES

$\Lambda_c(2595)^+$

$I(J^P) = 0(\frac{1}{2}^-)$ Status: ***

The $\Lambda_c^+\pi^+\pi^-$ mode is largely, and perhaps entirely, $\Sigma_c\pi$, which is just at threshold; since the Σ_c has $J^P = 1/2^+$, the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405)$.

$\Lambda_c(2595)^+$ MASS

The mass is obtained from the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass-difference measurements below.

VALUE (MeV)	DOCUMENT ID

$\Lambda_c(2595)^+ - \Lambda_c^+$ MASS DIFFERENCE

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
305.79±0.24 OUR FIT					
305.79±0.14±0.20	3.5k	AALTONEN	11H	CDF	$p\overline{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
305.6 ±0.3		[1] BLECHMAN	03		Threshold shift
309.7 ±0.9 ±0.4	19	ALBRECHT	97	ARG	$e^+e^- \approx$ 10 GeV
309.2 ±0.7 ±0.3	14 ± 4.5	FRABETTI	96	E687	γBe, $\overline{E}_\gamma \approx$ 220 GeV
307.5 ±0.4 ±1.0	112 ± 17	EDWARDS	95	CLE2	$e^+e^- \approx$ 10.5 GeV

[1] BLECHMAN 03 finds that a more sophisticated treatment than a simple Breit-Wigner for the proximity of the threshold of the dominant decay, $\Sigma_c(2455)\pi$, lowers the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass difference by 2 or 3 MeV. The analysis of AALTONEN 11H bears this out.

$\Lambda_c(2595)^+$ WIDTH

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
2.59±0.30±0.47	3.5k	[2] AALTONEN	11H	CDF	$p\overline{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$2.9\ ^{+2.9}_{-2.1}\ ^{+1.8}_{-1.4}$	19	ALBRECHT	97	ARG	$e^+e^- \approx$ 10 GeV
$3.9\ ^{+1.4}_{-1.2}\ ^{+2.0}_{-1.0}$	112 ± 17	EDWARDS	95	CLE2	$e^+e^- \approx$ 10.5 GeV

[2] AALTONEN 11H treats the three charged modes $\Lambda_c(2595)^+ \to \Sigma_c(2455)^{++}\pi^-$, $\Sigma_c(2455)^+\pi^0$, $\Sigma_c(2455)^0\pi^+$ separately in terms of a common coupling constant h_2 and obtains $h_2^2 = 0.36 \pm 0.08$. From this the width is determined.

$\Lambda_c(2595)^+$ DECAY MODES

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$\Lambda_c^+\pi^+\pi^-$	[a] $\approx$ 67 %
Γ_2	$\Sigma_c(2455)^{++}\pi^-$	24 $\pm$ 7 %
Γ_3	$\Sigma_c(2455)^0\pi^+$	24 $\pm$ 7 %
Γ_4	$\Lambda_c^+\pi^+\pi^-$ 3-body	18 $\pm$ 10 %
Γ_5	$\Lambda_c^+\pi^0$	[b] not seen
Γ_6	$\Lambda_c^+\gamma$	not seen

[a] Assuming isospin conservation, so that the other third is $\Lambda_c^+\pi^0\pi^0$.

[b] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+.

$\Lambda_c(2880)^+$

$I(J^P) = 0(\frac{5}{2}^+)$ Status: ***

A narrow peak seen in $\Lambda_c^+\pi^+\pi^-$ and in pD^0. It is not seen in pD^+, and therefore it is probably a Λ_c^+ and not a Σ_c. The evidence for spin 5/2 comes from the $\Sigma_c(2455)\pi$ decay angular distribution, and the evidence for parity + comes from agreement of the $\Sigma_c(2520)/\Sigma_c(2455)$ branching ratio with a prediction of heavy quark symmetry (see MIZUK 07).

$\Lambda_c(2940)^+$

$I(J^P) = 0(?^?)$ Status: ***

A fairly narrow peak of good statistical significance first seen in the pD^0 mass spectrum. It is not seen in pD^+, and thus it is probably a Λ_c^+ and not a Σ_c. It is also seen in $\Sigma_c(2455)^{0,++}\pi^\pm$.

$\Sigma_c(2455)$

$I(J^P) = 1(\frac{1}{2}^+)$ Status: ****

The angular distribution of $B^- \to \Sigma_c(2455)^0 \overline{p}$ favors $J = 1/2$ (as the quark model predicts). $J = 3/2$ is excluded by more than four σ see AUBERT 08BN.

$\Sigma_c(2455)$ MASSES

The masses are obtained from the mass-difference measurements that follow.

$\Sigma_c(2800)$

$I(J^P) = 1(?^?)$ Status: ***

Seen in the $\Lambda_c^+\pi^+$, $\Lambda_c^+\pi^0$, and $\Lambda_c^+\pi^-$ mass spectra.

$\Sigma_c(2800)$ MASSES

The charged ++ and + masses are obtained from the mass-difference measurements that follow. The neutral mass is dominated by the mass-difference measurement, but is pulled up somewhat by the less well-determined but considerably higher direct-mass measurement. It is possible, in fact, that AUBERT 08BN is seeing a different Σ_c.

Ξ_c^+

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

2460 ± 25	82	BIAGI	83	SPEC	Σ^-Be 135 GeV

[1] The systematic error was (wrongly) given the other way round in LESIAK 05; see the erratum.

[2] Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees *two* peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75 MeV lower. The latter is attributed to $\Xi_c^+ \to \Sigma^0 K^-\pi^+\pi^+ \to (\Lambda\gamma)K^-\pi^+\pi^+$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into question the interpretation of the lower peak of COTEUS 87.

Ξ_c^0

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

According to the quark model, the Ξ_c^0 (quark content dsc) and Ξ_c^+ form an isospin doublet, and the spin-parity ought to be $J^P = 1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^0 MASS

The fit uses the Ξ_c^0 and Ξ_c^+ mass and mass-difference measurements.

$\Xi_c'^+$

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

The $\Xi_c'^+$ and $\Xi_c'^0$ presumably complete the SU(3) sextet whose other members are the Σ_c^{++}, Σ_c^+, Σ_c^0, and Ω_c^0: see Fig. 3 in the Note on Charmed Baryons just before the Λ_c^+ Listings. The quantum numbers given above come from this presumption but have not been measured.

$\Xi_c'^+$ MASS

The mass is obtained from the mass-difference measurement that follows.

VALUE (MeV)	DOCUMENT ID

$\Xi_c(2645)$

$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$ Status: ***

A narrow peak seen in the $\Xi_c\pi$ mass spectrum. The natural assignment is that this is the $J^P = 3/2^+$ excitation of the Ξ_c in the same SU(4) multiplet as the $\Delta(1232)$, but the quantum numbers have not been measured.

$\Xi_c(2645)$ MASSES

The masses are obtained from the mass-difference measurements that follow.

$\Omega_c(2770)^0$

$I(J^P) = 0(\frac{3}{2}^+)$ Status: ***

The natural assignment is that this goes with the $\Sigma_c(2520)$ and $\Xi_c(2645)$ to complete the lowest mass $J^P = \frac{3}{2}^+$ SU(3) sextet, part of the SU(4) 20-plet that includes the $\Delta(1232)$. But J and P have not been measured.

$\Omega_c(2770)^0$ MASS

The mass is obtained from the mass-difference measurement that follows.

VALUE (MeV)	DOCUMENT ID

DOUBLY CHARMED BARYONS ($C = +2$)

$\Xi_{cc}^{++} = ucc$, $\Xi_{cc}^{+} = dcc$, $\Omega_{cc}^{+} = scc$

Ξ_{cc}^{+}

$I(J^P) = ?(?^?)$ Status: *

OMITTED FROM SUMMARY TABLE

This would presumably be an isospin-1/2 particle, a ccu Ξ_{cc}^{++} and a ccd Ξ_{cc}^{+}. However, opposed to the evidence cited below, the BABAR experiment has found no evidence for a Ξ_{cc}^{+} in a search in $\Lambda_c^+ K^- \pi^+$ and $\Xi_c^0 \pi^+$ modes, and no evidence of a Ξ_{cc}^{++} in $\Lambda_c^+ K^- \pi^+ \pi^+$ and $\Xi_c^0 \pi^+ \pi^+$ modes (AUBERT,B 06D). Nor have the BELLE and LHCb experiments found any evidence for a Ξ_{cc}^{+} in the $\Lambda_c^+ K^- \pi^+$ mode (CHISTOV 06 and AAIJ 13CD).

Λ_b^0 MEAN LIFE

See b-baryon Admixture section for data on b-baryon mean life average over species of b-baryon particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

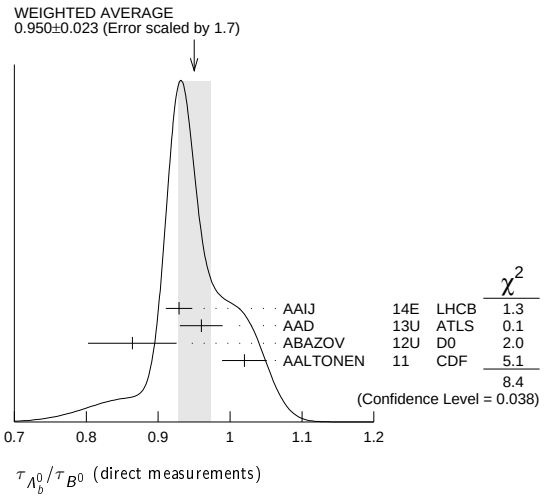
[17] Measured with $\Lambda_b^0 \to J/\psi(\mu^+\mu^-)\,\Lambda^0(p\pi^-)$ decays.

[18] Uses fully reconstructed $\Lambda_b \to J/\psi\Lambda$ decays.

[19] Uses $B^0 \to J/\psi K_S^0$ decays for denominator.

[20] Measures $1/\tau_{\Lambda_b^0} - 1/\tau_{B^0}$ and uses $\tau_{B^0} = 1.519 \pm 0.007$ ps to extract lifetime ratio.

[21] Measured mean life ratio using fully reconstructed decays.



Λ_b^0 DECAY MODES

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$ anything) and B($\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with B($b \to b$-baryon) were used to determine B($b \to b$-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $\Lambda_b \to \overline{\Lambda}_c$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

[a] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.

[b] Here h^- means π^- or K^-.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 8 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 4.5$ for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

VALUE (MeV)		DOCUMENT ID		TECN	COMMENT
5912.1±0.1±0.4	[1,2]	AAIJ	12AL	LHCB	pp at 7 TeV

[1] Observed in $\Lambda_b(5912)^0 \to \Lambda_b^0\pi^+\pi^-$ decays with 17.6 ± 4.8 candidates with a significance of 5.2 sigma.

[2] AAIJ 12AL measures $m(\Lambda_b(5912)^0) - m(\Lambda_b^0) = 292.60 \pm 0.12 \pm 0.04$ MeV. We have adjusted the measurement to our best value of $m(\Lambda_b^0) = 5619.5 \pm 0.4$ MeV. Our first error is their experiment's error and our second error is the systematic error from using our best values.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE (Λ_b, Ξ_b, Σ_b, Ω_b)

b-baryon ADMIXTURE MEAN LIFE

Each measurement of the b-baryon mean life is an average over an admixture of various b baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b-baryon mean life. More b-baryon flavor specific channels are not included in the measurement.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE DECAY MODES (Λ_b,Ξ_b,Σ_b,Ω_b)

These branching fractions are actually an average over weakly decaying *b*-baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the *b*-baryon production fraction B($b \to$ *b*-baryon).

The branching fractions B(*b*-baryon $\to \Lambda\ell^-\overline{\nu}_\ell$anything) and B($\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell$anything) are not pure measurements because the underlying measured products of these with B($b \to$ *b*-baryon) were used to determine B($b \to$ *b*-baryon), as described in the note "Production and Decay of *b*-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B \to D^\pm$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$p\mu^-\overline{\nu}$anything	($5.3^{+\ 2.2}_{-\ 1.9}$) %
Γ_2	$p\ell\overline{\nu}_\ell$anything	(5.1± 1.2) %
Γ_3	$p$anything	(64 ±21) %
Γ_4	$\Lambda\ell^-\overline{\nu}_\ell$anything	(3.5± 0.6) %
Γ_5	$\Lambda\ell^+\nu_\ell$anything	
Γ_6	Λanything	
Γ_7	$\Lambda_c^+\ell^-\overline{\nu}_\ell$anything	
Γ_8	$\Lambda/\overline{\Lambda}$anything	(36 ± 7) %
Γ_9	$\Xi^-\ell^-\overline{\nu}_\ell$anything	(6.0± 1.6) $\times 10^{-3}$

$\Gamma(\Lambda\ell^-\overline{\nu}_\ell$anything$)/\Gamma_{total}$ Γ_4/Γ

The values and averages in this section serve only to show what values result if one assumes our B($b \to$ *b*-baryon). They cannot be thought of as measurements since the underlying product branching fractions were also used to determine B($b \to$ *b*-baryon) as described in the note on "Production and Decay of *b*-Flavored Hadrons."

MAGNETIC MONOPOLES

Updated August 2013 by D. Milstead (Stockholm Univ.) and E.J. Weinberg (Columbia Univ.).

The symmetry between electric and magnetic fields in the sourcefree Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles, even though there is at present no strong theoretical motivation for these.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi}\frac{\hat{\mathbf{r}}}{r^2}\,. \tag{1}$$

Any vector potential $\mathbf{A}$ whose curl is equal to $\mathbf{B}$ must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π. Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges $Q_E^{\rm min}$ and $Q_M^{\rm min}$ obeying

$$Q_E^{\rm min} Q_M^{\rm min} = 2\pi\,. \tag{2}$$

(For monopoles which also carry an electric charge, called dyons, the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r}\times\mathbf{v} - 4\pi Q_E Q_M \hat{\mathbf{r}} \tag{3}$$

Requiring the radial component of $\mathbf{L}$ to be quantized in half-integer units yields Eq. (2).

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [2,3]. For example, a monopole could have both a U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. (2) and conclude that Q_M must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [4] and Polyakov [5], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field ϕ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, ϕ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle\phi\rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of ϕ in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of ϕ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\rm mon} \sim \frac{4\pi M_V}{e^2}\,. \tag{4}$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the electroweak theory, with SU(2)×U(1) broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\mathrm{SU(5)} \xrightarrow{M_X} \mathrm{SU(3)\times SU(2)\times U(1)} \xrightarrow{M_W} \mathrm{SU(3)\times U(1)} \tag{5}$$

has a monopole [6] with $Q_M = 2\pi/e$ and mass

$$M_{\rm mon} \sim \frac{4\pi M_{\rm X}}{g^2}\,, \tag{6}$$

where g is the SU(5) gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\rm mon} \sim 10^{17}$ – 10^{18} GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\mathrm{SO(10)} \xrightarrow{M_1} \mathrm{SU(4)} \times \mathrm{SU(2)} \times \mathrm{SU(2)} \xrightarrow{M_2} \mathrm{SU(3)} \times \mathrm{SU(2)} \times \mathrm{U(1)} \tag{7}$$

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [7].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon–monopole scattering. The surprising feature, pointed out by Callan [8] and Rubakov [9], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as $p + \text{monopole} \to e^+ + \pi^0 + \text{monopole}$ are essentially geometric; *i.e.*, $\sigma_{\Delta B}\beta \sim 10^{-27}$ cm^2, where $\beta = v/c$. Note, however, that intermediate mass monopoles arising at later stages of symmetry breakings, such as the doubly charged monopoles of the SO(10) theory, do not catalyze baryon number violation.

Production and Annihilation: GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [10] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [11]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

Astrophysical and Cosmological Bounds: If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu$G. A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\rm mag} \sim \begin{cases} c, & M \lesssim 10^{11}\mathrm{GeV}\ , \\ 10^{-3}c\left(\frac{10^{17}\,\mathrm{GeV}}{M}\right)^{1/2}, & M \gtrsim 10^{11}\mathrm{GeV}\ . \end{cases} \tag{8}$$

Accelerating these monopoles drains energy from the magnetic field. Parker [12] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. 13 for details), this Parker bound is

$$F < \begin{cases} 10^{-15}\,\mathrm{cm^{-2}\,sr^{-1}\,sec^{-1}}, & M \lesssim 10^{17}\,\mathrm{GeV}\ , \\ 10^{-15}\left(\frac{M}{10^{17}\,\mathrm{GeV}}\right)\mathrm{cm^{-2}\,sr^{-1}\,sec^{-1}}, & M \gtrsim 10^{17}\,\mathrm{GeV}\ . \end{cases} \tag{9}$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [14],

$$F < \left[\frac{M}{10^{17}\mathrm{GeV}} + (3\times 10^{-6})\right] 10^{-16}\,\mathrm{cm^{-2}sr^{-1}sec^{-1}}. \tag{10}$$

Considering magnetic fields in galactic clusters gives a bound [15] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction Ω_M of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\rm uniform} = 1.3\times 10^{-16}\Omega_M \left(\frac{10^{17}\,\mathrm{GeV}}{M}\right)\left(\frac{v}{10^{-3}c}\right)\mathrm{cm^{-2}sr^{-1}sec^{-1}}. \tag{11}$$

If we assume that $\Omega_M \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of Ω_M, and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [16–20], white dwarfs [21], and Jovian planets [22] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and

on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\Big(\frac{\sigma_{\Delta B}\beta}{10^{-27}\mathrm{cm}^2}\Big) \sim (10^{-18} - 10^{-29})\mathrm{cm}^{-2}\mathrm{sr}^{-1}\mathrm{sec}^{-1}. \qquad (12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of Eq. (12).

Searches for Magnetic Monopoles: To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24}Q_M^D$ [23](where Q_M^D is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass [1] [24]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [25]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

Search Techniques: Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [26,27].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

Searches for Monopoles Bound in Matter: Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [28]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [28].

Searches in Cosmic Rays: Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [29] or assigned a modest value (1mb) [30]. Searches which explicitly exploit the expected catalysed decays are discussed in the next section.

Although early cosmic ray searches using the induction technique [31] and NTDs [32] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim 10000\mathrm{m}^2$ for an isotropic flux. As shown in Fig. 1, this experiment has so far provided the most extensive β-dependent flux limits for GUT monopoles with Dirac charge [30]. Also shown are limits from an experiment at the OHYA mine in Japan [29], which used a $2000\mathrm{m}^2$ array of NTDs.

In Fig. 1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO and OYHA flux limits, results from the SLIM [33] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV). In addition to the results shown in Fig. 1, limits as low as $\sim 3 \times 10^{-18}$ $\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}$ and $\sim 10^{-17}$ $\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}$ were obtained for monopoles with $\beta > 0.8$ and $\beta > 0.625$ by the IceCube [34] and Antares [35] experiments, respectively. The most stringent constraints on the flux of ultra-relativistic monopoles have been obtained by the RICE [36] and ANITA-II experiments [37] at the South Pole which were sensitive to monopoles with γ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as 10^{-19} $\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{sr}^{-1}$.

Searches via the Catalysis of Nucleon-Decay: Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [38] and Macro [39] experiments, using

[1] Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

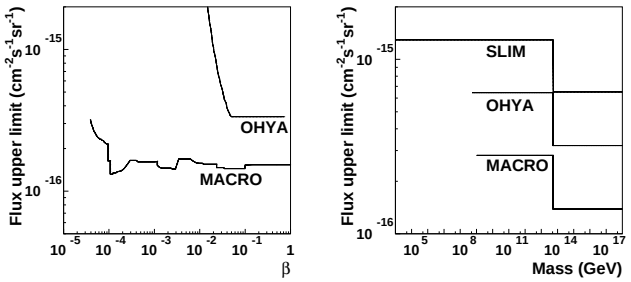

Figure 1: Upper flux limits for (a) GUT monopoles as a function of β (b) Monopoles as a function of mass for $\beta > 0.05$.

tracking detectors. Searches at IMB [40] and the underwater Lake Baikal experiment [41] which exploit the Cerenkov effect have also been made. The resulting β-dependent flux limits from these experiments typically vary between $\sim 10^{-16}$ and $\sim 10^{-14}\mathrm{cm}^{-2}\mathrm{sr}^{-1}\mathrm{s}^{-1}$ [25]. A recent search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [42]. A β-dependent of limit of $6.3 \times 10^{-24}(\frac{\beta}{10^{-3}})^2\mathrm{cm}^{-2}\mathrm{sr}^{-1}\mathrm{s}^{-1}$ was obtained.

Searches at Colliders: Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

Direct Searches at Colliders: Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 2 for recent results from high energy colliders.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in pp collisions at the LHC by the ATLAS experiment [43]. In this search, highly ionising particles leaving characteristic energy deposition profiles were sought. Tevatron searches have also been carried out by the CDF [44] and E882 [45] experiments. The CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [46], used

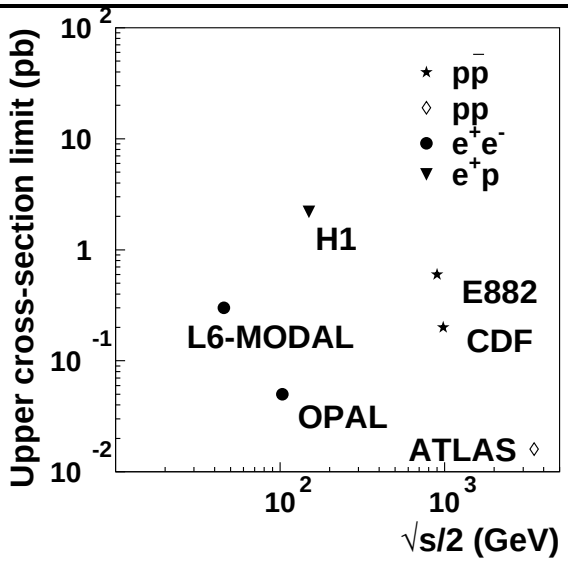

Figure 2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [47] and searches for trapped monopoles [48].

The only LEP-2 search was made by OPAL [49] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to $\sim$ 45 GeV. The L6-MODAL experiment [50] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [51]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [52] and PETRA [53]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [54,55].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [56]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

Indirect Searches at Colliders: It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [57,58]. Photon-based searches were made by the D0 [59] and L3 [60] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

[1] AAD 12CS searched for monopoles as highly ionising objects. The cross section limits are based on an assumed Drell Yan-like production process for spin 1/2 monopoles. The limits are mass- and scenario-dependent.

[2] ABBIENDI 08 assume production of spin 1/2 monopoles with effective charge $g\beta$ (n=1), via $e^+e^- \rightarrow \gamma^* \rightarrow M\overline{M}$, so that the cross section is proportional to $(1 + \cos^2\theta)$. There is no z information for such highly saturated tracks, so a parabolic track in the jet chamber is projected onto the xy plane. Charge per hit in the chamber produces a clean separation of signal and background.

[3] ABULENCIA 06K searches for high-ionizing signals in CDF central outer tracker and time-of-flight detector. For Drell-Yan $M\overline{M}$ production, the cross section limit implies $M > 360$ GeV at 95% CL.

[4] AKTAS 05A model-dependent limits as a function of monopole mass shown for arbitrary mass of 60 GeV. Based on search for stopped monopoles in the H1 Al beam pipe.

[5] AKTAS 05A limits with assumed elastic spin 0 monopole pair production.

[6] AKTAS 05A limits with assumed inelastic spin 1/2 monopole pair production.

[7] KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Cross section results moderately model dependent; interpretation as a mass lower limit depends on possibly invalid perturbation expansion.

[8] KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.

[9] KALBFLEISCH 00 result is for aluminum.

[10] KALBFLEISCH 00 result is for beryllium.

[11] HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.

[12] Multiphoton events.

[13] Cherenkov radiation polarization.

[14] Re-examines CERN neutrino experiments.

Monopole Production — Other Accelerator Searches

> 510			88–94	e^+e^-	[2] ACCIARRI	95C	L3

[1] ABBOTT 98K search for heavy pointlike Dirac monopoles via central production of a pair of photons with high transverse energies.

[2] ACCIARRI 95C finds a limit $B(Z \rightarrow \gamma\gamma\gamma) < 0.8 \times 10^{-5}$ (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

Monopole Flux — Cosmic Ray Searches

"Caty" in the charge column indicates a search for monopole-catalyzed nucleon decay.

[1] ABBASI 13 and ABBASI 10A were based on a Cherenkov signature in an array of optical modules which were sunk in the Antarctic ice cap. Limits are speed-dependent.

[2] ADRIAN-MARTINEZ 12A measurements were based on a Cherenkov signature in an underwater telescope in the Western Mediterranean Sea. Limits are speed-dependent.

[3] The limits from UENO 12 depend on the monopole speed and are also sensitive to assumed values of monopole mass and the catalysis cross section.

[4] HOGAN 08 and DETRIXHE 11 limits on relativistic monopoles are based on nonobservation of radio Cherenkov signals at the South Pole. Limits are speed-dependent.

[5] BALESTRA 08 exposed of nuclear track detector modules totaling 400 m^2 for 4 years at the Chacaltaya Laboratory (5230 m) in search for intermediate-mass monopoles with $\beta > 0.05$. The analysis is mainly based on three CR39 modules. For $M > 5 \times 10^{13}$ GeV there can be upward-going monopoles as well, hence the flux limit is half that obtained for less massive monopoles. Previous experiments (e.g. MACRO and OHYA (ORITO 91)) had set limits only for $M > 1 \times 10^9$ GeV.

[6] AMBROSIO 02B direct search final result for $m \geq 10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from β=4 $\times 10^{-5}$ (3.1×10^{-16} cm^{-2} sr^{-1} s^{-1}) to $\beta = 1 \times 10^{-4}$ (2.1×10^{-16} cm^{-2} sr^{-1} s^{-1}). Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.

[7] AMBROSIO 02C limit for catalysis of nucleon decay with catalysis cross section of $\approx$ 1 mb. The flux limit increases by $\sim$ 3 at the higher β limit, and increases to 1×10^{-14} cm^{-2} sr^{-1} s^{-1} if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m^2 sr.

[8] AMBROSIO 02D result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 02B.

[9] AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at β=1.1×10^{-4}, goes through a minimum at 0.61×10^{-15} near β=(1.1–2.7) $\times10^{-3}$, then rises to 0.84×10^{-15} at β=0.1. The global limit in this region is below the Parker bound at 10^{-15}. Less stringent limits are established for $4\times10^{-5}<\beta<1\times10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.

[10] AHLEN 94 limit for dyons extends down to β=0.9E−4 and a limit of 1.3E−14 extends to β = 0.8E−4. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.

[11] Catalysis of nucleon decay; sensitive to assumed catalysis cross section.

[12] ORITO 91 limits are functions of velocity. Lowest limits are given here.

[13] Used DKMPR mechanism and Penning effect.

[14] Assumes monopole attaches fermion nucleus.

[15] Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.

[16] Based on lack of high-energy solar neutrinos from catalysis in the sun.

[17] Anomalous long-range α (^{4}He) tracks.

[18] CABRERA 82 candidate event has single Dirac charge within ±5%.

[19] ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

[1] Catalysis of nucleon decay.

[2] ADAMS 93 limit based on "survival and growth of a small galactic seed field" is 10^{-16} ($m/10^{17}$ GeV) $cm^{-2}s^{-1}sr^{-1}$. Above 10^{17} GeV, limit 10^{-16} (10^{17} GeV/m) $cm^{-2}s^{-1}sr^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.

[3] Re-evaluates PARKER 70 limit for GUT monopoles.

Supersymmetric Particle Searches

SUPERSYMMETRY, PART I (THEORY)

Revised October 2013 by Howard E. Haber (UC Santa Cruz).

I.1. Introduction: Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa [1]. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [2]. Supersymmetry also provides a framework for the unification of particle physics and gravity [3–6] at the Planck energy scale, $M_{\rm P} \approx 10^{19}$ GeV, where the gravitational interactions become comparable in magnitude to the gauge interactions. Moreover, supersymmetry can provide an explanation of the large hierarchy between the energy scale that characterizes electroweak symmetry breaking (of order 100 GeV) and the Planck scale [7–10]. The stability of this large *gauge hierarchy* with respect to radiative quantum corrections is not possible to maintain in the Standard Model without an *unnatural* fine-tuning of the parameters of the fundamental theory at the Planck scale. In contrast, in a supersymmetric extension of the Standard Model, it is possible to maintain the gauge hierarchy with no fine-tuning of parameters, and provide a natural framework for elementary scalar fields.

If supersymmetry were an exact symmetry of nature, then particles and their *superpartners*, which differ in spin by half a unit, would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the supersymmetry breaking is *soft* [11,12], and the corresponding supersymmetry-breaking mass parameters are no larger than a few TeV. Whether this is still plausible in light of recent supersymmetry searches at the LHC [13] will be discussed in Section I.7.

In particular, soft-supersymmetry-breaking terms of the Lagrangian involve combinations of fields with total mass dimension of three or less, with some restrictions on the dimension-three terms as elucidated in Ref. 11. The impact of the soft terms becomes negligible at energy scales much larger than the size of the supersymmetry-breaking masses. Thus, a theory of *weak-scale supersymmetry*, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking, provides a *natural* framework for the origin and the stability of the gauge hierarchy [7–10].

The Standard Model cannot be the correct theory of fundamental particles and their interactions (applicable at all energy scales). However, no unambiguous experimental results currently exist that imply that the Standard Model breaks down at the TeV scale. The expectations of new physics beyond

the Standard Model at the TeV scale are based primarily on three theoretical arguments. First, a natural explanation of the gauge hierarchy demands new physics at the TeV scale [10]. Second, the unification of the three Standard Model gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the Standard Model (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of the Standard Model (MSSM), where superpartner masses lie below a few TeV, provides an example of successful gauge coupling unification [14]. Third, the existence of dark matter, which makes up approximately one quarter of the energy density of the universe, cannot be explained within the Standard Model of particle physics [15]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called *WIMP miracle*, which is reviewed in Ref. 16). The lightest supersymmetric particle is a promising (although not the unique) candidate for the dark matter [17–21]. Further aspects of dark matter can be found in Ref. 22.

Another phenomenon not explained by the Standard Model is the origin of the matter–antimatter asymmetry of the universe [23]. Models of baryogenesis must satisfy the three Sakharov conditions [24]: C and CP violation, baryon number violation and a departure from thermal equilibrium. For example, the matter–antimatter asymmetry in the early universe can be generated at the electroweak phase transition if the transition is sufficiently first-order [25]. These conditions are not satisfied in the Standard Model, since the CP violation is too small and the phase transition is not strongly first-order [25]. In contrast, it is possible to satisfy these conditions in supersymmetric extensions of the Standard Model, where new sources of CP-violation exist and supersymmetric loops provide corrections to the temperature-dependent effective potential that can render the transition sufficiently first-order. The MSSM parameter space in which electroweak baryogenesis occurs is strongly constrained by LHC data [26]. However, extended supersymmetric models provide new opportunities for successful electroweak baryogenesis [27].

I.2. Structure of the MSSM: The minimal supersymmetric extension of the Standard Model consists of the fields of the two-Higgs-doublet extension of the Standard Model and the corresponding supersymmetric partners [28,29]. A particle and its superpartner together form a supermultiplet. The corresponding field content of the supermultiplets of the MSSM and their gauge quantum numbers are shown in Table 1. The electric charge $Q = T_3 + \frac{1}{2}Y$ is determined in terms of the third component of the weak isospin (T_3) and the U(1) weak hypercharge (Y).

Table 1: The fields of the MSSM and their SU(3)×SU(2)×U(1) quantum numbers are listed. For simplicity, only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs super-multiplet, there is a corresponding anti-particle multiplet of charge-conjugated fermions and their associated scalar partners.

Field Content of the MSSM						
Super-multiplets	Super-field	Bosonic fields	Fermionic partners	SU(3)	SU(2)	U(1)
gluon/gluino	$\widehat{V}_8$	g	$\widetilde{g}$	8	1	0
gauge/	$\widehat{V}$	$W^{\pm}$, W^0	$\widetilde{W}^{\pm}$, $\widetilde{W}^0$	1	3	0
gaugino	$\widehat{V}'$	B	$\widetilde{B}$	1	1	0
slepton/	$\widehat{L}$	$(\widetilde{\nu}_L, \widetilde{e}_L^-)$	$(\nu, e^-)_L$	1	2	-1
lepton	$\widehat{E}^c$	$\widetilde{e}_R^-$	e_R^-	1	1	-2
squark/	$\widehat{Q}$	$(\widetilde{u}_L, \widetilde{d}_L)$	$(u, d)_L$	3	2	1/3
quark	$\widehat{U}^c$	$\widetilde{u}_R$	u_R	3	1	4/3
	$\widehat{D}^c$	$\widetilde{d}_R$	d_R	3	1	$-2/3$
Higgs/	$\widehat{H}_d$	(H_d^0, H_d^-)	$(\widetilde{H}_d^0, \widetilde{H}_d^-)$	1	2	-1
higgsino	$\widehat{H}_u$	(H_u^+, H_u^0)	$(\widetilde{H}_u^+, \widetilde{H}_u^0)$	1	2	1

The gauge supermultiplets consist of the gluons and their *gluino* fermionic superpartners and the SU(2)×U(1) gauge bosons and their *gaugino* fermionic superpartners. The matter supermultiplets consist of three generations of left-handed and right-handed quarks and leptons, their scalar superpartners (*squarks* and *sleptons*), and the corresponding antiparticles. The Higgs supermultiplets consist of two complex Higgs doublets, their *higgsino* fermionic superpartners, and the corresponding antiparticles. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of anomalies from the introduction of the higgsino superpartners. Moreover, without a second Higgs doublet, one cannot generate mass for both "up"-type and "down"-type quarks (and charged leptons) in a way consistent with the underlying supersymmetry [30–32].

The fields of a given supermultiplet are components of a *superfield*. Vector superfields contain the gauge boson fields and their gaugino partners. Chiral superfields contain the spin-0 and spin-1/2 fields of the matter or Higgs supermultiplets. A general supersymmetric Lagrangian is determined by three functions of the chiral superfields [6]: the superpotential, the Kähler potential, and the gauge kinetic function (which can be appropriately generalized to accommodate higher derivative terms [33]). Minimal forms for the Kähler potential and gauge kinetic function, which generate canonical kinetic energy terms for all the fields, are required for *renormalizable* globally supersymmetric theories. A renormalizable superpotential, which is at most cubic in the chiral superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and supersymmetry produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy

SU(3)×SU(2)×U(1) gauge invariance and B–L conservation (where B = baryon number and L = lepton number). Finally, the most general soft-supersymmetry-breaking terms consistent with these symmetries are added [11,12,34].

Although the MSSM is the focus of much of this review, there is some motivation for considering non-minimal supersymmetric extensions of the Standard Model. For example, extra structure is needed to generate non-zero neutrino masses as discussed in Section I.8. In addition, in order to address some theoretical issues and tensions associated with the MSSM, it has been fruitful to introduce one additional singlet Higgs superfield. The resulting next-to-minimal supersymmetric extension of the Standard Model (NMSSM) [35] is considered further in Sections I.5, I.7 and I.9. Finally, one is always free to add additional fields to the Standard Model along with the corresponding superpartners. However, only certain choices for the new fields (*e.g.*, the addition of complete SU(5) multiplets) will preserve the successful gauge coupling unification. Some examples will be briefly mentioned in Section I.9.

I.2.1. R-parity and the lightest supersymmetric particle: As a consequence of B–L invariance, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [36]. This implies that all the ordinary Standard Model particles have even R-parity, whereas the corresponding supersymmetric partners have odd R-parity. The conservation of R-parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, any initial state in a scattering experiment will involve ordinary (R-even) particles. Consequently, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. Moreover, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [19]. Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Moreover, as noted in Section I.1 and reviewed in Refs. [20,21], the stability of the LSP in R-parity-conserving supersymmetry makes it a promising candidate for dark matter.

I.2.2. The goldstino and gravitino: In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the SU(3)×SU(2)×U(1) gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the *goldstino* ($\widetilde{G}_{1/2}$) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [37].

However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global supersymmetry. If supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity [38]. In models of spontaneously-broken supergravity, the goldstino is "absorbed" by the *gravitino* ($\widetilde{G}$) [sometimes called $\widetilde{g}_{3/2}$ in the older literature], the spin-3/2 superpartner of the graviton [39]. By this super-Higgs mechanism, the goldstino is removed from the physical spectrum and the gravitino acquires a mass ($m_{3/2}$). In processes with center-of-mass energy $E \gg m_{3/2}$, the goldstino–gravitino equivalence theorem [40] states that the interactions of the helicity $\pm\frac{1}{2}$ gravitino (whose properties approximate those of the goldstino) dominate those of the helicity $\pm\frac{3}{2}$ gravitino. The interactions of gravitinos with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles [41].

I.2.3. Hidden sectors and the structure of supersymmetry breaking: It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken low-energy supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. An alternative scheme posits a theory consisting of at least two distinct sectors: a *hidden* sector consisting of particles that are completely neutral with respect to the Standard Model gauge group, and a *visible* sector consisting of the particles of the MSSM [34]. There are no renormalizable tree-level interactions between particles of the visible and hidden sectors. Supersymmetry breaking is assumed to originate in the hidden sector, and its effects are transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional *messenger* sector). Two theoretical scenarios that exhibit this structure are gravity mediated and gauge mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of *gravity mediated* supersymmetry breaking, gravity is the messenger of supersymmetry breaking [42–46]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by inverse powers of the Planck mass). In this scenario, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are roughly gravitational in strength [3,47]. Such a gravitino typically plays no role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [48]).

Under certain theoretical assumptions on the structure of the Kähler potential (the so-called sequestered form introduced in Ref. 49), supersymmetry breaking is due entirely to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [49]. In this case, gaugino masses are radiatively generated at one-loop and squark and slepton masses are flavor-diagonal. This approach is called *anomaly-mediated*

supersymmetry breaking (AMSB). Indeed, anomaly mediation is more generic than originally conceived, and provides a ubiquitous source of supersymmetry breaking [50]. However in the simplest formulation of AMSB as applied to the MSSM, the squared-masses of the sleptons are negative. This is the so-called tachyonic slepton problem. It may be possible to cure this fatal flaw in approaches beyond the minimal supersymmetric model [51]. Alternatively, one can assert that anomaly mediation is not the sole source of supersymmetry breaking, at least in the slepton sector.

In *gauge mediated* supersymmetry breaking (GMSB), gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where supersymmetry is broken, a messenger sector consisting of particles (messengers) with nontrivial SU(3)×SU(2)×U(1) quantum numbers, and the visible sector consisting of the fields of the MSSM [52–54]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Supersymmetry breaking is then transmitted to the MSSM via the virtual exchange of the messengers. In models of *direct gauge mediation*, there is no hidden sector. In particular, the sector in which the supersymmetry breaking originates includes fields that carry nontrivial Standard Model quantum numbers, which allows for the direct transmission of supersymmetry breaking to the MSSM [55]. In this case, no separate messenger sector distinct from the fundamental supersymmetry-breaking sector is required.

The gravitino mass in models of gauge mediated supersymmetry breaking is typically in the eV range (although in some cases it can be as large as a few GeV), which implies that $\widetilde{G}$ is the LSP [17]. In particular, the gravitino is a potential dark matter candidate (for a review and guide to the literature, see Ref. 21). Big bang nucleosynthesis also provides some interesting constraints on the gravitino and the properties of the next-to-lightest supersymmetric particle that decays into the gravitino LSP [56]. The couplings of the helicity $\pm\frac{1}{2}$ components of $\widetilde{G}$ to the particles of the MSSM (which approximate those of the goldstino as previously noted in Section I.2.2) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The concept of a hidden sector is more general than supersymmetry. *Hidden valley* models [57] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the Standard Model. The impact of a hidden valley on supersymmetric phenomenology at colliders can be significant if the LSP lies in the hidden sector [58].

I.2.4. Supersymmetry and extra dimensions:
Approaches to supersymmetry breaking have also been developed in the context of theories in which the number of space dimensions is greater than three. In particular, a number of supersymmetry-breaking mechanisms have been proposed that are inherently extra-dimensional [59]. The size of the extra dimensions can be significantly larger than $M_{\rm P}^{-1}$; in some cases of order $(\text{TeV})^{-1}$ or even larger [60,61].

For example, in one approach the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks supersymmetry lives on a second spatially-separated brane. Two examples of this approach are anomaly-mediated supersymmetry breaking [49] and gaugino-mediated supersymmetry breaking [62]. In both cases, supersymmetry breaking is transmitted through fields that live in the bulk (the higher-dimensional space between the two branes). This setup has some features in common with both gravity mediated and gauge mediated supersymmetry breaking (*e.g.*, a hidden and visible sector and messengers).

Alternatively, one can consider a higher-dimensional theory that is compactified to four spacetime dimensions. In this approach, supersymmetry is broken by boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [63]. The phenomenology of such models can be strikingly different from that of the usual MSSM [64].

I.2.5. Split-supersymmetry: If supersymmetry is not connected with the origin of the electroweak scale, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of *split-supersymmetry* [65], in which scalar superpartners of the quarks and leptons are significantly heavier (perhaps by many orders of magnitude) than 1 TeV, whereas the fermionic superpartners of the gauge and Higgs bosons have masses on the order of 1 TeV or below (protected by some chiral symmetry). With the exception of a single light neutral scalar whose properties are practically indistinguishable from those of the Standard Model Higgs boson, all other Higgs bosons are also assumed to be very heavy.

The recent observation of a Higgs boson at a mass of 126 GeV [66,67] implies that there is an upper bound in the MSSM on the mass scale that characterizes the top squarks in the range of 10 to 10^6 TeV [69,70]. It is not difficult to formulate models in which gaugino masses are one-loop suppressed relative to the masses of the squarks and sleptons. The higgsino mass scale may or may not be likewise suppressed depending on the details of the model [71]. Recently, a number of authors have considered a supersymmetric spectrum with the squarks, slepton and the heavy Higgs masses around 10^3 TeV, whereas gaugino masses are around 1 TeV [70,71]. In this scenario, only the lighter gaugino states are kinematically accessible at the LHC. The one light Higgs scalar of the model (identified with the observed scalar state at 126 GeV) is indistinguishable from the Standard Model Higgs boson.

The supersymmetry breaking required to produce such a split-supersymmetry spectrum would destabilize the gauge hierarchy, and thus yield no natural explanation for the scale of electroweak symmetry breaking. Nevertheless, models of split-supersymmetry can account for the dark matter (which is

assumed to be the LSP gaugino or higgsino) and gauge coupling unification, thereby preserving two of the good features of weak-scale supersymmetry.

I.3. Parameters of the MSSM: The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving and the supersymmetry-breaking sectors. A careful discussion of the conventions used here in defining the tree-level MSSM parameters can be found in Ref. 72. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

I.3.1. The supersymmetric-conserving parameters: The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings, g_s, g, and g', corresponding to the Standard Model gauge group SU(3)×SU(2)×U(1) respectively; (ii) a supersymmetry-conserving higgsino mass parameter μ; and (iii) Higgs-fermion Yukawa coupling constants, λ_u, λ_d, and λ_e, corresponding to the coupling of one generation of left- and right-handed quarks and leptons, and their superpartners to the Higgs bosons and higgsinos. Because there is no right-handed neutrino (and its superpartner) in the MSSM as defined here, a Yukawa coupling λ_ν is not included here. The complex μ parameter and Yukawa couplings enter via the most general renormalizable R-parity-conserving superpotential,

$$W = \lambda_d \widehat{H}_d \widehat{Q} \widehat{D}^c - \lambda_u \widehat{H}_u \widehat{Q} \widehat{U}^c + \lambda_e \widehat{H}_d \widehat{L} \widehat{E}^c + \mu \widehat{H}_u \widehat{H}_d \,, \qquad (1)$$

where the superfields are defined in Table 1 and the gauge group indices are suppressed. The reader is warned that in the literature, μ is sometimes defined with the opposite sign to the one given in Eq. (1).

I.3.2. The supersymmetry-breaking parameters: The supersymmetry-breaking sector contains the following sets of parameters: (i) three complex gaugino Majorana mass parameters, M_3, M_2, and M_1, associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) five diagonal scalar squared-mass parameters for the squarks and sleptons, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$ [corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of $(u,d)_L$, u^c_L, d^c_L, $(\nu,\, e^-)_L$, and e^c_L, where the superscript c indicates a charge-conjugated fermion]; and (iii) three Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with complex coefficients $\lambda_u A_U$, $\lambda_d A_D$, and $\lambda_e A_E$ (which define the so-called "A-parameters"). It is traditional to factor out the Yukawa couplings in the definition of the A-parameters (originally motivated by a simple class of gravity mediated supersymmetry-breaking models [3,5]). If the A-parameters defined as above are parametrically of the same order (or smaller) relative to other supersymmetry-breaking mass parameters, then only the third generation A-parameters are phenomenologically relevant. The reader is warned that the convention for the overall sign of the A-parameters varies in the literature.

Finally, we have (iv) three scalar squared-mass parameters: two of which (m_1^2 and m_2^2) are real parameters that contribute to the diagonal Higgs squared-masses, given by $m_1^2 + |\mu|^2$ and $m_2^2 + |\mu|^2$, and a third that contributes to the off-diagonal Higgs squared-mass term, $m_{12}^2 \equiv B\mu$ (which defines the complex "B-parameter"). The breaking of the electroweak symmetry SU(2)×U(1) to $\mathrm{U(1)_{EM}}$ is only possible after introducing the supersymmetry-breaking Higgs squared-mass parameters. Minimizing the resulting tree-level Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_d and v_u (also called v_1 and v_2, respectively, in the literature), and the CP-odd Higgs mass m_A (cf. Section I.5). Here, v_d [v_u] is the vacuum expectation value of the neutral component of the Higgs field H_d [H_u] that couples exclusively to down-type (up-type) quarks and leptons.

Note that $v_d^2 + v_u^2 = 2m_W^2/g^2 \simeq (174\ \mathrm{GeV})^2$ is fixed by the W mass and the SU(2) gauge coupling, whereas the ratio

$$\tan\beta = v_u/v_d \qquad (2)$$

is a free parameter. It is convenient to choose the phases of the Higgs fields such that m_{12}^2 is real and non-negative. In this case, we can adopt a convention where $0 \leq \beta \leq \pi/2$. The tree-level conditions for the scalar potential minimum relate the diagonal and off-diagonal Higgs squared-masses in terms of $m_Z^2 = \frac{1}{4}(g^2 + g'^2)(v_d^2 + v_u^2)$, the angle β and the CP-odd Higgs mass m_A:

$$\sin 2\beta = \frac{2m_{12}^2}{m_1^2 + m_2^2 + 2|\mu|^2} = \frac{2m_{12}^2}{m_A^2}\,, \qquad (3)$$

$$\tfrac{1}{2}m_Z^2 = -|\mu|^2 + \frac{m_1^2 - m_2^2\tan^2\beta}{\tan^2\beta - 1}\,. \qquad (4)$$

One must also guard against the existence of charge and/or color breaking global minima due to non-zero vacuum expectation values for the squark and charged slepton fields. This possibility can be avoided if the A-parameters are not unduly large [43,73].

Note that supersymmetry-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-supersymmetry-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with gauge-singlet superfields. The latter are not present in the MSSM; hence as noted in Ref. 12, these so-called non-standard soft-supersymmetry-breaking terms are benign. However, the coefficients of these terms (which have dimensions of mass) are expected to be significantly suppressed compared to the TeV-scale in a fundamental theory of supersymmetry-breaking [74]. Consequently, we follow the usual approach and omit these terms from further consideration.

I.3.3. MSSM-124: The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$,

and $M^2_{\widetilde{E}}$ are hermitian 3×3 matrices, and A_U, A_D, and A_E are complex 3×3 matrices. In addition, M_1, M_2, M_3, B, and μ are in general complex parameters. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings, λ_f ($f=u$, d, and e), are complex 3×3 matrices that are related to the quark and lepton mass matrices via: $M_f=\lambda_f v_f$, where $v_e\equiv v_d$ [with v_u and v_d as defined above Eq. (2)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. 75 shows that the MSSM possesses 124 independent parameters. Of these, 18 correspond to Standard Model parameters (including the QCD vacuum angle $\theta_{\rm QCD}$), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CP-violating phases in the gaugino/higgsino sector, 21 squark and slepton masses, 36 real mixing angles to define the squark and slepton mass eigenstates, and 40 CP-violating phases that can appear in squark and slepton interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [76].

I.4. The supersymmetric-particle spectrum: The supersymmetric particles (*sparticles*) differ in spin by half a unit from their Standard Model partners. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" to the end of the corresponding Standard Model particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass $M_{\widetilde{g}}=|M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix due to SU(2)×U(1) breaking effects. As a result, the physical states of definite mass are model-dependent linear combinations of the charged and neutral gauginos and higgsinos, called *charginos* and *neutralinos*, respectively. Like the gluino, the neutralinos are also Majorana fermions, which provide for some distinctive phenomenological signatures [77,78]. The supersymmetric partners of the quarks and leptons are spin-zero bosons: the *squarks*, charged *sleptons*, and *sneutrinos*, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. 79. The MSSM Feynman rules also are implicitly contained in a number of Feynman diagram and amplitude generation software packages (see *e.g.*, Refs. [80–82]).

It should be noted that all mass formulae quoted in this section are tree-level results. Radiative loop corrections will modify these results and must be included in any precision study of supersymmetric phenomenology [83]. Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The Supersymmetry Les Houches Accord (SLHA) [84] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators. Ultimately, these efforts will facilitate the reconstruction of the fundamental supersymmetric theory (and its breaking mechanism) from high-precision studies of supersymmetric phenomena at future colliders.

I.4.1. The charginos and neutralinos: The mixing of the charged gauginos ($\widetilde{W}^\pm$) and charged higgsinos (H_u^+ and H_d^-) is described (at tree-level) by a 2×2 complex mass matrix [85–87]:

$$M_C\equiv\begin{pmatrix} M_2 & \frac{1}{\sqrt{2}}gv_u \\ \frac{1}{\sqrt{2}}gv_d & \mu \end{pmatrix}. \qquad (5)$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [88,89] of the complex matrix M_C:

$$U^*M_CV^{-1}=\mathrm{diag}(M_{\widetilde{\chi}_1^+},M_{\widetilde{\chi}_2^+}), \qquad (6)$$

where U and V are unitary matrices, and the right-hand side of Eq. (6) is the diagonal matrix of (non-negative) chargino masses. The physical chargino states are denoted by $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^\pm$. These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of U and V [85–87]. The chargino masses correspond to the *singular values* [88] of M_C, *i.e.*, the positive square roots of the eigenvalues of $M_C^\dagger M_C$:

$$M^2_{\widetilde{\chi}_1^+,\widetilde{\chi}_2^+}=\tfrac{1}{2}\Big\{|\mu|^2+|M_2|^2+2m_W^2\mp\Big[\big(|\mu|^2+|M_2|^2+2m_W^2\big)^2 - 4|\mu|^2|M_2|^2-4m_W^4\sin^2 2\beta+8m_W^2\sin2\beta\,\mathrm{Re}(\mu M_2)\Big]^{1/2}\Big\}, \qquad (7)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^+}\le M_{\widetilde{\chi}_2^+}$. Note that the relative phase of M_2 and μ is meaningful.

The mixing of the neutral gauginos ($\widetilde{B}$ and $\widetilde{W}^0$) and neutral higgsinos ($\widetilde{H}_d^0$ and $\widetilde{H}_u^0$) is described (at tree-level) by a 4×4 complex symmetric mass matrix [85,86,90,91]:

$$M_N\equiv\begin{pmatrix} M_1 & 0 & -\frac{1}{2}g'v_d & \frac{1}{2}g'v_u \\ 0 & M_2 & \frac{1}{2}gv_d & -\frac{1}{2}gv_u \\ -\frac{1}{2}g'v_d & \frac{1}{2}gv_d & 0 & -\mu \\ \frac{1}{2}g'v_u & -\frac{1}{2}gv_u & -\mu & 0 \end{pmatrix}. \qquad (8)$$

To determine the physical neutralino states and their masses, one must perform a Takagi-diagonalization [88,89,92,93] of the complex symmetric matrix M_N:

$$W^TM_NW=\mathrm{diag}(M_{\widetilde{\chi}_1^0},M_{\widetilde{\chi}_2^0},M_{\widetilde{\chi}_3^0},M_{\widetilde{\chi}_4^0}), \qquad (9)$$

where W is a unitary matrix and the right-hand side of Eq. (9) is the diagonal matrix of (non-negative) neutralino masses. The

physical neutralino states are denoted by $\widetilde{\chi}_i^0$ ($i = 1, \ldots 4$), where the states are ordered such that $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$. The $\widetilde{\chi}_i^0$ are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of W (which is denoted by N^{-1} in Ref. 85). The neutralino masses correspond to the singular values of M_N, *i.e.*, the positive square roots of the eigenvalues of $M_N^\dagger M_N$. Exact formulae for these masses can be found in Refs. [90] and [94]. A numerical algorithm for determining the mixing matrix W has been given by Ref. 95.

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if $|M_1|$ and $|M_2|$ are small compared to m_Z and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure *photino*, $\widetilde{\gamma}$, the supersymmetric partner of the photon. If $|M_1|$ and m_Z are small compared to $|M_2|$ and $|\mu|$, then the lightest neutralino would be nearly a pure *bino*, $\widetilde{B}$, the supersymmetric partner of the weak hypercharge gauge boson. If $|M_2|$ and m_Z are small compared to $|M_1|$ and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure *winos*, $\widetilde{W}^\pm$, and $\widetilde{W}_3^0$, the supersymmetric partners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to $|M_1|$ and $|M_2|$, then the lightest chargino pair and neutralino would be nearly pure *higgsino* states, the supersymmetric partners of the Higgs bosons. Each of the above cases leads to a strikingly different phenomenology.

In the NMSSM, an additional Higgs singlet superfield is added to the MSSM. This superfield comprises two real Higgs scalar degrees of freedom and an associated neutral higgsino degree of freedom. Consequently, there are five neutralino mass eigenstates that are obtained by a Takagi-diagonalization of the 5×5 neutralino mass matrix. In many cases, the fifth neutralino state is dominated by its SU(2)×U(1) singlet component, and thus is very weakly coupled to the Standard Model particles and their superpartners.

I.4.2. The squarks, sleptons and sneutrinos: For a given fermion f, there are two supersymmetric partners, $\widetilde{f}_L$ and $\widetilde{f}_R$, which are scalar partners of the corresponding left-handed and right-handed fermion. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, in general $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is possible, in which case $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass eigenstates. For three generations of squarks, one must diagonalize 6×6 matrices corresponding to the basis $(\widetilde{q}_{iL}, \widetilde{q}_{iR})$, where $i = 1, 2, 3$ are the generation labels. For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and is treated in Ref. 96.)

Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [97]

$$\mathcal{M}^2 = \begin{pmatrix} M_{\widetilde{Q}}^2 + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M_{\widetilde{R}}^2 + m_q^2 + R_q \end{pmatrix}, \qquad (10)$$

where

$$X_q \equiv A_q - \mu^* (\cot\beta)^{2T_{3q}}, \qquad (11)$$

and $T_{3q} = \frac{1}{2}$ [$-\frac{1}{2}$] for $q = t$ [b]. The diagonal squared-masses are governed by soft-supersymmetry-breaking squared-masses $M_{\widetilde{Q}}^2$ and $M_{\widetilde{R}}^2 \equiv M_{\widetilde{U}}^2$ [$M_{\widetilde{D}}^2$] for $q = t$ [b], the corresponding quark masses m_t [m_b], and electroweak correction terms:

$$L_q \equiv (T_{3q} - e_q \sin^2\theta_W) m_Z^2 \cos 2\beta\,, \quad R_q \equiv e_q \sin^2\theta_W\, m_Z^2 \cos 2\beta\,, \qquad (12)$$

where $e_q = \frac{2}{3}$ [$-\frac{1}{3}$] for $q = t$ [b]. The off-diagonal squark squared-masses are proportional to the corresponding quark masses and depend on $\tan\beta$, the soft-supersymmetry-breaking A-parameters and the higgsino mass parameter μ. Assuming that the A-parameters are parametrically of the same order (or smaller) relative to other supersymmetry-breaking mass parameters, it then follows that $\widetilde{q}_L$–$\widetilde{q}_R$ mixing effects are small, with the possible exception of the third generation, where mixing can be enhanced by factors of m_t and $m_b \tan\beta$.

In the case of third generation $\widetilde{q}_L$–$\widetilde{q}_R$ mixing, the mass eigenstates (usually denoted by $\widetilde{q}_1$ and $\widetilde{q}_2$, with $m_{\widetilde{q}_1} < m_{\widetilde{q}_2}$) are determined by diagonalizing the 2×2 matrix $\mathcal{M}^2$ given by Eq. (10). The corresponding squared-masses and mixing angle are given by [97]:

$$m_{\widetilde{q}_{1,2}}^2 = \frac{1}{2}\left[\mathrm{Tr}\,\mathcal{M}^2 \mp \sqrt{(\mathrm{Tr}\mathcal{M}^2)^2 - 4\det\mathcal{M}^2}\right],$$

$$\sin 2\theta_{\tilde{q}} = \frac{2m_q|X_q|}{m_{\widetilde{q}_2}^2 - m_{\widetilde{q}_1}^2}\,. \qquad (13)$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions: $q \to \tau$ with $T_{3\tau} = -\frac{1}{2}$ and $e_\tau = -1$, and the replacement of the supersymmetry-breaking parameters: $M_{\widetilde{Q}}^2 \to M_{\widetilde{L}}^2$, $M_{\widetilde{D}}^2 \to M_{\widetilde{E}}^2$, and $A_q \to A_\tau$. For the neutral sleptons, $\widetilde{\nu}_R$ does not exist in the MSSM, so $\widetilde{\nu}_L$ is a mass eigenstate.

In the case of three generations, the supersymmetry-breaking scalar-squared masses [$M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, $M_{\widetilde{D}}^2$, $M_{\widetilde{L}}^2$, and $M_{\widetilde{E}}^2$] and the A-parameters [A_U, A_D, and A_E] are now 3×3 matrices as noted in Section I.3.3. The diagonalization of the 6×6 squark mass matrices yields $\widetilde{f}_{iL}$–$\widetilde{f}_{jR}$ mixing (for $i \neq j$). In practice, since the $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. 96 for examples in which the mixing between the second and third generation squarks is relevant).

I.5. The supersymmetric Higgs sector: Consider first the MSSM Higgs sector [31,32,98]. Despite the large number of potential CP-violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs sector is automatically CP-conserving. This follows from the fact that the only potentially complex parameter (m_{12}^2) of the MSSM Higgs potential can be chosen real and positive by rephasing the Higgs fields, in which case $\tan\beta$ is a real positive parameter. Consequently, the physical neutral Higgs scalars are CP-eigenstates. The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair ($H^\pm$), two CP-even neutral Higgs bosons (denoted by h^0 and H^0 where $m_h < m_H$), and one

CP-odd neutral Higgs boson (A^0). The recent discovery of a Standard Model-like Higgs boson at the LHC with a mass of 126 GeV [66,67] strongly suggests that this state should be identified with h^0, although the possibility that the 126 GeV state should be identified with H^0 cannot be completely ruled out [99].

In the NMSSM [35], the scalar component of the singlet Higgs superfield adds two additional neutral states to the Higgs sector. In this model, the tree-level Higgs sector can exhibit explicit CP-violation. If CP is conserved, then the two extra neutral scalar states are CP-even and CP-odd, respectively. These states can potentially mix with the neutral Higgs states of the MSSM. If scalar states exist that are dominantly singlet, then they are weakly coupled to Standard Model gauge bosons and fermions through their small mixing with the MSSM Higgs scalars. Consequently, it is possible that one (or both) of the singlet-dominated states is considerably lighter than the Higgs boson that was observed at the LHC.

I.5.1 The Tree-level Higgs sector: The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were specified above Eq. (2)] and quartic interaction terms governed by dimensionless couplings. The quartic interaction terms are manifestly supersymmetric at tree level (although these are modified by supersymmetry-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called "F-terms"), and (ii) interaction terms related by supersymmetry to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called "D-terms").

In the MSSM, F-term contributions to the quartic couplings are absent. As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings. Due to the resulting constraint on the form of the two-Higgs-doublet scalar potential, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan\beta$ [defined in Eq. (2)] and one Higgs mass usually taken to be m_A. From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle α (which measures the mixture of the original $Y = \pm 1$ Higgs doublet states in the physical CP-even neutral scalars), and the Higgs boson self-couplings. Moreover, the tree-level mass of the lighter CP-even Higgs boson is bounded, $m_h \leq m_Z|\cos 2\beta| \leq m_Z$ [31,32]. This bound can be substantially modified when radiative corrections are included, as discussed in Section I.5.2.

In the NMSSM, the superpotential contains a trilinear term that couples the two $Y = \pm 1$ Higgs doublet superfields and the singlet Higgs superfield. The coefficient of this term is denoted by λ. Consequently, the tree-level bound for the mass of the lightest CP-even MSSM Higgs boson is modified [100],

$$m_h^2 \leq m_Z^2 \cos^2 2\beta + \lambda^2 v^2 \sin^2 2\beta\,, \qquad (14)$$

where $v \equiv (v_u^2 + v_d^2)^{1/2} = 174$ GeV. If one demands that λ should stay finite below the Planck scale, then λ is constrained to lie below about 0.7. However, in light of the observed Higgs mass of 126 GeV, there is some phenomenological motivation for considering larger values of λ [101].

I.5.2 The radiatively-corrected Higgs sector: When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual supersymmetric particles that can appear in loops. The impact of these corrections can be significant [102]. The qualitative behavior of these radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries and the off-diagonal entries of the top-squark squared-mass matrix [Eq. (10)] are small in comparison to the geometric mean of the two top-squark squared-masses, $M_{\rm S}^2 \equiv M_{\tilde{t}_1} M_{\tilde{t}_2}$. In this case (assuming $m_A > m_Z$), the predicted upper bound for m_h is approximately given by

$$m_h^2 \lesssim m_Z^2 \cos^2 2\beta + \frac{3g^2 m_t^4}{8\pi^2 m_W^2}\left[\ln\left(\frac{M_{\rm S}^2}{m_t^2}\right) + \frac{X_t^2}{M_{\rm S}^2}\left(1 - \frac{X_t^2}{12 M_{\rm S}^2}\right)\right], \qquad (15)$$

where $X_t \equiv A_t - \mu\cot\beta$ is proportional to the off-diagonal entry of the top-squark squared-mass matrix (which for simplicity is taken here to be real). The Higgs mass upper limit is saturated when $\tan\beta$ is large (*i.e.*, $\cos^2 2\beta \sim 1$) and $X_t = \sqrt{6}\, M_S$. This value of X_t defines the so-called *maximal mixing* scenario.

A more complete treatment of the radiative corrections [103] shows that Eq. (15) somewhat overestimates the true upper bound of m_h. These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield $m_h \lesssim 135$ GeV in the large $\tan\beta$ regime (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [103].

In addition, one-loop radiative corrections can introduce CP-violating effects in the Higgs sector, which depend on some of the CP-violating phases among the MSSM-124 parameters [104]. Although these effects are more model-dependent, they can have a non-trivial impact on the Higgs searches at LHC and at future colliders. A summary of the MSSM Higgs mass limits based on searches at LEP, Tevatron and LHC and the corresponding references to the literature can be found in Ref. 67.

In the NMSSM, the dominant radiative correction to Eq. (14) is the same as the one given in Eq. (15). However, in contrast to the MSSM, one does not need as large a boost from the radiative corrections to achieve a Higgs mass of 126 GeV. For example, the observed Higgs mass is easily achieved in the NMSSM parameter regime where $\tan\beta \sim 2$ and $\lambda \sim 0.7$.

I.6. Restricting the MSSM parameter freedom: In Sections I.4 and I.5, we surveyed the parameters that comprise the MSSM-124. However, in its most general form, the MSSM-124 is not a phenomenologically-viable theory over most of its parameter space. This conclusion follows from the observation

that a generic point in the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers L_e, L_μ, and L_τ; (ii) unsuppressed flavor-changing neutral currents (FCNCs); and (iii) new sources of CP violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of CP violation [68]. In particular, in weak-scale supersymmetry some combinations of the complex phases of the gaugino-mass parameters, the A-parameters, and μ must be less than on the order of 10^{-2}–10^{-3} to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [105–107]. The non-observation of FCNCs [108–110] places additional strong constraints on the off-diagonal matrix elements of the squark and slepton soft-supersymmetry-breaking squared-masses and A-parameters (see Section I.3.3). As a result of the phenomenological deficiencies listed above, almost the entire MSSM-124 parameter space is ruled out! This theory is viable only at very special "exceptional" regions of the full parameter space.

The MSSM-124 is also theoretically incomplete as it provides no explanation for the origin of the supersymmetry-breaking parameters (and in particular, why these parameters should conform to the exceptional regions of the parameter space mentioned above). Moreover, there is no understanding of the choice of parameters that leads to the breaking of the electroweak symmetry. What is needed ultimately is a fundamental theory of supersymmetry breaking, which would provide a rationale for a set of soft-supersymmetry-breaking terms that is consistent with all phenomenological constraints.

The successful unification of the SU(3)×SU(2)×U(1) gauge couplings in supersymmetric grand unified theories [8,65,111,112] suggests that the high-energy structure of the theory may be considerably simpler than its low-energy realization. In a top-down approach, the dynamics that governs the more fundamental theory at high energies is used to derive the effective broken-supersymmetric theory at the TeV scale. A suitable choice for the high energy dynamics is one that yields a TeV-scale theory that satisfies all relevant phenomenological constraints.

In this Section, we examine a number of theoretical frameworks that potentially yield phenomenologically viable regions of the MSSM-124 parameter space. The resulting supersymmetric particle spectrum is then a function of a relatively small number of input parameters. This is accomplished by imposing a simple structure on the soft-supersymmetry-breaking terms at a common high-energy scale M_X (typically chosen to be the Planck scale, $M_{\rm P}$, the grand unification scale, $M_{\rm GUT}$, or the messenger scale, $M_{\rm mess}$). Using the renormalization group equations, one can then derive the low-energy MSSM parameters relevant for collider physics. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory.

Examples of this scenario are provided by models of gravity mediated, anomaly mediated and gauge mediated supersymmetry breaking, to be discussed in more detail below. In some of these approaches, one of the diagonal Higgs squared-mass parameters is driven negative by renormalization group evolution [113]. In such models, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

I.6.1. Gaugino mass unification:

One prediction that arises in many grand unified supergravity models and gauge mediated supersymmetry-breaking models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale $M_{\rm X}$:

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}\,. \tag{16}$$

Due to renormalization group running, the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5M_2\,, \qquad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2. \tag{17}$$

In this case, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ, and $\tan\beta$. It then follows that the lightest neutralino must be heavier than 46 GeV due to the non-observation of charginos at LEP [114]. If in addition $|\mu| \gg |M_1| \gtrsim m_Z$, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders.

Although Eqs. (16) and (17) are often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters, M_i, to be independent parameters to be determined by experiment. Indeed, an approximately massless neutralino *cannot* be ruled out at present by a model-independent analysis [115].

It is possible that the tree-level masses for the gauginos are absent. In this case, the gaugino mass parameters arise at one-loop and do not satisfy Eq. (17). For example, the gaugino masses in AMSB models arise entirely from a model-independent contribution derived from the super-conformal anomaly [49,116]. In this case, Eq. (17) is replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}\,, \tag{18}$$

where $m_{3/2}$ is the gravitino mass and the b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups, $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (18) yields $M_1 \simeq 2.8M_2$ and $M_3 \simeq -8.3M_2$, which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos, $\widetilde{W}^\pm$, $\widetilde{W}^0$ (cf. Table 1), over most of the MSSM parameter space. For example, if $|\mu| \gg m_Z$, then Eq. (18) implies that $M_{\widetilde{\chi}_1^\pm} \simeq M_{\widetilde{\chi}_1^0} \simeq M_2$ [117]. The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (17) [118,119].

Finally, it should be noted that the unification of gaugino masses (and scalar masses) can be accidental. In particular, the energy scale where unification takes place may not be directly related to any physical scale. One version of this phenomenon has been called *mirage unification* and can occur in certain theories of fundamental supersymmetry breaking [120].

I.6.2. The constrained MSSM: mSUGRA, CMSSM, ... In the *minimal* supergravity (mSUGRA) framework [3–5,42–44], a form of the Kähler potential is employed that yields minimal kinetic energy terms for the MSSM fields [46]. As a result, the soft-supersymmetry-breaking parameters at the high-energy scale M_X take a particularly simple form in which the scalar squared-masses and the A-parameters are flavor-diagonal and universal [44]:

$$\begin{aligned} &M_{\widetilde{Q}}^2(M_X) = M_{\widetilde{U}}^2(M_X) = M_{\widetilde{D}}^2(M_X) = m_0^2\mathbf{1}\,, \\ &M_{\widetilde{L}}^2(M_X) = M_{\widetilde{E}}^2(M_X) = m_0^2\mathbf{1}\,, \\ &m_1^2(M_X) = m_2^2(M_X) = m_0^2\,, \\ &A_U(M_X) = A_D(M_X) = A_E(M_X) = A_0\mathbf{1}\,, \end{aligned} \tag{19}$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. As in the Standard Model, this approach exhibits minimal flavor violation [121,122], whose unique source is the nontrivial flavor structure of the Higgs-fermion Yukawa couplings. The gaugino masses are also unified according to Eq. (16).

Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one must use the *low-energy* values for $M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, and $M_{\widetilde{D}}^2$ in Eq. (10). Through the renormalization group running with boundary conditions specified in Eqs. (17) and (19), one can show that the low-energy values of $M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, and $M_{\widetilde{D}}^2$ depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. 123.

In the mSUGRA approach, four flavors of squarks (with two squark eigenstates per flavor) are nearly mass-degenerate. If $\tan\beta$ is not very large, $\widetilde{b}_R$ is also approximately degenerate in mass with the first two generations of squarks. The $\widetilde{b}_L$ mass and the diagonal $\widetilde{t}_L$ and $\widetilde{t}_R$ masses are typically reduced relative to the common squark mass of the first two generations. In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. As noted below Eq. (10), third-generation squark masses and tau-slepton masses are sensitive to the strength of the respective $\widetilde{f}_L$–$\widetilde{f}_R$ mixing. The LSP is typically the lightest neutralino, $\widetilde{\chi}_1^0$, which is dominated by its bino component. Regions of the mSUGRA parameter space in which the LSP is electrically charged do exist but are not phenomenologically viable [19].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model parameters (excluding the Higgs mass), one must specify m_0, $m_{1/2}$, A_0, the Planck-scale values for μ and B-parameters (denoted by μ_0 and B_0), and the gravitino mass $m_{3/2}$. Without additional model assumptions, $m_{3/2}$ is independent of the parameters that govern the mass spectrum of the superpartners of the Standard Model [44]. In principle, A_0, B_0, μ_0, and $m_{3/2}$ can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ [the sign of μ_0, denoted $\mathrm{sgn}(\mu_0)$ below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0\,,\ A_0\,,\ m_{1/2}\,,\ \tan\beta\,,\ \text{and}\ \ \mathrm{sgn}(\mu_0)\,, \tag{20}$$

and an independent gravitino mass $m_{3/2}$ (in addition to the 18 parameters of the Standard Model). This framework is conventionally called the *constrained minimal supersymmetric extension of the Standard Model* (CMSSM).

In the early literature, additional conditions were obtained by assuming a simplified form for the hidden sector that provides the fundamental source of supersymmetry breaking. Two additional relations emerged among the mSUGRA parameters [42,46]: $B_0 = A_0 - m_0$ and $m_{3/2} = m_0$. These relations characterize a theory that was called minimal supergravity when first proposed. In the more recent literature, it has been more common to omit these extra conditions in defining the mSUGRA model (in which case the mSUGRA model and the CMSSM are synonymous). The authors of Ref. 124 advocate restoring the original nomenclature in which the mSUGRA model is defined with the extra conditions as originally proposed. Additional mSUGRA variations can be considered where different relations among the CMSSM parameters are imposed.

One can also relax the universality of scalar masses by decoupling the squared-masses of the Higgs bosons and the squarks/sleptons. This leads to the non-universal Higgs mass models (NUHMs), thereby adding one or two new parameters to the CMSSM depending on whether the diagonal Higgs scalar squared-mass parameters (m_1^2 and m_2^2) are set equal (NUHM1) or taken to be independent (NUHM2) at the high energy scale M_X^2. Clearly, this modification preserves the minimal flavor violation of the mSUGRA approach. Nevertheless, the mSUGRA approach and its NUHM generalizations are probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [125]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In the framework of supergravity, if anomaly mediation is the sole source of supersymmetry breaking, then the gaugino mass parameters, diagonal scalar squared-mass parameters, and the supersymmetry-breaking trilinear scalar interaction terms (proportional to $\lambda_f A_F$) are determined in terms of the beta functions of the gauge and Yukawa couplings and the anomalous dimensions of the squark and slepton fields [49,116,119]. As noted in Section I.2.3, this approach yields tachyonic sleptons in the MSSM unless additional sources of supersymmetry breaking are present. In the *minimal* AMSB (mAMSB) scenario, a universal squared-mass parameter, m_0^2, is added to the AMSB expressions for the diagonal scalar squared-masses [119]. Thus, the mAMSB spectrum and its interaction strengths are determined by four parameters, m_0^2, $m_{3/2}$, $\tan\beta$ and $\mathrm{sgn}(\mu_0)$.

The mAMSB scenario appears to be ruled out based on the observed value of the Higgs boson mass, assuming an upper limit on M_S of a few TeV, since the mAMSB constraint on A_F implies that the maximal mixing scenario cannot be achieved [cf. Eq. (15)]. Indeed, under the stated assumptions, the mAMSB Higgs mass upper bound lies below the observed Higgs mass value [126]. Thus within the AMSB scenario, either an additional supersymmetry-breaking contribution to $\lambda_f A_F$ and/or new ingredients beyond the MSSM are required.

I.6.3. Gauge mediated supersymmetry breaking: In contrast to models of gravity mediated supersymmetry breaking, the universality of the fundamental soft-supersymmetry-breaking squark and slepton squared-mass parameters is guaranteed in gauge mediated supersymmetry breaking (GMSB) because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [53,54]. In GMSB models, the mass scale of the messenger sector (or its equivalent) is sufficiently below the Planck scale such that the additional supersymmetry-breaking effects mediated by supergravity can be neglected.

In the minimal GMSB approach, there is one effective mass scale, Λ, that determines all low-energy scalar and gaugino mass parameters through loop effects, while the resulting A-parameters are suppressed. In order that the resulting superpartner masses be of order 1 TeV or less, one must have $\Lambda \sim 100$ TeV. The origin of the μ and B-parameters is quite model-dependent, and lies somewhat outside the ansatz of gauge mediated supersymmetry breaking.

The simplest GMSB models appear to be ruled out based on the observed value of the Higgs boson mass. Due to suppressed A parameters, it is difficult to boost the contributions of the radiative corrections in Eq. (15) to obtain a Higgs mass as large as 126 GeV. However, this conflict can be alleviated in more complicated GMSB models [127]. To analyze these generalized GMSB models, it has been especially fruitful to develop model-independent techniques that encompass all known GMSB models [128]. These techniques are well-suited for a comprehensive analysis [129] of the phenomenological profile of gauge mediated supersymmetry breaking.

The gravitino is the LSP in GMSB models, as noted in Section I.2.3. As a result, the next-to-lightest supersymmetric particle (NLSP) now plays a crucial role in the phenomenology of supersymmetric particle production and decays. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\widetilde{\chi}_1^0$ and $\widetilde{\tau}_R^{\pm}$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$, $\widetilde{\chi}_1^0 \to Z\widetilde{G}$, $\widetilde{\chi}_1^0 \to h^0\widetilde{G}$ or $\widetilde{\tau}_R^{\pm} \to \tau^{\pm}\widetilde{G}$), with lifetimes and branching ratios that depend on the model parameters. There are also GMSB scenarios in which there are several nearly degenerate so-called co-NLSP's, any one of which can be produced at the penultimate step of a supersymmetric decay chain [130]. For example, in the slepton co-NLSP case, all three right-handed sleptons are close enough in mass and thus can each play the role of the NLSP.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [54,131]. For example, a long-lived $\widetilde{\chi}_1^0$-NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the $\widetilde{\chi}_1^0$-LSP). On the other hand, if $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would contain a photon. In contrast, in the case of a $\widetilde{\tau}_R^{\pm}$-NLSP, the $\widetilde{\tau}_R^{\pm}$ would either be long-lived or would decay inside the detector into a τ-lepton plus missing energy.

I.6.4. The phenomenological MSSM: Of course, any of the theoretical assumptions described in this Section could be wrong and must eventually be tested experimentally. To facilitate the exploration of MSSM phenomena in a more model-independent way while respecting the constraints noted at the beginning of this Section, the phenomenological MSSM (pMSSM) has been introduced [132].

The pMSSM is governed by 19 independent real parameters beyond the Standard Model, which include the three gaugino mass parameters M_1, M_2 and M_3, the Higgs sector parameters m_A and $\tan\beta$, the Higgsino mass parameter μ, five squark and slepton squared-mass parameters for the degenerate first and second generations ($M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, $M_{\widetilde{D}}^2$, $M_{\widetilde{L}}^2$ and $M_{\widetilde{E}}^2$), the five corresponding squark and slepton squared-mass parameters for the third generation, and three third-generation A-parameters (A_t, A_b and A_τ). As previously noted, the first and second generation A-parameters can be neglected as their phenomenological consequences are negligible.

I.7. Experimental data confronts the MSSM:

At present, there is no evidence for weak-scale supersymmetry from the data analyzed by the LHC experiments. Recent LHC data has been especially effective in ruling out the existence of colored supersymmetric particles (primarily the gluino and the first generation of squarks) with masses below about 1 TeV [13,133]. The precise mass limits are model dependent. For example, higher mass colored superpartners have been ruled out in the context of the CMSSM. In more generic frameworks

of the MSSM, regions of parameter space can be identified in which lighter squarks and gluinos below 1 TeV cannot be definitely ruled out. Details of these constraints can be found in Ref. 13. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [108–110].

In light of the negative results in the search for supersymmetry, one must confront the tension that exists between the theoretical expectations for the magnitude of the supersymmetry-breaking parameters and the non-observation of supersymmetric phenomena.

I.7.1 Naturalness constraints and the little hierarchy:

In Section I, weak-scale supersymmetry was motivated as a natural solution to the hierarchy problem, which could provide an understanding of the origin of the electroweak symmetry-breaking scale without a significant fine-tuning of the fundamental parameters that govern the MSSM. In this context, the soft-supersymmetry-breaking masses must be generally of the order of 1 TeV or below [134]. This requirement is most easily seen in the determination of m_Z by the scalar potential minimum condition. In light of Eq. (4), to avoid the fine-tuning of MSSM parameters, the soft-supersymmetry-breaking squared-masses m_1^2 and m_2^2 and the higgsino squared-mass $|\mu|^2$ should all be roughly of $\mathcal{O}(m_Z^2)$. Many authors have proposed quantitative measures of fine-tuning [134–136]. One of the simplest measures is the one given by Barbieri and Giudice [134],

$$\Delta_i \equiv \left| \frac{\partial \ln m_Z^2}{\partial \ln p_i} \right| , \qquad \Delta \equiv \max\ \Delta_i \, , \tag{21}$$

where the p_i are the MSSM parameters at the high-energy scale M_X, which are set by the fundamental supersymmetry-breaking dynamics. The theory is more fine-tuned as Δ becomes larger.

One can apply the fine-tuning measure to any explicit model of supersymmetry breaking. For example, in the approaches discussed in Section I.6, the p_i are parameters of the model at the energy scale M_X where the soft-supersymmetry-breaking operators are generated by the dynamics of supersymmetry breaking. Renormalization group evolution then determines the values of the parameters appearing in Eq. (4) at the electroweak scale. In this way, Δ is sensitive to all the supersymmetry-breaking parameters of the model (see e.g. Ref. 137).

As anticipated, there is a tension between the present experimental lower limits on the masses of colored supersymmetric particles [138] and the expectation that supersymmetry-breaking is associated with the electroweak symmetry-breaking scale. Moreover, this tension is exacerbated by the observed value of the Higgs mass ($m_h \simeq 126$ GeV), which is not far from the the MSSM upper bound ($m_h \lesssim 135$ GeV) [which depends on the top-squark mass and mixing as noted in Section I.5.2]. If $M_{\rm SUSY}$ characterizes the scale of supersymmetric particle masses, then one would crudely expect $\Delta \sim M_{\rm SUSY}^2/m_Z^2$. For example, if $M_{\rm SUSY} \sim 1$ TeV then there must be at least a $\Delta^{-1} \sim 1\%$ fine-tuning of the MSSM parameters to achieve the observed value of m_Z. This separation of the electroweak symmetry-breaking and supersymmetry-breaking scales is an example of the *little hierarchy problem* [140,141].

However, one must be very cautious when drawing conclusions about the viability of weak-scale supersymmetry to explain the origin of electroweak symmetry breaking [142]. First, one must decide the largest tolerable value of Δ within the framework of weak-scale supersymmetry (should it be $\Delta \sim 10$? 100? 1000?). Second, the fine-tuning parameter Δ depends quite sensitively on the structure of the supersymmetry-breaking dynamics, such as the value of M_X and relations among supersymmetry-breaking parameters in the fundamental high energy theory [143]. For example, in so-called focus point supersymmetry models [144], all squark masses can be as heavy as 5 TeV *without* significant fine-tuning. This can be attributed to a focusing behavior of the renormalization group evolution where certain relations hold among the high-energy values of the scalar squared-mass supersymmetry-breaking parameters.

Among the colored superpartners, the third generation squarks generically have the most significant impact on the naturalness constraints [145], while their masses are the least constrained by the LHC data. Hence, in the absence of any relation between third generation squarks and those of the first two generations, the naturalness constraints due to present LHC data can be considerably weaker than those obtained in the CMSSM. Indeed, models with first and second generation squark masses in the multi-TeV range do not generically require significant fine tuning. Such models have the added benefit that undesirable FCNCs mediated by squark exchange are naturally suppressed [146]. Other MSSM mass spectra that are compatible with moderate fine tuning have been considered in Refs. [133,143,147].

The lower bounds on squark and gluino masses may not be as large as suggested by the experimental analyses based on the CMSSM or simplified models [148]. For example, mass bounds for the gluino and the first and second generation squarks based on the CMSSM can often be evaded in alternative or extended MSSM models, *e.g.*, compressed supersymmetry [149] and stealth supersymmetry [150]. Moreover, experimental limits on the masses for the third generation squarks (which enter the fine-tuning considerations more directly) and color-neutral supersymmetric particles are less constrained than the masses of other colored supersymmetric states.

Finally, one can also consider extensions of the MSSM in which the degree of fine-tuning is relaxed. For example, it has already been noted in Section I.5.2 that it is possible to accommodate the observed Higgs mass more easily in the NMSSM due to contributions to m_h^2 proportional to the parameter λ. This means that we do not have to rely on a contribution to the Higgs mass from the radiative corrections to boost the Higgs mass sufficiently above its tree-level bound. In turn, this allows for smaller top squark masses, which are more consistent with the demands of naturalness. The reduction of the fine-tuning in various NMSSM models was initially advocated in Ref. 151, and

more recently has been exhibited in Refs. [101,152]. Naturalness can also be relaxed in extended supersymmetric models with vector-like quarks [153] and in gauge extensions of the MSSM [154].

Thus, it is premature to conclude, after the first few years of LHC operation at just above half the design energy and with less than a quarter of the design luminosity, that weak-scale supersymmetry is on the verge of exclusion.

I.7.2 Constraints from virtual exchange of supersymmetric particles

There are a number of low-energy measurements that are sensitive to the effects of new physics through indirect searches via supersymmetric loop effects. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment, $a_\mu \equiv \frac{1}{2}(g-2)_\mu$, as reviewed in Ref. 155. The Standard Model prediction for a_μ exhibits a 3.6σ deviation from the experimentally observed value [156]. This discrepancy is difficult to accommodate in the constrained supersymmetry models of Section I.6.2 and I.6.3 given the present sparticle mass bounds. Nevertheless, there are regions of the more general pMSSM parameter space that are consistent with the observed value of a_μ [157].

The rare inclusive decay $b \to s\gamma$ also provides a sensitive probe to the virtual effects of new physics beyond the Standard Model. Recent experimental measurements of $B \to X_s+\gamma$ [159] are in very good agreement with the theoretical Standard Model predictions of Ref. 160. Since supersymmetric loop corrections can contribute an observable shift from the Standard Model predictions, the absence of any significant deviations places useful constraints on the MSSM parameter space [161].

The rare decay $B_s \to \mu^+\mu^-$ is especially sensitive to supersymmetric loop effects, with some loop contributions scaling as $\tan^6\beta$ when $\tan\beta \gg 1$ [162]. The recent observation of this rare decay mode by the LHCb Collab. [163] is consistent with the predicted Standard Model rate. The absence of a *significant* deviation in these and other B-physics observables from their Standard Model predictions also places useful constraints on the MSSM parameter space [110,139,164].

Finally, we note that the constraints from precision electroweak observables [165] are easily accommodated in models of weak-scale supersymmetry [166]. Thus, robust regions of the MSSM parameter space, compatible with the results of direct and indirect searches for supersymmetry, remain unconstrained.

I.8. Massive neutrinos in low-energy supersymmetry: In the minimal Standard Model and its supersymmetric extension, there are no right-handed neutrinos, and Majorana mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing [167,168], any viable model of fundamental particles must provide a mechanism for generating neutrino masses [169]. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [170]. Although one can devise models for generating massive Dirac neutrinos [171], the most common approaches for incorporating neutrino masses are based on L-violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of L-violating supersymmetric models will now be considered.

I.8.1. The supersymmetric seesaw: Neutrino masses can be incorporated into the Standard Model by introducing SU(3)×SU(2)×U(1) singlet right-handed neutrinos (ν_R) and super-heavy Majorana masses (typically near the grand unification mass scale) for the ν_R. In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and the ν_R. The Higgs vacuum expectation value then induces an off-diagonal ν_L–ν_R masses on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified with the light neutrinos observed in nature. This is the seesaw mechanism [172].

It is straightforward to construct a supersymmetric generalization of the seesaw model of neutrino masses [173,174]. In the seesaw-extended Standard Model, lepton number is broken due to the presence of $\Delta L = 2$ terms in the Lagrangian (which include the Majorana mass terms for the superheavy neutrinos). Consequently, the seesaw-extended MSSM conserves R-parity. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino–antisneutrino mixing phenomena [174,175].

I.8.2. R-parity-violating supersymmetry: In order to incorporate massive neutrinos in supersymmetric models while retaining the minimal particle content of the MSSM, one must relax the assumption of R-parity invariance. The most general R-parity-violating (RPV) model involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors [176]. Each new interaction term violates either B or L conservation. For example, starting from the MSSM superpotential previously given in Eq. (1) [suitably generalized to three generations of quarks, leptons and their superpartners], consider the effect of adding the following new terms:

$$(\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}^c_n + (\lambda'_L)_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}^c_n + (\lambda_B)_{pmn}\widehat{U}^c_p\widehat{D}^c_m\widehat{D}^c_n\,, \quad (22)$$

where p, m, and n are generation indices, and gauge group indices are suppressed. Eq. (22) yields new scalar-fermion Yukawa couplings consisting of all possible combinations involving two Standard Model fermions and one scalar superpartner.

Note that the term in Eq. (22) proportional to λ_B violates B, while the other two terms violate L. Even if all the terms of Eq. (22) are absent, there is one more possible supersymmetric source of R-parity violation. Namely, one can add a term to the superpotential, $(\mu_L)_p\widehat{H}_u\widehat{L}_p$, where $\widehat{H}_u$ is the $Y = 1$ Higgs doublet superfield given in Table 1. This term is the RPV generalization of the higgsino mass parameter μ of the MSSM, in which the $Y = -1$ Higgs/higgsino supermultiplet $\widehat{H}_d$ is replaced by the slepton/lepton supermultiplet $\widehat{L}_p$. The RPV-parameters $(\mu_L)_p$ also violate L.

Phenomenological constraints derived from data on various low-energy B- and L-violating processes can be used to establish limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [176,177]. If more than one coefficient is simultaneously non-zero, then the limits are in general more complicated [178]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B or L invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which B is conserved, but L is violated. It is possible to enforce baryon number conservation (and the stability of the proton), while allowing for lepton-number-violating interactions by imposing a discrete $\mathbf{Z_3}$ baryon *triality* symmetry on the low-energy theory [179], in place of the standard $\mathbf{Z_2}$ R-parity. Since the distinction between the Higgs and matter supermultiplets is lost in RPV models where L is violated, the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos are now possible, leading to more complicated mass matrices and mass eigenstates than in the MSSM. Recent attempts to fit neutrino masses and mixing in this framework can be found in Ref. 180.

Alternatively, one can consider imposing a lepton parity such that all lepton superfields are odd [181,182]. In this case, only the B-violating term in Eq. (22) survives, and L is conserved. Models of this type have been considered in Ref. 183. Since L is conserved, the mixing of the lepton and Higgs superfields is forbidden. However, one expects that lepton parity cannot be exact due to quantum gravity effects. Remarkably, the standard $\mathbf{Z_2}$ R-parity and the $\mathbf{Z_3}$ baryon triality are stable with respect to quantum gravity effects, as they can be identified as residual discrete symmetries that arise from broken non-anomalous gauge symmetries [181].

The supersymmetric phenomenology of the RPV models exhibits features that are distinct from that of the MSSM [176]. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Indeed, the sparticle mass bounds obtained in searches for R-parity-conserving supersymmetry can be considerably relaxed in certain RPV models due to the absence of large missing transverse energy signatures [184]. This can alleviate some of the tension with naturalness discussed in Section I.7.1.

Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving supersymmetry models [176].

In RPV models with lepton number violation (these include low-energy supersymmetry models with baryon triality mentioned above), both $\Delta L=1$ and $\Delta L=2$ phenomena are allowed, leading to neutrino masses and mixing [185], neutrinoless double-beta decay [186], sneutrino-antisneutrino mixing [187], and resonant s-channel production of sneutrinos in e^+e^- collisions [188] and charged sleptons in $p\bar{p}$ and pp collisions [189].

I.9. Extensions beyond the MSSM: Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the μ parameter of the MSSM. Although μ is a supersymmetric-*preserving* parameter, it must be of order the effective supersymmetry-breaking scale of the MSSM to yield a consistent supersymmetric phenomenology [190]. Any natural solution to the so-called μ-problem must incorporate a symmetry that enforces $\mu = 0$ and a small symmetry-breaking parameter that generates a value of μ that is not parametrically larger than the effective supersymmetry-breaking scale [191]. A number of proposed mechanisms in the literature (*e.g.*, see Refs. [190–193]) provide concrete examples of a natural solution to the μ-problem of the MSSM.

In extensions of the MSSM, new compelling solutions to the μ-problem are possible. For example, one can replace μ by the vacuum expectation value of a new SU(3)×SU(2)×U(1) singlet scalar field. This is the NMSSM, which yields phenomena that were briefly discussed in Sections I.4, I.5 and I.7. The NMSSM superpotential consists only of trilinear terms whose coefficients are dimensionless. There are some advantages to extending the NMSSM further to the USSM [93] by adding a new broken U(1) gauge symmetry [194], under which the singlet field is charged.

Alternatively, one can consider a generalized version of the NMSSM (called the GNMSSM in Ref. 152), where all possible renormalizable terms in the superpotential are allowed, which yields new supersymmetric mass terms (analogous to the μ term of the MSSM). Although the GNMSSM does not solve the μ-problem, it does exhibit regions of parameter space in which the degree of fine-tuning is relaxed, as discussed in Section I.7.1.

It is also possible to add higher dimensional Higgs multiplets, such as Higgs triplet superfields [195], provided a custodial-symmetric model (in which the ρ-parameter of precision electroweak physics is close to 1 [165]) can be formulated. Such models can provide a rich phenomenology of new signals for future LHC studies.

All supersymmetric models discussed in this review possess self-conjugate fermions—the Majorana gluinos and neutralinos. However, it is possible to add additional chiral superfields in the adjoint representation. The spin-1/2 components of these new superfields can pair up with the gauginos to form Dirac gauginos [196,197]. Such states appear in models of so-called supersoft supersymmetry breaking [198], in some generalized GMSB models [199] and in R-symmetric supersymmetry [27,200]. Such approaches often lead to improved naturalness and/or significantly relaxed flavor constraints. The

implications of models of Dirac gauginos on the observed Higgs boson mass and its properties is addressed in Ref. 201.

For completeness, we briefly note other MSSM extensions considered in the literature. These include an enlarged electroweak gauge group beyond SU(2)×U(1) [202]; and/or the addition of new (possibly exotic) matter supermultiplets such as vector-like fermions and their superpartners [153,203].

SUPERSYMMETRY, PART II (EXPERIMENT)

Written September 2013 by O. Buchmueller (Imperial College London) and P. de Jong (Nikhef).

II.1. Introduction

Supersymmetry (SUSY), a transformation relating fermions to bosons and vice versa [1–9], is one of the most compelling possible extensions of the Standard Model of particle physics (SM) that could be discovered at high-energy colliders such as the Large Hadron Collider (LHC) at CERN.

On theoretical grounds SUSY is motivated as a generalization of space-time symmetries. A low-energy realization of SUSY, *i.e.*, SUSY at the TeV scale, is, however, not a necessary consequence. Instead, low-energy SUSY is motivated by the possible cancellation of quadratic divergences in radiative corrections to the Higgs boson mass [10–15]. Furthermore, it is intriguing that a weakly interacting, (meta)stable supersymmetric particle might make up some or all of the dark matter in the universe [16–18]. In addition, SUSY predicts that gauge couplings, as measured experimentally at the electroweak scale, unify at an energy scale $\mathcal{O}(10^{16})$GeV ("GUT scale") near the Planck scale [19–25].

In the minimal supersymmetric extension to the Standard Model, the so called MSSM [26,27,11], a supersymmetry transformation relates every fermion and gauge boson in the SM to a supersymmetric partner with half a unit of spin difference, but otherwise with the same properties and quantum numbers. These are the "sfermions": squarks ($\tilde{q}$) and sleptons ($\tilde{\ell}$, $\tilde{\nu}$), and the "gauginos". The MSSM Higgs sector contains two doublets, for up-type quarks and for down-type quarks and charged leptons respectively, and the partners of the Higgs doublets are known as "higgsinos." The charged weak gauginos

and higgsinos mix to "charginos" ($\tilde{\chi}^{\pm}$), and the neutral ones mix to "neutralinos" ($\tilde{\chi}^0$). The SUSY partners of the gluons are known as "gluinos" ($\tilde{g}$). The fact that such particles are not yet observed leads to the conclusion that, if supersymmetry is realized, it is a broken symmetry. A description of SUSY in the form of an effective Lagrangian with only "soft" SUSY breaking terms and SUSY masses at the TeV scale maintains cancellation of quadratic divergences in particle physics models.

The phenomenology of SUSY is to a large extent determined by the SUSY breaking mechanism and the SUSY breaking scale. This determines the SUSY particle masses, the mass hierarchy, the field contents of physical particles, and their decay modes. In addition, phenomenology crucially depends on whether the multiplicative quantum number of R-parity [27], $R = (-1)^{3(B-L)+2S}$, where B and L are baryon and lepton numbers and S is the spin, is conserved or violated. If R-parity is conserved, SUSY particles (sparticles), which have odd R-parity, are produced in pairs and the decays of each SUSY particle must involve an odd number of lighter SUSY particles. The lightest SUSY particle (LSP) is then stable and often assumed to be a weakly interacting massive particle (WIMP). If R-parity is violated, new terms λ_{ijk}, λ'_{ijk} and λ''_{ijk} appear in the superpotential, where ijk are generation indices; λ-type couplings appear between lepton superfields only, λ''-type are between quark superfields only, and λ'-type couplings connect the two. R-parity violation implies lepton and/or baryon number violation. More details of the theoretical framework of SUSY are discussed elsewhere in this volume [28].

Today low-energy data from flavor physics experiments, high-precision electroweak observables as well as astrophysical data impose strong constraints on the allowed SUSY parameter space. Recent examples of such data include measurements of the rare B-meson decay $B_s \to \mu^+\mu^-$ [29,30], and accurate determinations of the cosmological dark matter relic density constraint [31,32].

These indirect constraints are often more sensitive to higher SUSY mass scales than experiments searching for direct sparticle production at colliders, but the interpretation of these results is often strongly model dependent. In contrast, direct searches for sparticle production at collider experiments are less subject to interpretation ambiguities and therefore they play a crucial role in the search for SUSY.

The discovery of a new scalar boson with a mass around 126 GeV compatible with a Higgs boson imposes constraints on SUSY, which are discussed elsewhere [28,33].

In this review we limit ourselves to direct searches, covering data analyses at LEP, HERA, the Tevatron and the LHC. With the advent of the LHC, the experimental situation is changing rapidly. Compared to earlier PDG reviews, more emphasis is given to LHC results; for more details on LEP and Tevatron constraints, see earlier PDG reviews [34].

II.2. Experimental search program

The electron-positron collider LEP was operational at CERN between 1989 and 2000. In the initial phase, center-of-mass energies around the Z-peak were probed, but after 1995 the LEP experiments collected a significant amount of luminosity at higher center-of-mass energies, some 235 pb^{-1} per experiment at $\sqrt{s} \geq 204$ GeV, with a maximum $\sqrt{s}$ of 209 GeV.

Searches for new physics at e^+e^- colliders benefit from the clean experimental environment and the fact that momentum balance can be measured not only in the plane transverse to the beam, but also in the direction along the beam (up to the beam pipe holes), defined as the longitudinal direction. Searches at LEP are dominated by the data samples taken at the highest center-of-mass energies.

Significant constraints on SUSY have been set by the CDF and D0 experiments at the Tevatron, a proton-antiproton collider at a center-of-mass energy of up to 1.96 TeV. CDF and D0 have collected integrated luminosities between 10 and 11 fb^{-1} each up to the end of collider operations in 2011.

The electron-proton collider HERA provided collisions to the H1 and ZEUS experiments between 1992 and 2007, at a center-of-mass energy up to 318 GeV. A total integrated luminosity of approximately 0.5 fb^{-1} has been collected by each experiment. Since in ep collisions no annihilation process takes place, SUSY searches at HERA typically look for R-parity violating production of single SUSY particles.

The landscape of SUSY searches, however, has significantly changed since the LHC has started proton-proton operation at a center-of-mass energy of 7 TeV in 2010. By the end of 2011 the experiments ATLAS and CMS had collected about 5 fb^{-1} of integrated luminosity each, and the LHCb experiment had collected approximately 1 fb^{-1}. In 2012, the LHC operated at a center-of-mass energy of 8 TeV, and ATLAS and CMS collected approximately 20 fb^{-1} each, whereas LHCb collected 2 fb^{-1}.

Proton-(anti)proton colliders produce interactions at higher center-of-mass energies than those available at LEP, and cross sections of QCD-mediated processes are larger, which is reflected in the higher sensitivity for SUSY particles carrying color charge: squarks and gluinos. Large background contributions from Standard Model processes, however, pose challenges to trigger and analysis. Such backgrounds are dominated by multijet production processes, including, particularly at the LHC, those of top quark production, as well as jet production in association with vector bosons. The proton momentum is shared between its parton constituents, and in each collision only a fraction of the total center-of-mass energy is available in the hard parton-parton scattering. Since the parton momenta in the longitudinal direction are not known on an event-by-event basis, use of momentum conservation constraints in an analysis is restricted to the transverse plane, leading to the definition of transverse variables, such as the missing transverse momentum, and the transverse mass. Proton-proton collisions at the LHC differ from proton-antiproton collisions at the Tevatron in the

sense that there are no valence anti-quarks in the proton, and that gluon-initiated processes play a more dominant role. The increased center-of-mass energy of the LHC compared to the Tevatron significantly extends the kinematic reach for SUSY searches. This is reflected foremost in the sensitivity for squarks and gluinos, but also for other SUSY particles.

The main production mechanisms of massive colored sparticles at hadron colliders are squark-squark, squark-gluino and gluino-gluino production; when "squark" is used "antisquark" is also implied. The typical SUSY search signature at hadron colliders contains high-p_{T} jets, which are produced in the decay chains of heavy squarks and gluinos, and significant missing momentum originating from the two LSPs produced at the end of the decay chain. Assuming R-parity conservation, the LSPs are neutral and weakly interacting massive particles which escape detection.

Selection variables designed to separate the SUSY signal from the Standard Model backgrounds include H_{T}, $E_{\mathrm{T}}^{\mathrm{miss}}$, and m_{eff}. The quantities H_{T} and $E_{\mathrm{T}}^{\mathrm{miss}}$ refer to the measured transverse energy and missing transverse momentum in the event, respectively. They are usually defined as the scalar (H_{T}) and negative vector sum ($E_{\mathrm{T}}^{\mathrm{miss}}$) of the transverse jet energies or transverse calorimeter clusters energies measured in the event. The quantity m_{eff} is referred to as the effective mass of the event and is defined as $m_{\mathrm{eff}} = H_{\mathrm{T}} + |E_{\mathrm{T}}^{\mathrm{miss}}|$. The peak of the m_{eff} distribution for SUSY signal events correlates with the SUSY mass scale, in particular with the mass difference between the primary produced SUSY particle and the LSP [35], whereas the Standard Model backgrounds dominate at low m_{eff}. Additional reduction of multijet backgrounds can be achieved by demanding isolated leptons or photons in the final states.

In the past few years alternative approaches have been developed to increase the sensitivity to pair production of heavy sparticles with masses around 1 TeV focusing on the kinematics of their decays, and to further suppress the background from multijet production. Prominent examples of these new approaches are searches using the α_{T} [36–40], *razor* [41], *stransverse mass* (m_{T2}) [42], and *contransverse mass* (m_{CT}) [43] variables.

II.3. Interpretation of results

Since the mechanism by which SUSY is broken is unknown, a general approach to SUSY via the most general soft SUSY breaking Lagrangian adds a significant number of new free parameters. For the minimal supersymmetric standard model, MSSM, *i.e.*, the model with the minimal particle content, these comprise 105 new parameters. A phenomenological analysis of SUSY searches leaving all these parameters free is not feasible. For the practical interpretation of SUSY searches at colliders several approaches are taken to reduce the number of free parameters.

One approach is to assume a SUSY breaking mechanism and lower the number of free parameters through the assumption of additional constraints. In particular in past years, interpretations of experimental results were predominately performed in constrained models of gravity mediated [44,45], gauge mediated [46,47], and anomaly mediated [48,49] SUSY breaking. Before the start of the LHC and even during its first year of operation, the most popular model for interpretation of collider based SUSY searches was the constrained MSSM (CMSSM) [44,50,51], which in the literature is also referred to as minimal supergravity, or MSUGRA. The CMSSM is described by five parameters: the common sfermion mass m_0, the common gaugino mass $m_{1/2}$, and the common trilinear coupling parameter A_0, all expressed at the GUT scale, the ratio of the vacuum expectation values of the Higgs fields for up-type and down-type fermions $\tan\beta$, and the sign of the higgsino mass parameter μ, defined at the electroweak scale. In gauge mediation models, the paradigm of general gauge mediation (GGM) [52] is slowly replacing minimal gauge mediation, denoted traditionally as GMSB (gauge mediated SUSY breaking).

These constrained SUSY models are theoretically well motivated and provide a rich spectrum of experimental signatures. Therefore, they represent a useful framework to benchmark performance, compare limits or reaches and assess the expected sensitivity of different search strategies. However, with universality relations imposed on the soft SUSY breaking parameters, they do not cover all possible kinematic signatures and mass relations of SUSY. In such scenarios the squarks are often nearly degenerate in mass, in particular for the first and second generation. The exclusion of parameter space in the CMSSM and in CMSSM-inspired models is mainly driven by first and second generation squark production together with gluino production.

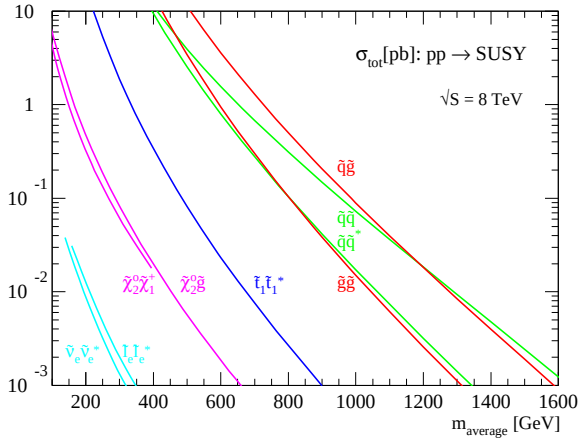

Figure 1: Cross sections for pair production of different sparticles as a function of their mass at the LHC for a center-of-mass energy of 8 TeV [53]. Typically the production cross section of colored squarks and gluinos is several orders of magnitude larger than the one for leptons or charginos. Except for the explicitly shown pair production of stops, production cross sections for squarks assumes mass degeneracy of left- and right-handed u, d, s, c and b squarks.

As shown in Fig. 1 [53] these processes possess the largest production cross sections in proton-proton collisions, and thus the LHC searches typically provide the tightest mass limits on these colored sparticles. This, however, implies that the allowed parameter space of constrained SUSY models today has been restrained significantly by searches from ATLAS and CMS. Furthermore, confronting the remaining allowed parameter space with other collider and non-collider measurements, which are directly or indirectly sensitive to contributions from SUSY, the overall compatibility of these models with all data is significantly worse than in the pre-LHC era (see section II.7 for further discussion), indicating that very constrained models like the CMSSM might no longer be good benchmark scenarios to solely characterize the results of SUSY searches at the LHC.

For this reasons, an effort has been made in the past years to complement the traditional constrained models with more flexible interpretation approaches.

One answer to study a broader and more comprehensive subset of the MSSM is via the phenomenological-MSSM, or pMSSM [54–56]. It is derived from the MSSM, using experimental data to eliminate parameters that are free in principle but have already been highly constrained by measurements of *e.g.*, flavor mixing and CP-violation. This effective approach reduces the number of free parameters in the MSSM to typically 19, making it a practical compromise between the full MSSM and highly constrained models such as the CMSSM.

Even less dependent on fundamental assumptions are interpretations in terms of so-called simplified models [57–60]. Such models assume a limited set of SUSY particle production and decay modes and leave open the possibility to vary masses and other parameters freely. Therefore, simplified models enable comprehensive studies of individual SUSY topologies, and are useful for optimization of the experimental searches over a wide parameter space. As a consequence, since 2011 ATLAS and CMS have adopted simplified models as the primary framework to provide interpretations of their searches. Today, almost every individual search provides interpretations of their results in one or even several simplified models that are characteristic of SUSY topologies probed by the analysis.

However, while these models are very convenient for the interpretation of individual SUSY production and decay topologies, care must be taken when applying these limits to more complex SUSY spectra. Therefore, in practise, simplified model limits are often used as an approximation of the constraints that can be placed on sparticle masses in more complex SUSY spectra. Yet, depending on the assumed SUSY spectrum, the sparticle of interest, and the considered simplified model limit, this approximation can lead to a significant mistake, typically an overestimation, in the assumed constraint on the sparticle mass (see for example [61]) . Only on a case-by-case basis can it be determined whether the limit of a given simplified model represents a good approximation of the true underlying constraint that can be applied on a sparticle mass in a complex SUSY spectrum. In the following, we will always point out explicitly the assumptions that have entered the limits when quoting interpretations from simplified models.

This review covers results up to September 2013 and since none of the searches performed so far have shown significant excess above the SM background prediction, the interpretation of the presented results are exclusion limits on SUSY parameter space.

II.4. Exclusion limits on gluino and squark masses

Gluinos and squarks are the SUSY partners of gluons and quarks, and thus carry color charge. Limits on squark masses of the order 100 GeV have been set by the LEP experiments [62]. However, due to the colored production of this particles at hadron colliders (see e.g. Fig. 1), hadron collider experiments are able to set much tighter mass limits.

Today, the results of the LHC experiments dominate the search for direct squark and gluino production. Pair production of these massive colored sparticles at hadron colliders generally involve both s-channel and t-channel parton-parton interactions. Since there is a negligible amount of bottom and top quark content in the proton, top- and bottom squark production proceeds through s-channel diagrams only with smaller cross sections. In the past, experimental analyses of squark and/or gluino production typically assumed the first and second generation squarks to be approximately degenerate in mass. However, in order to have even less model dependent interpretations of the searches, the experiments have started to also provide simplified model limits on individual first or second generation squarks.

Assuming R-parity conservation and assuming gluinos to be heavier than squarks, squarks will predominantly decay to a quark and a neutralino or chargino, if kinematically allowed. The decay may involve the lightest neutralino (typically the LSP) or chargino, but, depending on the masses of the gauginos, may involve heavier neutralinos or charginos. For pair production of first and second generation squarks, the simplest decay modes involve two jets and missing momentum, with potential extra jets stemming from initial state or final state radiation (ISR/FSR) or from decay modes with longer cascades. Similarly, gluino pair production leads to four jets and missing momentum, and possibly additional jets from ISR/FSR or cascades. Associated production of a gluino and a (anti-)squark is also possible, in particular if squarks and gluinos have similar masses, typically leading to three or more jets in the final state. In cascades, isolated photons or leptons may appear from the decays of sparticles such as neutralinos or charginos. Final states are thus characterized by significant missing transverse momentum, and at least two, and possibly many more high p_{T} jets, which can be accompanied by one or more isolated objects like photons or leptons, including τ leptons, in the final state. Table 1 shows a schematic overview of characteristic final state signatures of gluino and squark production for different mass hierarchy hypotheses and assuming decays involving the lightest neutralino.

Table 1: Typical search signatures at hadron colliders for direct gluino and first- and second-generation squark production assuming different mass hierarchies.

Mass Hierarchy	Main Production	Dominant Decay	Typical Signature
$m_{\tilde{q}} << m_{\tilde{g}}$	$\tilde{q}\bar{\tilde{q}}, \tilde{q}\tilde{q}$	$\tilde{q} \to q\tilde{\chi}_1^0$	≥ 2 jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X
$m_{\tilde{q}} \approx m_{\tilde{g}}$	$\tilde{q}\tilde{g}, \bar{\tilde{q}}\tilde{g}$	$\tilde{q} \to q\tilde{\chi}_1^0$	≥ 3 jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X
		$\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$	
$m_{\tilde{q}} >> m_{\tilde{g}}$	$\tilde{g}\tilde{g}$	$\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$	≥ 4 jets + $E_{\mathrm{T}}^{\mathrm{miss}}$ + X

II.4.1 Exclusion limits on the gluino mass

Limits set by the Tevatron experiments on the gluino mass assume the framework of the CMSSM, with $\tan\beta = 5$ (CDF) or $\tan\beta = 3$ (D0), $A_0 = 0$ and $\mu < 0$, and amount to lower limits of about 310 GeV for all squark masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [63,64]. During the first year of physics operation of the LHC in 2010, these limits have been superseded by those provided by ATLAS and CMS.

Today, limits on the gluino mass have been set using up to approximately 20 fb^{-1} of data recorded at a center-of-mass energy of 8 TeV. As shown in Fig. 2, the ATLAS collaboration places limits for several searches in the framework of the CMSSM, assuming $\tan\beta = 30$, $A_0 = -2m_0$, and $\mu > 0$ For low m_0 the inclusive all-hadronic search considering at least two to six jets [65] provides the most stringent limit, while for values of m_0 above $\approx$ 1600 GeV a more dedicated search [66] requiring zero or one isolated lepton accompanied with at least three jets identified to originate from bottom quarks (b-jets) takes over. The limits at low m_0 are mainly driven by squark-gluino and squark-squark production and at high m_0 gluino pair production dominates. As also indicated in Fig. 1, all other particle production modes do not play a significant role for limits in the CMSSM. In this constrained model gluino masses below around 1300 GeV [66] are excluded by the ATLAS collaboration for all squark masses, while for equal squark and gluino masses, the limit is about 1700 GeV [65]. The CMS collaboration has not yet provided an interpretation of their 8 TeV searches in the CMSSM but based on the performance reported for simplified models it is expected that the limits are similar to those shown in Fig. 2.

Limits on the gluino mass have also been established in the framework of simplified models. Assuming only gluino pair production, in particular three primary decay chains of the gluino have been considered by the LHC experiments for interpretations of their search results. The first decay chain $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ assumes gluino mediated production of first and second generation squarks which leads to four light flavor quarks in the final state. Therefore, inclusive all-hadronic analyses searching for multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ final states are utilized to put limits on this simplified model. These limits are derived as a function of the gluino and neutralino (LSP) mass. As shown

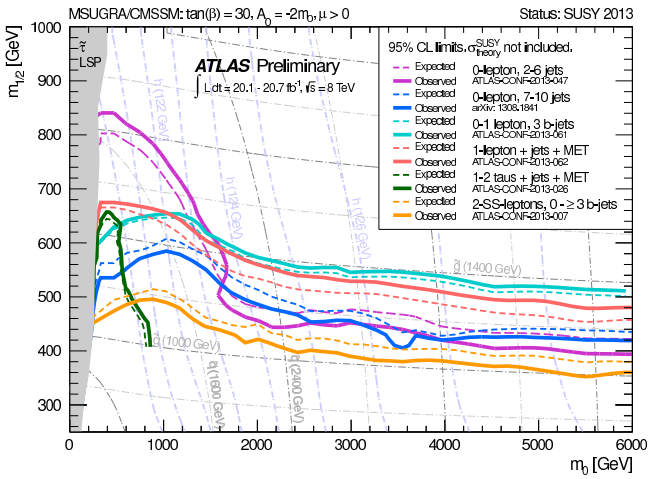

Figure 2: Limits, at 95% C.L., derived from several different ATLAS searches in the CMSSM parameters m_0 and $m_{1/2}$, assuming $\tan\beta = 30$, $A_0 = -2m_0$ and $\mu > 0$.

in Fig. 3 (left), using the cross section from next-to-leading order QCD corrections and the resummation of soft gluon emission at next-to-leading-logarithmic accuracy as reference, the CMS collaboration [67] excludes in this simplified model gluino masses below approximately 1200 GeV, for a massless neutralino. In scenarios where neutralinos are not very light, the efficiency of the analyses is reduced by the fact that jets are less energetic, and there is less missing transverse momentum in the event. This leads to weaker limits when the mass difference $\Delta m = m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$ is reduced. For example, for neutralino masses above about 450 GeV no limit on the gluino mass can be set for this decay chain. Therefore, limits on gluino masses are strongly affected by the assumption of the neutralino mass. Similar results for this simplified model have been obtained by ATLAS [65].

The second important decay chain of the gluino considered for interpretation in a simplified model is $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$. Here the decay is mediated via bottom squarks and thus leads to four jets from b quarks and $E_{\mathrm{T}}^{\mathrm{miss}}$ in the final state. Also for this topology inclusive all-hadronic searches provide the highest sensitivity. However, with four b quarks in the final state, the use of secondary vertex reconstruction for the identification of jets originating from b quarks provides a powerful handle on the SM background. Therefore, in addition to a multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ signature these searches also require several jets to be tagged as b-jets. As shown in Fig. 3 (middle), for this simplified model CMS [68] excludes gluino masses below $\approx$ 1200 GeV for a massless neutralino, while for neutralino masses above $\approx$ 650 GeV no limit on the gluino mass can be set. Comparable limits for this simplified model are provided by a search from ATLAS [66].

Not only first and second generation squarks or bottom squarks may be the product of gluino decays but also, if

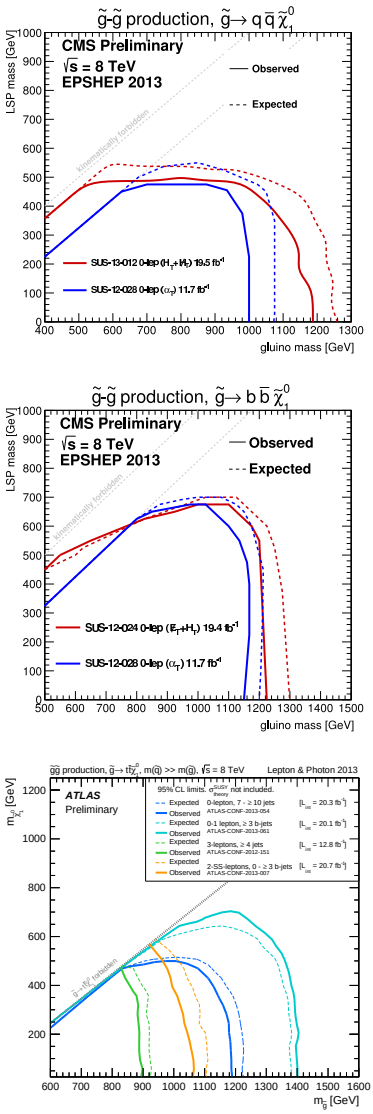

Figure 3: Upper mass limits, at 95% C.L., on gluino pair production for the decay chains $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ (left), $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$ (middle), and $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$ (right). The limits are defined in the framework of simplified models assuming a single decay chain, (i.e. 100% branching fraction). The left and middle plot show limits from the CMS collaboration, while the displayed limits for $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$ are obtained from ATLAS searches.

kinematically allowed, top squarks via the decay $\tilde{g} \to \tilde{t}t$. This leads to a "four tops" final state $ttttt\tilde{\chi}_1^0\tilde{\chi}_1^0$ and defines the third important simplified model, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$, characterizing gluino pair production. The topology of this decay is very rich in different experimental signatures: as many as four isolated leptons, four b-jets, several light flavor quark jets, and significant missing momentum from the neutrinos in the W decay and from the two neutralinos. Therefore, in contrast to the other two simplified models, dedicated searches optimized for this particular final state provide the best mass limit on the gluino for this simplified model. As shown in Fig. 3 (right), the ATLAS search [66] requiring significant $E_{\mathrm{T}}^{\mathrm{miss}}$, zero or one isolated lepton, and at least three jets identified as b-jets provides the strongest limit on the gluino mass. At 95% C.L. it rules out a gluino mass below $\approx$ 1400 GeV for $m_{\tilde{\chi}_1^0} < 300$ GeV. For neutralino masses above $\approx$ 700 GeV, no limit can be placed on the gluino mass for this simplified model. A CMS search [69] also especially optimized for this decay topology by requiring one isolated lepton and high jet multiplicity obtains similar limits.

When comparing the limits in Fig. 3 for the three different simplified models it becomes apparent that more parameter space can be excluded when the gluino decay chain is mediated via third generation squarks. The reason for this is the better control of the SM background by means of identification of b-jets as well as dedicated topology requirements like high jet multiplicity or isolated leptons for these special signatures. However, this variation in sensitivity of the searches for different gluino decay chains is also a clear indication that care must be taken when limits from these simplified models are applied to SUSY models possessing more complex underlying spectra.

If the gluino decay is suppressed, for example if squark masses are high, gluinos may live longer than typical hadronization times. It is expected that such gluinos will hadronize to semi-stable strongly interacting particles known as R-hadrons. Searches for R-hadrons exploit the typical signature of stable charged massive particles in the detector. As shown in Fig. 4, the CMS experiment excludes semi-stable gluino R-hadrons with masses below approximately 1.3 TeV [70]. The limits depend on the probability for gluinos to form bound states known as gluinoballs, as these are neutral and not observed in the tracking detectors. Similar limits are obtained by the ATLAS experiment [71].

Alternatively, since such R-hadrons are strongly interacting, they may be stopped in the calorimeter or in other material, and decay later into energetic jets. These decays are searched for by identifying the jets outside the time window associated with bunch-bunch collisions [72–74]. The latest ATLAS analysis [73] based on the full 2011 and 2012 data set combined (28 fb^{-1}) places limits at 95% C.L. on gluino production over almost 16 orders of magnitude in gluino lifetime. For $m_{\tilde{\chi}_1^0} > 100$ GeV, assuming a 100% branching fraction for gluino decay to gluon (or $q\bar{q}$) + neutralino, gluinos with lifetimes from 10 μs to 1000 s and $m_{\tilde{g}} < 857$ GeV are excluded. When SUSY spectra are compressed, this limits weakens to $m_{\tilde{g}} < 572$ GeV for $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} < 100$ GeV .

In summary, for interpretations in the CMSSM, simplified models, and semi-stable R-hadrons, the best limits on the gluino mass range from around 1200 GeV to about 1400 GeV, while for interpretations in the context of stopped R-hadrons the limit on $m_{\tilde{g}}$ is around 850 GeV. All these limits weaken significantly for compressed SUSY spectra when the mass difference $m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$ is reduced.

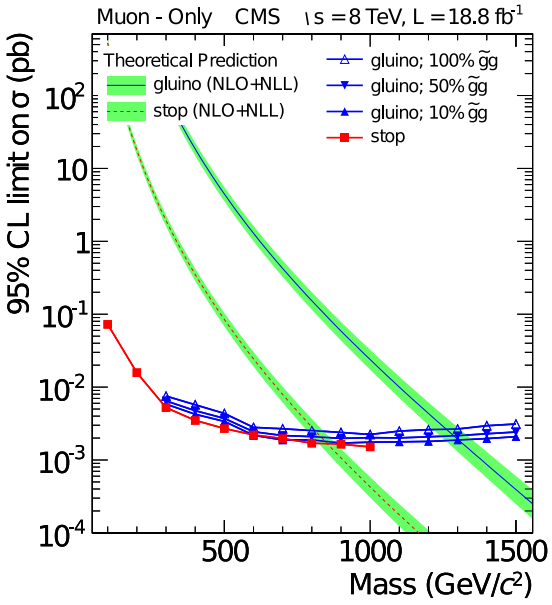

Figure 4: Observed 95% C.L. upper limits on the cross section for (semi-)stable top squarks or gluinos. For gluinos, different fractions of gluinoball states produced after hadronization scenarios are indicated. The observed limits are compared with the predicted theoretical cross sections where the bands represent the theoretical uncertainties on the cross section values.

R-parity violating gluino decays are searched for in multijet final states without missing transverse momentum. CDF [75], ATLAS [76] and CMS [77] put limits on the cross section for such decays.

II.4.2. Exclusion limits on first and second generation squark masses

Limits on first and second generation squark masses set by the Tevatron experiments assume the CMSSM model, and amount to lower limits of about 380 GeV for all gluino masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [63,64].

At the LHC, limits on squark masses have been set using up to approximately 20 fb^{-1} of data at 8 TeV. As shown in Fig. 2, the ATLAS collaboration [65] excludes in the framework of the CMSSM squark masses below $\approx$ 1600 GeV for all gluino masses. For equal squark and gluino masses, the limit is about 1700 GeV.

Interpretations in simplified models are typically characterizing squark pair production with only one decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$. Here it is assumed that the left and right-handed $\tilde{u}$, $\tilde{d}$, $\tilde{s}$ and $\tilde{c}$ squarks are degenerate in mass. Furthermore, it is assumed that the mass of the gluino is very high and thus contributions of the corresponding t-channel diagrams to squark pair production are negligible. Therefore, the total production cross section for this simplified model is eight times the production cross section of an individual squark (e.g. $\tilde{u}_L$). The CMS collaboration provides interpretations of two all-hadronic searches [67,78] for this simplified model. As displayed in Fig. 5, best observed exclusion of squark masses is just below 800 GeV for a light neutralino. The effects of heavy neutralinos on squark limits are similar to those discussed in the gluino case (see section II.4.1) and only for neutralino masses below $\approx$ 300 GeV squark masses can be excluded. Results from the ATLAS collaboration [65] for this simplified model are similar.

For the same analysis ATLAS also provides an interpretation of their search result in a simplified model assuming strong production of first and second generation squarks in association with gluinos. This interpretation excludes squark masses below $\approx$ 1400 GeV for all gluino masses as well as gluino masses below $\approx$ 1400 GeV for all squark masses. For equal squark and gluino masses, the limit is about 1700 GeV and therefore very similar to limits provided in the CMSSM.

If the assumption of mass degenerate first and second generation squarks is dropped and only the production of a single light squark is assumed, the limits weaken significantly. This is shown as the much smaller exclusion region in Fig. 5, which represents the 95% C.L. upper limit of pair production of a single light squark, with the gluino and all other squarks decoupled to very high masses. With a best observed limit of only $\approx$ 450 GeV for a massless neutralino and a neutralino mass of $\approx$ 100 GeV above which no limit can be placed, the exclusion reach of the LHC experiments for single light squark is rather weak. It should be noted that this limit is not a result of a simple scaling of the above mentioned mass limits assuming eightfold mass degeneracy but it also takes into account that for an eight times lower production cross section the analyses must probe kinematic regions of phase space that are closer to the ones of SM background production. Since signal acceptance and the ratio of expected signal to SM background events of the analyses are typically worse in this region of phase space not only the 1/8 reduction in production cross section but also a worse analysis sensitivity are responsible for the much weaker limit on single squark pair production.

R-parity violating production of single squarks via a λ'-type coupling has been studied at HERA. In such models, a lower limit on the squark mass of the order of 275 GeV has been set for electromagnetic-strength-like couplings $\lambda' = 0.3$ [79].

II.4.3. Exclusion limits on third generation squark masses

SUSY at the TeV-scale is often motivated by naturalness arguments, most notably as a solution to stabilize quadratic divergences in radiative corrections to the Higgs boson mass. In this context, the most relevant terms for SUSY phenomenology arise from the interplay between the masses of the third generation squarks and the Yukawa coupling of the top quark to the Higgs boson. This motivates a potential constraint on the masses of the top squarks and the left-handed bottom squark. Due to the large top quark mass, significant mixing between

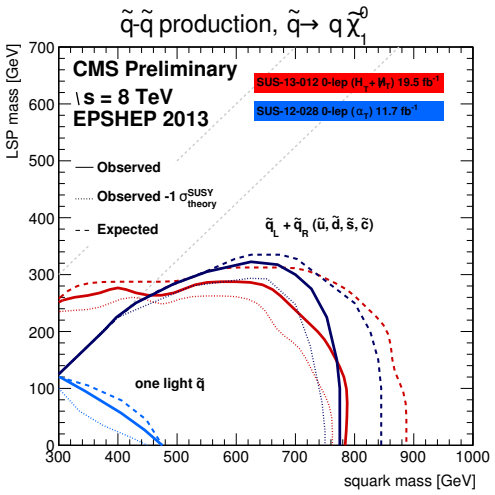

Figure 5: 95% C.L. exclusion contours in the squark-neutralino mass plane defined in the framework of simplified models assuming a single decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$. Two assumptions for the squark pair production cross sections are displayed; a) eightfold degeneracy for the masses of the first and second generation squarks (red and dark blue contours) and b) only one light flavor squark (light blue contours). For the α_T based CMS analysis [78](light and dark blue contours), the diagonal part of $m_{\tilde{q}} - m_{\tilde{\chi}_1^0} < 200$ GeV is not directly kinematically accessible and therefore no limit is provided. The other CMS analysis [67] (red limit contours) shown in this plot provides a limit beyond this mass difference by allowing significant contributions from signal events with hard ISR jets in the interpretation of the result.

$\tilde{t}_L$ and $\tilde{t}_R$ is expected, leading to a lighter mass state $\tilde{t}_1$ and a heavier mass state $\tilde{t}_2$. In the MSSM, the lightest top squark ($\tilde{t}_1$) can be the lightest squark.

The discovery of a Higgs boson at a mass around 126 GeV has consequences for third generation squarks in the MSSM, which are discussed elsewhere [28]. As a consequence, and in the absence of a SUSY discovery so far, searches for third generation squark production have become a major focus of the SUSY search program at the LHC. For this reason direct and gluino mediated top and/or bottom squark production processes, leading to experimental signatures that are rich in jets originating from bottom quarks, are either subject of reinterpretation of inclusive analyses or targets for dedicated searches. The latter ones have become especially important for searches of direct top squark production.

Direct production of top and bottom squark pairs at hadron colliders is suppressed with respect to first generation squarks, due to the absence of t and b quarks in the proton (see e.g. the example of direct top squark production in Fig. 1). At the LHC, assuming eightfold mass degeneracy for light flavor squarks as reference, this suppression is at the level of two orders of magnitude for top and bottom squark masses of around 600 GeV. Moreover, at the LHC, there is a very large background of top quark pair production, making especially the experimental analysis of top squark pair production a challenge.

Bottom squarks are expected to decay predominantly to $b\tilde{\chi}^0$ giving raise to the characteristic multi b-jet and $E_{\mathrm{T}}^{\mathrm{miss}}$ signature. Direct production of bottom squark pairs has been studied at the Tevatron and at the LHC. Limits from the Tevatron are $m_{\tilde{b}} > 247$ GeV for a massless neutralino [80,81](see also Fig. 6). Using the 2011 data the LHC experiments were able to surpass these limits and based on the full 2012 data set, as shown in Fig. 6, using an all-hadronic search requiring significant $E_{\mathrm{T}}^{\mathrm{miss}}$ and two jets reconstructed as b-jets, ATLAS has set a limit of $m_{\tilde{b}} >\approx 650$ GeV for the same scenario. For $m_{\tilde{\chi}_1^0} \approx 280$ GeV or higher no limit can be placed on direct bottom squark pair production in this simplified model [82]. The latest CMS results for this simplified model are featured in [78] and exhibit a similar reach.

Further bottom squark decay modes have also been studied by ATLAS and CMS. For example, in a simplified model for the $\tilde{b} \to t\tilde{\chi}^{\pm}$ decay mode, bottom squark quark masses below approximately 450 GeV are excluded [83,84].

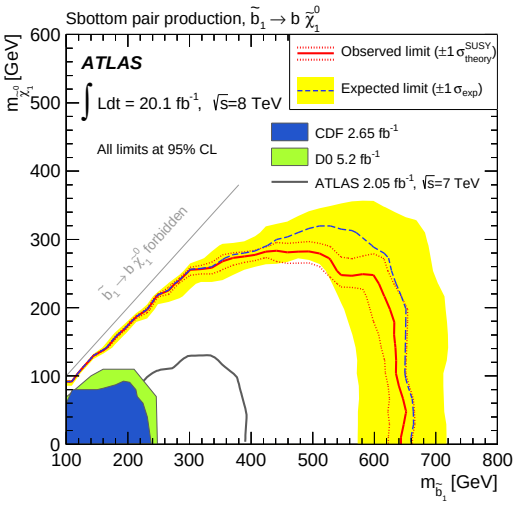

Figure 6: 95% C.L. exclusion contours in the sbottom-neutralino mass plane defined in the framework of a simplified model assuming a single decay chain of $\tilde{b} \to b\tilde{\chi}_1^0$.

The top squark decay modes depend on the SUSY mass spectrum, and on the $\tilde{t}_L$-$\tilde{t}_R$ mixture of the top squark mass eigenstate. If kinematically allowed, the two-body decays $\tilde{t} \to t\tilde{\chi}^0$ (requires $m_{\tilde{t}} - m_{\tilde{\chi}^0} > m_t$) and $\tilde{t} \to b\tilde{\chi}^{\pm}$ (requires $m_{\tilde{t}} - m_{\tilde{\chi}^{\pm}} > m_b$) are expected to dominate. If not, the top squark decay may proceed either via the two-body decay $\tilde{t} \to c\tilde{\chi}^0$ or through $\tilde{t} \to bf\bar{f}'\tilde{\chi}^0$ (where f and $\bar{f}'$ denote a fermion-antifermion pair with appropriate quantum numbers). For $m_{\tilde{t}} - m_{\tilde{\chi}^0} > m_b$ the latter decay chain represents a four-body decay with a W boson, charged Higgs H, slepton $\tilde{\ell}$, or light flavor squark

$\tilde{q}$, exchange. If the exchanged W boson and/or sleptons are kinematically allowed to be on-shell ($m_{\tilde{t}} - m_{\tilde{\chi}^\pm} > m_b + m_W$ and/or $m_{\tilde{t}} - m_{\tilde{\ell}} > m_b$), the three-body decays $\tilde{t} \to Wb\tilde{\chi}^0$ and/or $\tilde{t} \to bl\tilde{\ell}$ will become dominant. For further discussion on top squark decays see for example [85].

Limits from LEP on the $\tilde{t}_1$ mass are $m_{\tilde{t}} > 96$ GeV in the charm plus neutralino final state, and > 93 GeV in the lepton, b-quark and sneutrino final state [62].

The Tevatron experiments have performed a number of searches for top squarks, often assuming direct pair production. In the $b\ell\tilde{\nu}$ decay channel, and assuming a 100% branching fraction, limits are set as $m_{\tilde{t}} > 210$ GeV for $m_{\tilde{\nu}} < 110$ GeV and $m_{\tilde{t}} - m_{\tilde{\nu}} > 30$ GeV, or $m_{\tilde{t}} > 235$ GeV for $m_{\tilde{\nu}} < 50$ GeV [86,87]. In the $\tilde{t} \to c\tilde{\chi}^0$ decay mode, a top squark with a mass below 180 GeV is excluded for a neutralino lighter than 95 GeV [88,89]. In both analyses, no limits on the top squark can be set for heavy sneutrinos or neutralinos. In the $\tilde{t} \to b\tilde{\chi}_1^\pm$ decay channel, searches for a relatively light top squark have been performed in the dilepton final state [90,91]. The CDF experiment sets limits in the $\tilde{t} - \tilde{\chi}_1^0$ mass plane for various branching fractions of the chargino decay to leptons and for two value of $m_{\tilde{\chi}_1^\pm}$. For $m_{\tilde{\chi}_1^\pm} = 105.8$ GeV and $m_{\tilde{\chi}_1^0} = 47.6$ GeV, top squarks between 128 and 135 GeV are excluded for W-like leptonic branching fractions of the chargino.

Today the LHC experiments have improved these limits substantially. As shown in the right plot of Fig. 7, limits on the top squark mass assuming a simplified model with a single decay chain of $\tilde{t} \to t\tilde{\chi}_1^0$ reach up to almost 700 GeV for light neutralinos, while for $m_{\tilde{\chi}_1^0} > 240$ GeV no limits can be provided. The most important searches for this top squark decay topology are dedicated searches requiring zero or one isolated lepton, modest $E_{\rm T}^{\rm miss}$, and four or more jets out of which at least one jet must be reconstructed as b-jet [92–93]. To increase the sensitivity to this decay topology different signal regions are considered in these ATLAS analyses. A search of the CMS collaboration requiring one isolated lepton and using a boosted decision tree for a dedicated optimization in the $m_{\tilde{t}} - m_{\tilde{\chi}_1^0}$ plane [94] provides a comparable limit for this simplified model.

Assuming that the top squark decay exclusively proceeds via the chargino mediated decay chain $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{\pm(*)}\tilde{\chi}_1^0$ yields stop mass exclusion limits that vary strongly with the assumptions made on the $\tilde{t} - \tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ mass hierarchy (see Fig. 7 left plot). Above the universal chargino mass limit of $m_{\tilde{\chi}_1^\pm} > 103.5$ GeV from LEP (see section II.5.1) the strongest limits are placed for nearly mass degenerate chargino and neutralinos. For $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 5$ GeV, a stop mass of ≈ 650 GeV for a light $\tilde{\chi}_1^0$ is excluded, while no limit can be placed for $m_{\tilde{\chi}_1^0} > 280$ GeV [82]. These limits, however, can weaken significantly when other assumptions about the mass hierarchy are imposed. For example, as also shown in Fig. 7, if the chargino becomes nearly mass degenerate with the top squark the key experimental signature turns from an all-hadronic final state with b-jets and $E_{\rm T}^{\rm miss}$ into a multi-lepton and $E_{\rm T}^{\rm miss}$

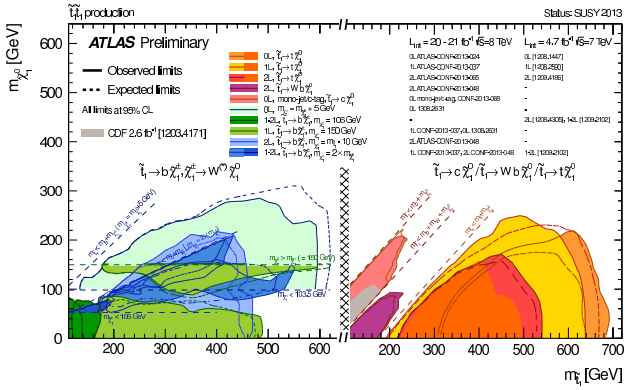

Figure 7: 95% C.L. exclusion contours in the $m_{\tilde{t}} - m_{\tilde{\chi}_1^0}$ plane for different top squark decay chains and different searches from the ATLAS collaboration. The plot on the right shows simplified model limits for three different decay chains; $\tilde{t} \to c\tilde{\chi}_1^0$ (W and t forbidden), $\tilde{t} \to Wb\tilde{\chi}_1^0$ (t forbidden), and $\tilde{t} \to t\tilde{\chi}_1^0$ (t allowed), which represent three different kinematic regions of the top squark decay. The plot to the left shows simplified model limits for the top decay chain via a chargino: $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{\pm(*)}\tilde{\chi}_1^0$. For this case, several exemplary hypotheses on the $\tilde{t} - \tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ mass hierarchy are assumed.

topology. Assuming $m_{\tilde{\chi}_1^\pm} = m_{\tilde{t}} - 10$ GeV provides a best limit of $m_{\tilde{t}} = 470$ GeV for neutralino masses below 100 GeV, whereas for $m_{\tilde{\chi}_1^0} > 200$ GeV no limit can be obtained [95]. As for the decay with top quarks in the final state, the CMS analysis [94] also provides comparable limits for this decay chain.

If the decays $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^\pm$, $\tilde{\chi}_1^\pm \to W^{\pm(*)}\tilde{\chi}_1^0$ are kinematically forbidden, the decay chains $\tilde{t} \to Wb\tilde{\chi}^0$ and $\tilde{t} \to c\tilde{\chi}^0$ can become important. As shown in the right plot of Fig. 7, ATLAS provides for the kinematic region $m_{\tilde{t}} - m_{\tilde{\chi}^\pm} > m_b + m_W$ upper limits on top squark mass of ≈ 230 GeV for a neutralino lighter than ≈ 100 GeV [95], while the boosted decision tree based CMS analysis pushes this limit to about 320 GeV for neutralino masses below ≈ 200 GeV [94]. For the kinematic region in which even the production of real W bosons is not allowed, ATLAS improves the Tevatron limit on $\tilde{t} \to c\tilde{\chi}^0$ substantially. Based on a combination of a monojet analysis and a dedicated charm quark identification algorithm, a top squark with a mass below 240 GeV is excluded for a neutralino lighter than 200 GeV [96].

R-parity violating production of single top squarks has been searched for at LEP, HERA, and the Tevatron. For example, an analysis from the ZEUS collaboration [97] makes an interpretation of its search result assuming top squarks to be produced via a λ' coupling and decay either to $b\tilde{\chi}_1^\pm$ or R-parity-violating to a lepton and a jet. Limits are set on λ'_{131} as a function of the top squark mass in an MSSM framework with gaugino mass unification at the GUT scale. The search for top squark pair production in the context of R-parity violating supersymmetry has now also become a focus

point for searches at the LHC. Recently the CMS collaboration has performed a search for top squarks using a variety of multilepton final states [98]. It provides lower limits on the top squark mass in models with non-zero leptonic R-parity violating couplings λ_{122} and λ_{233}. For a bino mass of 200 GeV, these limits are 1020 GeV and 820 GeV, respectively. The analysis also provides limits in a model with the semileptonic R-parity violating coupling λ'_{233}.

Top squarks can also be long-lived and hadronize to a R-hadron, for example in the scenario where the top squark is the next-to-lightest SUSY particle (NLSP), with a small mass difference to the LSP. Searches for massive stable charged particles are sensitive to such top squarks. As shown in Fig. 4 for the CMS analysis [70], the LHC experiments have set limits $m_{\tilde{t}} > 800$ GeV in such scenarios, surpassing significantly the earlier Tevatron limits of about 300 GeV [99,100].

It should be noted that limits discussed in this section belong to different top and bottom squark decay channels, different sparticle mass hierarchies, and different simplified decay scenarios. Therefore, care must be taken when interpreting these limits in the context of more complete SUSY models.

II.4.4. Summary of exclusion limits on squarks and gluinos assuming R-Parity conservation

A summary of the most important squark and gluino mass limits for different interpretation approaches assuming R-parity conservation is shown in Table 2.

For gluino masses rather similar limits, ranging from 1.2 TeV to 1.4 TeV, are obtained from different model assumptions indicating that the LHC is indeed probing for a large region in SUSY parameter space direct gluino production at the 1 TeV scale and beyond. However, for neutralino masses above approximately 700 GeV in the best case, ATLAS and CMS searches cannot place any limits on the gluino mass.

Limits on direct squark production, on the other hand, depend strongly on the chosen model. Especially for direct production of top squarks there are still large regions in parameter space where masses below 0.5 TeV cannot be excluded. This is also true for first and second generation squarks when only one single squark is considered. Furthermore, for neutralino masses above $\approx$ 300 GeV no limit on any direct squark production scenario can be placed by the LHC.

Table 2: Summary of squark mass and gluino mass limits using different interpretation approaches assuming R-parity conservation. Masses in this table are provided in GeV. Further details about assumption and analyses from which these limits are obtained are discussed in the corresponding sections of the text.

Model	Assumption	$m_{\tilde{q}}$	$m_{\tilde{g}}$
CMSSM	$m_{\tilde{q}} \approx m_{\tilde{g}}$	$\approx$ 1700	$\approx$ 1700
	all $m_{\tilde{q}}$	-	$\approx$ 1300
	all $m_{\tilde{g}}$	$\approx$ 1600	-
Simplified model $\tilde{g}\tilde{q}, \tilde{g}\bar{\tilde{q}}$	$m_{\tilde{\chi}^0_1}$= 0, $m_{\tilde{q}} \approx m_{\tilde{g}}$	$\approx$ 1700	$\approx$ 1700
	$m_{\tilde{\chi}^0_1}$= 0, all $m_{\tilde{q}}$	-	$\approx$ 1400
	$m_{\tilde{\chi}^0_1}$= 0, all $m_{\tilde{g}}$	$\approx$ 1400	-
Simplified models $\tilde{g}\tilde{g}$

$\tilde{t} \to c\tilde{\chi}^0_1$	$m_{\tilde{\chi}^0_1} < \approx$ 200	$\approx$ 250	-
$[m_{\tilde{t}} - m_{\tilde{\chi}^0} > m_c]$			

II.5. Exclusion limits on the masses of charginos and neutralinos

Charginos and neutralinos result from mixing of the charged wino and higgsino states, and the neutral bino, wino and higgsino states, respectively. The mixing is determined by a limited number of parameters. For charginos these are the wino mass parameter M_2, the higgsino mass parameter μ, and $\tan\beta$, and for neutralinos these are the same parameters plus the bino mass parameter M_1. The mass states are four charginos $\tilde{\chi}^+_1$, $\tilde{\chi}^-_1$, $\tilde{\chi}^+_2$ and $\tilde{\chi}^-_2$, and four neutralinos $\tilde{\chi}^0_1$, $\tilde{\chi}^0_2$, $\tilde{\chi}^0_3$ and $\tilde{\chi}^0_4$, ordered in increasing mass. Depending on the mixing, the chargino and neutralino composition is dominated by specific states, which are referred to as bino-like ($M_1 << M_2, \mu$), wino-like ($M_2 << M_1, \mu$), or higgsino-like ($\mu << M_1, M_2$). If gaugino mass unification at the GUT scale is assumed, a relation between M_1 and M_2 at the electroweak scale follows: $M_1 = 5/3 \tan^2\theta_W M_2 \approx 0.5 M_2$, with θ_W the weak mixing angle. Charginos and neutralinos carry no color charge, and only have electroweak couplings (neglecting gravity).

II.5.1. Exclusion limits on chargino masses

If kinematically allowed, two body decay modes such as $\tilde{\chi}^\pm \to \tilde{f}\bar{f}'$ (including $\ell\tilde{\nu}$ and $\tilde{\ell}\nu$) are dominant. If not, three body decay $\tilde{\chi}^\pm \to f\bar{f}'\tilde{\chi}^0$ are mediated through virtual W

bosons or sfermions. If sfermions are heavy, the W mediation dominates, and $f\bar{f}'$ are distributed with branching fractions similar to W decay products. If, on the other hand, sleptons are light enough to play a significant role in the decay mediation, leptonic final states will be enhanced.

At LEP, charginos have been searched for in fully-hadronic, semi-leptonic and fully leptonic decay modes [101,102]. A general lower limit on the lightest chargino mass of 103.5 GeV is derived, except in corners of phase space with low electron sneutrino mass, where destructive interference in chargino production, or two-body decay modes, play a role. The limit is also affected if the mass difference between $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ is small; dedicated searches for such scenarios set a lower limit of 92 GeV.

At the Tevatron, charginos are searched for via associated production of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ [103,104]. Decay modes involving multi-lepton final states provide the best discrimination against the large multijet background. Analyses look for at least three charged isolated leptons, for two leptons with missing transverse momentum, or for two leptons with the same charge. Depending on the $(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0)$ and/or $(\tilde{\chi}_2^0 - \tilde{\chi}_1^0)$ mass differences, leptons may be soft.

At the LHC, the search strategy is similar to that at the Tevatron. As shown in Fig. 1, pair production of chargino and neutralinos at the LHC, for masses of several hundreds of GeV, is at least two orders of magnitude smaller than for colored SUSY particles (e.g. top squark pair production). For this reason a high statistics data sample is required to improve the sensitivity of LEP and Tevatron searches for direct chargino/neutralino production. With the data collected in 2012, ATLAS and CMS have now started to surpass in regions of SUSY parameter space the limits from LEP and Tevatron. Chargino pair production is searched for in the dilepton plus missing momentum final state. In the interpretation of the results, both ATLAS [105] and CMS [106] assume mediation through light sleptons; the analyses do not yet place limits on charginos decaying via a W boson. In the light slepton scenario, chargino mass limits up to 550 GeV are set for massless LSPs, but no limits on the chargino mass can be set for $\tilde{\chi}_1^0$ heavier than 150 GeV. The trilepton plus missing momentum final state is used to set limits on $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ production, assuming wino-like $\tilde{\chi}^\pm$ and $\tilde{\chi}_2^0$, bino-like $\tilde{\chi}_1^0$, and $m_{\tilde{\chi}^\pm} = m_{\tilde{\chi}_2^0}$, leaving $m_{\tilde{\chi}^\pm}$ and $m_{\tilde{\chi}_1^0}$ free. Again, the branching fraction of leptonic final states is determined by the slepton masses. If the decay is predominantly mediated by a light $\tilde{\ell}_\mathrm{L}$, i.e. $\tilde{\ell}_\mathrm{R}$ is assumed to be heavy, the three lepton flavors will be produced in equal amounts. It is assumed that $\tilde{\ell}_\mathrm{L}$ and sneutrino masses are equal, and diagrams with sneutrinos are included. In this scenario, ATLAS [107] and CMS [106] exclude chargino masses below 730 GeV for massless LSPs; no limits are set for LSPs above 350 GeV. If the decay is dominated by a light $\tilde{\ell}_\mathrm{R}$, the chargino cannot be a pure wino but needs to have a large higgsino component, preferring the decays to tau leptons. Assuming that also the $\tilde{\chi}_2^0$ decay leads to two tau leptons in the final state, CMS sets limits of 350 GeV on the chargino mass for massless LSPs [106]. ATLAS assumes a simplified model in which staus are significantly lighter than the other sleptons in order to search for a similar multi-tau final state, and sets a similar limit on the chargino mass [108]. If sleptons are heavy, the chargino is assumed to decay to a W boson plus LSP, and the $\tilde{\chi}_2^0$ into either Z plus LSP, or Higgs plus LSP. In the WZ channel, ATLAS [107] and CMS [106] limits on the chargino mass reach 300 GeV for massless LSPs, but no limits are set for LSPs heavier than 100 GeV. The WH channel is also investigated, for $m_H = 126$ GeV and using Higgs decays to $b\bar{b}$ (ATLAS [109]) or Higgs decays to $b\bar{b}$, WW, ZZ and $\tau^+\tau^-$ (CMS [110]) , assuming a SM-like branching fraction in these final states. Chargino mass limits extend up to 287 GeV for massless LSPs, but vanish for LSPs above 50 GeV. The CMS results on electroweak gaugino searches are summarized in Fig. 8, the ATLAS results are similar.

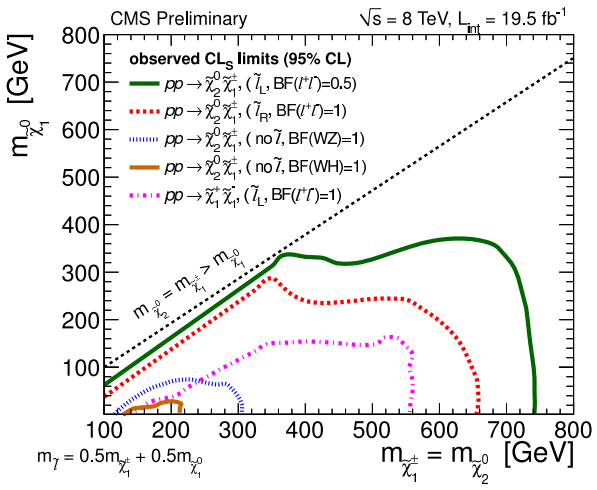

Figure 8: A summary of limits on chargino and neutralino masses as obtained by CMS.

In both the wino region (a characteristic of anomaly-mediated SUSY breaking models) and the higgsino region of the MSSM, the mass splitting between $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ is small. In such scenarios, charginos may be long-lived. Charginos decaying in the detectors away from the primary vertex could lead to signatures such as kinked-tracks, or apparently disappearing tracks, since, for example, the pion in $\tilde{\chi}_1^\pm \to \pi^\pm\tilde{\chi}_1^0$ might be too soft to be reconstructed. At the LHC, a search has been performed for such disappearing tracks, and interpreted within anomaly-mediated SUSY breaking models. Charginos with lifetimes between 0.1 and 10 ns are excluded for chargino masses up to 500 GeV [111]. Within AMSB models, a lower limit on the chargino mass of 270 GeV is set, for a mass difference with the LSP of 160 MeV and a lifetime of 0.2 ns.

Charginos with a lifetime longer than the time needed to pass through the detector appear as charged stable massive particles. Limits have been derived by the LEP experiments [112]

and by D0 at the Tevatron [100]. D0 results exclude higgsino-like stable charginos below 244 GeV, and gaugino-like stable charginos below 278 GeV.

II.5.2. Exclusion limits on neutralino masses

In a considerable part of the MSSM parameter space, and in particular when demanding that the LSP carries no electric or color charge, the lightest neutralino $\tilde{\chi}_1^0$ is the LSP. If R-parity is conserved, such a $\tilde{\chi}_1^0$ is stable. Since it is weakly interacting, it will typically escape detectors unseen. Limits on the invisible width of the Z boson apply to neutralinos with a mass below 45.5 GeV, but depend on the Z-neutralino coupling. Such a coupling could be small or even absent; in such a scenario there is no general lower limit on the mass of the lightest neutralino [113]. In models with gaugino mass unification and sfermion mass unification at the GUT scale, a lower limit on the neutralino mass is derived from limits from direct searches, notably for charginos and sleptons, and amounts to 47 GeV [114]. Assuming a constraining model like the CMSSM, this limit increases to 50 GeV at LEP; however the strong constraints now set by the LHC increase such CMSSM-derived $\tilde{\chi}_1^0$ mass limits to well above 200 GeV [115].

Even though a LSP neutralino is only weakly interacting, collider experiments are not totally blind to neutralino pair production. Pair production of neutralinos accompanied by initial state radiation could lead to an observable final state. At LEP, final states with only a single isolated photon were studied, but backgrounds from neutrino pair production were too large. At hadron colliders, monojet final states have been used to set limits on dark matter properties using an effective Lagrangian approach [116–118].

In gauge-mediated models, the LSP is typically a gravitino, and the phenomenology is determined by the nature of the NLSP. A NLSP neutralino will decay to a gravitino and a SM particle whose nature is determined by the neutralino composition. Final states with two high p_{T} photons and missing momentum are searched for, and interpreted in gauge mediation models with bino-like neutralinos [119–123]. Assuming only gluino pair production and a bino-like neutralino produced in gluino decay, limits on gluino masses of about 1 TeV are set for all neutralino masses, as shown in Fig. 9 for the CMS diphoton analysis.

Assuming the production of at least two neutralinos per event, neutralinos with large non-bino components can also be searched for in final states with missing momentum plus any two bosons out of the collection γ, Z, Higgs. Searches for final states with Z ($\rightarrow \ell^+\ell^-$) bosons and missing transverse momentum have been performed at the Tevatron [124] and at the LHC [125,126], and are interpreted in such models.

In gauge mediation models, NLSP neutralino decays need not be prompt, and experiments have searched for late decays. CDF have searched for delayed $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ decays using the timing of photon signals in the calorimeter [127]. CMS has used the same technique at the LHC [128]. Results are given as upper limits on the neutralino production cross section as a function of neutralino mass and lifetime. D0 has looked at the direction of showers in the electromagnetic calorimeter with a similar goal [129], and ATLAS has searched for photon candidates that do not point back to the primary vertex [130].

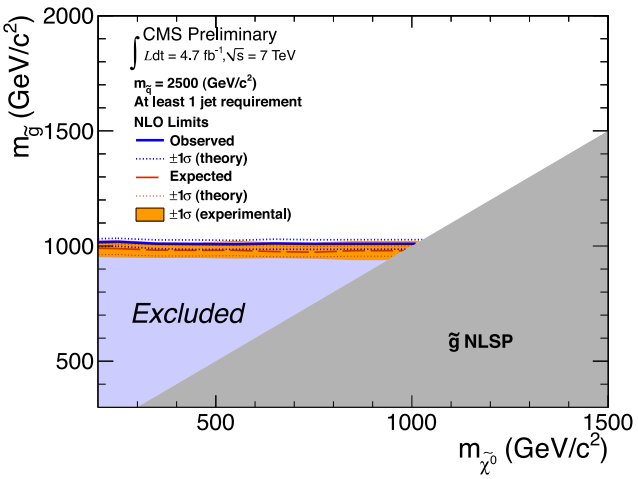

Figure 9: Observed 95% C.L. limits on the gluino mass as a function of the neutralino mass, in general gauge mediation models assuming only gluino pair production, with a bino-like neutralino produced in gluino decay, and a neutralino decay to photon plus gravitino.

Heavier neutralinos, in particular $\tilde{\chi}_2^0$, have been searched for in their decays to the lightest neutralino plus a γ, a Z boson or a Higgs boson. Limits on electroweak production of $\tilde{\chi}_2^0$ plus $\tilde{\chi}_1^\pm$ from trilepton analyses have been discussed in the section on charginos; the assumption of equal mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ make the limits on chargino masses apply to $\tilde{\chi}_2^0$ as well. Heavier neutralinos in the decay chains of colored particles are searched for by the presence of missing momentum plus an isolated high-energy photon [123] or leptons [129,131–132]. In $\tilde{\chi}_2^0$ decays to $\tilde{\chi}_1^0$ and a lepton pair, the lepton pair invariant mass distribution may show a structure that can be used to measure the $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$ mass difference in case of a signal [133], but it can also be used in the search itself, in order to suppress background [134].

The lightest neutralino can decay in models with R-parity violation. If the decay involves a non-zero λ coupling, the final state will be a multi-lepton one. Searches for events with four or more isolated charged leptons by ATLAS [135] and CMS [136] are interpreted in such models. An ATLAS search for events with isolated muons and a displaced vertex is interpreted in a model with R-parity violating neutralino decay involving a non-zero λ' coupling [137].

Table 3: Summary of weak gaugino mass limits, assuming R-parity conservation. Masses in the table are provided in GeV. Further details about assumptions and analyses from which these limits are obtained are discussed in the text.

Assumption	m_χ
$\tilde{\chi}_1^\pm$, all $\Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0)$	> 92
$\tilde{\chi}_1^\pm$ $\Delta m > 5$, $m_{\tilde{\nu}} > 300$	> 103.5
$\tilde{\chi}_1^\pm$, $m_{(\tilde{\ell},\tilde{\nu})} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	
$m_{\tilde{\chi}_1^0} \approx 0$	$103.5 - 115, > 550$
$\tilde{\chi}_1^\pm$, $m_{\tilde{\chi}_1^0} > 150$	no LHC limit
$\tilde{\chi}_1^\pm$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_L} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 730
$m_{\tilde{\chi}_1^0} > 350$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_R} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 350
$m_{\tilde{\chi}_1^0} > 100$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WZ) = 1$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 300
$m_{\tilde{\chi}_1^0} > 100$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WH) = 1$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 280
$m_{\tilde{\chi}_1^0} > 50$	no LHC limit

II.6. Exclusion limits on slepton masses

In models with slepton and gaugino mass unification at the GUT scale, the right-handed slepton, $\tilde{\ell}_R$, is expected to be lighter than the left-handed slepton, $\tilde{\ell}_L$. For tau sleptons there may be considerable mixing between the L and R states, leading to a significant mass difference between the lighter $\tilde{\tau}_1$ and the heavier $\tilde{\tau}_2$.

II.6.1. Exclusion limits on the masses of charged sleptons

The most model-independent searches for selectrons, smuons and staus originate from the LEP experiments [138]. Smuon production only takes place via s-channel γ^*/Z exchange. Search results are often quoted for $\tilde{\mu}_R$, since it is typically lighter than $\tilde{\mu}_L$ and has a weaker coupling to the Z boson; limits are therefore conservative. Decays are expected to be dominated by $\tilde{\mu}_R \to \mu\tilde{\chi}_1^0$, leading to two non-back-to-back muons and missing momentum. Limits are calculated in the MSSM under the assumption of gaugino mass unification at the GUT scale, and depend on the mass difference between the smuon and $\tilde{\chi}_1^0$. A $\tilde{\mu}_R$ with a mass below 94 GeV is excluded for $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10$ GeV. The selectron case is similar to the smuon case, except that an additional production mechanism is provided by t-channel neutralino exchange. The $\tilde{e}_R$ lower mass limit is 100 GeV for $m_{\tilde{\chi}_1^0} < 85$ GeV. Due to the t-channel neutralino exchange, $\tilde{e}_R\tilde{e}_L$ pair production was possible at LEP, and a lower limit of 73 GeV was set on the selectron mass regardless of the neutralino mass by scanning over MSSM parameter space [139]. The potentially large mixing between $\tilde{\tau}_L$ and $\tilde{\tau}_R$ not only makes the $\tilde{\tau}_1$ light, but can also make its coupling to the Z boson small. LEP lower limits on the $\tilde{\tau}$ mass range between 87 and 93 GeV depending on the $\tilde{\chi}_1^0$ mass, for $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 7$ GeV [138].

As shown in Fig. 1, at the LHC pair production of sleptons is not only heavily suppressed with respect to pair production of colored SUSY particles but is also almost two orders of magnitude smaller than pair production of chargino and neutralinos. Therefore, only with the 2012 LHC data ATLAS and CMS are starting to surpass the sensitivity of the LEP analyses.

ATLAS and CMS have searched for direct production of selectron pairs and smuon pairs at the LHC, with each slepton decaying to its corresponding SM partner lepton and the $\tilde{\chi}_1^0$ LSP. ATLAS [105] and CMS [106] set limits in this model of 220 GeV for $\tilde{\ell}_R$, and 290 GeV for $\tilde{\ell}_L$, for a massless $\tilde{\chi}_1^0$ and assuming equal selectron and smuon masses, as shown in Fig. 10. The limits deteriorate with increasing $\tilde{\chi}_1^0$ mass due to decreasing missing momentum and lepton momentum. As a consequence, there is a gap between LEP and LHC limits for $\tilde{\chi}_1^0$ masses above 20 GeV, and no limits are set for $\tilde{\chi}_1^0$ masses above 90 GeV ($\tilde{\ell}_R$) or above 150 GeV ($\tilde{\ell}_L$).

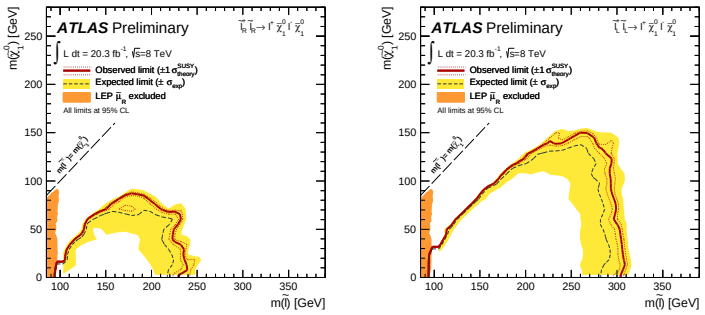

Figure 10: Exclusion limits on $\tilde{\ell}_R$ masses (left) and $\tilde{\ell}_L$ masses (right), assuming equal selectron and smuon masses in both scenarios, and assuming a 100% branching fraction for $\tilde{\ell} \to \ell\tilde{\chi}_1^0$.

In gauge-mediated SUSY breaking models, sleptons can be (co-)NLSPs, *i.e.*, the next-to-lightest SUSY particles and almost degenerate in mass, decaying to a lepton and a gravitino. This decay can either be prompt, or the slepton can have a non-zero lifetime. Combining several analyses, lower mass limits on $\tilde{\mu}_R$ of 96.3 GeV and on $\tilde{e}_R$ of 66 GeV are set for all slepton lifetimes at LEP [140]. In a considerable part of parameter space in these models, the $\tilde{\tau}$ is the NLSP. The LEP experiments have set lower limits on the mass of such a $\tilde{\tau}$ between 87 and 97 GeV, depending on the $\tilde{\tau}$ lifetime. ATLAS has searched for final states with τs, jets and missing transverse momentum, and has interpreted the results in GMSB

models setting limits on the model parameters [141]. CMS has interpreted a multilepton analysis in terms of limits on gauge mediation models with slepton (co-)NLSP [142]. CDF has put limits on gauge mediation models at high $\tan\beta$ and slepton (co-)NLSP using an analysis searching for like-charge light leptons and taus [143].

Limits also exist on sleptons in R-parity violating models, both from LEP and the Tevatron experiments. From LEP, lower limits on $\tilde{\mu}_{\rm R}$ and $\tilde{e}_{\rm R}$ masses in such models are 97 GeV, and the limits on the stau mass are very close: 96 GeV [144].

Charged slepton decays may be kinematically suppressed, for example in the scenario of a NLSP slepton with a very small mass difference to the LSP. Such a slepton may appear to be a stable charged massive particle. Interpretation of searches at LEP for such signatures within GMSB models with stau NLSP or slepton co-NLSP exclude masses up to 99 GeV [112]. Searches of stable charged particles at the Tevatron [99,100] and at the LHC [145,70] are also interpreted in terms of limits on stable charged sleptons. The limits obtained at the LHC exclude stable staus with masses below 339 GeV when produced directly in pairs, and below 500 GeV when staus are produced both directly and indirectly in the decay of other particles in a GMSB model. Drell-Yan production of $q = 1$ stable lepton-like particles is excluded for masses below 574 GeV [70].

II.6.2. Exclusion limits on sneutrino masses

The invisible width of the Z boson puts a lower limit on the sneutrino mass of about 45 GeV. Tighter limits are derived from other searches, notably for gauginos and sleptons, under the assumption of gaugino and sfermion mass universality at the GUT scale, and amount to approximately 94 GeV in the MSSM [146]. It is possible that the lightest sneutrino is the LSP; however, a left-handed sneutrino LSP is ruled out as a cold dark matter candidate [147,148].

Production of pairs of sneutrinos in R-parity violating models has been searched for at LEP [144]. Assuming fully leptonic decays via λ-type couplings, lower mass limits between 85 and 100 GeV are set. At the Tevatron [149,150] and at the LHC [151], searches have focused on scenarios with resonant production of a sneutrino, decaying to $e\mu$, $\mu\tau$ and $e\mu$ final states. No signal has been seen, and limits have been set on sneutrino masses as a function of the value of relevant RPV couplings. As an example, the ATLAS analysis excludes a resonant tau sneutrino with a mass below 800 GeV for $\lambda_{312} > 0.01$ and $\lambda'_{311} > 0.01$ [151].

II.7. Global interpretations

Apart from the interpretation of direct searches for sparticle production at colliders in terms of limits on masses of individual SUSY particles, model-dependent interpretations of allowed SUSY parameter space are derived from global SUSY fits. Typically these fits combine the results from collider experiments with indirect constraints on SUSY as obtained from low-energy experiments, flavor physics, high-precision electroweak results, and astrophysical data.

Table 4: Summary of slepton mass limits from LEP and LHC, assuming R-parity conservation and 100% branching fraction for $\tilde{\ell} \to \ell\tilde{\chi}^0_1$. Masses in this table are provided in GeV.

Assumption	$m_{\tilde{\ell}}$
$\tilde{\mu}_{\rm R}$, $\Delta m(\tilde{\mu}_{\rm R}, \tilde{\chi}^0_1) > 10$	> 94
$\tilde{e}_{\rm R}$, $\Delta m(\tilde{e}_{\rm R}, \tilde{\chi}^0_1) > 10$	> 94
$\tilde{e}_{\rm R}$, any Δm	> 73
$\tilde{\tau}_{\rm R}$, $\Delta m((\tilde{\tau}_{\rm R}, \tilde{\chi}^0_1) > 7$	> 87
$\tilde{\nu}_e$, $\Delta m(\tilde{e}_{\rm R}, \tilde{\chi}^0_1) > 10$	> 94
$m_{\tilde{e}_{\rm R}} = m_{\tilde{\mu}_{\rm R}}$, $m_{\tilde{\chi}^0_1} \approx 0$	> 220
$m_{\tilde{\chi}^0_1} > \approx 90$	no LHC limit
$m_{\tilde{e}_{\rm L}} = m_{\tilde{\mu}_{\rm L}}$, $m_{\tilde{\chi}^0_1} \approx 0$	> 290
$m_{\tilde{\chi}^0_1} > \approx 150$	no LHC limit

In the pre-LHC era these fits were mainly dominated by indirect constraints. Even for very constrained models like the CMSSM, the allowed parameter space, in terms of squark and gluino masses, ranged from several hundreds of GeV to a few TeV. Furthermore, these global fits indicated that squarks and gluino masses in the range of 500 to 1000 GeV were the preferred region of parameter space, although values as high as few TeV were allowed with lower probabilities [152].

With ATLAS and CMS now probing mass scales around 1 TeV and even beyond, the importance of the direct searches for global analyses of allowed SUSY parameter space has strongly increased. For example, imposing the new experimental limits on constrained supergravity models pushes the most likely values of first generation squark and gluino masses significantly beyond 1 TeV, typically resulting in overall values of fit quality much worse than those in the pre-LHC era [115]. Although these constrained models are not yet ruled out, the extended experimental limits impose tight constraints on the allowed parameter space.

For this reason, the emphasis of global SUSY fits has shifted towards less-constrained SUSY models. Especially interpretations in the pMSSM [153] but also in simplified models have been useful to generalize SUSY searches, for example to redesign experimental analyses in order to increase their sensitivity for compressed spectra, where the mass of the LSP is much closer to squark and gluino masses than predicted, for example, by the CMSSM. As shown in Table 2, for neutralino masses above a few hundred GeV the current set of ATLAS and CMS searches cannot exclude the existence of light squarks and also gluinos above approximately 1 TeV are not yet fully excluded.

Furthermore, the discovery of a Higgs boson with a mass around 126 GeV has triggered many studies regarding the compatibility of SUSY parameter space with this new particle. Much of it is still work in progress and it will be interesting to see how the interplay between the results from direct SUSY searches and more precise measurements of the properties of the

See key on page 547

Higgs boson will unfold in the forthcoming era of high-energy running of the LHC.

II.8. Summary and Outlook

Direct searches for SUSY, combined with limits from high-precision experiments that look for new physics in loops, put SUSY under considerable scrutiny. In particular the absence of any observation of new phenomena at the first run of the LHC, at $\sqrt{s} = 7$ and 8 TeV, place significant constraints on SUSY parameter space. Today, inclusive searches probe production of gluinos in the rage of $1.0 - 1.4$ TeV, first and second generation squarks to about 1.0 TeV , third generation squarks at scales around 600 GeV, electroweak gauginos at scales around $300 - 500$ GeV, and sleptons around 200 GeV. However, depending on the assumptions made of the underlying SUSY spectrum these limits can also weaken considerably. An overview of the current landscape of SUSY searches and corresponding exclusion limits at the LHC is shown in Fig. 11 from the ATLAS experiment [154]. The corresponding results of the CMS experiment are similar [155].

The interpretation of results at the LHC has moved away from constrained models like the CMSSM towards a large set of simplified models, or the pMSSM. On the one hand this move is because the LHC limits have put constrained models like the CMSSM under severe pressure, while on the other hand simplified models leave more freedom to vary parameters and form a better representation of the underlying sensitivity of analyses. However, these interpretations in simplified models do not come without a price: the decomposition of a potentially complicated reality in a limited set of individual decay chains can be significantly incomplete. Therefore, quoted limits in simplified models are only valid under the explicit assumptions made in these models, assumptions that are usually stated on the plots, and in the relevant LHC papers. Interpretations of simplified models in generic cases, ignoring the assumptions made, can lead to overestimation of limits on SUSY parameter space. In this context, the limit range of $1.0 - 1.4$ TeV on generic colored SUSY particles only hold for light neutralinos, in the R-parity conserving MSSM. Limits on third generation squarks and electroweak gauginos also only hold for light neutralinos, and under specific assumptions for decay modes and slepton masses. In general, SUSY below the 1 TeV scale is not yet ruled out.

The next run of the LHC, at $\sqrt{s} = 13$ TeV or higher, with significantly larger integrated luminosities, will present again a great opportunity for SUSY searches. The operation at higher energy will increase the production cross section for SUSY particles, shown in Fig. 1, substantially. While typically for masses around 500 GeV the increase is about 3 to 5 times the production cross section at 8 TeV, this becomes an increase of almost two orders of magnitude for a SUSY mass scale of 1.5 to 2 TeV. Apart from pushing the sensitivity of LHC searches to higher mass scales, further LHC data will also help to reduce holes and gaps that are left behind in today's SUSY limits. These could be, for example, due to compressed particle spectra, stealth SUSY, or the violation of R-parity.

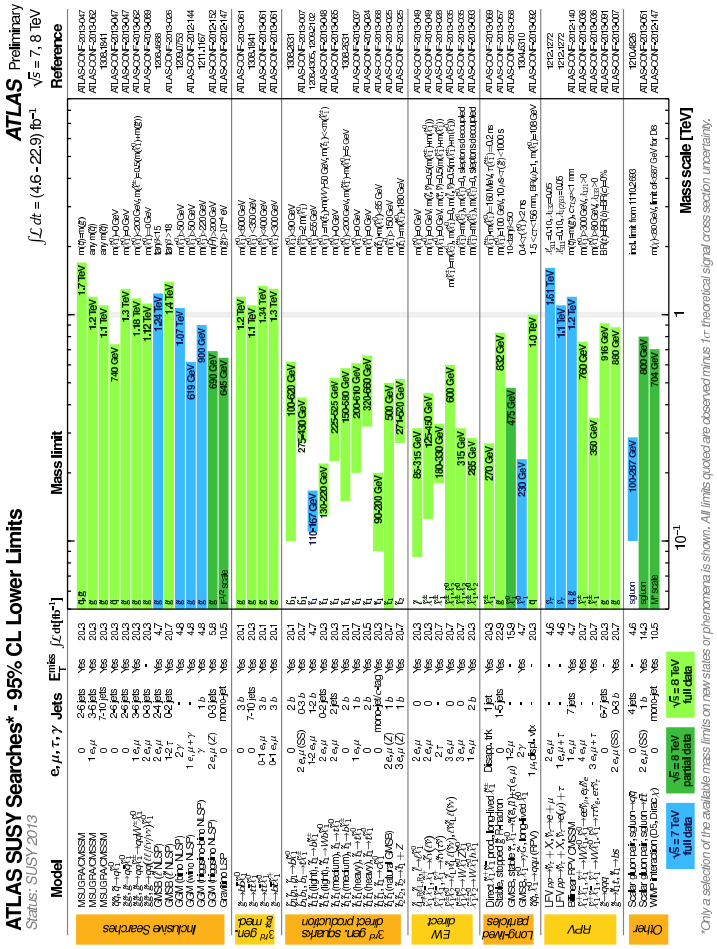

Figure 11: Overview of the current landscape of SUSY searches at the LHC. The plot shows exclusion mass limits of ATLAS for different searches and interpretation assumptions. The corresponding results of CMS are comparable.

SUPERSYMMETRIC MODEL ASSUMPTIONS

The exclusion of particle masses within a mass range (m_1, m_2) will be denoted with the notation "none m_1–m_2" in the VALUE column of the following Listings. The latest unpublished results are described in the "Supersymmetry: Experiment" review.

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that R-parity (R) is conserved. Unless otherwise indicated, the results also assume that:

1) The $\widetilde{\chi}_1^0$ is the lighest supersymmetric particle (LSP)
2) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, where $\widetilde{f}_{L,R}$ refer to the scalar partners of left- and right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R-parity violation ($\not{R}$) are characterized by a superpotential of the form: $\lambda_{ijk} L_i L_j e^c_k + \lambda'_{ijk} L_i Q_j d^c_k + \lambda''_{ijk} u^c_i d^c_j d^c_k$, where i, j, k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\overline{E}$, $LQ\overline{D}$, and $\overline{UDD}$. Mass limits in the presence of $\not{R}$ will often refer to "direct" and "indirect" decays. Direct refers to $\not{R}$ decays of the particle in consideration. Indirect refers to cases where $\not{R}$ appears in the decays of the LSP.

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino ($\widetilde{G}$) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and $m_{\widetilde{G}}$ is then neglected

in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lighest supersymmetric particle (NLSP), and are assumed to decay to their even-R partner plus $\widetilde{G}$. If the lifetime is short enough for the decay to take place within the detector, $\widetilde{G}$ is assumed to be undetected and to give rise to missing energy ($\not{E}$) or missing transverse energy ($\not{E}_T$) signatures.

When needed, specific assumptions on the eigenstate content of $\widetilde{\chi}^0$ and $\widetilde{\chi}^\pm$ states are indicated, using the notation $\widetilde{\gamma}$ (photino), $\widetilde{H}$ (higgsino), $\widetilde{W}$ (wino), and $\widetilde{Z}$ (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

CONTENTS:

$\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

$\widetilde{\chi}_1^0$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\widetilde{\chi}_2^0$, $\widetilde{\chi}_3^0$, $\widetilde{\chi}_4^0$ section below.

We have divided the $\widetilde{\chi}_1^0$ listings below into five sections:

1) Accelerator limits for stable $\widetilde{\chi}_1^0$,
2) Bounds on $\widetilde{\chi}_1^0$ from dark matter searches,
3) $\widetilde{\chi}_1^0 - p$ elastic cross section (spin-dependent, spin-independent interactions),
4) Other bounds on $\widetilde{\chi}_1^0$ from astrophysics and cosmology, and
5) Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) mass limit.

Accelerator limits for stable $\widetilde{\chi}_1^0$

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\widetilde{\chi}_i^0\widetilde{\chi}_j^0$ ($i \geq 1$, $j \geq 2$), $\widetilde{\chi}_1^+\widetilde{\chi}_1^-$, and (in the case of hadronic collisions) $\widetilde{\chi}_1^+\widetilde{\chi}_2^0$ pairs. The mass limits on $\widetilde{\chi}_1^0$ are either direct, or follow indirectly from the constraints set by the non-observation of $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from e^+e^- collisions up to $\sqrt{s}$=184 GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal **C15** 1 (2000)) of this Review. $\Delta m = m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$.

		[6] DREINER	09	THEO	

[1] ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 <$5000 GeV, $-1000 < \mu <$1000 GeV and tanβ from 1 to 40. This limit supersedes ABBIENDI 00H.

[2] HEISTER 04 data collected up to 209 GeV. Updates earlier analysis of selectrons from HEISTER 02E, includes a new analysis of charginos and neutralinos decaying into stau and uses results on charginos with initial state radiation from HEISTER 02J. The limit is based on the direct search for charginos and neutralinos, the constraints from the slepton search and the Higgs mass limits from HEISTER 02 using a top mass of 175 GeV, interpreted in a framework with universal gaugino and sfermion masses. Assuming the mixing in the stau sector to be negligible, the limit improves to 43.1 GeV. Under the assumption of MSUGRA with unification of the Higgs and sfermion masses, the limit improves to 50 GeV, and reaches 53 GeV for $A_0 = 0$. These limits include and update the results of BARATE 01.

[3] ABDALLAH 03M uses data from $\sqrt{s} =$ 192–208 GeV. A limit on the mass of $\widetilde{\chi}_1^0$ is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$, $\widetilde{\chi}_1^0\widetilde{\chi}_3^0$, as well as $\widetilde{\chi}_2^0\widetilde{\chi}_3^0$ and $\widetilde{\chi}_2^0\widetilde{\chi}_4^0$ giving rise to cascade decays, and $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$, followed by the decay $\widetilde{\chi}_2^0 \rightarrow \widetilde{\tau}\tau$. The results hold for the parameter space defined by values of $M_2 <$ 1 TeV, $|\mu| \leq$ 2 TeV with the $\widetilde{\chi}_1^0$ as LSP. The limit is obtained for tan$\beta = 1$ and large m_0, where $\widetilde{\chi}_2^0\widetilde{\chi}_4^0$ and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the $m_h^{\max}$ scenario with m_t=174.3 GeV. These limits update the results of ABREU 00J.

[4] ABDALLAH 03M uses data from $\sqrt{s} =$ 192–208 GeV. An indirect limit on the mass of $\widetilde{\chi}_1^0$ is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and $\widetilde{\tau}\tau$ final states), for charginos (for all Δm_+) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of $M_2 <$ 1 TeV, $|\mu| \leq$ 2 TeV with the $\widetilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the $m_h^{\max}$ scenario assuming m_t=174.3 GeV are included. The limit is obtained for tan$\beta \geq$ 5 when stau mixing leads to mass degeneracy between $\widetilde{\tau}_1$ and $\widetilde{\chi}_1^0$ and the limit is based on $\widetilde{\chi}_2^0$ production followed by its decay to $\widetilde{\tau}_1\tau$. In the pathological scenario where m_0 and $|\mu|$ are large, so that the $\widetilde{\chi}_2^0$ production cross section is negligible, and where there is mixing in the stau sector but not in stop nor sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs 40–42 for the dependence of the limit on tanβ and $m_{\widetilde{\nu}}$. These limits update the results of ABREU 00W.

[5] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq$ tan$\beta \leq$ 60, $0 \leq M_2 \leq$ 2 TeV, $m_0 \leq$ 500 GeV, $|\mu| \leq$ 2 TeV The minimum mass limit is reached for tanβ=1 and large m_0. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. The limit improves to 48 GeV for $m_0 \gtrsim$ 200 GeV and tan$\beta \gtrsim$ 10. See their Figs. 6–8 for the tanβ and m_0 dependence of the limits. Updates ACCIARRI 98F.

[6] DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ_1^0 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_2, μ and the slepton and squark masses.

Bounds on $\widetilde{\chi}_1^0$ from dark matter searches

These papers generally exclude regions in the $M_2 - \mu$ parameter plane assuming that $\widetilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments, telescopes, or by the absence of a signal in underground neutrino detectors. The latter signal is expected if $\widetilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν's.

[1] AARTSEN 13 is based on data collected during 317 effective days with the IceCube 79-string detector including the DeepCore sub-array. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 20–5000 GeV.

[2] AARTSEN 13C is based on data collected during 339.8 effective days with the IceCube 59-string detector. They looked for interactions of ν_μ's from neutralino annihilations in nearby galaxies and galaxy clusters. They obtain limits on the neutralino annihilation cross section for neutralino masses in the range 30–100, 000 GeV.

[3] ABRAMOWSKI 13 place upper limits on the annihilation cross section with $\gamma\gamma$ final states in the energy range of 0.5–25 TeV.

[4] ACKERMANN 13A is based on 3.7 years of data with Fermi-LAT and search for monochromatic gamma-rays in the energy range of 5–300 GeV from dark matter annihilations. No globally significant lines are reported.

[5] ADRIAN-MARTINEZ 13 is based on data from the ANTARES neutrino telescope. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 50–10, 000 GeV.

[6] BERGSTROM 13, JIN 13, and KOPP 13 derive limits on the mass and annihilation cross section using AMS-02 data. JIN 13 also sets a limit on the lifetime of the dark matter particle.

[7] BOLIEV 13 is based on data collected during 24.12 years of live time with the Bakson Underground Scintillator Telescope. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent and spin independent neutralino-proton cross section for neutralino masses in the range 10–1000 GeV.

[8] ABBASI 12 is based on data collected during 812 effective days with AMANDA II and 149 days of the IceCube 40-string detector combined with the data of ABBASI 09B. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. No excess is observed. They also obtain limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 50–5000 GeV.

[9] ABRAMOWSKI 11 place upper limits on the annihilation cross section with $\gamma\gamma$ final states.

[10] ABDO 10 place upper limits on the annihilation cross section with $\gamma\gamma$ or $\mu^+\mu^-$ final states.

[11] ACKERMANN 10 place upper limits on the annihilation cross section with $b\overline{b}$ or $\mu^+\mu^-$ final states.

[12] ABBASI 09B is based on data collected during 104.3 effective days with the IceCube 22-string detector. They looked for interactions of ν_μ's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent neutralino–proton cross section for neutralino masses in the range 250–5000 GeV.

[13] ACHTERBERG 06 is based on data collected during 421.9 effective days with the AMANDA detector. They looked for interactions of ν_μs from the centre of the Earth over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into W^+W^- and $b\overline{b}$ at the centre of the Earth for MSSM parameters compatible with the relic dark matter density, see their Fig. 7.

[14] ACKERMANN 06 is based on data collected during 143.7 days with the AMANDA-II detector. They looked for interactions of ν_μs from the Sun over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into W^+W^- in the Sun for SUSY model parameters compatible with the relic dark matter density, see their Fig. 3.

[15] DEBOER 06 interpret an excess of diffuse Galactic gamma rays observed with the EGRET satellite as originating from π^0 decays from the annihilation of neutralinos into quark jets. They analyze the corresponding parameter space in a supergravity inspired MSSM model with radiative electroweak symmetry breaking, see their Fig. 3 for the preferred region in the $(m_0, m_{1/2})$ plane of a scenario with large $\tan\beta$.

[16] AMBROSIO 99 and DESAI 04 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the Sun and the Earth.

[17] LOSECCO 95 reanalyzed the IMB data and places lower limit on $m_{\widetilde{\chi}^0_1}$ of 18 GeV if the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector.

[18] MORI 93 excludes some region in M_2–μ parameter space depending on $\tan\beta$ and lightest scalar Higgs mass for neutralino dark matter $m_{\widetilde{\chi}^0} > m_W$, using limits on upgoing muons produced by energetic neutrinos from neutralino annihilation in the Sun and the Earth.

[19] BOTTINO 92 excludes some region M_2-μ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account.

[20] BOTTINO 91 excluded a region in $M_2-\mu$ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy.

[21] GELMINI 91 exclude a region in $M_2-\mu$ plane using dark matter searches.

[22] KAMIONKOWSKI 91 excludes a region in the M_2–μ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0} \lesssim 50$ GeV. See Fig. 8 in the paper.

[23] MORI 91B exclude a part of the region in the M_2–μ plane with $m_{\widetilde{\chi}^0_1} \lesssim 80$ GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0} \lesssim 80$ GeV.

[24] OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

$\widetilde{\chi}^0_1$-p elastic cross section

Experimental results on the $\widetilde{\chi}^0_1$-p elastic cross section are evaluated at $m_{\widetilde{\chi}^0_1}$=100 GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form $\overline{\chi}\gamma^\mu\gamma^5\chi\overline{q}\gamma_\mu\gamma^5 q$) and spin-independent interactions ($\overline{\chi}\chi\overline{q}q$). For calculational details see GRIEST 88B, ELLIS 88D, BARBIERI 89C, DREES 93B, ARNOWITT 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Physics," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

[1] The strongest limit is 0.006 pb and occurs at $m_\chi = 60$ GeV. APRILE 13 also presents limits for the scattering on neutrons. At 100 GeV, the upper limit is 4×10^{-4} pb and the strongest limit is 3.5×10^{-4} pb at 45 GeV.

[2] This result updates LEBEDENKO 09A. The strongest limit is 8×10^{-3} pb at $m_\chi = 50$ GeV. Limit applies to the neutralino neutron elastic cross section.

[3] This result updates ARCHAMBAULT 09. The strongest limit is 0.032 pb at $m_\chi = 20$ GeV.

[4] The strongest limit is 6×10^{-3} at $m_\chi = 60$ GeV.

[5] The strongest limit is 1.8 pb and occurs at $m_\chi = 100$ GeV.

[6] The strongest limit is 5.7×10^{-3} at $m_\chi = 35$ GeV.

[7] This result updates LEE 07A. The strongest limit is at $m_\chi = 80$ GeV.

[8] Predictions for the spin-dependent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[9] The strongest limit is 0.6 pb and occurs at m_χ= 30 GeV. The limit for scattering on neutrons is 0.01 pb at m_χ= 100 GeV, and the strongest limit is 0.0045 pb at m_χ= 30 GeV.

[10] Limit applies to neutron elastic cross section.

[11] The strongest upper limit is 0.25 pb and occurs at $m_\chi \simeq 40$ GeV.

[12] The strongest upper limit is 4 pb and occurs at $m_\chi \simeq 60$ GeV. The limit on the neutron spin-dependent elastic cross section is 0.07 pb. This latter limit is improved in AHMED 09, where a limit of 0.02 pb is obtained at $m_\chi = 100$ GeV. The strongest limit in AHMED 09 is 0.018 pb and occurs at $m_\chi = 60$ GeV.

[13] The strongest upper limit is 1.2 pb and occurs at $m_\chi \simeq 40$ GeV. The limit on the neutron spin-dependent cross section is 35 pb.

[14] The strongest upper limit is 0.35 pb and occurs at $m_\chi \simeq 60$ GeV.

[15] The strongest upper limit is 1.2 pb and occurs $m_\chi \simeq 30$ GeV.

[16] ELLIS 04 calculates the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses. In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-4}, see ELLIS 03E.

[17] The strongest upper limit is 0.75 pb and occurs at $m_\chi \approx 70$ GeV.

[18] The strongest upper limit is 30 pb and occurs at $m_\chi \approx 20$ GeV.

[19] The strongest upper limit is 8 pb and occurs at $m_\chi \simeq 30$ GeV.

[20] ELLIS 01C calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. In models with nonuniversal Higgs masses, the upper limit to the cross section is 6×10^{-4}.

[21] The strongest upper limit is 3 pb and occurs at $m_\chi \simeq 60$ GeV. The limits are for inelastic scattering $X^0 + {}^{129}\mathrm{Xe} \rightarrow X^0 + {}^{129}\mathrm{Xe}^*$ (39.58 keV).

[22] The strongest upper limit is 4.4 pb and occurs at $m_\chi \simeq 60$ GeV.

[23] The strongest upper limit is about 35 pb and occurs at $m_\chi \simeq 15$ GeV.

[1] AALSETH 13 presents 90% CL limits on the elastic cross section for masses in the range 4–25 GeV in addition to a region of interest at about 8 GeV. The strongest upper limit is 2×10^{-5} pb at $m_\chi = 14$ GeV.

[2] AGNESE 13 presents 90% CL limits on the elastic cross section for masses in the range 7–100 GeV using the Si based detector. The strongest upper limit is 1.8×10^{-6} pb at $m_\chi = 50$ GeV. This limit is improved to 7×10^{-7} pb in AGNESE 13A.

[3] LI 13B presents 90% CL limits on the elastic cross section for masses in the range 4–40 GeV. The strongest upper limit is 4×10^{-5} pb at $m_\chi = 14$ GeV.

[4] This result updates LEBEDENKO 09. The strongest limit is 3.9×10^{-8} pb at $m_\chi = 52$ GeV.

[5] ANGLOHER 12 presents results of 730 kg days from the CRESST-II dark matter detector. They find two maxima in the likelihood function corresponding to best fit WIMP masses of 25.3 and 11.6 GeV with elastic cross sections of 1.6×10^{-6} and 3.7×10^{-5} pb respectively, see their Table 4. The statistical significance is more than 4σ.

[6] APRILE 12 updates the result of APRILE 11B. The strongest upper limit is $< 2.0\times10^{-9}$ pb and occurs at $m_\chi \simeq 50$ GeV.

[7] The strongest limit is 6.1×10^{-5} pb at $m_\chi = 20$ GeV.

[8] Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 5 fb^{-1} LHC data and XENON100.

[9] The strongest limit is 1.4×10^{-7} at $m_\chi = 60$ GeV.

[10] Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 5 fb^{-1} LHC data and XENON100.

[11] The strongest limit is 4.7×10^{-6} at $m_\chi = 35$ GeV.

[12] Predictions for the spin-independent elastic cross section based on a Bayesian approach to electroweak observables in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 5 fb^{-1} LHC data and XENON100.

[13] This result updates LEE 07A. The strongest limit is 2.1×10^{-7} at $m_\chi = 70$ GeV.

[14] AHMED 11A gives combined results from CDMS and EDELWEISS. The strongest limit is at $m_\chi = 90$ GeV.

[15] ARMENGAUD 11 updates result of ARMENGAUD 10. Strongest limit at $m_\chi = 85$ GeV.

[16] The strongest upper limit is $< 3.8\times10^{-8}$ pb and occurs at $m_\chi \simeq 70$ GeV. AHMED 10 updates the results of AHMED 09.

[17] The strongest upper limit is 4.8×10^{-7} pb and occurs at $m_\chi = 50$ GeV.

[18] The strongest upper limit is 5.1×10^{-8} pb and occurs at $m_\chi \simeq 30$ GeV. The values quoted here are based on the analysis performed in ANGLE 08 with the update from SORENSEN 09.

[19] The strongest upper limit is 6.6×10^{-7} pb and occurs at $m_\chi \simeq 65$ GeV.

[20] AKERIB 06A updates the results of AKERIB 05. The strongest upper limit is 1.6×10^{-7} pb and occurs at $m_\chi \approx 60$ GeV.

[21] The strongest upper limit is also close to 1.0×10^{-6} pb and occurs at $m_\chi \simeq 70$ GeV. BENOIT 06 claim that the discrimination power of ZEPLIN-I measurement (ALNER 05A) is not reliable enough to obtain a limit better than 1×10^{-3} pb. However, SMITH 06 do not agree with the criticisms of BENOIT 06.

[22] The strongest upper limit is also close to 1.4×10^{-6} pb and occurs at $m_\chi \simeq 70$ GeV.

[23] AKERIB 04 is incompatible with BERNABEI 00 most likely value, under the assumption of standard WIMP-halo interactions. The strongest upper limit is 4×10^{-7} pb and occurs at $m_\chi \simeq 60$ GeV.

[24] Predictions for the spin-independent elastic cross section in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[25] KIM 02 and ELLIS 04 calculate the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses.

[26] In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-6} (2×10^{-11} when constraint from the BNL g–2 experiment are included), see ELLIS 03E. ELLIS 05 display the sensitivity of the elastic scattering cross section to the π-Nucleon Σ term.

[27] PIERCE 04A calculates the χp elastic scattering cross section in the framework of models with very heavy scalar masses. See Fig. 2 of the paper.

[28] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 80$ GeV.

[29] Under the assumption of standard WIMP-halo interactions, Akerib 03 is incompatible with BERNABEI 00 most likely value at the 99.98% CL. See Fig. 4.

[30] BAER 03A calculates the χp elastic scattering cross section in several models including the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[31] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.

[32] ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is 3×10^{-6} pb and occurs at $m_\chi \simeq 30$ GeV.

[33] BENOIT 02 excludes the central result of DAMA at the 99.8%CL.

[34] The strongest upper limit is 2×10^{-5} pb and occurs at $m_\chi \simeq 40$ GeV.

[35] The strongest upper limit is 7×10^{-6} pb and occurs at $m_\chi \simeq 46$ GeV.

[36] The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \simeq 32$ GeV

[37] BOTTINO 01 calculates the χ-p elastic scattering cross section in the framework of the following supersymmetric models: N=1 supergravity with the radiative breaking of the electroweak gauge symmetry, N=1 supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.

[38] Calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[39] ELLIS 01C calculates the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range 2×10^{-8}–1.5×10^{-7} at $\tan\beta$=50. In models with nonuniversal Higgs masses, the upper limit to the cross section is 4×10^{-7}.

[40] ACCOMANDO 00 calculate the χ-p elastic scattering cross section in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models with nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to $< 9\times10^{-8}$ ($\tan\beta < 55$).

[41] BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4σ and are consistent, for a particular model framework quoted there, with m_{X^0}=44^{+12}_{-9} GeV and a spin-independent X^0-proton cross section of $(5.4 \pm 1.0)\times10^{-6}$ pb. See also BERNABEI 01 and BERNABEI 00C.

[42] FENG 00 calculate the χ-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At $\tan\beta$=50, the range is 8×10^{-8}–4×10^{-7}.

[43] BERNABEI 99 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 99.6%CL and are consistent, for the particular model

framework considered there, with m_{X^0}=59 $^{+17}_{-14}$ GeV and spin-independent X^0-proton cross section of $(7.0^{+0.4}_{-1.2}) \times 10^{-6}$ pb (1 σ errors).

[44] BERNABEI 98 search for annual modulation of the WIMP signal. The data are consistent, for the particular model framework considered there, with m_{X^0}=59 $^{+36}_{-19}$ GeV and spin-independent X^0-proton cross section of $(1.0^{+0.1}_{-0.4}) \times 10^{-5}$ pb (1 σ errors).

Other bounds on $\tilde{\chi}_1^0$ from astrophysics and cosmology

Most of these papers generally exclude regions in the $M_2 - \mu$ parameter plane by requiring that the $\tilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

[1] ELLIS 00 updates ELLIS 98. Uses LEP e^+e^- data at $\sqrt{s}$=202 and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on tanβ improve to > 2.7 ($\mu > 0$), > 2.2 ($\mu < 0$) when scalar mass universality is assumed and > 1.9 (both signs of μ) when Higgs mass universality is relaxed.

[2] CABRERA 13 and STREGE 13 place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with and without non-universal Higgs masses using the 5.8 fb^{-1}, $\sqrt{s} = 7$ TeV ATLAS supersymmetry searches and XENON100 results.

[3] ELLIS 13B place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with and without Higgs mass universality. Models with universality below the GUT scale are also considered.

[4] Implications of the LHC result on the Higgs mass and on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[5] BALAZS 12 and STREGE 12 place constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using the 1 fb^{-1} LHC supersymmetry searches, the 5 fb^{-1} Higgs mass constraints, both with $\sqrt{s} = 7$ TeV, and XENON100 results.

[6] BECHTLE 12 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, using the 5 fb^{-1} LHC and XENON100 data.

[7] BESKIDT 12 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, the 5 fb^{-1} LHC and the XENON100 data.

[8] BELANGER 04 and BOTTINO 12 (see also BOTTINO 03, BOTTINO 03A and BOTTINO 04) do not assume gaugino or scalar mass unification.

[9] BUCHMUELLER 12A places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, using the 5 fb^{-1} LHC and XENON100 data.

[10] FENG 12B places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry and large sfermion masses using the 1 fb^{-1} LHC supersymmetry searches, the 5 fb^{-1} LHC Higgs mass constraints both with $\sqrt{s} = 7$ TeV, and XENON100 results.

[11] FOWLIE 12A places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches, using the 5 fb^{-1} LHC and XENON100 data.

[12] BUCHMUELLER 11 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches and including supersymmetry breaking relations between A and B parameters.

[13] Places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal Higgs masses.

[14] ELLIS 10 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale.

[15] BUCHMUELLER 09 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

[16] DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ_1^0 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_2, μ and the slepton and squark masses.

[17] BUCHMUELLER 08 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

[18] CALIBBI 07 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale including the effects of right-handed neutrinos.

[19] ELLIS 07 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry with universality below the GUT scale.

[20] ALLANACH 06 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[21] DE-AUSTRI 06 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[22] BALTZ 04 places constraints on the SUSY parameter space in the framework of $N = 1$ supergravity models with radiative breaking of the electroweak gauge symmetry.

[23] Limit assumes a pseudo scalar mass < 200 GeV. For larger pseudo scalar masses, $m_\chi >$ 18(29) GeV for tan$\beta = 50(10)$. Bounds from WMAP, $(g-2)_\mu$, $b \to s\gamma$, LEP.

[24] ELLIS 04B places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters. See also ELLIS 03D.

[25] PIERCE 04A places constraints on the SUSY parameter space in the framework of models with very heavy scalar masses.

[26] BAER 03, CHATTOPADHYAY 03, ELLIS 03C and LAHANAS 03 place constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark matter density.

[27] BOEHM 00B and ELLIS 03 place constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of χ-$\tilde{t}$ co-annihilations.

[28] LAHANAS 02 places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.

[29] BARGER 01C use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[30] ELLIS 01B places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large tanβ.

[31] FENG 00 explores cosmologically allowed regions of MSSM parameter space with multi-TeV masses.

[32] ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of $\chi - \tilde{\tau}_R$ coannihilations.

[33] EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.

[34] Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking.

[35] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim$ 350 GeV for m_t = 174 GeV.

[36] DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.

[37] FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the MSSM.

[38] MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.

[39] LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.

[40] MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.

[41] GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.

[42] NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to narrow cosmologically allowed parameter space.

[43] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim$ 350 GeV for $m_t \leq 200$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim$ 1 TeV for $m_t \leq 200$ GeV.

[44] ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region.

[45] Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim$ 550 GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim$ 3.2 TeV.

[46] KRAUSS 83 finds $m_{\widetilde{\gamma}}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that limits depend strongly on reheated temperature. For example a new allowed region $m_{\widetilde{\gamma}}$ = 4–20 MeV exists if $m_{\text{gravitino}}$ <40 TeV. See figure 2.

Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses. In the following, $\widetilde{G}$ is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

[1] AAD 13AP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing non-pointing photons in a diphoton plus missing transverse energy final state. No excess is observed above the background expected from Standard Model processes. The results are used to set 95% C.L. exclusion limits in the context of gauge-mediated supersymmetric breaking models, with the lightest neutralino being the next-to-lightest supersymmetric particle and decaying with a lifetime in excess of 0.25 ns into a photon and a gravitino. For limits in the NLSP lifetime versus Λ plane, for the SPS8 model, see their Fig. 8.

[2] AAD 13Q searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing a high-p_T isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. Intermediate neutralino masses between 220 and 380 GeV are excluded at 95% C.L, regardless of the squark and gluino masses, purely on the basis of the expected weak production.

[3] AAD 13R looked in 4.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section of neutralinos via squarks for various $m_{\widetilde{q}}$, $m_{\widetilde{\chi}_1^0}$ in an R-parity violating scenario with $\lambda'_{211} \neq 0$, as a function of the neutralino lifetime, see their Fig. 6.

[4] AALTONEN 13I searched in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events containing $\not{E}_T$ and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No evidence of delayed photon production is observed.

[5] CHATRCHYAN 13AH searched in 4.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing $\not{E}_T$ and a delayed photon that arrives late in the detector relative to the time expected from prompt production. No significant excess above the expected background was found and limits were set on the pair production of $\widetilde{\chi}_1^0$ depending on the neutralino proper decay length, see Fig. 8. Supersedes CHATRCHYAN 12BK.

[6] AAD 12CP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons and large $\not{E}_T$ due to $\widetilde{\chi}_1^0 \rightarrow \gamma\widetilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP, see Figs. 6 and 7. The other sparticle masses were decoupled, tanβ = 2 and $c\tau_{NLSP}$ < 0.1 mm. Also, in the framework of the SPS8 model, limits are presented in Fig. 8.

[7] AAD 12CT searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of R-parity violating supersymmetry in which charginos are pair-produced and then decay into a W-boson and a $\widetilde{\chi}_1^0$, which in turn decays through an RPV coupling into two charged leptons ($e^{\pm}e^{\mp}$ or $\mu^{\pm}\mu^{\mp}$) and a neutrino. In this model, limits are set on the neutralino mass as a function of the chargino mass, see Fig. 3a. Limits are also set in an R-parity violating mSUGRA model, see Fig. 3b.

[8] AAD 12R looked in 33 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing new, heavy particles that decay at a significant distance from their production point into a final state containing a high-momentum muon and charged hadrons. No excess over the expected background is observed and limits are placed on the production cross-section of neutralinos via squarks for various ($m_{\widetilde{q}}$, $m_{\widetilde{\chi}_1^0}$) in an R-parity violating scenario with $\lambda'_{211} \neq 0$, as a function of the neutralino lifetime, see their Fig. 8. Superseded by AAD 13R.

[9] ABAZOV 12AD looked in 6.2 fb^{-1} of pp collisions at $\sqrt{s}$ = 1.96 TeV for events with a photon, a Z-boson, and large $\not{E}_T$ in the final state. This topology corresponds to a GMSB model where pairs of neutralino NLSPs are either pair produced promptly or from decays of other supersymmetric particles and then decay to either $Z\widetilde{G}$ or $\gamma\widetilde{G}$. No significant excess over the SM expectation is observed and a limit at 95% C.L. on the cross section is derived as a function of the effective SUSY breaking scale Λ, see Fig. 3. Assuming N_{mes} = 2, M_{mes} = 3 Λ, tanβ = 3, μ = 0.75 M_1, and C_{grav} = 1, the model is excluded at 95% C.L. for values of Λ < 87 TeV.

[10] CHATRCHYAN 12BK searched in 2.23 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons and large $\not{E}_T$ due to $\widetilde{\chi}_1^0 \rightarrow \gamma\widetilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the pair production of $\widetilde{\chi}_1^0$ depending on the neutralino lifetime, see Fig. 6.

[11] CHATRCHYAN 11B looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with an isolated lepton (e or μ), a photon and $\not{E}_T$ which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.

[12] AALTONEN 10 searched in 2.6 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\widetilde{\chi}^{\pm}$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying into $\widetilde{\chi}_1^0$ which itself decays in GMSB to $\gamma\widetilde{G}$. There is no excess of events beyond expectation. An upper limit on the cross section is calculated in the GMSB model as a function of the $\widetilde{\chi}_1^0$ mass and lifetime, see their Fig. 2. A limit

is derived on the $\tilde{\chi}_1^0$ mass of 149 GeV for $\tau_{\tilde{\chi}_1^0} \ll 1$ ns, which improves the results of previous searches.

[13] ABAZOV 10P looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least two isolated γs and large $\not{E}_T$. These could be the signature of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ production, decaying to $\tilde{\chi}_1^0$ and finally $\tilde{\chi}_1^0 \to \gamma\tilde{G}$ in a GMSB framework. No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section is derived for $N_{mes} = 1$, $\tan\beta = 15$ and $\mu > 0$, see their Fig. 2. This allows them to set a limit on the effective SUSY breaking scale $\Lambda > 124$ TeV, from which the excluded $\tilde{\chi}_1^0$ mass range is obtained.

[14] AALTONEN 08U searched in 570 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events that contain a time-delayed photon, at least one jet, and large $\not{E}_T$. The time-of-arrival is measured for each electromagnetic tower with a resolution of 0.50 ns. The number of observed events in the signal region is consistent with the background estimation. An upper limit on the cross section is derived as a function of the $\tilde{\chi}_1^0$ mass and lifetime, shown in their Fig. 24. The comparison with the NLO cross section for GMSB yields an exclusion of the $\tilde{\chi}_1^0$ mass as a function of its lifetime, see Fig. 25. See ABULENCIA 07P for a previous analysis of the same data set.

[15] ABAZOV 08F looked in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\tilde{\chi}_1^0 \to \gamma\tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 91.5$ TeV. Supersedes the results of ABAZOV 05A. Superseded by ABAZOV 10P.

[16] ABAZOV 08X searched in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with electron pairs. Their vertex, reconstructed from the directions measured in the segmented electromagnetic calorimeter, is required to be away from the primary interaction point. Such delayed decays might be expected for a Higgsino-like $\tilde{\chi}_1^0$ in GMSB. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted as a function of the lifetime for several ranges of dielectron invariant masses, see their Fig. 3.

[17] ABULENCIA 07H searched in 346 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least three leptons (e or μ) from the decay of $\tilde{\chi}_1^0$ via $LL\overline{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.

[18] ABAZOV 06D looked in 360 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with three leptons originating from the pair production of charginos and neutralinos, followed by $R\!\!\!/$ decays mediated by $LL\overline{E}$ couplings. One coupling is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $ee\ell$, $\mu\mu\ell$ nor $ee\tau$ ($\ell = e, \mu$) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their Table III and Fig. 4.

[19] ABAZOV 06P looked in 380 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 2 opposite sign isolated muons which might arise from the decays of neutralinos into $\mu\mu\nu$ via $R\!\!\!/$ couplings $LL\overline{E}$. No events are observed in the decay region defined by a radius between 5 and 20 cm, in agreement with the SM expectation. Limits are set on the cross-section times branching ratio as a function of lifetime, shown in their Fig. 3. This limit excludes the SUSY interpretation of the NuTeV excess of dimuon events reported in ADAMS 01.

[20] ABBIENDI 06B use 600 pb^{-1} of data from $\sqrt{s} = 189$–209 GeV. They look for events with diphotons + $\not{E}$ final states originating from prompt decays of pair-produced neutralinos in a GMSB scenario with $\tilde{\chi}_1^0$ NLSP. Limits on the cross-section are computed as a function of m($\tilde{\chi}_1^0$), see their Fig. 14. The limit on the $\tilde{\chi}_1^0$ mass is for a pure Bino state assuming a prompt decay, with lifetimes up to 10^{-9}s. Supersedes the results of ABBIENDI 04N.

[21] ABDALLAH 05B use data from $\sqrt{s} = 180$–209 GeV. They look for events with single photons + $\not{E}$ final states. Limits are computed in the plane (m($\tilde{G}$) , m($\tilde{\chi}_1^0$)), shown in their Fig. 9b for a pure Bino state in the GMSB framework and in Fig. 9c for a no-scale supergravity model. Supersedes the results of ABREU 00Z.

[22] ABDALLAH 05B use data from $\sqrt{s} = 130$–209 GeV. They look for events with diphotons + $\not{E}$ final states and single photons not pointing to the vertex, expected in GMSB when the $\tilde{\chi}_1^0$ is the NLSP. Limits are computed in the plane (m($\tilde{G}$), m($\tilde{\chi}_1^0$)), see their Fig. 10. The lower limit is derived on the $\tilde{\chi}_1^0$ mass for a pure Bino state assuming a prompt decay and $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 2\, m_{\tilde{\chi}_1^0}$. It improves to 100 GeV for $m_{\tilde{e}_R} = m_{\tilde{e}_L} = 1.1\, m_{\tilde{\chi}_1^0}$. and the limit in the plane (m($\tilde{\chi}_1^0$), m($\tilde{e}_R$)) is shown in Fig. 10b. For long-lived neutralinos, cross-section limits are displayed in their Fig 11. Supersedes the results of ABREU 00Z.

[23] ACOSTA 05E looked in 202 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\tilde{\chi}^\pm$ in pairs or associated to a $\tilde{\chi}_2^0$, decaying to a $\tilde{\chi}_1^0$ which itself decays promptly in GMSB to $\gamma\tilde{G}$. No events are selected at large $\not{E}_T$ compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\,\Lambda$, $N = 1$, $\tan\beta = 15$ and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 69$ TeV. Supersedes the results of ABE 99I.

[24] AKTAS 05 data collected at 319 GeV with 64.3 pb^{-1} of e^+p and 13.5 pb^{-1} of e^-p. They look for $R\!\!\!/$ resonant $\tilde{\chi}_1^0$ production via t-channel exchange of a $\tilde{e}$, followed by prompt GMSB decay of the $\tilde{\chi}_1^0$ to $\gamma\tilde{G}$. Upper limits at 95% on the cross section are derived, see their Figure 4, and compared to two example scenarios. In Figure 5, they display 95% exclusion limits in the plane of $M(\tilde{\chi}_1^0)$ versus $M(\tilde{e}_L) - M(\tilde{\chi}_1^0)$ for the two scenarios and several values of the λ' Yukawa coupling.

[25] ABBIENDI 04N use data from $\sqrt{s} = 189$–209 GeV, setting limits on $\sigma(e^+e^- \to XX) \times B^2(X \to Y\gamma)$, with Y invisible (see their Fig. 4). Limits on $\tilde{\chi}_1^0$ masses for a specific model are given. Supersedes the results of ABBIENDI,G 00D.

[26] ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192$–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan\beta < 35$, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t = 174.3$ GeV (see Table 2 for other m_t values).

[27] The limit improves to 73 GeV for $\mu < 0$.

[28] ABDALLAH 04M use data from $\sqrt{s} = 192$–208 GeV to derive limits on sparticle masses under the assumption of $R\!\!\!/$ with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid in the ranges $90 < m_0 < 500$ GeV, $0.7 < \tan\beta < 30$, $-200 < \mu < 200$ GeV, $0 < M_2 < 400$ GeV. Supersedes the result of ABREU 01D and ABREU 00U.

[29] The limit improves to 39.5 GeV for $LL\overline{E}$ couplings.

[30] ACHARD 04E use data from $\sqrt{s} = 189$–209 GeV. They look for events with single photons + $\not{E}$ final states. Limits are computed in the plane (m($\tilde{G}$), m($\tilde{\chi}_1^0$)), shown in their Fig. 8c for a no-scale supergravity model, excluding, e.g., Gravitino masses below 10^{-5} eV for neutralino masses below 172 GeV. Supersedes the results of ACCIARRI 99R.

[31] ACHARD 04E use data from $\sqrt{s} = 189$–209 GeV. They look for events with diphotons + $\not{E}$ final states. Limits are computed in the plane (m($\tilde{\chi}_1^0$), m($\tilde{e}_R$)), see their Fig. 8d. The limit on the $\tilde{\chi}_1^0$ mass is for a pure Bino state assuming a prompt decay, with $m_{\tilde{e}_L} = 1.1\, m_{\tilde{\chi}_1^0}$ and $m_{\tilde{e}_R} = 2.5\, m_{\tilde{\chi}_1^0}$. Supersedes the results of ACCIARRI 99R.

[32] ABDALLAH 03D use data from $\sqrt{s} = 161$–208 GeV. They look for 4-tau + $\not{E}$ final states, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP, and 4-lepton + $\not{E}$ final states, expected in the co-NLSP scenario, and assuming a short-lived $\tilde{\chi}_1^0$ (m($\tilde{G}$)<1 eV). Limits are computed in the plane (m($\tilde{\tau}_1$), m($\tilde{\chi}_1^0$)) from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production from the same paper to cover prompt decays and for the case of $\tilde{\chi}_1^0$ NLSP from ABREU 00Z. The limit above is reached for a single generation of messengers and when the $\tilde{\tau}_1$ is the NLSP. Stronger limits are obtained when more messenger generations are assumed or when the other sleptons are co-NLSP, see their Fig. 10. Supersedes the results of ABREU 01G.

[33] HEISTER 03C use the data from $\sqrt{s} = 189$–209 GeV to search for $\gamma\,\not{E}_T$ final states with non-pointing photons and $\gamma\gamma\,\not{E}_T$ events. Interpreted in the framework of Minimal GMSB, a lower bound on the $\tilde{\chi}_1^0$ mass is obtained as function of its lifetime. For a laboratory lifetime of less than 3 ns, the limit at 95% CL is 98.8 GeV. For other lifetimes, see their Fig. 5. These results are interpreted in a more general GMSB framework in HEISTER 02R.

[34] HEISTER 03C use the data from $\sqrt{s} = 189$–209 GeV to search for $\gamma\,\not{E}_T$ final states. They obtained an upper bound on the cross section for the process $e^+e^- \to \tilde{G}\tilde{\chi}_1^0$, followed by the prompt decay $\tilde{\chi}_1^0 \to \gamma\tilde{G}$, shown in their Fig. 4. These results supersede BARATE 98H.

[35] ACHARD 02 searches for the production of sparticles in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $\overline{UDD}$ couplings and increases to 40.2 GeV for $LL\overline{E}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[36] HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\tilde{\chi}_1^0$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\not{E}$ or a single γ not pointing to the interaction vertex. For the $\tilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\not{E}$ or $4\ell\not{E}$ (from $\tilde{\chi}_1^0\tilde{\chi}_1^0$) production), including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limits are valid whichever is the NLSP. The absolute mass bound on the $\tilde{\chi}_1^0$ for any lifetime includes indirect limits from the chargino search, and from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. Limits on the universal SUSY mass scale Λ are also derived in the paper. Supersedes the results from BARATE 00G.

[37] ABBIENDI 01 looked for final states with $\gamma\gamma\not{E}$, $\ell\ell\not{E}$, with possibly additional activity and four leptons + $\not{E}$ to search for prompt decays of $\tilde{\chi}_1^0$ or $\tilde{\ell}_1$ in GMSB. They derive limits in the plane ($m_{\tilde{\chi}_1^0}$,$m_{\tilde{\tau}_1}$), see Fig. 6, allowing either the $\tilde{\chi}_1^0$ or a $\tilde{\ell}_1$ to be the NLSP. Two scenarios are considered: $\tan\beta$=2 with the 3 sleptons degenerate in mass and $\tan\beta$=20 where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}$=189 GeV.

[38] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[39] ADAMS 01 looked for neutral particles with mass > 2.2 GeV, produced by 900 GeV protons incident on a Beryllium oxide target and decaying through weak interactions into $\mu\mu$, μe, or $\mu\pi$ final states in the decay channel of the NuTeV detector (E815) at Fermilab. The number of observed events is $3\,\mu\mu$, $0\,\mu e$, and $0\,\mu\pi$ with an expected background of 0.069 ± 0.010, 0.13 ± 0.02, and 0.14 ± 0.02, respectively. The $\mu\mu$ events are consistent with the $R\!\!\!/$ decay of a neutralino with mass around 5 GeV. However, they share several aspects with ν-interaction backgrounds. An upper limit on the differential production cross section of neutralinos in pp interactions as function of the decay length is given in Fig. 3.

[40] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the neutralino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$. The limit disappears for $\tan\beta < 1.2$ and it improves to 50 GeV for $\tan\beta > 20$.

[41] BARATE 99E looked for the decay of gauginos via R-violating couplings $LQ\overline{D}$. The bound is significantly reduced for smaller values of m_0. Data collected at $\sqrt{s}$=130–172 GeV.

[42] ABREU 98 uses data at $\sqrt{s}$=161 and 172 GeV. Upper bounds on $\gamma\gamma\not{E}$ cross section are obtained. Similar limits on $\gamma\not{E}$ are also given, relevant for $e^+e^- \to \tilde{\chi}_1^0\tilde{G}$ production.

[43] BARATE 98S looked for the decay of gauginos via R-violating coupling $LL\overline{E}$. The bound improves to 25 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at $\sqrt{s}$=130–172 GeV.

[44] ELLIS 97 reanalyzed the LEP2 ($\sqrt{s}$=161 GeV) limits of $\sigma(\gamma\gamma+E_{\rm miss})<0.2$ pb to exclude $m_{\tilde{\chi}_1^0}<63$ GeV if $m_{\tilde{e}_L}=m_{\tilde{e}_R}<150$ GeV and $\tilde{\chi}_1^0$ decays to $\gamma\tilde{G}$ inside detector.

[45] CABIBBO 81 consider $\tilde{\gamma} \to \gamma+$ goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

$\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, $\tilde{\chi}_4^0$ (Neutralinos) MASS LIMITS

Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply only to $\tilde{\chi}_2^0$, $\tilde{\chi}_3^0$, and $\tilde{\chi}_4^0$. $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{e}$, $\tilde{\gamma}$, $\tilde{q}$, $\tilde{g}$), and on the $\tilde{e}$ mass exchanged in $e^+e^- \to \tilde{\chi}_i^0\tilde{\chi}_j^0$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\tilde{\chi}^0} - m_{\tilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g, the neutralino is a pure photino ($\tilde{\gamma}$), pure z-ino ($\tilde{Z}$), or pure neutral higgsino ($\tilde{H}^0$), the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. $\Delta m = m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$.

[1] AAD 13 searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the $\tilde{\chi}_1^0$. Supersedes AAD 12AS.

[2] CHATRCHYAN 12BJ searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production were set in a number of simplified models, see Figs. 7 to 12. Most limits are for exactly 3 jets.

[3] ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 <$5000 GeV, $-1000 < \mu <$1000 GeV and tanβ from 1 to 40. This limit supersedes ABBIENDI 00H.

[4] ABREU 00W combines data collected at $\sqrt{s}$=189 GeV with results from lower energies. The mass limit is obtained by constraining the MSSM parameter space with gaugino and sfermion mass universality at the GUT scale, using the results of negative direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states) from ABREU 01, for charginos from ABREU 00J and ABREU 00T (for all Δm_+), and for charged sleptons from ABREU 01B. The results hold for the full parameter space defined by all values of M_2 and $|\mu| \leq 2$ TeV with the $\tilde{\chi}_1^0$ as LSP.

[5] AAD 12AS searched in 2.06 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).

[6] AAD 12T looked in 1 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons (e or μ). Same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with $\not{E}_T > 250$ GeV and on same-sign dilepton events with $\not{E}_T > 100$ GeV. The latter limit is interpreted in a simplified electroweak gaugino production model.

[7] ABULENCIA 07N searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with two same sign leptons (e or μ) from the decay of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0 X$ and large $\not{E}_T$. A slight excess of 13 events is observed over a SM background expectation of 7.8 ± 1.1. However, the kinematic distributions do not show any anomalous deviation from expectations in any particular region of parameter space.

[8] ABDALLAH 05B use data from $\sqrt{s}$ = 130–209 GeV, looking for events with diphotons + $\not{E}$. Limits on the cross-section are computed in the plane (m($\tilde{\chi}_2^0$), m($\tilde{\chi}_1^0$)), see Fig. 12. Supersedes the results of ABREU 00Z.

[9] ACHARD 04E use data from $\sqrt{s}$ = 189–209 GeV, looking for events with diphotons + $\not{E}$. Limits are computed in the plane (m($\tilde{\chi}_2^0$), m($\tilde{e}_R$)), for $\Delta m > 10$ GeV, see Fig. 7. Supersedes the results of ACCIARRI 99R.

[10] ACHARD 02 searches for the production of sparticles in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\tilde{\chi}_2^0$ holds for $\overline{UDD}$ couplings and increases to 84.0 GeV for $LL\overline{E}$ couplings. The same $\tilde{\chi}_3^0$ limit holds for both $LL\overline{E}$ and $\overline{UDD}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[11] ABREU 01B used data from $\sqrt{s}$=189 GeV to search for the production of $\tilde{\chi}_i^0\tilde{\chi}_j^0$. They looked for di-jet and di-lepton pairs with $\not{E}$ for events from $\tilde{\chi}_i^0\tilde{\chi}_j^0$ with the decay $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_1^0$; multi-jet and multi-lepton pairs with or without additional photons to cover the cascade decays $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_2^0$, followed by $\tilde{\chi}_j^0 \to f\overline{f}\tilde{\chi}_1^0$ or $\tilde{\chi}_j^0 \to \gamma\tilde{\chi}_1^0$; multi-tau final states from $\tilde{\chi}_2^0 \to \tilde{\tau}\tau$ with $\tilde{\tau} \to \tau\tilde{\chi}_1^0$. See Figs. 9 and 10 for limits on the (μ,M_2) plane for tanβ=1.0 and different values of m_0.

[12] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[13] ABREU 00U searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and tanβ.

[14] ABBIENDI 99F looked for $\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_1^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.075–0.80 pb in the region $m_{\tilde{\chi}_2^0}+m_{\tilde{\chi}_1^0} > m_Z$, $m_{\tilde{\chi}_2^0}$=91–183 GeV, and $\Delta m > 5$ GeV. See Fig. 7 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[15] ABBIENDI 99F looked for $\gamma\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.08–0.37 pb for $m_{\tilde{\chi}_2^0}$=45–81.5 GeV, and $\Delta m > 5$ GeV. See Fig. 11 for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[16] ABBOTT 98C searches for trilepton final states (ℓ=e,μ). See footnote to ABBOTT 98C in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 103$ GeV.

[17] ABE 98J searches for trilepton final states (ℓ=e,μ). See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result for $m_{\tilde{\chi}_2^0}$ corresponds to the best limit within the selected range of parameters, obtained for $m_{\tilde{q}} > m_{\tilde{g}}$, tan$\beta$=2, and μ=−600 GeV.

[18] ACCIARRI 98F is obtained from direct searches in the $e^+e^- \to \tilde{\chi}_{1,2}^0\tilde{\chi}_2^0$ production channels, and indirectly from $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ searches within the MSSM. See footnote to ACCIARRI 98F in the chargino Section for further details on the assumptions. Data taken at $\sqrt{s}$ = 130–172 GeV.

[19] ACCIARRI 98V looked for $\gamma(\gamma)\not{E}$ final states at $\sqrt{s}$=183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_{1,2}^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$. See Figs. 4a and 6a for explicit limits in the $(m_{\tilde{\chi}_2^0}, m_{\tilde{\chi}_1^0})$ plane.

[20] BARATE 98H looked for $\gamma\gamma$ $\not{E}$ final states at $\sqrt{s}$ = 161,172 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.4–0.8 pb for $m_{\tilde{\chi}_2^0}$ = 10–80 GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV. See Fig. 6 and 7 for explicit limits in the $(\tilde{\chi}_2^0,\tilde{\chi}_1^0)$ plane and in the $(\tilde{\chi}_2^0,\tilde{e}_R)$ plane.

[21] BARATE 98J looked for $\gamma\gamma$ $\not{E}$ final states at $\sqrt{s}$ = 161–183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0\tilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}_2^0 \to \gamma\tilde{\chi}_1^0$ of 0.08–0.24 pb for $m_{\tilde{\chi}_2^0} < 91$ GeV. The bound above is for the specific case of $\tilde{\chi}_1^0 = \tilde{H}^0$ and $\tilde{\chi}_2^0 = \tilde{\gamma}$ and $m_{\tilde{e}_R}$ = 100 GeV.

[22] ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on $\sigma(\tilde{\chi}_1^\pm\tilde{\chi}_2^0) \times B(\tilde{\chi}_1^\pm \to \ell\nu_\ell\tilde{\chi}_1^0) \times B(\tilde{\chi}_2^0 \to \ell^+\ell^-\tilde{\chi}_1^0)$ as a function of $m_{\tilde{\chi}_1^0}$. Limits range from 3.1 pb ($m_{\tilde{\chi}_1^0}$ = 45 GeV) to 0.6 pb ($m_{\tilde{\chi}_1^0}$ = 100 GeV).

[23] ABE 96K looked for trilepton events from chargino-neutralino production. They obtained lower bounds on $m_{\tilde{\chi}_2^0}$ as a function of μ. The lower bounds are in the 45–50 GeV range for gaugino-dominant $\tilde{\chi}_2^0$ with negative μ, if tanβ <10. See paper for more details of the assumptions.

$\tilde{\chi}_1^\pm$, $\tilde{\chi}_2^\pm$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino ($\tilde{\chi}_1^\pm$) of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions at energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_1^+\tilde{\chi}_1^-$ and (in the case of hadronic collisions) $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pairs, including the effects of cascade decays. The mass limits on $\tilde{\chi}_1^\pm$ are either direct, or follow indirectly from the constraints set by the non-observation of $\tilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ. For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\tilde{\chi}_1^\pm} \lesssim \sqrt{s}/2$. The still unpublished combination of the results of the four LEP collaborations from the 2000 run of LEP2 at $\sqrt{s}$ up to $\simeq$ 209 GeV yields a lower mass limit of 103.5 GeV valid for general MSSM models. The limits become however weaker in certain regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences $\Delta m_+ = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ or $\Delta m_\nu = m_{\tilde{\chi}_1^\pm} - m_{\tilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\tilde{\chi}_1^\pm$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the following limits are valid are indicated in the comment lines or in the footnotes.

[1] AAD 13 searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 and 3, and in simplified models, see Fig. 4. For the simplified models with intermediate slepton decays, degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ masses up to 500 GeV are excluded at 95% C.L. for very large mass differences with the $\tilde{\chi}_1^0$. Supersedes AAD 12AS.

[2] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for gauginos decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of wino-like chargino pair production, where the chargino always decays to the lightest neutralino via an intermediate on-shell charged slepton, see Fig. 2(b). Chargino masses between 110 and 340 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0}$ = 10 GeV. Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[3] AAD 12CT searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing four or more leptons (electrons or muons) and either moderate values of missing transverse momentum or large effective mass. No significant excess is found in the data. Limits are presented in a simplified model of R-parity violating supersymmetry in which charginos are pair-produced and then decay into a W-boson and a $\tilde{\chi}_1^0$, which in turn decays through an RPV coupling into two charged leptons ($e^\pm e^\mp$ or $e^\pm\mu^\mp$) and a neutrino. In this model, chargino masses up to 540 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0}$ above 300 GeV, see Fig. 3a. The limit deteriorates for lighter $\tilde{\chi}_1^0$. Limits are also set in an R-parity violating mSUGRA model, see Fig. 3b.

[4] CHATRCHYAN 12BJ searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for direct electroweak production of charginos and neutralinos in events with at least two leptons, jets and missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of $\tilde{\chi}_1^\pm\tilde{\chi}_2^0$ pair production were set in a number of simplified models, see Figs. 7 to 12.

[5] ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 <$5000 GeV, $-1000 < \mu <$1000 GeV and tanβ from 1 to 40. This limit supersedes ABBIENDI 00H.

[6] ABBIENDI 03H used e^+e^- data at $\sqrt{s}$ = 188–209 GeV to search for chargino pair production in the case of small Δm_+. They select events with an energetic photon, large $\not{E}$ and little hadronic or leptonic activity. The bound applies to higgsino-like charginos with zero lifetime and a 100% branching ratio $\tilde{\chi}_1^\pm \to \tilde{\chi}_1^0 W^*$. The mass limit for gaugino-like charginos, in case of non-universal gaugino masses, is of 92 GeV for $m_{\tilde{\nu}}$ = 1000 GeV and is lowered to 74 GeV for $m_{\tilde{\nu}} \geq$ 100 GeV. Limits in the plane ($m_{\tilde{\chi}_1^\pm}$, Δm_+) are shown in Fig. 7. Exclusion regions are also derived for the AMSB scenario in the ($m_{3/2}$, tanβ) plane, see their Fig. 9.

[7] ABDALLAH 03M searches for the production of charginos using data from $\sqrt{s}$ = 192 to 208 GeV to investigate topologies with multiple leptons, jets plus leptons, multi-jets, or isolated photons. The first limit holds for tan$\beta \geq$ 1 and is obtained at Δm_+= 3 GeV in the higgsino region. For $\Delta m_+ \geq$ 10 (5) GeV and large m_0, the limit improves to 102.7 (101.7) GeV. For the region of small Δm_+, all data from $\sqrt{s}$ = 130 to 208 GeV are used to investigate final states with heavy stable charged particles, decay vertices inside the detector and soft topologies with a photon from initial state radiation. The second limit is obtained in the higgsino region, assuming gaugino mass universality at the GUT scale and 1<tanβ <50. For the case of non-universality of gaugino masses, the parameter space is scanned in the domain 1<tanβ <50 and, for $\Delta m_+ <$ 3 GeV, for

values of M_1, M_2 and μ such that $M_2 \leq 2M_1 \leq 10\,M_2$ and $|\mu| \geq M_2$. The third limit is obtained in the gaugino region. See Fig. 36 for the dependence of the low Δm_+ limits on Δm_+. These limits include and update the results of ABREU 00J and ABREU 00T.

[8] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays), for charginos and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\widetilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the $m_h^{\max}$ scenario assuming m_t= 174.3 GeV are included. The quoted limit applies if there is no mixing in the third family or when $m_{\widetilde{\tau}_1} - m_{\widetilde{\chi}_1^0} > 6$ GeV. If mixing is included the limit degrades to 90 GeV. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[9] HEISTER 02J search for chargino production with small Δm_+ in final states with a hard isolated initial state radiation photon and few low-momentum particles, using 189–208 GeV data. This search is sensitive in the intermediate Δm_+ region. Combined with searches for $\not{E}$ topologies and for stable charged particles, the above bound is obtained for m_0 larger than few hundred GeV, 1<tanβ < 300 and holds for any chargino field contents. For light scalars, the general limit reduces to the one from the Z^0, but under the assumption of gaugino and sfermion mass unification the above bound is recovered. See Figs. 4–6 for the more general dependence of the limits on Δm_+. Updates BARATE 98X.

[10] ACCIARRI 00D data collected at $\sqrt{s}$=189 GeV. The results hold over the full parameter space defined by $0.7 \leq \tan\beta \leq 60$, $0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 2$ TeV $m_0 \leq 500$ GeV. The results of slepton searches from ACCIARRI 99W are used to help set constraints in the region of small m_0. See their Figs. 5 for the tanβ and M_2 dependence on the limits. See the text for the impact of a large B($\widetilde{\chi}^\pm \to \tau\widetilde{\nu}_\tau$) on the result. The region of small Δm_+ is excluded by the analysis of ACCIARRI 00K. Updates ACCIARRI 98F.

[11] ACCIARRI 00K searches for the production of charginos with small Δm_+ using data from $\sqrt{s}$=189 GeV. They investigate soft final states with a photon from initial state radiation. The results are combined with the limits on prompt decays from ACCIARRI 00D and from heavy stable charged particles from ACCIARRI 99L (see Heavy Charged Lepton Searches). The production and decay branching ratios are evaluated within the MSSM, assuming heavy sfermions. The parameter space is scanned in the domain 1<tanβ <50, 0.3 <M_1/M_2 <50, and 0< $|\mu|$ <2 TeV. The limit is obtained in the higgsino region and improves to 78.6 GeV for gaugino-like charginos. The limit is unchanged for light scalar quarks. For light $\widetilde{\tau}$ or $\widetilde{\nu}_\tau$, the limit is unchanged in the gaugino-like region and is lowered by 0.8 GeV in the higgsino-like case. For light $\widetilde{\mu}$ or $\widetilde{\nu}_\mu$, the limit is unchanged in the higgsino-like region and is lowered by 0.9 GeV in the gaugino-like region. No direct mass limits are obtained for light $\widetilde{e}$ or $\widetilde{\nu}_e$.

[12] AALTONEN 13Q searched in 6.0 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for evidence of chargino-neutralino associated production in like-sign dilepton final states. One lepton is identified as the hadronic decay of a tau lepton, while the other is an electron or muon. Good agreement with the Standard Model predictions is observed and limits are set on the chargino-neutralino cross section for simplified gravity- and gauge-mediated models, see their Figs 2 and 3.

[13] AAD 12AS searched in 2.06 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for charginos and neutralinos decaying to a final state with three leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the phenomenological MSSM, see Fig. 2 (top), and in simplified models, see Fig. 2 (bottom).

[14] AAD 12T looked in 1 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for the production of supersymmetric particles decaying into final states with missing transverse momentum and exactly two isolated leptons (e or μ). Opposite-sign and same-sign dilepton events were separately studied. Additionally, in opposite-sign events, a search was made for an excess of same-flavor over different-flavor lepton pairs. No excess over the expected background is observed and limits are placed on the effective production cross section of opposite-sign dilepton events with $\not{E}_T > 250$ GeV and on same-sign dilepton events with $\not{E}_T > 100$ GeV. The latter limit is interpreted in a simplified electroweak gaugino production model as a lower chargino mass limit.

[15] CHATRCHYAN 11B looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with an isolated lepton (e or μ), a photon and $\not{E}_T$ which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.

[16] CHATRCHYAN 11V looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with ≥ 3 isolated leptons (e, μ or τ), with or without jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tan$\beta = 3$ (see Fig. 5).

[17] AALTONEN 09G searched in 976 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons ($\mu\mu\mu$ or $\mu\mu e$) with a low, 5 GeV, p_T threshold, and large $\not{E}_T$ from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The results are combined with the analysis of AALTONEN 07J to set a limit on the $\widetilde{\chi}_1^\pm$ mass for a mSUGRA scenario with no slepton mixing.

[18] ABAZOV 09T searched in 2.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons (e, μ or hadronically decaying τ) from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$ and large $\not{E}_T$. No evidence for a signal is observed. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass under the assumption that $m_{\widetilde{\chi}_1^\pm} = m_{\widetilde{\chi}_2^0}$ = 2 $m_{\widetilde{\chi}_1^0}$, tanβ = 3, $\mu > 0$ and that the sleptons are heavier than the $\widetilde{\chi}_1^\pm$, see their Fig. 8. A chargino lighter than 138 GeV is excluded in the "3l-max" scenario. Exclusion regions in the (m_0, $m_{1/2}$) plane are shown in their Fig. 9 for a mSUGRA scenario with tanβ = 3, $A_0 = 0$ and $\mu > 0$. The tanβ dependence of this exclusion is illustrated in Fig. 10. Supersedes the results of ABAZOV 05U.

[19] AALTONEN 08AE searched in 2.0 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with trileptons (e, μ or a charged isolated track from τ) from the decay of $p\overline{p} \to \widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$ and large $\not{E}_T$. The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass. Exclusion regions in the (m_0, $m_{1/2}$) plane are shown in their Fig. 2 for a mSUGRA scenario. When the $\widetilde{\chi}_1^\pm$ is nearly mass degenerate with the $\widetilde{\tau}_1$ the leptons are too soft and no limit is obtained. For the case $m_0 = 60$ GeV a lower limit of 145 GeV on the chargino mass is obtained in this mSUGRA scenario.

[20] AALTONEN 08L searched in 0.7 to 1.0 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with one high-p_T electron or muon and two additional leptons (e or μ) from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass. The results are compared to three MSSM scenarios. An exclusion on chargino and neutralino production is only obtained in a scenario of no mixing between sleptons, yielding nearly equal branching ratios to all three lepton flavors. It amounts to $m_{\widetilde{\chi}_1^\pm} > 151$ GeV, while the analysis is not sensitive to chargino masses below about 110 GeV. The analyses have been combined with the analyses of AALTONEN 07J and ABULENCIA 07N. The observed limits for the combination are less stringent than the one obtained for the high-p_T analysis due to slight excesses in the other channels.

[21] ABAZOV 08F looked in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying to a $\widetilde{\chi}_1^0$ which itself decays promptly in GMSB to $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\Lambda$, $N = 1$, tanβ = 15 and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 91.5$ TeV. Supersedes the results of ABAZOV 05A.

[22] AALTONEN 07J searched in 0.7 to 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with either two same sign leptons (e or μ) or trileptons from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$ and large $\not{E}_T$. The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass. The results, shown in their Fig. 2, are compared to several MSSM scenarios. The strongest exclusion is in the case of no mixing between sleptons, yielding nearly equal branching ratios to all three lepton flavors, and amounting to $m_{\widetilde{\chi}_1^\pm} > 129$ GeV. This analysis includes the same sign dilepton analysis of ABULENCIA 07N.

[23] ABULENCIA 07H searched in 346 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least three leptons (e or μ) from the decay of $\widetilde{\chi}_1^0$ via $LL\overline{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\widetilde{\chi}_1^0$ and $\widetilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.

[24] ABULENCIA 07N searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with two same sign leptons (e or μ) from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$ and large $\not{E}_T$. A slight excess of 13 events is observed over a SM background expectation of 7.8 ± 1.1. However, the kinematic distributions do not show any anomalous deviation from expectations in any particular region of parameter space.

[25] ABAZOV 06D looked in 360 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with three leptons originating from the pair production of charginos and neutralinos, followed by $\not{R}$ decays mediated by $LL\overline{E}$ couplings. One coupling is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $ee\ell$, $\mu\mu\ell$ nor $ee\tau$ ($\ell = e, \mu$) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their Table III and Fig. 4.

[26] ABAZOV 05A looked in 263 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying to a $\widetilde{\chi}_1^0$ which itself decays promptly in GMSB to $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$. No significant excess was found at large $\not{E}_T$ compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\,\Lambda$, $N = 1$, tanβ = 15 and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 79.6$ TeV. Very similar results are obtained for different choices of parameters, see their Table 2. Supersedes the results of ABBOTT 98.

[27] ACOSTA 05E looked in 202 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV for diphoton events with large $\not{E}_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying to a $\widetilde{\chi}_1^0$ which itself decays promptly in GMSB to $\gamma\widetilde{G}$. No events are selected at large $\not{E}_T$ compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M = 2\,\Lambda$, $N = 1$, tanβ = 15 and $\mu > 0$, see Figure 2. It also excludes $\Lambda < 69$ TeV. Supersedes the results of ABE 99I.

[28] ABDALLAH 04H use data from LEP 1 and $\sqrt{s}$ = 192–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region 1< $m_{3/2}$ <50 TeV, 0< m_0 <1000 GeV, 1.5<tanβ <35, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for m_t = 174.3 GeV (see Table 2 for other m_t values).

[29] The limit improves to 73 GeV for $\mu < 0$.

[30] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid in the ranges 90< m_0 <500 GeV, 0.7<tanβ <30, $-200 < \mu <$200 GeV, 0< M_2 <400 GeV. Supersedes the result of ABREU 01D and ABREU 00U.

[31] The limit improves to 103 GeV for $LL\overline{E}$ couplings.

[32] ABDALLAH 03D use data from $\sqrt{s}$ = 183–208 GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\widetilde{\tau}_1$ is the NLSP and assuming a short-lived $\widetilde{\chi}_1^\pm$. Limits are obtained in the plane (m($\widetilde{\tau}$),m($\widetilde{\chi}_1^\pm$)) for different domains of m($\widetilde{G}$), after combining these results with the search for slepton pair production from the same paper. The limit above is valid if the $\widetilde{\tau}_1$ is the NLSP for all values of m($\widetilde{G}$) provided m($\widetilde{\chi}_1^\pm$) − m($\widetilde{\tau}_1$) $\geq$ 0.3 GeV. For larger m($\widetilde{G}$) > 100 eV the limit improves to 102 GeV, see their Fig. 11. In the co-NLSP scenario, the limits are 96 and 102 GeV for all m($\widetilde{G}$) and m($\widetilde{G}$) > 100 eV, respectively. Supersedes the results of ABREU 01G.

[33] HEISTER 03G searches for the production of charginos prompt decays. in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–209 GeV. The search is performed for indirect decays, assuming one coupling at a time to be non-zero. The limit holds for tanβ=1.41. Excluded regions in the (μ,M_2) plane are shown in their Fig. 3.

[34] ACHARD 02 searches for the production of sparticles in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and

indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\widetilde{\chi}_1^\pm$ holds for $\overline{UDD}$ couplings and increases to 103.0 GeV for $LL\overline{E}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[35] GHODBANE 02 reanalyzes DELPHI data at $\sqrt{s}$=189 GeV in the presence of complex phases for the MSSM parameters.

[36] ABREU 01C looked for τ pairs with $\not{E}$ at $\sqrt{s}$=183–189 GeV to search for the associated production of charginos, followed by the decay $\widetilde{\chi}^\pm \to \tau J$, J being an invisible massless particle. See Fig. 6 for the regions excluded in the (μ, M_2) plane.

[37] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[38] BARATE 01B searches for the production of charginos in the case of R prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189–202 GeV. The search is performed for indirect decays, assuming one coupling at a time to be nonzero. Updates BARATE 00H.

[39] ABREU 00V use data from $\sqrt{s}$= 183–189 GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\widetilde{\tau}_1$ is the NLSP and assuming a short-lived $\widetilde{\chi}_1^\pm$. Limits are obtained in the plane $(m_{\widetilde{\tau}}, m_{\widetilde{\chi}_1^\pm})$ for different domains of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The limit above is valid for all values of $m_{\widetilde{G}}$.

[40] CHO 00B studied constraints on the MSSM spectrum from precision EW observables. Global fits favour charginos with masses at the lower bounds allowed by direct searches. Allowing for variations of the squark and slepton masses does not improve the fits.

[41] ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings using data from $\sqrt{s}$=183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the $\overline{UDD}$ couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the chargino mass are obtained for non-zero $LL\overline{E}$ couplings $> 10^{-5}$ and assuming decays via a W^*.

[42] MALTONI 99B studied the effect of light chargino-neutralino to the electroweak precision data with a particular focus on the case where they are nearly degenerate ($\Delta m_\pm \sim 1$ GeV) which is difficult to exclude from direct collider searches. The quoted limit is for higgsino-like case while the bound improves to 56 GeV for wino-like case. The values of the limits presented here are obtained in an update to MALTONI 99B, as described in MALTONI 00.

[43] ABE 98J searches for trilepton final states (ℓ=e,μ). Efficiencies are calculated using mass relations in the Minimal Supergravity scenario, exploring the domain of parameter space defined by 1.1 $<\tan\beta <$ 8, $-1000 < \mu$(GeV)< -200, and $m_{\widetilde{q}}/m_{\widetilde{g}}$=1–2. In this region $m_{\widetilde{\chi}_1^\pm} \sim m_{\widetilde{\chi}_2^0}$ and $m_{\widetilde{\chi}_1^\pm} \sim 2m_{\widetilde{\chi}_1^0}$. Results are presented in Fig. 1 as upper bounds on $\sigma(p\overline{p} \to \widetilde{\chi}_1^\pm \widetilde{\chi}_2^0)\times$B($3\ell$). Limits range from 0.8 pb ($m_{\widetilde{\chi}_1^\pm}$=50 GeV) to 0.23 pb ($m_{\widetilde{\chi}_1^\pm}$=100 GeV) at 95%CL. The gaugino mass unification hypothesis and the assumed mass relation between squarks and gluinos define the value of the leptonic branching ratios. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\widetilde{q}} > m_{\widetilde{g}}$, $\tan\beta$=2, and μ=$-$600 GeV. Mass limits for different values of $\tan\beta$ and μ are given in Fig. 2.

[44] ACKERSTAFF 98K looked for dilepton+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. Limits on $\sigma(e^+e^- \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-)\times$B$^2(\ell)$, with B($\ell$)=B($\chi^+ \to \ell^+\nu_\ell\chi_1^0$) (B($\ell$)=B($\chi^+ \to \ell^+\overline{\nu}_\ell$)), are given in Fig. 16 (Fig. 17).

[45] ACKERSTAFF 98L limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The dependence on the trilinear-coupling parameter A is studied, and found negligible. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97H) and for all values of m_0 where the condition $\Delta m_{\widetilde{\nu}} > 2.0$ GeV is satisfied. $\Delta m_\nu > 10$ GeV if $\widetilde{\chi}^\pm \to \ell\overline{\nu}_\ell$. The limit improves to 84.5 GeV for m_0=1 TeV. Data taken at $\sqrt{s}$=130–172 GeV.

[46] ACKERSTAFF 98V excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\widetilde{\chi}_1^\pm, \widetilde{\chi}_2^0 \to q\overline{q}\widetilde{g}$ from total hadronic cross sections at $\sqrt{s}$=130–172 GeV. See paper for the case of nonuniversal gaugino mass.

[47] CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large $\tan\beta$.

[48] KALINOWSKI 97 studies the constraints on the chargino-neutralino parameter space from limits on $\Gamma(W \to \widetilde{\chi}_1^\pm\widetilde{\chi}_1^0)$ achievable at LEP2. This is relevant when $\widetilde{\chi}_1^\pm$ is "invisible," i.e., if $\widetilde{\chi}_1^\pm$ dominantly decays into $\widetilde{\nu}_\ell\ell^\pm$ with little energy for the lepton. Small otherwise allowed regions could be excluded.

[49] ABE 96K looked for trilepton events from chargino-neutralino production. The bound on $m_{\widetilde{\chi}_1^\pm}$ can reach up to 47 GeV for specific choices of parameters. The limits on the combined production cross section times 3-lepton branching ratios range between 1.4 and 0.4 pb, for 45$<m_{\widetilde{\chi}_1^\pm}(GeV)<$100. See the paper for more details on the parameter dependence of the results.

Long-lived $\widetilde{\chi}^\pm$ (Chargino) MASS LIMITS

Limits on charginos which leave the detector before decaying.

[1] AAD 13H searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for direct electroweak production of long-lived charginos in the context of AMSB scenarios. The search is based on the signature of a high-momentum isolated track with few associated hits in the outer part of the tracking system, arising from a chargino decay into a neutralino and a low-momentum pion. The p_T spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained, see Fig. 6. In the minimal AMSB framework with $\tan\beta$ = 5, and $\mu > 0$, a chargino having a mass below 103 (85) GeV for a chargino-neutralino mass splitting $\Delta m_{\widetilde{\chi}_1^0}$ of 160 (170) MeV is excluded at the 95% C.L. See Fig. 7 for more precise bounds.

[2] AAD 12BJ looked in 1.02 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for signatures of decaying charginos resulting in isolated tracks with few associated hits in the outer region of the tracking system. The p_T spectrum of the tracks was found to be consistent with the SM expectations. Constraints on the lifetime and the production cross section were obtained. In the minimal AMSB framework with $m_{3/2} < 32$ TeV, $m_0 < 1.5$ TeV, $\tan\beta$ = 5, and $\mu > 0$, a chargino having a mass below 92 GeV and a lifetime between 0.5 ns and 2 ns is excluded at the 95% C.L. See their Fig. 8 for more precise bounds.

[3] ABAZOV 09M searched in 1.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with direct production of a pair of charged massive stable particles identified by their TOF. The number of the observed events is consistent with the predicted background. The data are used to constrain the production cross section as a function of the $\widetilde{\chi}_1^\pm$ mass, see their Fig. 2. The quoted limit improves to 206 GeV for gaugino-like charginos.

[4] ABBIENDI 03L used e^+e^- data at $\sqrt{s}$ = 130–209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

[5] ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from $\sqrt{s}$= 130 to 189 GeV. These limits include and update the results of ABREU 98P.

[6] AAD 13BD searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing tracks with no associated hits in the outer region of the tracking system resulting from the decay of charginos that are nearly mass degenerate with the lightest neutralino, as is often the case in AMSB scenarios. No significant excess above the background expectation is observed for candidate tracks with large transverse momentum. Constraints on chargino properties are obtained and in the minimal AMSB model, a chargino mass below 270 GeV is excluded at 95% C.L., see their Fig. 7.

[7] ABAZOV 13B looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on gaugino- and higgsino-like charginos, see their Table 20 and Fig. 23.

[8] ABAZOV 12L looked in 5.2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events in which one or more particles are reconstructed as muons but have speed and ionization energy loss inconsistent with muons produced in beam collisions. Long-lived pair-produced gaugino-like charginos are excluded below 267 GeV at 95% C.L. using the nominal value of the NLO production cross section.

[9] ABAZOV 12L looked in 5.2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events in which one or more particles are reconstructed as muons but have speed and ionization energy loss inconsistent with muons produced in beam collisions. Long-lived pair-produced Higgsino-like charginos are excluded below 217 GeV at 95% C.L. using the nominal value of the NLO production cross section.

[10] BARATE 97K uses e^+e^- data collected at $\sqrt{s}$ = 130–172 GeV. Limit valid for $\tan\beta = \sqrt{2}$ and $m_{\widetilde{\nu}} > 100$ GeV. The limit improves to 86 GeV for $m_{\widetilde{\nu}} > 250$ GeV.

$\widetilde{\nu}$ (Sneutrino) MASS LIMIT

The limits may depend on the number, $N(\widetilde{\nu})$, of sneutrinos assumed to be degenerate in mass. Only $\widetilde{\nu}_L$ (not $\widetilde{\nu}_R$) is assumed to exist. It is possible that $\widetilde{\nu}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the fit of the final results obtained by the LEP Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{\rm inv.} < 2.0$ MeV, LEP-SLC 06): $m_{\widetilde{\nu}} > 43.7$ GeV ($N(\widetilde{\nu})$=1) and $m_{\widetilde{\nu}} > 44.7$ GeV ($N(\widetilde{\nu})$=3) .

[1] AAD 11Z looked in 1.07 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with one electron and one muon of opposite charge from the production of $\tilde{\nu}_\tau$ via an $\not{R}$ λ'_{311} coupling and followed by a decay via λ_{312} into $e + \mu$. No evidence for an (e, μ) resonance over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\tilde{\nu}}$ for three values of λ_{312}, see their Fig. 2. Masses $m_{\tilde{\nu}} < 1.32$ (1.45) TeV are excluded for $\lambda'_{311} = 0.10$ and $\lambda_{312} = 0.05$ ($\lambda'_{311} = 0.11$ and $\lambda_{312} = 0.07$).

[2] ABDALLAH 03M uses data from $\sqrt{s} = 192$–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \leq 1$ TeV with the $\tilde{\chi}^0_1$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of $\tan\beta$. These limits update the results of ABREU 00W.

[3] HEISTER 02N derives a bound on $m_{\tilde{\nu}_e}$ by exploiting the mass relation between the $\tilde{\nu}_e$ and $\tilde{e}$, based on the assumption of universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 and the search described in the $\tilde{e}$ section. In the MSUGRA framework with radiative electroweak symmetry breaking, the limit improves to $m_{\tilde{\nu}_e} > 130$ GeV, assuming a trilinear coupling A_0=0 at the GUT scale. See Figs. 5 and 7 for the dependence of the limits on $\tan\beta$.

[4] ADRIANI 93M limit from $\Delta\Gamma(Z)$(invisible)< 16.2 MeV.

[5] DECAMP 92 limit is from Γ(invisible)/$\Gamma(\ell\ell) = 5.91 \pm 0.15$ ($N_\nu = 2.97 \pm 0.07$).

[6] ALEXANDER 91F limit is for one species of $\tilde{\nu}$ and is derived from Γ(invisible, new)/$\Gamma(\ell\ell)$ < 0.38.

[7] AAD 13AI searched in 4.6 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for evidence of heavy particles decaying into $e\mu$, $e\tau$ or $\mu\tau$ final states. No significant excess above the Standard Model expectation is observed, and 95% C.L. exclusions are placed on the cross section times branching ratio for the production of an R-parity-violating supersymmetric tau sneutrino, see their Fig. 2. For couplings $\lambda'_{311} = 0.10$ and $\lambda_{i3k} = 0.05$, the lower limits on the $\tilde{\nu}_\tau$ mass are 1610, 1110, 1100 GeV in the $e\mu$, $e\tau$, and $\mu\tau$ channels, respectively.

[8] AAD 11H looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with one electron and one muon of opposite charge from the production of $\tilde{\nu}_\tau$ via an $\not{R}$ λ'_{311} coupling and followed by a decay via λ_{312} into $e + \mu$. No evidence for an excess over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\tilde{\nu}}$ for several values of λ_{312}, see their Fig. 2. Superseded by AAD 11Z.

[9] AALTONEN 10Z searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events from the production $d\overline{d} \to \tilde{\nu}_\tau$ with the subsequent decays $\tilde{\nu}_\tau \to e\mu$, $\mu\tau$, $e\tau$ in the MSSM framework with $\not{R}$. Two isolated leptons of different flavor and opposite charges are required, with τs identified by their hadronic decay. No statistically significant excesses are observed over the SM background. Upper limits on λ'^2_{311} times the branching ratio are listed in their Table III for various $\tilde{\nu}_\tau$ masses. Limits on the cross section times branching ratio for $\lambda'_{311} = 0.10$ and $\lambda_{i3k} = 0.05$, displayed in Fig. 2, are used to set limits on the $\tilde{\nu}_\tau$ mass of 558 GeV for the $e\mu$, 441 GeV for the $\mu\tau$ and 442 GeV for the $e\tau$ channels.

[10] ABAZOV 10M looked in 5.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with exactly one pair of high p_T isolated $e\mu$ and a veto against hard jets. No evidence for an excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Fig. 3. These limits are translated into limits on couplings as a function of $m_{\tilde{\nu}_\tau}$ as shown on their Fig. 4. As an example, for $m_{\tilde{\nu}_\tau} =$ 100 GeV and $\lambda_{312} \leq 0.07$, couplings $\lambda'_{311} > 7.7 \times 10^{-4}$ are excluded.

[11] AALTONEN 09V searched in 2.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with an oppositely charged pair originating from the $\not{R}$ production of a sneutrino decaying to dimuons. A limit is derived on the cross section times branching ratio, B, of $\tilde{\nu} \to \mu\mu$ for several values of the coupling λ', see their Fig. 3. For λ'^2B = 0.01, the range 100 GeV $\leq m_{\tilde{\nu}} \leq$ 810 GeV is excluded.

[12] ABAZOV 08Q searched in 1.04 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with $\not{R}$ where a sneutrino is produced by $LQ\overline{D}$ couplings and decays via $LL\overline{E}$ couplings, focusing on $\tilde{\nu}_\tau$, hence on the λ'_{311} and λ_{312} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and displayed in their Fig. 2. Exclusion regions are determined for the $\tilde{\nu}_\tau$ mass as a function of both couplings, see their Fig. 3. As an indication, for $\tilde{\nu}_\tau$ masses of 100 GeV and $\lambda_{312} = 0.01$, values of $\lambda'_{311} \geq 1.6 \times 10^{-3}$ are excluded at the 95% C.L. Superseded by ABAZOV 10M.

[13] SCHAEL 07A searches for the s- or t-channel exchange of sneutrinos in the case of $\not{R}$ with $LL\overline{E}$ couplings by studying di-lepton production at $\sqrt{s} = 189$–209 GeV. Limits are obtained on the couplings as a function of the $\tilde{\nu}$ mass, see their Figs. 22-24. The results of this analysis are combined with BARATE 00I.

[14] ABAZOV 06I looked in 380 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via $\not{R}$ couplings $LQ\overline{D}$. The data are in agreement with the SM expectation. They set limits on resonant slepton production and derive exclusion contours on λ'_{211} in the mass plane of $\tilde{\ell}$ versus $\tilde{\chi}^0_1$ assuming a MSUGRA model with $\tan\beta = 5$, $\mu < 0$ and $A_0 = 0$, see their Fig. 3. For $\lambda'_{211} \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABAZOV 02H.

[15] ABDALLAH 06C searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+\ell^-(\gamma)$ final states (ℓ=e,μ,τ) from 675 pb^{-1} of e^+e^- data at $\sqrt{s}$=130–207 GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of $\not{R}$ with $\lambda LL\overline{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the (λ,$m_{\tilde{\nu}}$) plane are given in Fig. 16. These limits include and update the results of ABREU 00S.

[16] ABULENCIA 06M searched in 344 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with $\not{R}$ where a sneutrino is produced by $LQ\overline{D}$ couplings and decays via $LL\overline{E}$ couplings, focusing on $\tilde{\nu}_\tau$, hence on the λ'_{311} and λ_{132} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and exclusion regions determined for the $\tilde{\nu}_\tau$ mass as a function of both couplings, see their Fig. 3. As an indication, $\tilde{\nu}_\tau$ masses are excluded up to 300 GeV for $\lambda'_{311} \geq 0.01$ and $\lambda_{132} \geq 0.02$. Superseded by AALTONEN 10Z.

[17] ABULENCIA 05A looked in $\sim$ 200 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for dimuon and dielectron events. They may originate from the $\not{R}$ production of a sneutrino decaying to dileptons. No significant excess rate was found compared to the background expectation. A limit is derived on the cross section times branching ratio, B, of $\tilde{\nu} \to ee$, $\mu\mu$ of 25 fb at high mass, see their Figure 2. Sneutrino masses are excluded at 95% CL below 680, 620, 460 GeV (ee channel) and 665, 590, 450 GeV ($\mu\mu$ channel) for a λ' coupling and branching ratio such that $\lambda'^2 B = 0.01$, 0.005, 0.001, respectively.

[18] ACOSTA 05R looked in 195 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for ditau events with one identified hadronic tau decay and one other tau decay. They may originate from the $\not{R}$ production of a sneutrino decaying to $\tau\tau$. No significant excess rate was found compared to the background expectation, dominated by Drell-Yan. A limit is derived on the cross section times branching ratio, B, of $\tilde{\nu} \to \tau\tau$, see their Figure 3. Sneutrino masses below 377 GeV are excluded at 95% CL for a λ' coupling to $d\overline{d}$ and branching ratio such that $\lambda'^2 B = 0.01$.

[19] ABBIENDI 04F use data from $\sqrt{s} = 189$–209 GeV. They derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $\tan\beta = 1.5$, $\mu = -200$ GeV, and a BR for the decay given by CMSSM, assuming no sensitivity to other decays. Limits are quoted for $m_{\tilde{\chi}^0} = 60$ GeV and degrade for low-mass $\tilde{\chi}^0_1$. For $\tilde{\nu}_e$ the direct (indirect) limits with $LL\overline{E}$ couplings are 89 (95) GeV and with $LQ\overline{D}$ they are 89 (88) GeV. For $\tilde{\nu}_{\mu,\tau}$ the direct (indirect) limits with $LL\overline{E}$ couplings are 79 (81) GeV and with $LQ\overline{D}$ they are 74 (no limit) GeV. Supersedes the results of ABBIENDI 00.

[20] ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192$–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan\beta < 35$, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t = 174.3$ GeV (see Table 2 for other m_t values).

[21] The limit improves to 114 GeV for $\mu < 0$.

[22] ABDALLAH 04M use data from $\sqrt{s} = 189$–208 GeV. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays the limit on $\tilde{\nu}_e$ decreases to 96 GeV if the constraint from the neutralino is not used and for direct decays it remains 96 GeV. For indirect decays the limit on $\tilde{\nu}_\mu$ decreases to 82 GeV if the constraint from the neutralino is not used and to 83 GeV for direct decays. For indirect decays the limit on $\tilde{\nu}_\tau$ decreases to 82 GeV if the constraint from the neutralino is not used and improves to 91 GeV for direct decays. Supersedes the results of ABREU 00U.

[23] ABDALLAH 03F looked for events of the type $e^+e^- \to \tilde{\nu} \to \tilde{\chi}^0\nu$, $\tilde{\chi}^\pm\ell^\mp$ followed by $\not{R}$ decays of the $\tilde{\chi}^0$ via λ_{1j1} (j = 2,3) couplings in the data at $\sqrt{s} = 183$–208 GeV.

From a scan over the SUGRA parameters, they derive upper limits on the λ_{1j1} couplings as a function of the sneutrino mass, see their Figs. 5–8.

[24] ACOSTA 03E search for $e\mu$, $e\tau$ and $\mu\tau$ final states, and sets limits on the product of production cross-section and decay branching ratio for a $\tilde{\nu}$ in RPV models (see Fig. 3).

[25] HEISTER 03G searches for the production of sneutrinos in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect $\overline{\nu}$ decays via $\overline{UDD}$ couplings and $\Delta m > 10$ GeV. Stronger limits are reached for ($\overline{\nu}_e$,$\overline{\nu}_{\mu,\tau}$) for $LL\overline{E}$ direct (100,90) GeV or indirect (98,89) GeV and for $LQ\overline{D}$ direct (–,79) GeV or indirect (91,78) GeV couplings. For $LL\overline{E}$ indirect decays, use is made of the bound $m(\tilde{\chi}^0_1) > 23$ GeV from BARATE 98S. Supersedes the results from BARATE 01B.

[26] ABAZOV 02H looked in 94 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via $\not{R}$ couplings $LQ\overline{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the (m_0,$m_{1/2}$) plane, examples being shown in Fig. 2.

[27] ACHARD 02 searches for the associated production of sneutrinos in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for ($\tilde{\nu}_e$,$\tilde{\nu}_{\mu,\tau}$) for $LL\overline{E}$ indirect (99,78) GeV and for $\overline{UDD}$ direct or indirect (99,70) GeV decays. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $\overline{UDD}$ couplings and increases to 152.7 GeV for $LL\overline{E}$ couplings.

[28] HEISTER 02F searched for single sneutrino production via $e\gamma \to \tilde{\nu}_j \ell_k$ mediated by $\not{R}$ $LL\overline{E}$ couplings, decaying directly or indirectly via a $\tilde{\chi}^0_1$ and assuming a single coupling to be nonzero at a time. Final states with three leptons and possible $\not{E}_T$ due to neutrinos were selected in the 189–209 GeV data. Limits on the couplings λ_{1jk} as function of the sneutrino mass are shown in Figs. 10–14. The couplings λ_{232} and λ_{233} are not accessible and λ_{121} and λ_{131} are measured with better accuracy in sneutrino resonant production. For all tested couplings, except λ_{133}, the limits are significantly improved compared to the low-energy limits.

[29] ABBIENDI 00R studied the effect of s- and t-channel τ or μ sneutrino exchange in $e^+e^- \to e^+e^-$ at $\sqrt{s}$=130–189 GeV, via the R-parity violating coupling $\lambda_{1i1}L_1L_ie_1$ (i=2 or 3). The limits quoted here hold for $\lambda_{1j1} >$0.13, and supersede the results of ABBIENDI 99. See Fig. 11 for limits on $m_{\tilde{\nu}}$ versus coupling.

[30] ABBIENDI 00R studied the effect of s-channel τ sneutrino exchange in $e^+e^- \to \mu^+\mu^-$ at $\sqrt{s}$=130–189 GeV, in presence of the R-parity violating couplings $\lambda_{i3j}L_iL_3e_j$ (i=1 and 2), with λ_{131}=λ_{232}. The limits quoted here hold for $\lambda_{131} > 0.09$, and supersede the results of ABBIENDI 99. See Fig. 12 for limits on $m_{\tilde{\nu}}$ versus coupling.

[31] ABREU 00S searches for anomalies in the production cross sections and forward-backward asymmetries of the $\ell^+\ell^-(\gamma)$ final states (ℓ=e,μ,τ) from e^+e^- collisions at $\sqrt{s}$=130–189 GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of $\not{R}$ with $\lambda LL\overline{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the (λ,$m_{\tilde{\nu}}$) plane are given in Fig. 5. These limits include and update the results of ABREU 99A.

[32] ACCIARRI 00P use the dilepton total cross sections and asymmetries at $\sqrt{s}$=m_Z and $\sqrt{s}$=130–189 GeV data to set limits on the effect of $\not{R}$ $LL\overline{E}$ couplings giving rise to μ or τ sneutrino exchange. See their Fig. 5 for limits on the sneutrino mass versus couplings.

[33] BARATE 00I studied the effect of s-channel and t-channel τ or μ sneutrino exchange in $e^+e^- \to e^+e^-$ at $\sqrt{s}$= 130–183 GeV, via the R-parity violating coupling $\lambda_{1i1}L_1L_ie^c_1$ (i=2 or 3). The limits quoted here hold for $\lambda_{1j1} > 0.1$. See their Fig. 15 for limits as a function of the coupling. Superseded by SCHAEL 07A.

[34] BARATE 00I studied the effect of s-channel τ sneutrino exchange in $e^+e^- \to \mu^+\mu^-$ at $\sqrt{s}$= 130–183 GeV, in presence of the R-parity violating coupling $\lambda_{i3j}L_iL_3e^c_j$ (i=1 and 2). The limits quoted here hold for $\sqrt{|\lambda_{131}\lambda_{232}|} > 0.2$. See their Fig. 16 for limits as a function of the coupling. Superseded by SCHAEL 07A.

[35] ABBIENDI 99 studied the effect of t-channel electron sneutrino exchange in $e^+e^- \to \tau^+\tau^-$ at $\sqrt{s}$=130–183 GeV, in presence of the R-parity violating couplings $\lambda_{131}L_1L_3e^c_1$. The limits quoted here hold for $\lambda_{131} > 0.6$.

[36] ACCIARRI 97U studied the effect of the s-channel tau-sneutrino exchange in $e^+e^- \to e^+e^-$ at $\sqrt{s}$=m_Z and $\sqrt{s}$=130–172 GeV, via the R-parity violating coupling $\lambda_{131}L_1L_ie^c_1$. The limits quoted here hold for $\lambda_{131} > 0.05$. Similar limits were studied in $e^+e^- \to \mu^+\mu^-$ together with $\lambda_{232}L_2L_3e^c_2$ coupling.

[37] CARENA 97 studied the constraints on chargino and sneutrino masses from muon $g-2$. The bound can be important for large tanβ.

[38] BUSKULIC 95E looked for $Z \to \tilde{\nu}\overline{\tilde{\nu}}$, where $\tilde{\nu} \to \nu\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[39] BECK 94 limit can be inferred from limit on Dirac neutrino using $\sigma(\tilde{\nu}) = 4\sigma(\nu)$. Also private communication with H.V. Klapdor-Kleingrothaus.

[40] FALK 94 puts an upper bound on $m_{\tilde{\nu}}$ when $\tilde{\nu}$ is LSP by requiring its relic density does not overclose the Universe.

[41] SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86.

CHARGED SLEPTONS

This section contains limits on charged scalar leptons ($\tilde{\ell}$, with ℓ=e,μ,τ). Studies of width and decays of the Z boson (use is made here of $\Delta\Gamma_{\rm inv} < 2.0$ MeV, LEP 00) conclusively rule out $m_{\tilde{\ell}_R} < 40$ GeV (41 GeV for $\tilde{\ell}_L$) , independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\tilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting Δm= $m_{\tilde{\ell}} - m_{\tilde{\chi}^0_1}$. The mass and composition of $\tilde{\chi}^0_1$ may affect the selectron production rate in e^+e^- collisions through t-channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\tilde{\ell}_1$=$\tilde{\ell}_R$ sinθ_ℓ + $\tilde{\ell}_L$ cosθ_ℓ. It is generally assumed that only $\tilde{\tau}$ may have significant mixing. The coupling to the Z vanishes for θ_ℓ=0.82. In the high-energy limit of e^+e^- collisions the interference between γ and Z exchange leads to a minimal cross section for θ_ℓ=0.91, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\tilde{\ell}_R}$ are quoted, it is understood that limits on $m_{\tilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\tilde{\chi}^0_1$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\tilde{\ell}^+\tilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of e^+e^- collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos ($\tilde{G}$), $m_{\tilde{G}}$ is assumed to be negligible relative to all other masses.

[1] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for sleptons decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}^0_1} = 20$ GeV. See also Fig. 2(a). Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[2] ABBIENDI 04 search for $\tilde{e}_R\tilde{e}_R$ production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$ and for the limit at tanβ=35 This limit supersedes ABBIENDI 00G.

[3] ACHARD 04 search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq$ tan$\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99W.

[4] ABDALLAH 03M looked for acoplanar dielectron + $\not{E}$ final states at $\sqrt{s}$ = 189–208 GeV. The limit assumes μ=$-$200 GeV and tanβ=1.5 in the calculation of the production cross section and B($\tilde{e} \to e\tilde{\chi}^0_1$). See Fig. 15 for limits in the ($m_{\tilde{e}_R}$, $m_{\tilde{\chi}^0_1}$) plane. These limits include and update the results of ABREU 01

[5] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 <$1 TeV, $|\mu| \leq$ 1 TeV with the $\tilde{\chi}^0_1$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[6] HEISTER 02E looked for acoplanar dielectron + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $\mu < -200$ GeV and tanβ=2 for the production cross section and B($\tilde{e} \to e\tilde{\chi}^0_1$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[7] HEISTER 02N search for $\tilde{e}_R\tilde{e}_L$ and $\tilde{e}_R\tilde{e}_R$ production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on $m_{\tilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq$ tan$\beta \leq 50$ and $-10 \leq \mu \leq 10$ TeV. The region of small $|\mu|$, where cascade decays are important, is covered by a search for $\tilde{\chi}^0_1\tilde{\chi}^0_3$ in final states with

leptons and possibly photons. Limits on $m_{\tilde{e}_L}$ are derived by exploiting the mass relation between the $\tilde{e}_L$ and $\tilde{e}_R$, based on universal m_0 and $m_{1/2}$. When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to $m_{\tilde{e}_R}$ >77(75) GeV and $m_{\tilde{e}_L}$ >115(115) GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to $m_{\tilde{e}_R}$ >95 GeV and $m_{\tilde{e}_L}$ >152 GeV, assuming a trilinear coupling A_0=0 at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on tanβ.

[8] ABBIENDI 04F use data from $\sqrt{s}$ = 189–209 GeV. They derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for tanβ = 1.5, $\mu = -200$ GeV, with, in addition, $\Delta m \geq 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays via $LL\overline{E}$ or $LQ\overline{D}$ couplings. For indirect decays, the limits on the $\tilde{e}_R$ mass are respectively 99 and 92 GeV for $LL\overline{E}$ and $LQ\overline{D}$ couplings and $m_{\tilde{\chi}^0} = 10$ GeV and degrade slightly for larger $\tilde{\chi}^0_1$ mass. Supersedes the results of ABBIENDI 00.

[9] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid for $\mu = -200$ GeV, tanβ = 1.5, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $UD\overline{D}$ decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for $\overline{UDD}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit improves to 95 GeV if the constraint from the neutralino is used and to 94 GeV if it is not used. For indirect decays via $\overline{UDD}$ couplings it remains unchanged when the neutralino constraint is not used. Supersedes the result of ABREU 00U.

[10] HEISTER 03G searches for the production of selectrons in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $LQ\overline{D}$ couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{e},R} > 96$ GeV) and indirect decays ($m_{\tilde{e},R} > 96$ GeV for $m(\tilde{\chi}^0_1) > 23$ GeV from BARATE 98S) and for $\overline{UDD}$ indirect decays ($m_{\tilde{e},R} > 94$ GeV with $\Delta m > 10$ GeV). Supersedes the results from BARATE 01B.

[11] ACHARD 02 searches for the production of selectrons in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (79 GeV) and for $\overline{UDD}$ direct or indirect (96 GeV) decays.

[12] BARATE 01 looked for acoplanar dielectron + $\not{E}_T$ final states at 189 to 202 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the production cross section and 100% branching ratio for $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[13] ABBIENDI 00J looked for acoplanar dielectron + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes $\mu < -100$ GeV and tanβ=1.5 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{e} \rightarrow e\tilde{\chi}^0_1$. See their Fig. 12 for the dependence of the limit on Δm and tanβ.

[14] ABREU 00U studies decays induced by R-parity violating $LL\overline{E}$ couplings, using data from $\sqrt{s}$=189 GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits assume a neutralino mass limit of 30 GeV, also derived in ABREU 00U. Updates ABREU 00I. Superseded by ABDALLAH 04M.

[15] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as a function of $m_{\tilde{G}}$, from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[16] BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the schannel. Data collected at $\sqrt{s}$=189 GeV.

[17] ACCIARRI 99I establish indirect limits on $m_{\tilde{e}_R}$ from the regions excluded in the M_2 versus m_0 plane by their chargino and neutralino searches at $\sqrt{s}$=130–183 GeV. The situations where the $\tilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\tilde{\ell}$ is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct decays with $\overline{UDD}$ couplings; $LL\overline{E}$ couplings or indirect decays lead to a stronger limit.

[18] ACCIARRI 98F looked for acoplanar dielectron+$\not{E}_T$ final states at $\sqrt{s}$=130–172 GeV. The limit assumes μ=−200 GeV, and zero efficiency for decays other than $\tilde{e}_R \rightarrow e\tilde{\chi}^0_1$. See their Fig. 6 for the dependence of the limit on Δm.

[19] BARATE 98K looked for $e^+e^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the evaluation of the production cross section. See Fig. 4 for limits on the ($m_{\tilde{e}_R}$,$m_{\tilde{\chi}^0_1}$) plane and for the effect of cascade decays.

[20] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via gaugino-like neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See paper for dependences in $m(\tilde{q})$, $m(\tilde{\chi}^0_1)$.

[21] AID 96C used positron+jet events with missing energy and momentum to look for $e^+q \rightarrow \tilde{e}\tilde{q}$ via neutralino exchange with decays into $(e\tilde{\chi}^0_1)(q\tilde{\chi}^0_1)$. See the paper for dependences on $m_{\tilde{q}}$, $m_{\tilde{\chi}^0_1}$.

[1] AAD 13B searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for sleptons decaying to a final state with two leptons (e and μ) and missing transverse energy. No excess beyond the Standard Model expectation is observed. Limits are derived in a simplified model of direct left-handed slepton pair production, where left-handed slepton masses between 85 and 195 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}^0_1} = 20$ GeV. See also Fig. 2(a). Exclusion limits are also derived in the phenomenological MSSM, see Fig. 3.

[2] ABBIENDI 04 search for $\tilde{\mu}_R\tilde{\mu}_R$ production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\tilde{\mu}_R \rightarrow \mu\tilde{\chi}^0_1$, the limit improves to 94.0 GeV for $\Delta m > 4$ GeV. See Fig. 11 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$ at several values of the branching ratio. This limit supersedes ABBIENDI 00G.

[3] ACHARD 04 search for $\tilde{\mu}_R\tilde{\mu}_R$ production in acoplanar di-muon final states in the 192–209 GeV data. Limits on $m_{\tilde{\mu}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq$ tan$\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\tilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99W.

[4] ABDALLAH 03M looked for acoplanar dimuon + $\not{E}$ final states at $\sqrt{s}$ = 189–208 GeV. The limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}^0_1$) = 100%. See Fig. 16 for limits on the ($m_{\tilde{\mu}_R}$, $m_{\tilde{\chi}^0_1}$) plane. These limits include and update the results of ABREU 01.

[5] ABDALLAH 03M uses data from $\sqrt{s}$ = 192–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $\lvert\mu\rvert \leq 1$ TeV with the $\tilde{\chi}^0_1$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tanβ. These limits update the results of ABREU 00W.

[6] HEISTER 02E looked for acoplanar dimuon + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}^0_1$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[7] ABAZOV 06I looked in 380 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via $\not{R}$ couplings $LQ\overline{D}$. The data are in agreement with the SM expectation. They set limits on resonant slepton production and derive exclusion contours on λ'_{211} in the mass plane of $\tilde{\ell}$ versus $\tilde{\chi}^0_1$ assuming a MSUGRA model with tan$\beta = 5$, $\mu < 0$ and $A_0 = 0$, see their Fig. 3. For $\lambda'_{211} \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABAZOV 02H.

[8] ABBIENDI 04F use data from $\sqrt{s}$ = 189–209 GeV. They derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for tanβ = 1.5, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays with $LL\overline{E}$ couplings and improves to 75 GeV for $LQ\overline{D}$ couplings. The limits on the $\tilde{\mu}_R$ mass for indirect decays are respectively 94 and 87 GeV for $LL\overline{E}$ and $LQ\overline{D}$ couplings and $m_{\tilde{\chi}^0} = 10$ GeV. Supersedes the results of ABBIENDI 00.

[9] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid for $\mu = -200$ GeV, tanβ = 1.5, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $UD\overline{D}$ decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for $\overline{UDD}$ couplings, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit improves to 90 GeV if the constraint from the neutralino is used and remains at 87 GeV if it is not used. For indirect decays via $\overline{UDD}$ couplings it degrades to 85 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 00U.

[10] HEISTER 03G searches for the production of smuons in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by $\not{R}$ $LQ\overline{D}$ couplings and improves to 90 GeV for indirect decays (for $\Delta m > 10$ GeV). Limits are also given for $LL\overline{E}$ direct ($m_{\tilde{\mu}R} > 87$ GeV) and indirect decays ($m_{\tilde{\mu}R} > 96$ GeV for $m(\tilde{\chi}^0_1) > 23$ GeV from BARATE 98S) and for $\overline{UDD}$ indirect decays ($m_{\tilde{\mu}R} > 85$ GeV for $\Delta m > 10$ GeV). Supersedes the results from BARATE 01B.

[11] ABAZOV 02H looked in 94 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via $\not{R}$ couplings $LQ\overline{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the (m_0,$m_{1/2}$) plane, examples being shown in Fig. 2.

[12] ACHARD 02 searches for the production of smuons in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (87 GeV) and for $\overline{UDD}$ direct or indirect (86 GeV) decays.

[13] BARATE 01 looked for acoplanar dimuon + $\not{E}_T$ final states at 189 to 202 GeV. The limit assumes 100% branching ratio for $\tilde{\mu} \rightarrow \mu\tilde{\chi}^0_1$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[14] ABBIENDI 00J looked for acoplanar dimuon + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes B($\tilde{\mu} \rightarrow \mu\tilde{\chi}^0_1$)=1. Using decay branching ratios derived from the

MSSM, a lower limit of 65 GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 10 and 13 for the dependence of the limit on the branching ratio and on Δm.

[15] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\widetilde{G}}$, see their Fig. 12.

[16] BARATE 98K looked for $\mu^+\mu^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the $(m_{\widetilde{\mu}_R}, m_{\widetilde{\chi}^0_1})$ plane and for the effect of cascade decays.

[1] ABBIENDI 04 search for $\widetilde{\tau}\widetilde{\tau}$ production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on $m_{\widetilde{\chi}^0_1}$ and for the limit at tanβ=35. Under the assumption of 100% branching ratio for $\widetilde{\tau}_R \rightarrow \tau\widetilde{\chi}^0_1$, the limit improves to 89.8 GeV for $\Delta m > 8$ GeV. See Fig. 12 for the dependence of the limits on $m_{\widetilde{\chi}^0_1}$ at several values of the branching ratio and for their dependence on θ_τ. This limit supersedes ABBIENDI 00G.

[2] ACHARD 04 search for $\widetilde{\tau}\widetilde{\tau}$ production in acoplanar di-tau final states in the 192–209 GeV data. Limits on $m_{\widetilde{\tau}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0, $1 \leq$ tan$\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\widetilde{\chi}^0_1}$.

[3] ABDALLAH 03M looked for acoplanar ditaus + $\not{E}$ final states at $\sqrt{s}$ = 130–208 GeV. A dedicated search was made for low mass $\widetilde{\tau}$s decoupling from the Z^0. The limit assumes B($\widetilde{\tau} \rightarrow \tau\widetilde{\chi}^0_1$) = 100%. See Fig. 20 for limits on the $(m_{\widetilde{\tau}}, m_{\widetilde{\chi}^0_1})$ plane and as function of the $\widetilde{\chi}^0_1$ mass and of the branching ratio. The limit in the low-mass region improves to 29.6 and 31.1 GeV for $\widetilde{\tau}_R$ and $\widetilde{\tau}_L$, respectively, at $\Delta m > m_\tau$. The limit in the high-mass region improves to 84.7 GeV for $\widetilde{\tau}_R$ and $\Delta m > 15$ GeV. These limits include and update the results of ABREU 01.

[4] HEISTER 02E looked for acoplanar ditau + $\not{E}_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($\widetilde{\tau} \rightarrow \tau\widetilde{\chi}^0_1$)=1. See their Fig. 4 for the dependence of the limit on Δm. These limits include and update the results of BARATE 01.

[5] AAD 12AF searched in 2 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two tau leptons, jets and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C.L. lower limit of 32 TeV on the mGMSB breaking scale Λ is set for M_{mess} = 250 TeV, N_5 = 3, $\mu > 0$ and C_{grav} = 1, independent of tanβ.

[6] AAD 12AG searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with at least one hadronically decaying tau lepton, jets, and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C.L. lower limit of 30 TeV on the mGMSB breaking scale Λ is set for M_{mess} = 250 TeV, N_5 = 3, $\mu > 0$ and C_{grav} = 1, independent of tanβ. For large values of tanβ, the limit on Λ increases to 43 TeV.

[7] AAD 12CM searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with at least one tau lepton, zero or one additional light lepton (e/μ) jets, and large $\not{E}_T$ in a GMSB framework. No significant excess above the expected background was found and an upper limit on the visible cross section for new phenomena is set. A 95% C. L. lower limit of 54 TeV on the mGMSB breaking scale Λ is set for M_{mess} = 250 TeV, N_5 = 3, $\mu > 0$ and C_{grav} = 1, for tan$\beta > 20$. Here the $\widetilde{\tau}_1$ is the NLSP.

[8] ABBIENDI 06B use 600 pb^{-1} of data from $\sqrt{s}$ = 189–209 GeV. They look for events from pair-produced staus in a GMSB scenario with $\widetilde{\tau}$ NLSP including prompt $\widetilde{\tau}$ decays to ditaus + $\not{E}$ final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of m($\widetilde{\tau}$) and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space.

[9] ABBIENDI 04F use data from $\sqrt{s}$ = 189–209 GeV. They derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for tanβ = 1.5, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays with $LL\overline{E}$ couplings and improves to 75 GeV for $LQ\overline{D}$ couplings. The limit on the $\widetilde{\tau}_R$ mass for indirect decays is 92 GeV for $LL\overline{E}$ couplings at $m_{\widetilde{\chi}^0} = 10$ GeV and no exclusion is obtained for $LQ\overline{D}$ couplings. Supersedes the results of ABBIENDI 00.

[10] ABDALLAH 04H use data from LEP 1 and $\sqrt{s}$ = 192–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50$ TeV, $0 < m_0 < 1000$ GeV, $1.5 <$ tan$\beta < 35$, both signs of μ. The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for m_t = 174.3 GeV (see Table 2 for other m_t values).

[11] The limit improves to 75 GeV for $\mu < 0$.

[12] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ couplings. The results are valid for $\mu = -200$ GeV, tanβ = 1.5, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit decreases to 86 GeV if the constraint from the neutralino is not used. Supersedes the result of ABREU 00U.

[13] ABDALLAH 03D use data from $\sqrt{s}$ = 130–208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m($\widetilde{G}$), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays. The above limit is reached for the stau decaying promptly, m($\widetilde{G}$) < 6 eV, and is computed for stau mixing yielding the minimal cross section. Stronger limits are obtained for longer lifetimes, See their Fig. 9. Supersedes the results of ABREU 01G.

[14] HEISTER 03G searches for the production of stau in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings with $\Delta m > 10$ GeV. Limits are also given for $LL\overline{E}$ direct ($m_{\widetilde{\tau}_R} > 87$ GeV) and indirect decays ($m_{\widetilde{\tau}_R} > 95$ GeV for $m(\widetilde{\chi}^0_1) > 23$ GeV from BARATE 98S) and for $LQ\overline{D}$ indirect decays ($m_{\widetilde{\tau}_R} > 76$ GeV). Supersedes the results from BARATE 01B.

[15] ACHARD 02 searches for the production of staus in the case of $\not{R}$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (86 GeV) and for $\overline{UDD}$ direct or indirect (75 GeV) decays.

[16] HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\widetilde{\chi}^0_1$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma\not{E}$ or a single γ not pointing to the interaction vertex. For the $\widetilde{\ell}$ NLSP case, the topologies consist of $\ell\ell\not{E}$, including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limit remains valid whichever is the NLSP. The absolute mass bound on the $\widetilde{\chi}^0_1$ for any lifetime includes indirect limits from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. In the co-NLSP scenario, limits $m_{\widetilde{e}_R} > 83$ GeV (neglecting t-channel exchange) and $m_{\widetilde{\mu}_R} > 88$ GeV are obtained independent of the lifetime. Supersedes the results from BARATE 00G.

[17] BARATE 01 looked for acoplanar ditau + $\not{E}_T$ final states at 189 to 202 GeV. A slight excess (with 1.2% probability) of events is observed relative to the expected SM background. The limit assumes 100% branching ratio for $\widetilde{\tau} \rightarrow \tau\widetilde{\chi}^0_1$. See their Fig. 1 for the dependence of the limit on Δm. These limits include and update the results of BARATE 99Q.

[18] ABBIENDI 00J looked for acoplanar ditau + $\not{E}_T$ final states at $\sqrt{s}$= 161–183 GeV. The limit assumes B($\widetilde{\tau} \rightarrow \tau\widetilde{\chi}^0_1$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 60 GeV at Δm >9 GeV is obtained for $\mu < -100$ GeV and tanβ=1.5. See their Figs. 11 and 14 for the dependence of the limit on the branching ratio and on Δm.

[19] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The above limit assumes the degeneracy of stau and smuon. For limits at different $m_{\widetilde{G}}$, see their Fig. 12.

[20] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. The above limit is reached for the stau mixing yielding the minimal cross section and decaying promptly. Stronger limits are obtained for longer lifetimes or for $\widetilde{\tau}_R$; see their Fig. 11. For $10 \leq m_{\widetilde{G}} \leq 310$ eV, the whole range $2 \leq m_{\widetilde{\tau}_1} \leq 80$ GeV is excluded. Supersedes the results of ABREU 99C and ABREU 99F.

[21] BARATE 98K looked for $\tau^+\tau^-\gamma\gamma + \not{E}$ final states at $\sqrt{s}$= 161–184 GeV. See Fig. 4 for limits on the $(m_{\widetilde{\tau}_R}, m_{\widetilde{\chi}^0_1})$ plane and for the effect of cascade decays.

Degenerate Charged Sleptons

Unless stated otherwise in the comment lines or in the footnotes, the following limits assume 3 families of degenerate charged sleptons.

[1] BARATE 01 looked for acoplanar dilepton + $\not{E}_T$ and single electron (for $\tilde{e}_R\tilde{e}_L$) final states at 189 to 202 GeV. The limit assumes μ=−200 GeV and tanβ=2 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\tilde{\ell} \to \ell\tilde{\chi}_1^0$. The slepton masses are determined from the GUT relations without stau mixing. See their Fig. 1 for the dependence of the limit on Δm.

[2] ABBIENDI 06B use 600 pb^{-1} of data from $\sqrt{s}$ = 189–209 GeV. They look for events from pair-produced staus in a GMSB scenario with $\tilde{\ell}$ co-NLSP including prompt $\tilde{\ell}$ decays to dileptons + $\not{E}$ final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of m($\tilde{\ell}$) and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space. The highest mass limit is reached for $\tilde{\mu}_R$, from which the quoted mass limit is derived by subtracting m_τ.

[3] ABDALLAH 03D use data from $\sqrt{s}$ = 130–208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m($\tilde{G}$), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays The above limit is reached for prompt decays and assumes the degeneracy of the sleptons. For limits at different m($\tilde{G}$), see their Fig. 9. Supersedes the results of ABREU 01G.

[4] ACHARD 02 searches for the production of sparticles in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ or $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale and no mixing in the slepton sector, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $LL\overline{E}$ couplings and increases to 88.7 GeV for $\overline{UDD}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

[5] ABBIENDI 01 looked for final states with $\gamma\gamma\not{E}$, $\ell\ell\not{E}$, with possibly additional activity and four leptons + $\not{E}$ to search for prompt decays of $\tilde{\chi}_1^0$ or $\tilde{\ell}_1$ in GMSB. They derive limits in the plane ($m_{\tilde{\chi}_1^0}$,$m_{\tilde{\tau}_1}$), see Fig. 6, allowing either the $\tilde{\chi}_1^0$ or a $\tilde{\ell}_1$ to be the NLSP. Two scenarios are considered: tanβ=2 with the 3 sleptons degenerate in mass and tanβ=20 where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}$=189 GeV. For tanβ=20, the obtained limits are $m_{\tilde{\tau}_1} > 69$ GeV and $m_{\tilde{e}_1,\tilde{\mu}_1} > 88$ GeV.

[6] ABREU 01 looked for acoplanar dilepton + diphoton + $\not{E}$ final states from $\tilde{\ell}$ cascade decays at $\sqrt{s}$=130–189 GeV. See Fig. 9 for limits on the (μ,M_2) plane for $m_{\tilde{\ell}}$=80 GeV, tanβ=1.0, and assuming degeneracy of $\tilde{\mu}$ and $\tilde{e}$.

[7] ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from $R\!\!\!/$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or $\overline{UDD}$ couplings at $\sqrt{s}$=189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\tilde{\chi}_1^0$ or a $\tilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 99I.

[8] ABREU 00V use data from $\sqrt{s}$= 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\tilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\tilde{G}}$, see their Fig. 12.

[9] The above limit assumes the degeneracy of stau and smuon.

Long-lived $\tilde{\ell}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. Selectron limits from e^+e^- collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

[1] ABBIENDI 03L used e^+e^- data at $\sqrt{s}$ = 130–209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for $\tilde{\mu}_L$ and $\tilde{\tau}_L$. The bounds are valid for colorless spin 0 particles with lifetimes longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

[2] ABREU 00Q searches for the production of pairs of heavy, charged stable particles in e^+e^- annihilation at $\sqrt{s}$= 130–189 GeV. The upper bound improves to 88 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$. These limits include and update the results of ABREU 98P.

[3] ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at $\sqrt{s}$=130–183 GeV. The upper bound improves to 82.2 GeV for $\tilde{\mu}_L$, $\tilde{\tau}_L$.

[4] The BARATE 98K mass limit improves to 82 GeV for $\tilde{\mu}_L$,$\tilde{\tau}_L$. Data collected at $\sqrt{s}$=161–184 GeV.

[5] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing long-lived massive particles in a GMSB framework. No significant excess above the expected background was found. A 95% C.L. lower limit of 300 GeV is placed on long-lived $\tilde{\tau}$'s in the GMSB model with $M_{mess} = 250$ TeV, $N_S = 3$, $\mu > 0$, for tanβ = 5–20. The lower limit on the GMSB breaking scale Λ was found to be 99–110 TeV, for tanβ values between 5 and 40, see Fig. 4 (top). Also, directly produced long-lived sleptons, or sleptons decaying to long-lived ones, are excluded at 95% C.L. up to a $\tilde{\tau}$ mass of 278 GeV for models with slepton splittings smaller than 50 GeV.

[6] ABAZOV 13B looked in 6.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events with muon-like particles that have both speed and ionization energy loss inconsistent with muons produced in beam collisions. In the absence of an excess, limits are set at 95% C.L. on the production cross section of stau leptons in the mass range 100–300 GeV, see their Table 20 and Fig. 23.

[7] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{\tau}_1$'s. No evidence for an excess over the expected background is observed. Supersedes CHATRCHYAN 12L.

[8] CHATRCHYAN 13AB limits are derived for pair production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for direct pair $\tilde{\tau}_1$ production.

[9] CHATRCHYAN 13AB limits are derived for the production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 8 and Table 7). The limit given here is valid for the production of $\tilde{\tau}_1$ from both direct pair production and from the decay of heavier supersymmetric particles.

[10] CHATRCHYAN 12L looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{\tau}_1$'s. No evidence for an excess over the expected background is observed. Limits are derived for the production of $\tilde{\tau}_1$ as a function of mass in minimal GMSB scenarios along the Snowmass Points and Slopes (SPS) line 7 (see Fig. 3). The limit given here is valid for the production of $\tilde{\tau}_1$ in the decay of heavier supersymmetric particles.

[11] AAD 11P looked in 37 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two heavy stable particles, reconstructed in the Inner tracker and the Muon System and identified by their time of flight in the Muon System. No evidence for an excess over the SM expectation is observed. Limits on the mass are derived, see Fig. 3, for $\tilde{\tau}$ in a GMSB scenario and for sleptons produced by electroweak processes only, in which case the limit degrades to 110 GeV.

$\tilde{q}$ (Squark) MASS LIMIT

For $m_{\tilde{q}} > 60$–70 GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from e^+e^- collisions depend on the mixing angle of the lightest mass eigenstate $\tilde{q}_1 = \tilde{q}_R \sin\theta_q + \tilde{q}_L \cos\theta_q$. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\tilde{q} \to q\tilde{\chi}_1$ decays if $\Delta m = m_{\tilde{q}} - m_{\tilde{\chi}_1^0} \gtrsim 5$ GeV. For smaller values of Δm, current constraints on the invisible width of the Z ($\Delta\Gamma_{\rm inv} < 2.0$ MeV, LEP 00) exclude $m_{\tilde{u}_{L,R}}$ <44 GeV, $m_{\tilde{d}_R}$ <33 GeV, $m_{\tilde{d}_L}$ <44 GeV and, assuming all squarks degenerate, $m_{\tilde{q}}$ <45 GeV.

Limits made obsolete by the most recent analyses of e^+e^-, $p\overline{p}$, and ep collisions can be found in previous Editions of this *Review*.

[1] AAD 13L searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no high-p_T electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks and gluinos of equal mass are excluded for masses below 1360 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 1320 GeV are excluded at 95% C.L. for gluino masses below 2 TeV. See Figures 10–15 for more precise bounds.

[2] AAD 13Q searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing a high-p_T isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. For neutralino masses greater than 220 GeV, squark masses below 1020 GeV are excluded at 95% C.L.

[3] CHATRCHYAN 13 looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two opposite-sign leptons (e, μ, τ), jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 6.

[4] CHATRCHYAN 13G searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing 0,1,2, $\ge$ 3 b-jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0, and μ > 0, squarks and gluinos of equal mass are excluded for masses below 1250 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 7.

[5] CHATRCHYAN 13H searched in 4.96 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons, $\ge$ 4 jets and low $\not{E}_T$ due to $\widetilde{q}\to \gamma\widetilde{\chi}^0_1$ decays in a stealth SUSY framework, where the $\widetilde{\chi}^0_1$ decays through a singlino ($\widetilde{S}$) intermediate state to $\gamma S\,\widetilde{G}$, with the singlet state S decaying to two jets. No significant excess above the expected background was found and limits were set in a particular R-parity conserving stealth SUSY model. The model assumes $m_{\widetilde{\chi}^0_1}$ = 0.5 $m_{\widetilde{q}}$, $m_{\widetilde{S}}$ = 100 GeV and m_S = 90 GeV. Under these assumptions, squark masses less than 1430 GeV were excluded at the 95% C.L.

[6] CHATRCHYAN 13T searched in 11.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least two energetic jets and significant $\not{E}_T$, using the α_T variable to discriminate between processes with genuine and misreconstructed $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in simplified models where the decay $\widetilde{q}\to q\widetilde{\chi}^0_1$ takes place with a branching ratio of 100%, assuming an eightfold degeneracy of the masses of the first two generation squarks, see Fig. 8 and Table 9. Also limits in the case of a single light squark are given.

[7] AAD 12AX searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for supersymmetry in events containing jets, missing transverse momentum and one isolated electron or muon. No excess over the expected SM background is observed and model-independent limits are set on the cross section of new physics contributions to the signal regions. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks and gluinos of equal mass are excluded for masses below 820 GeV at 95% C.L. Limits are also set on simplified models for squark production and decay via an intermediate chargino and on supersymmetric models with bilinear R-parity violation. Supersedes AAD 11G.

[8] AAD 12CJ searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing one or more isolated leptons (electrons or muons), jets and $\not{E}_T$. The observations are in good agreement with the SM expectations and exclusion limits have been set in number of SUSY models. In the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0, and μ > 0, 95% C.L. exclusion limits have been derived for $m_{\widetilde{q}}$ < 1200 GeV, assuming equal squark and gluino masses. In minimal GMSB, values of the effective SUSY breaking scale Λ < 50 TeV are excluded at 95% C.L. for tanβ < 45. Also exclusion limits in a number of simplified models have been presented, see Figs. 10 and 12.

[9] AAD 12CP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two photons and large $\not{E}_T$ due to $\widetilde{\chi}^0_1 \rightarrow \gamma\widetilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the squark mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP. The other sparticle masses were decoupled, tanβ = 2 and $c\tau_{NLSP}$ < 0.1 mm. Also, in the framework of the SPS8 model, a 95% C.L. lower limit was set on the breaking scale Λ of 196 TeV.

[10] AAD 12W searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks and gluinos of equal mass are excluded for masses below 950 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, squark masses below 875 GeV are excluded at 95% C.L.

[11] CHATRCHYAN 12 looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with e and/or μ and/or jets, a large total transverse energy, and $\not{E}_T$. The event selection is based on the dimensionless razor variable R, related to the $\not{E}_T$ and M_R, an indicator of the heavy particle mass scale. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 3, 10 and 50 (see Fig. 7 and 8). Limits are also obtained for Simplified Model Spectra.

[12] CHATRCHYAN 12AE searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with at least three jets and large missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of squarks in a scenario where $\widetilde{q} \rightarrow q\widetilde{\chi}^0_1$ with a 100% branching ratio, see Fig. 3. For $m_{\widetilde{\chi}^0_1}$ < 200 GeV, values of $m_{\widetilde{q}}$ below 760 GeV are excluded at 95% C.L. Also limits in the CMSSM are presented, see Fig. 2.

[13] CHATRCHYAN 12AL looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for anomalous production of events with three or more isolated leptons. Limits on squark and gluino masses are set in $R\!\!\!/$ SUSY models with leptonic $LL\overline{E}$ couplings, λ_{123} > 0.05, and hadronic $\overline{UDD}$ couplings, λ''_{112} > 0.05 , see their Fig. 5. In the $\overline{UDD}$ case the leptons arise from supersymmetric cascade decays. A very specific supersymmetric spectrum is assumed. All decays are prompt.

[14] CHATRCHYAN 12AT searched in 4.73 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks with masses below 1110 GeV are excluded at 95% C.L. Squarks and gluinos of equal mass are excluded for masses below 1180 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 6.

[15] AAD 11B looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with same or opposite charge dileptons (e or μ) and $\not{E}_T$ from the production of squarks and gluinos with leptonic decays from $\widetilde{\chi}^\pm_1$ or $\widetilde{\chi}^0_2$. No evidence for an excess over the SM expectation is observed, and limits are derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 2) and in the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane under the assumptions tanβ = 4, μ = 1.5 M, $m_{\widetilde{\chi}^0_2}$ = M - 100 GeV, $m_{\widetilde{\ell}_L}$ = M/2, $m_{\widetilde{\chi}^0_1}$ = 100 GeV, where M = min($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) (see Fig. 3). The exclusion limit for a compressed spectrum is 590 GeV for the same charge and 450 GeV for the opposite charge events.

[16] AAD 11C looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with jets, same flavor opposite charge dileptons (e or μ) and $\not{E}_T$ from the production of squarks and gluinos with decays $\widetilde{q} \rightarrow q\widetilde{\chi}^0_2$ and $\widetilde{\chi}^0_2 \rightarrow \ell^+\ell^-\widetilde{\chi}^0_1$. No evidence for an excess over the SM expectation is observed, and a limit is derived in the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane under the assumptions tanβ = 4, μ = 1.5 M, $m_{\widetilde{\chi}^0_2}$ = M - 100 GeV, $m_{\widetilde{\ell}_L}$ = M/2, $m_{\widetilde{\chi}^0_1}$ = 100 GeV, where M = min($m_{\widetilde{g}}$, $m_{\widetilde{q}}$). The excluded mass region is shown in a plane of ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$), see their Fig. 3. The exclusion limit for a compressed spectrum is 503 GeV.

[17] AAD 11G looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with a single lepton (e or μ), jets and $\not{E}_T$ from the production of squarks and gluinos. No evidence for an excess over the SM expectation is observed, and a limit is derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 3, see Fig. 2.

[18] AAD 11N looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 jets and $\not{E}_T$. Four signal regions were defined, and the background model was found to be in good agreement with the data. Limits are derived in the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane (see Fig. 2) for a simplified model where degenerate masses of the squarks of the first two generations are assumed, $m_{\widetilde{\chi}^0_1}$ = 0, and all other masses including third generation squarks are set to 5 TeV. Limits are also derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 3) for tanβ = 3.

[19] CHATRCHYAN 11W looked in 1.14 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 jets, large total jet energy, and $\not{E}_T$. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T = E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. Given the lack of an excess over the SM backgrounds, limits are derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 4) for tanβ = 10. The limits are only weakly dependent on tanβ and A_0.

[20] AALTONEN 09S searched in 2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 jets and $\not{E}_T$. No evidence for a signal is observed. A limit is derived for a mSUGRA scenario in the $m_{\widetilde{q}}$ versus $m_{\widetilde{g}}$ plane, see their Fig. 2. For $m_{\widetilde{g}}$ < 340 GeV the bound increases to 400 GeV.

[21] ABAZOV 08G looked in 2.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV for events with acoplanar jets or multijets with large $\not{E}_T$. No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific MSUGRA parameter values, see Figure 3. Similar results would be obtained for a large class of parameter sets. Supersedes the results of ABAZOV 06C.

[22] ACHARD 04 search for the production of $\widetilde{q}\widetilde{q}$ of the first two generations in acoplanar di-jet final states in the 192–209 GeV data. Degeneracy of the squark masses is assumed either for both left and right squarks or for right squarks only, as well as B($\widetilde{q} \rightarrow q\widetilde{\chi}^0_1$) = 1 See Fig. 7 for the dependence of the limits on $m_{\widetilde{\chi}^0_1}$. This limit supersedes ACCIARRI 99V.

[23] ABBOTT 01D looked in $\sim$ 108 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with ee, $\mu\mu$, or $e\mu$ accompanied by at least 2 jets and $\not{E}_T$. Excluded regions are obtained in the MSUGRA framework from a scan over the parameters 0<m_0 <300 GeV, 10<$m_{1/2}$ <110 GeV, and 1.2 <tanβ <10.

[24] BARATE 01 looked for acoplanar dijets + $\not{E}_T$ final states at 189 to 202 GeV. The limit assumes B($\widetilde{q} \rightarrow q\widetilde{\chi}^0_1$)=1, with $\Delta m = m_{\widetilde{q}} - m_{\widetilde{\chi}^0_1}$. It applies to tan$\beta$=4, μ=−400 GeV. See their Fig. 2 for the exclusion in the ($m_{\widetilde{q}}$,$m_{\widetilde{g}}$) plane. These limits include and update the results of BARATE 99Q.

[25] ABE 96D searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing E_T. The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for fixed tanβ = 4.0, μ = −400 GeV, and m_{H^+} = 500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario.

[26] CHATRCHYAN 2013AO searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two opposite-sign isolated leptons accompanied by hadronic jets and $\not{E}_T$. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 8.

[27] CHATRCHYAN 13AV searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for new heavy particle pairs decaying into jets (possibly b-tagged), leptons and $\not{E}_T$ using the Razor variables. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 3. The results are also interpreted in various simplified models, see Fig. 4.

[28] CHATRCHYAN 13W searched in 4.93 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with one or more photons, hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on squark masses in the general gauge-mediated SUSY breaking model (GGM), for both a wino-like and bino-like neutralino NLSP scenario, see Fig. 5.

[29] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the fist and second generation squarks and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

[30] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the first and second generation squarks, the gluino, and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

[31] AAD 11AE looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 same charge isolated leptons (e, μ) and $\geq$ 1 jet. They are assumed to come from $\widetilde{q}\widetilde{q}$ production, where the $\widetilde{q}$ decays to $\widetilde{\chi}^\pm_1$ or $\widetilde{\chi}^0_2$ with equal branching ratios, followed by the decays $\widetilde{\chi}^\pm_1 \rightarrow W^\pm\widetilde{\chi}^0_1$ and $\widetilde{\chi}^0_2 \rightarrow Z^0\widetilde{\chi}^0_1$. No evidence for an excess over the expected background is observed. Limits are derived on the cross sections as a function of the masses of the $\widetilde{q}$, $\widetilde{\chi}^\pm_1/\widetilde{\chi}^0_2$ and $\widetilde{\chi}^0_1$ (see Fig. 9 and 10).

[32] AAD 11AF looked in 1.34 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with 6 up to 8 jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 10 (see Fig. 5). The limit improves to $m_{\widetilde{g}}$ > 680 GeV for $m_{\widetilde{q}}$ = 2 $m_{\widetilde{g}}$.

[33] AARON 11 looked in 255 pb^{-1} of e^+p and 183 pb^{-1} of e^-p collisions at $\sqrt{s}$ = 319 GeV for events with at least 1 lepton and jets from R_p violation with $LQ\overline{D}$ couplings, assuming dominance of a single λ'_{ijk} coupling. No evidence for an excess over the SM expectation is observed, and limits are derived in the (λ', $m_{\widetilde{q}}$) plane for the MSSM with tanβ = 6, see their Figs. 7 and 8. Limits are also derived in a CMSSM-type scenario.

[34] AARON 11C looked in 281 pb^{-1} of e^+p and 165 pb^{-1} of e^-p collisions at $\sqrt{s}$ =319 GeV and $\sqrt{s}$ =301 GeV for contact interactions measured from deviations of the dσ/dQ^2 of neutral current events. They are interpreted in the framework of R-parity violation with $LQ\overline{D}$ couplings. No evidence for an excess over the SM expectation is observed, and limits are derived for $m_{\widetilde{q}}/\lambda'$, see Table 4.

[35] CHATRCHYAN 11AC looked in 36 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 3 jets, a large total transverse energy, and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane and the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane for tanβ = 10 (see Fig. 10). Limits are also obtained for Simplified Model Spectra.

[36] CHATRCHYAN 11C looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$=7 TeV for events with opposite charge isolated dileptons (e or μ), jets and $\not{E}_T$ from pair production of $\widetilde{g}$ and $\widetilde{q}$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 3 (see Fig. 4).

[37] CHATRCHYAN 11G looked in 36 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 isolated photons, $\geq$ 1 jet and $\not{E}_T$, which may arise in a generalized gauge mediated model from the decay of a $\widetilde{\chi}^0_1$ NLSP. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark versus gluino mass (see Fig. 4) for several values of $m_{\widetilde{\chi}^0_1}$.

[38] CHATRCHYAN 11Q looked in 36 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with a single isolated lepton (e or μ), $\geq$ 4 jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 10 (see Fig. 7).

[39] CHATRCHYAN 11V looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 3 isolated leptons (e, μ or τ), with or without jets and $\not{E}_T$. Multi-lepton final states originate from $\widetilde{q} \rightarrow \widetilde{\chi}^0 + X$, followed by $\widetilde{\chi}^0 \rightarrow \widetilde{\ell}^\pm\ell^\mp$ and $\widetilde{\ell} \rightarrow \ell\widetilde{G}$. No evidence for an excess over the expected background is observed. Limits are derived (see Fig. 4) for a GMSB-type scenario with mass-degenerate right-handed sleptons (slepton co-NLSP scenario).

[40] CHATRCHYAN 11V looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 3 isolated leptons (e, μ or τ), with or without jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the $R\!\!\!/$ framework (see

Fig. 4) in the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane assuming the dominance of a λ_{122} or λ_{123} coupling, $m_{\widetilde{\chi}^0_1}$ = 300 GeV, $m_{\widetilde{\ell}}$ = 1000 GeV, and decoupled wino and Higgsino.

[41] KHACHATRYAN 11I looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 jets and $\not\!\!E_T$. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T = E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 5) for tanβ = 3. Superseded by CHATRCHYAN 11W.

[42] ABAZOV 09S looked in 0.96 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 jets, a tau decaying hadronically and $\not\!\!E_T$ from the production $\widetilde{q}_L\,\widetilde{q}_R$, with the taus originating from the decay of a $\widetilde{\chi}^0_2$ or $\widetilde{\chi}^\pm_1$. The results were combined with ABAZOV 08G which searched for events with jets and $\not\!\!E_T$ without requiring taus. No evidence for an excess over the SM expectation is observed. The excluded region is shown for an mSUGRA model in a plane of $m_{1/2}$ versus m_0 in the "tau corridor," see their Figs. 5 and 6. The largest excluded squark mass in the corridor is 340 GeV for the tau analysis only and 410 GeV for the combined analysis.

[43] SCHAEL 07A studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating couplings $LQ\overline{D}$ at $\sqrt{s}$ = 189–209 GeV. The limit here refers to the case j = 1, 2 and holds for λ'_{1jk} of electromagnetic strength. The results of this analysis are combined with BARATE 00I.

[44] CHEKANOV 05A search for lepton flavor violating processes $e^\pm p \to \ell X$, where $\ell = \mu$ or τ with high p_T, in 130 pb^{-1} at 300 and 318 GeV. Such final states may originate from LQD couplings with simultaneously non-zero λ'_{1jk} and λ'_{ijk} (i=2 or 3). The quoted mass bounds hold for a u-type squark, assume a λ' of electromagnetic strength and contributions from only direct squark decays. For d-type squarks the bounds are strengthened to 278 and 275 GeV for the μ and τ final states, respectively. Supersedes the results of CHEKANOV 02.

[45] AKTAS 04D looked in 77.8 pb^{-1} of $e^\pm p$ collisions at $\sqrt{s}$ = 319 GeV for resonant production of $\widetilde{q}$ by R-parity violating $LQ\overline{D}$ couplings assuming that one of the λ' couplings dominates over all others. They consider final states with or without leptons and/or jets and/or $\not\!\!p_T$ resulting from direct and indirect decays. They combine the channels to derive limits on λ'_{1j1} and λ'_{11k} as a function of the squark mass, see their Figs. 8 and 9, from a scan over the parameters 70 $< M_2 <$ 350 GeV, $-300 < \mu < 300$ GeV, tanβ = 6, for a fixed mass of 90 GeV for degenerate sleptons and an LSP mass $>$ 30 GeV. The quoted limits refer to $\lambda' = 0.3$, with U=u,c,t and D=d,s,b. Supersedes the results of ADLOFF 01B. Superseded by AARON 11.

[46] ADLOFF 03 looked for the s-channel production of squarks via $R\!\!\!/\ LQ\overline{D}$ couplings in 117.2 pb^{-1} of e^+p data at $\sqrt{s}$ = 301 and 319 GeV and of e^-p data at $\sqrt{s}$ = 319 GeV. The comparison of the data with the SM differential cross section allows limits to be set on couplings for processes mediated through contact interactions. They obtain lower bounds on the value of $m_{\widetilde{q}}/\lambda'$ of 710 GeV for the process $e^+\overline{u} \to \overline{\widetilde{d}}^k$ (and charge conjugate), mediated by λ'_{11k}, and of 430 GeV for the process $e^+d \to \widetilde{u}^j$ (and charge conjugate), mediated by λ'_{1j1}. Superseded by AARON 11C.

[47] CHEKANOV 03B used 131.5 pb^{-1} of e^+p and e^-p data taken at 300 and 318 GeV to look for narrow resonances in the eq or νq final states. Such final states may originate from $LQ\overline{D}$ couplings with non-zero λ'_{1j1} (leading to $\widetilde{u}_j$) or λ'_{11k} (leading to $\widetilde{d}_k$). See their Fig. 8 and explanations in the text for limits. The quoted mass bound assumes that only direct squark decays contribute.

[48] HEISTER 03G searches for the production of squarks in the case of $R\!\!\!/$ prompt decays with $\overline{UDD}$ direct couplings at at $\sqrt{s}$ = 189–209 GeV.

[49] ABAZOV 02F looked in 77.5 pb^{-1} of $p\overline{p}$ collisions at 1.8 TeV for events with $\geq 2\mu + \geq$ 4jets, originating from associated production of squarks followed by an indirect $R\!\!\!/$ decay (of the $\widetilde{\chi}^0_1$) via $LQ\overline{D}$ couplings of the type λ'_{2jk} where j=1,2 and k=1,2,3. Bounds are obtained in the MSUGRA scenario by a scan in the range $0 \leq M_0 \leq$ 400 GeV, $60 \leq m_{1/2} \leq$ 120 GeV for fixed values A_0=0, μ <0, and tanβ=2 or 6. The bounds are weaker for tanβ=6. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for tanβ=2 and 6, respectively.

[50] ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, using events with one electron, $\geq$ 4 jets, and large $\not\!\!E_T$. The results are compared to a MSUGRA scenario with μ <0, A_0=0, and tanβ=3 and allow to exclude a region of the (m_0,$m_{1/2}$) shown in Fig. 11.

[51] ABBIENDI 02 looked for events with an electron or neutrino and a jet in e^+e^- at 189 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Figs. 8–9, assuming that only direct squark decays contribute.

[52] ABBIENDI 02B looked for events with an electron or neutrino and a jet in e^+e^- at 189–209 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute. The quoted limits are read off from Fig. 4. Supersedes the results of ABBIENDI 02.

[53] ACHARD 02 searches for the production of squarks in the case of $R\!\!\!/$ prompt decays with $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for indirect decays. Stronger limits are reached for ($\widetilde{u}_R$,$\widetilde{d}_R$) direct (80,56) GeV and ($\widetilde{u}_L$,$\widetilde{d}_L$) direct or indirect (87,86) GeV decays.

[54] CHEKANOV 02 search for lepton flavor violating processes $e^+p \to \ell X$, where $\ell = \mu$ or τ with high p_T, in 47.7 pb^{-1} of e^+p collisions at 300 GeV. Such final states may originate from $LQ\overline{D}$ couplings with simultaneously nonzero λ'_{1jk} and λ'_{ijk} (i=2 or 3). The quoted mass bound assumes that only direct squark decays contribute.

[55] BARATE 01B searches for the production of squarks in the case of $R\!\!\!/$ prompt decays with $LL\overline{E}$ indirect or $\overline{UDD}$ direct couplings at $\sqrt{s}$=189–202 GeV. The limit holds for direct decays mediated by $R\!\!\!/\ \overline{UDD}$ couplings. Limits are also given for $LL\overline{E}$ indirect decays ($m_{\widetilde{u}_R} >$ 90 GeV and $m_{\widetilde{d}_R} >$ 89 GeV). Supersedes the results from BARATE 00H.

[56] BREITWEG 01 searches for squark production in 47.7 pb^{-1} of e^+p collisions, mediated by $R\!\!\!/$ couplings $LQ\overline{D}$ and leading to final states with $\not\!\!\nu$ and $\geq$ 1 jet, complementing the e^+X final states of BREITWEG 00E. Limits are derived on $\lambda'\sqrt{\beta}$, where β is the branching fraction of the squarks into e^+q+$\overline{\nu}q$, as function of the squark mass, see their Fig. 15. The quoted mass limit assumes that only direct squark decays contribute.

[57] ABBOTT 00C searched in $\sim$ 94 pb^{-1} of $p\overline{p}$ collisions for events with $\mu\mu$+jets, originating from associated production of leptoquarks. The results can be interpreted as limits on production of squarks followed by direct $R\!\!\!/$ decay via $\lambda'_{2jk}L_2Q_jd^c_k$ couplings. Bounds are obtained on the cross section for branching ratios of 1 and of 1/2, see their Fig. 4. The former yields the limit on the $\widetilde{u}_L$. The latter is combined with the bound of ABBOTT 99J from the $\mu\nu$+jets channel and of ABBOTT 98E and ABBOTT 98J from the $\nu\nu$+jets channel to yield the limit on $\widetilde{d}_R$.

[58] ACCIARRI 00P studied the effect on hadronic cross sections of t-channel down-type squark exchange via R-parity violating coupling $\lambda'_{1jk}L_1Q_jd^c_k$. The limit here refers to the case j=1,2, and holds for λ'_{1jk}=0.3. Data collected at $\sqrt{s}$=130–189 GeV, superseding the results of ACCIARRI 98J.

[59] AFFOLDER 00K searched in $\sim$ 88 pb^{-1} of $p\overline{p}$ collisions for events with 2–3 jets, at least one being b-tagged, large $\not\!\!E_T$ and no high p_T leptons. Such $\nu\nu$+b-jets events would originate from associated production of squarks followed by direct $R\!\!\!/$ decay via $\lambda'_{ij3}L_iQ_jd^c_3$ couplings. Bounds are obtained on the production cross section assuming zero branching ratio to charged leptons.

[60] BARATE 00I studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating coupling $\lambda'_{1jk}L_1Q_jd^c_k$. The limit here refers to the case j=1,2, and holds for λ'_{1jk}=0.3. A 50 GeV limit is found for up-type squarks with k=3. Data collected at $\sqrt{s}$= 130–183 GeV. Superseded by SCHAEL 07A.

[61] BREITWEG 00E searches for squark exchange in e^+p collisions, mediated by $R\!\!\!/$ couplings $LQ\overline{D}$ and leading to final states with an identified e^+ and $\geq$ 1 jet. The limit applies to up-type squarks of all generations, and assumes B($\widetilde{q} \to qe$)=1.

[62] ABBOTT 99 searched for $\gamma\not\!\!E_T$ + $\geq$ 2 jet final states, and set limits on $\sigma(p\overline{p} \to \widetilde{q}$+X)·B($\widetilde{q} \to \gamma\not\!\!E_T$X). The quoted limits correspond to $m_{\widetilde{g}} \geq m_{\widetilde{q}}$, with B($\widetilde{\chi}^0_2 \to \widetilde{\chi}^0_1\gamma$)=1 and B($\widetilde{\chi}^0_1 \to \widetilde{G}\gamma$)=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\widetilde{G}$ decay) for $m_{\widetilde{g}}$=$m_{\widetilde{q}}$.

[63] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\widetilde{\chi}^0_1$ LSP via $R\!\!\!/\ LQ\overline{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the (m_0,$m_{1/2}$) plane under the assumption that A_0=0, μ < 0, tanβ=2 and any one of the couplings $\lambda'_{1jk} > 10^{-3}$ (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing tanβ or μ >0.

[64] ABBOTT 99L consider events with three or more jets and large $\not\!\!E_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses. See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\widetilde{q}}$ and $m_{\widetilde{g}}$.

[65] ABE 99M looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\widetilde{q} \to q\widetilde{\chi}^0_1$ and $\widetilde{\chi}^0_1 \to eq\overline{q}'$, assuming $R\!\!\!/$ coupling $L_1Q_jD^c_k$, with j=2,3 and k=1,2,3. They assume five degenerate squark flavors, B($\widetilde{q} \to q\widetilde{\chi}^0_1$)=1, B($\widetilde{\chi}^0_1 \to eq\overline{q}'$)=0.25 for both e^+ and e^-, and $m_{\widetilde{g}} \geq$ 200 GeV. The limit is obtained for $m_{\widetilde{\chi}^0_1} \geq m_{\widetilde{q}}/2$ and improves for heavier gluinos or heavier χ^0_1.

[66] ABREU 99G looked for events with an electron or neutrino and a jet in e^+e^- at 183 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute.

[67] ABBOTT 98E searched in $\sim$ 115 pb^{-1} of $p\overline{p}$ collisions for events with $e\nu$+jets, originating from associated production of squarks followed by direct $R\!\!\!/$ decay via $\lambda'_{1jk}L_1Q_jd^c_k$ couplings. Bounds are obtained by combining these results with the previous bound of ABBOTT 97B from the ee+jets channel and with a reinterpretation of ABACHI 96B $\nu\nu$+jets channel.

[68] ABE 98S looked in $\sim$ 110 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with $\mu\mu$+jets originating from associated production of squarks followed by direct $R\!\!\!/$ decay via $\lambda'_{2jk}L_2Q_jd^c_k$ couplings. Bounds are obtained on the production cross section times the square of the branching ratio, see Fig. 2. Mass limits result from the comparison with theoretical cross sections and branching ratio equal to 1 for $\widetilde{u}_L$ and 1/2 for $\widetilde{d}_R$.

[69] ACKERSTAFF 98V and ACCIARRI 98J studied the interference of t-channel squark ($\widetilde{d}_R$) exchange via R-parity violating $\lambda'_{1jk}L_1Q_jd^c_k$ coupling in $e^+e^- \to q\overline{q}$. The limit is for λ'_{1jk}=0.3. See paper for related limits on $\widetilde{u}_L$ exchange. Data collected at $\sqrt{s}$=130–172 GeV.

[70] BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+q \to \bar{e}\bar{q}$ via gaugino-like neutralino exchange with decays into ($e\widetilde{\chi}^0_1$)($q\widetilde{\chi}^0_1$). See paper for dependences in $m_{\widetilde{e}}$, $m_{\widetilde{\chi}^0_1}$.

[71] DATTA 97 argues that the squark mass bound by ABACHI 95C can be weakened by 10–20 GeV if one relaxes the assumption of the universal scalar mass at the GUT-scale so that the $\widetilde{\chi}^\pm_1$,$\widetilde{\chi}^0_2$ in the squark cascade decays have dominant and invisible decays to $\widetilde{\nu}$.

[72] DERRICK 97 looked for lepton-number violating final states via R-parity violating couplings $\lambda'_{ijk}L_iQ_jd_k$. When $\lambda'_{11k}\lambda'_{ijk} \neq 0$, the process $eu \to \widetilde{d}^*_k \to \ell_i u_j$ is possible. When $\lambda'_{1j1}\lambda'_{ijk} \neq 0$, the process $e\overline{d} \to \widetilde{u}^*_j \to \ell_i\overline{d}_k$ is possible. 100% branching

fraction $\tilde{q} \to \ell j$ is assumed. The limit quoted here corresponds to $\tilde{t} \to \tau q$ decay, with λ'=0.3. For different channels, limits are slightly better. See Table 6 in their paper.

[73] HEWETT 97 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{q} \to q\tilde{g}$) from ALITTI 93 quoted in "Limits for Excited q (q^*) from Single Production," ABE 96 in "SCALE LIMITS for Contact Interactions: $\Lambda(qqqq)$," and unpublished CDF, DØ bounds. The bound applies to the gluino mass of 5 GeV, and improves for lighter gluino. The analysis has gluinos in parton distribution function.

[74] TEREKHOV 97 improved the analysis of TEREKHOV 96 by including di-jet angular distributions in the analysis.

[75] AID 96C used positron+jet events with missing energy and momentum to look for $e^+q \to \tilde{e}\tilde{q}$ via neutralino exchange with decays into $(e\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. See the paper for dependences on $m_{\tilde{e}}$, $m_{\tilde{\chi}_1^0}$.

[76] TEREKHOV 96 reanalyzed the limits on possible resonances in di-jet mode ($\tilde{u} \to u\tilde{g}$) from ABE 95N quoted in "MASS LIMITS for g_A (axigluon)." The bound applies only to the case with a light gluino.

[77] ABACHI 95C assume five degenerate squark flavors with $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0$ $\mu = -250$ GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for m_{gluino} >547 GeV.

[78] ABE 95T looked for a cascade decay of five degenerate squarks into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu = -40$ GeV, $\tan\beta = 1.5$, and heavy gluinos, the range 50<$m_{\tilde{q}}$ (GeV)<110 is excluded at 90% CL. See the paper for details.

[79] ABE 92L assume five degenerate squark flavors and $m_{\tilde{q}_L} = m_{\tilde{q}_R}$. ABE 92L includes the effect of cascade decay, for a particular choice of parameters, $\mu = -250$ GeV, $\tan\beta = 2$. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\tilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10–20 GeV higher if $B(\tilde{q} \to q\tilde{\gamma}) = 1$. Limit assumes GUT relations between gaugino masses and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\tilde{\chi}_1^0} \approx m_{\tilde{g}}/6$. This last relation implies that as $m_{\tilde{g}}$ increases, the mass of $\tilde{\chi}_1^0$ will eventually exceed $m_{\tilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\tilde{g}}$ >410 GeV. m_{H^+}=500 GeV.

[80] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay $\tilde{q} \to q\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[81] NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

Long-lived $\tilde{q}$ (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L\cos\theta_q + \tilde{q}_R\sin\theta_q$.

The coupling to the Z^0 boson vanishes for up-type squarks when θ_u=0.98, and for down type squarks when θ_d=1.17.

[1] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{t}$ are excluded for masses up to 683 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[2] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{b}$ are excluded for masses up to 612 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[3] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on sbottom masses for the decay $\tilde{b} \to b\tilde{\chi}_1^0$, for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.

[4] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on stop masses for the decay $\tilde{t} \to t\tilde{\chi}_1^0$, for different lifetimes, and for a neutralino mass of 100 GeV, see their Table 6 and Fig 10.

[5] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{t}_1$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of stops as a function of mass in the cloud interaction model (see Fig. 8 and Table 6). In the charge-suppressed model, the limit decreases to 818 GeV.

[6] AALTONEN 09Z searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with direct production of a pair of charged massive stable particles identified by their TOF. No excess of events is observed over the expected background. The data are used to set a bound on the production cross section, and the result is compared with the pair production cross section of stable stops as a function of the $\tilde{t}$ mass, see their Fig. 2.

[7] HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for hadronizing stable squarks. Combining their results on searches for charged and neutral R-hadrons with JANOT 03, a lower limit of 15.7 GeV on the mass is obtained. Combining this further with the results of searches for tracks with anomalous ionization in data from 183 to 208 GeV yields the quoted bounds.

[8] ABREU 98P assumes that 40% of the squarks will hadronize into a charged hadron, and 60% into a neutral hadron which deposits most of its energy in hadron calorimeter. Data collected at $\sqrt{s}$=130–183 GeV.

$\tilde{b}$ (Sbottom) MASS LIMIT

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1 = \tilde{b}_L\cos\theta_b + \tilde{b}_R\sin\theta_b$. Coupling to the Z vanishes for $\theta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region $\lesssim$40 GeV is available in the literature at this time from e^+e^- collisions. In the Listings below, we use $\Delta m = m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0}$.

[1] CHATRCHYAN 13T searched in 11.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least two energetic jets and significant $\not\!\!E_T$, using the α_T variable to discriminate between processes with genuine and misreconstructed $\not\!\!E_T$. No significant excess above the Standard Model expectations is observed. Limits are set on sbottom masses in simplified models where the decay $\tilde{b} \rightarrow b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

[2] CHATRCHYAN 13V searched in 10.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two isolated same-sign dileptons and at least two b-jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the bottom mass in a simplified models where the decay $\tilde{b} \rightarrow t\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \rightarrow W^{\pm}\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\tilde{\chi}_1^{\pm}$, for $m_{\tilde{\chi}_1^0}$ = 50 GeV, see Fig. 4.

[3] AAD 12AN searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for scalar bottom quarks in events with large missing transverse momentum and two b-jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an R-parity conserving minimal supersymmetric scenario, assuming B($\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$) = 100%, see their Fig. 2.

[4] CHATRCHYAN 12AI looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two same-sign leptons (e, μ), but not necessarily same flavor, at least 2 b-jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in a simplified model for sbottom pair production, where the sbottom decays through $\tilde{b}_1 \rightarrow t\tilde{\chi}_1 W$, see Fig. 8.

[5] CHATRCHYAN 12BO searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for scalar bottom quarks in events with large missing transverse momentum and two b-jets in the final state. The data are found to be consistent with the Standard Model expectations. Limits are set in an R-parity conserving minimal supersymmetric scenario, assuming B($\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$) = 100%, see their Fig. 2.

[6] AALTONEN 10R searched in 2.65 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with $\not\!\!E_T$ and exactly two jets, at least one of which is b-tagged. The results are in agreement with the SM prediction, and a limit on the cross section of 0.1 pb is obtained for the range of masses 80 < $m_{\tilde{b}_1}$ < 280 GeV assuming that the sbottom decays exclusively to $b\tilde{\chi}_1^0$. The excluded mass region in the framework of conserved R_p is shown in a plane of ($m_{\tilde{b}_1}$, $m_{\tilde{\chi}_1^0}$), see their Fig.2.

[7] ABAZOV 10L looked in 5.2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 b-jets and $\not\!\!E_T$ from the production of $\tilde{b}_1\tilde{b}_1$. No evidence for an excess over the SM expectation is observed, and a limit on the cross section is derived under the assumption of 100% branching ratio. The excluded mass region in the framework of conserved R_p is shown in a plane of ($m_{\tilde{b}_1}$,$m_{\tilde{\chi}_1^0}$), see their Fig. 3b. The exclusion also extends to $m_{\tilde{\chi}_1^0}$ = 110 GeV for 160< $m_{\tilde{b}_1}$ < 200 GeV.

[8] ABULENCIA 06I searched in 156 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for multijet events with large $\not\!\!E_T$. They request at least 2 b-tagged jets and no isolated leptons. They investigate the production of gluinos decaying into $\tilde{b}_1 b$ followed by $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$. Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and gluinos, see their Fig.3.

[9] ACHARD 04 search for the production of $\tilde{b}\overline{\tilde{b}}$ in acoplanar b-tagged di-jet final states in the 192–209 GeV data. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99V.

[10] JANOT 04 reanalyzes $e^+e^- \rightarrow$ hadrons total cross section data with $\sqrt{s}$ = 20–209 GeV from PEP, PETRA, TRISTAN, SLC, and LEP and constrains the mass of $\tilde{b}_1$ assuming it decays quickly to hadrons.

[11] ABDALLAH 03M looked for $\tilde{b}$ pair production in events with acoplanar jets and $\not\!\!E$ at $\sqrt{s}$ = 189–208 GeV. The limit improves to 87 (98) GeV for all θ_b (θ_b = 0) for Δm > 10 GeV. See Fig. 24 and Table 11 for other choices of Δm. These limits include and update the results of ABREU,P 00D.

[12] ABBIENDI 02H search for events with two acoplanar jets and $\not\!\!p_T$ in the 161–209 GeV data. The limit assumes 100% branching ratio and uses the exclusion at large Δm from CDF (AFFOLDER 00D). For θ_b=0, the bound improves to > 96.9 GeV. See Fig. 4 and Table 6 for the more general dependence on the limits on Δm. These results supersede ABBIENDI 99M.

[13] HEISTER 02K search for bottom squarks in final states with acoplanar jets with b tagging, using 183–209 GeV data. The mass bound uses the CDF results from AFFOLDER 00D. See Fig. 5 for the more general dependence of the limits on Δm. Updates BARATE 01.

[14] SAVINOV 01 use data taken at $\sqrt{s}$=10.52 GeV, below the $B\overline{B}$ threshold. They look for events with a pair of leptons with opposite charge and a fully reconstructed hadronic D or D^* decay. These could originate from production of a light-sbottom hadron followed by $\bar{B} \rightarrow D^{(*)}\ell^-\bar{\nu}$, in case the $\tilde{\nu}$ is the LSP, or $\bar{B} \rightarrow D^{(*)}\pi\ell^-$, in case of $\not{R}$. The mass range 3.5 ≤ $M(\bar{B})$ ≤ 4.5 GeV was explored, assuming 100% branching ratio for either of the decays. In the $\tilde{\nu}$LSP scenario, the limit holds only for $M(\tilde{\nu})$ less than about 1 GeV and for the D^* decays it is reduced to the range 3.9–4.5 GeV. For the $\not{R}$ decay, the whole range is excluded.

[15] AFFOLDER 00D search for final states with 2 or 3 jets and $\not\!\!E_T$, one jet with a b tag. See their Fig. 3 for the mass exclusion in the $m_{\tilde{t}}$, $m_{\tilde{\chi}_1^0}$ plane.

[16] AAD 13AU searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks. Assuming that the decay $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$ takes place 100% of the time, a $\tilde{b}_1$ mass below 620 GeV is excluded for $m_{\tilde{\chi}_1^0}$ < 120 GeV. For more details, see their Fig. 5.

[17] CHATRCHYAN 13AT provides interpretations of various searches for supersymmetry by the CMS experiment based on 4.73–4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV in the framework of simplified models. Limits are set on the sbottom mass in a simplified models where sbottom quarks are pair-produced and the decay $\tilde{b} \rightarrow b\tilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 4.

[18] AAD 11K looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of $\tilde{b}$. No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of sbottom, see Fig. 4.

[19] AAD 11O looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with jets, of which at least one is a b-jet, and $\not\!\!E_T$. No excess above the Standard Model was found. Limits are derived in the ($m_{\tilde{g}}$, $m_{\tilde{b}_1}$) plane (see Fig. 2) under the assumption of 100% branching ratios and $\tilde{b}_1$ being the lightest squark. The quoted limit is valid for $m_{\tilde{b}_1}$ < 500 GeV. A similar approach for $\tilde{t}_1$ as the lightest squark with $\tilde{g} \rightarrow \tilde{t}_1 t$ and $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^{\pm}$ with 100% branching ratios leads to a gluino mass limit of 520 GeV for 130 < $m_{\tilde{t}_1}$ < 300 GeV. Limits are also derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 40, see Fig. 4, and in scenarios based on the gauge group SO(10).

[20] CHATRCHYAN 11D looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with ≥ 2 jets, at least one of which is b-tagged, and $\not\!\!E_T$, where the b-jets are decay products of $\tilde{t}$ or $\tilde{b}$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 50 (see Fig. 2).

[21] AALTONEN 09R searched in 2.5 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 b-tagged jets and $\not\!\!E_T$, originating from the decay $\tilde{g} \rightarrow b\tilde{b}$ followed by $\tilde{b} \rightarrow b\tilde{\chi}_1^0$. Both decays are assumed to have 100% branching ratio. No significant deviation from the SM prediction is observed. An upper limit on the gluino pair production cross section is calculated as a function of the gluino mass, see their Fig. 2. A limit is derived in the $m_{\tilde{b}}$ versus $m_{\tilde{g}}$ plane which improves the results of previous searches, see their Fig. 3.

[22] AALTONEN 07E searched in 295 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for multijet events with large $\not\!\!E_T$. They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom versus $\tilde{\chi}_1^0$, see their Fig. 5. Superseded by AALTONEN 10R.

[23] ABAZOV 06R looked in 310 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with 2 or 3 jets and large $\not\!\!E_T$ with at least 1 b-tagged jet and a veto against isolated leptons. No excess is observed relative to the SM background expectations. Limits are set on the sbottom pair production cross-section under the assumption that the only decay mode is into $b\tilde{\chi}_1^0$. Exclusion contours are derived in the plane of sbottom versus neutralino masses, shown in their Fig. 2. The observed limit is more constraining than the expected one due to a lack of events corresponding to large sbottom masses. Superseded by ABAZOV 10L.

[24] ABDALLAH 04M use data from $\sqrt{s}$ = 192–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $\overline{UDD}$ couplings. The results are valid for μ = −200 GeV, tanβ = 1.5, Δm > 5 GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect $\overline{UDD}$ decays using the neutralino constraint of 38.0 GeV, also derived in ABDALLAH 04M, and assumes no mixing. For indirect decays it remains at 78 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 01D.

[25] ABDALLAH 03C looked for events of the type $q\overline{q}R^{\pm}R^{\pm}$, $q\overline{q}R^{\pm}R^0$, or $q\overline{q}R^0R^0$ in e^+e^- interactions at $\sqrt{s}$ = 189–208 GeV. The $R^{\pm}$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy due to their reduced energy loss in the calorimeters. Excluded mass regions in the (m($\tilde{b}$), m($\tilde{g}$)) plane for m($\tilde{g}$) > 2 GeV are obtained for several values of the probability for the gluino to fragment into $R^{\pm}$ or R^0, as shown in their Fig. 19. The limit improves to 94 GeV for θ_b=0.

[26] BERGER 03 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from radiative decays of Υ(nS) into sbottomonium. The constraints apply only if $\tilde{b}_1$ lives long enough to permit formation of the sbottomonium bound state. A small region of mass in the $m_{\tilde{b}_1} - m_{\tilde{g}}$ plane survives current experimental constraints from CLEO.

[27] HEISTER 03G searches for the production of $\tilde{b}$ pairs in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s}$ = 189–209 GeV. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings. It improves to 90 GeV for indirect decays mediated by $\not{R}$ $LL\overline{E}$ couplings and to 80 GeV for indirect decays mediated by $\not{R}$ $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B.

[28] HEISTER 03H use their results on bounds on stable squarks, on stable gluinos and on squarks decaying to a stable gluino from the same paper to derive a mass limit on $\tilde{b}$, see their Fig. 13. The limit for a long-lived $\tilde{b}_1$ is 92 GeV.

[29] ACHARD 02 searches for the production of squarks in the case of $\not{R}$ prompt decays with $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for indirect decays and reaches 55 GeV for direct decays.

[30] BAEK 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. It is noted that CP-violating couplings in the MSSM parameters relax the strong constraints otherwised derived from CP conservation.

[31] BECHER 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from radiative B meson decays, and sets limits on the off-diagonal flavor-changing couplings $qb\tilde{g}$ (q=d,s).

[32] CHEUNG 02B studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.

[33] CHO 02 studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. Strong constraints are obtained for CP-conserving MSSM couplings.

[34] BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos (m∼ 12–16 GeV) with subsequent 2-body decay into a light sbottom (m∼ 2–5.5 GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must

either decay hadronically via a R-parity- and B-violating interaction, or be long-lived. Constraints on the mass spectrum are derived from the measurements of time-averaged B^0-$\overline{B}^0$ mixing.

[35] ABBOTT 99F looked for events with two jets, with or without an associated muon from b decay, and $\not{E}_T$. See Fig. 2 for the dependence of the limit on $m_{\widetilde{\chi}^0_1}$. No limit for $m_{\widetilde{\chi}^0_1} > 47$ GeV. Superseded by ABAZOV 06R.

$\widetilde{t}$ (Stop) MASS LIMIT

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\widetilde{t}_1 = \widetilde{t}_L \cos\theta_t + \widetilde{t}_R \sin\theta_t$. The coupling to the Z vanishes when $\theta_t = 0.98$. In the Listings below, we use $\Delta m \equiv m_{\widetilde{t}_1} - m_{\widetilde{\chi}^0_1}$ or $\Delta m \equiv m_{\widetilde{t}_1} - m_{\widetilde{\nu}}$, depending on relevant decay mode. See also bounds in "$\widetilde{q}$ (Squark) MASS LIMIT." Limits made obsolete by the most recent analyses of e^+e^- and $p\overline{p}$ collisions can be found in previous Editions of this *Review*.

[1] AAD 13T searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for pair production of light $\widetilde{t}_1$ squarks with masses similar to, or lighter than, the top quark mass. Final states containing exclusively one or two leptons (electrons or muons), large missing transverse momentum, light jets and b-jets are used to reconstruct the top squark pair system. The $\widetilde{t}_1$ is assumed to decay through $\widetilde{t}_1 \to b\widetilde{\chi}^\pm_1$ with a 100 % branching ratio. The chargino is then assumed to decay through a virtual W boson, $\widetilde{\chi}^\pm_1 \to W^*\widetilde{\chi}^0_1$. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a simplified model as a function of $m_{\widetilde{t}_1}$ and $m_{\widetilde{\chi}^0_1}$, for either $m_{\widetilde{\chi}^\pm_1} = 2\, m_{\widetilde{\chi}^0_1}$ or for a fixed choice of $m_{\widetilde{\chi}^\pm_1} = 106$ GeV, see Fig. 2. Assuming $m_{\widetilde{\chi}^\pm_1} = 106$ GeV, $\widetilde{t}_1$ masses between 123 and 167 GeV are excluded at 95% C.L for $m_{\widetilde{\chi}^0_1} = 55$ GeV.

[2] CHATRCHYAN 13BS searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with a single isolated lepton, hadronic jets, large $\not{E}_T$, and large transverse mass. No significant excess above the Standard Model expectations is observed. Limits are set on stop masses in simplified models where the decay $\widetilde{t} \to t\widetilde{\chi}^0_1$ takes place with a branching ratio which has been varied between 50% and 100%, see Fig. 12, and where the decay $\widetilde{t} \to b\widetilde{\chi}^\pm_1$, $\widetilde{\chi}^\pm_1 \to W^\pm\widetilde{\chi}^0_1$ takes place with a branching ratio of 100%, with varying intermediate mass of the $\widetilde{\chi}^\pm_1$, see Fig. 11.

[3] AAD 12AH searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for pair production of $\widetilde{t}_1$ in events with two same-flavor, opposite-sign leptons (e or μ) with invariant mass consistent with the Z boson, large missing transverse momentum and jets in the final state. At least one of the jets is identified as originating from a b-quark. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a GMSB scenario where the $\widetilde{\chi}^0_1$ is the NLSP and is purely higgsino-like. Other model parameters are $\tan\beta = 10$, $m_{\widetilde{u}_3} = m_{\widetilde{q}_3} = -A_t/2$. Scalar top masses below 240 GeV are excluded for all values of $m_{\widetilde{\chi}^0_1} > m_Z$.

[4] AAD 12CB searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for pair production of $\widetilde{t}_1$ in events with two opposite-sign leptons (electrons or muons), jets, and $\not{E}_T$. The $\widetilde{t}_1$ is assumed to decay through $\widetilde{t}_1 \to t\widetilde{\chi}^0_1$ with a 100% branching ratio. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a simplified model as a function of $m_{\widetilde{t}_1}$ and $m_{\widetilde{\chi}^0_1}$, see Fig. 2. Assuming a massless $\widetilde{\chi}^0_1$, a $\widetilde{t}_1$ with a mass of 300 GeV is excluded at 95% C.L.

[5] AAD 12CE searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for pair production of $\tilde{t}_1$ where $\tilde{t}_1 \to t\tilde{\chi}_1^0$ with a 100 % branching ratio and where both tops decay hadronically. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a simplified model as a function of $m_{\tilde{t}_1}$ and $m_{\tilde{\chi}_1^0}$, see Fig. 4. For a massless $\tilde{\chi}_1^0$, masses of $\tilde{t}_1$ between 370 GeV and 465 GeV are excluded at 95% C.L. The upper limit deteriorates to 445 GeV for $m_{\tilde{\chi}_1^0} < 50$ GeV.

[6] AAD 12CF searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for pair production of $\tilde{t}_1$ in events with one isolated electron or muon, jets, and $\not{E}_T$. The $\tilde{t}_1$ is assumed to decay through $\tilde{t}_1 \to t\tilde{\chi}_1^0$ a 100 % branching ratio. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a simplified model as a function of $m_{\tilde{t}_1}$ and $m_{\tilde{\chi}_1^0}$, see Fig. 2. For a massless $\tilde{\chi}_1^0$, masses of $\tilde{t}_1$ between 230 GeV and 440 GeV are excluded at 95% C.L. The upper limit deteriorates to 400 GeV for $m_{\tilde{\chi}_1^0} < 125$ GeV and the lower limit is increased to about 330 GeV.

[7] AAD 12CL searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for pair production of $\tilde{t}_1$ in events with two opposite-sign leptons (electrons or muons), jets, and $\not{E}_T$. The $\tilde{t}_1$ is assumed to decay through $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ with a 100 % branching ratio. The chargino is then assumed to decay through a virtual W boson, $\tilde{\chi}_1^\pm \to W^*\tilde{\chi}_1^0$. The data are found to be consistent with the Standard Model expectations. The results are interpreted in a simplified model as a function of $m_{\tilde{t}_1}$ and $m_{\tilde{\chi}_1^0}$ for a fixed choice of $m_{\tilde{\chi}_1^\pm} = 106$ GeV, see Fig. 2. Assuming $m_{\tilde{\chi}_1^\pm}$=106 GeV, $\tilde{t}_1$ masses below 130 GeV are excluded at 95% C.L. for $m_{\tilde{\chi}_1^0} < 70$ GeV.

[8] AAD 12J looked in 2.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for evidence of lepton flavor violating interactions in the $e\mu$ continuum due to a t-channel exchange of an R-parity violating scalar top quark. No deviations from the SM expectations were found. Limits on R-parity violating couplings are calculated as a function of the scalar stop mass, see their Fig. 4b.

[9] AALTONEN 12AO searched in 2.6 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events containing $\not{E}_T$ and at least two jets, of which at least one is identified as originating from a charm quark. No excess over the expected SM background is observed. Limits are set on the production of $\tilde{t}_1$ in the assumption that the only decay model is into $c\tilde{\chi}_1^0$ and for $m_{\tilde{\chi}_1^0}$ = 90 GeV, see Fig. 2. According to Fig. 2 there is an exclusion gap from 100–130 GeV.

[10] ABAZOV 12H looked in 7.3 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events containing one muon, one tau decaying hadronically, at least one jet, and missing transverse energy. No evidence for an excess over the SM expectation is observed and 95% C.L. limits are set in the plane ($m_{\tilde{t}_1}$, $m_{\tilde{\nu}}$), see their Fig. 5 (where B($\tilde{t}_1 \to b\mu\tilde{\nu}$) = B($\tilde{t}_1 \to b\tau\tilde{\nu}$) = 1/3) and Fig. 6 (where B($\tilde{t}_1 \to b\mu\tilde{\nu}$) = 0.1 and B($\tilde{t}_1 \to b\tau\tilde{\nu}$) = 0.8).

[11] ABAZOV 12L looked in 5.2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for charged massive long-lived particles in events in which one or more particles are reconstructed as muons but have speed and ionization energy loss inconsistent with muons produced in beam collisions. Long-lived stops with mass below 285 GeV are excluded at 95% C.L, using the nominal value of the NLO production cross section. For the latter, a charge survival probability of 38% has been assumed

[12] ABAZOV 11N looked in 5.4 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with exactly one e and μ and $\not{E}_T$ from the production of $\tilde{t}_1\tilde{t}_1$. No evidence for an excess over the SM expectation is observed, and a limit is derived in a plane of ($m_{\tilde{t}_1}$, $m_{\tilde{\nu}}$), see their Fig. 4, under the assumption of 100% branching ratio for $\tilde{t}_1 \to b\ell\tilde{\nu}$.

[13] AALTONEN 10Y searched in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with an oppositely charged lepton pair (e or μ), $\not{E}_T$ and at least one jet. A limit is derived on the cross section assuming 100% branching ratio of $\tilde{t}_1 \to b\ell\tilde{\nu}$ and an invisible $\tilde{\nu}$, see their Fig. 10. In Fig. 11, the exclusion contour is shown in the plane of ($m_{\tilde{t}_1}$,$m_{\tilde{\nu}}$).

[14] ABAZOV 08Z looked in 995 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with exactly 2 jets, at least one being tagged as heavy quark, and $\not{E}_T$, originating from stop pair production. Branching ratios are assumed to be 100% for $\tilde{t}_1 \to c\tilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{t}}$ versus $m_{\tilde{\chi}_1^0}$, see their Fig. 5. No limit can be obtained for $m_{\tilde{\chi}_1^0} > 70$ GeV. Supersedes the results of ABAZOV 07B.

[15] ABAZOV 04 looked at 108.3pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.8 TeV for events with e+μ+$\not{E}_T$ as signature for the 3- and 4-body decays of stop into $b\ell\nu\tilde{\chi}^0$ final states. For the $b\ell\tilde{\nu}$ channel they use the results from ABAZOV 02C. No significant excess is observed compared to the Standard Model expectation and limits are derived on the mass of $\tilde{t}_1$ for the 3- and 4-body decays in the ($m_{\tilde{t}}$, $m_{\tilde{\chi}^0}$) plane, see their Figure 4.

[16] ACHARD 04 search in the 192–209 GeV data for the production of $\tilde{t}\,\overline{\tilde{t}}$ in acoplanar di-jet final states and, in case of $b\ell\tilde{\nu}$ ($b\tau\tilde{\nu}$) final states, two leptons (taus). The limits for θ_t= 0 improve to 95, 96 and 93 GeV, respectively. All limits assume 100% branching ratio for the respective decay modes. See Fig. 6 for the dependence of the limits on $m_{\tilde{\chi}_1^0}$. These limits supersede ACCIARRI 99V.

[17] ABDALLAH 03M looked for $\tilde{t}$ pair production in events with acoplanar jets and $\not{E}$ at $\sqrt{s}$ = 189–208 GeV. See Fig. 23 and Table 11 for other choices of Δm. These limits include and update the results of ABREU,P 00D.

[18] ABBIENDI 02H looked for events with two acoplanar jets, $\not{p}_T$, and, in the case of $b\ell\tilde{\nu}$ final states, two leptons, in the 161–209 GeV data. The bound for $c\tilde{\chi}_1^0$ applies to the region where $\Delta m < m_W + m_b$, else the decay $\tilde{t}_1 \to b\tilde{\chi}_1^0 W^+$ becomes dominant. The limit for $b\ell\tilde{\nu}$ assumes equal branching ratios for the three lepton flavors and for $b\tau\tilde{\nu}$ 100% for this channel. For θ_t=0, the bounds improve to > 97.6 GeV ($c\tilde{\chi}_1^0$), > 96.0 GeV ($b\ell\tilde{\nu}$), and > 95.5 ($b\tau\tilde{\nu}$). See Figs. 5–6 and Table 5 for the more general dependence of the limits on Δm. These results supersede ABBIENDI 99M.

[19] HEISTER 02K search for top squarks in final states with jets (with/without b tagging or leptons) or long-lived hadrons, using 183–209 GeV data. The absolute mass bound is obtained by varying the branching ratio of $\tilde{t} \to c\tilde{\chi}_1^0$ and the lepton fraction in $\tilde{t} \to b\tilde{\chi}_1^0 f\overline{f}'$ decays. The mass bound for $\tilde{t} \to c\tilde{\chi}_1^0$ uses the CDF results from AFFOLDER 00D and for $\tilde{t} \to b\ell\tilde{\nu}$ the DØ results from ABAZOV 02C. See Figs. 2–5 for the more general dependence of the limits on Δm. Updates BARATE 01 and BARATE 00P.

[20] AAD 13AU searched in 20.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing two jets identified as originating from b-quarks and large missing transverse momentum. No excess of events above the expected level of Standard Model background was found. Exclusion limits at 95% C.L. are set on the masses of third-generation squarks. Assuming that the decay $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ takes place 100% of the time, a $\tilde{t}_1$ mass below 580 GeV (440 GeV) is excluded for Δm = $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ = 5 GeV (20 GeV) and for $m_{\tilde{\chi}_1^0}$ = 100 GeV. For more details, see their Fig. 6.

[21] CHATRCHYAN 13BN searched in 19.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with three or more isolated leptons and b-quark jets. No excess above the Standard Model expectations is observed. Limits are set on stop masses in $R\!\!\!/$ SUSY models with leptonic $LL\overline{E}$ couplings, see Fig. 2. Also limits have been set in a model with $LQ\overline{D}$ couplings.

[22] CHATRCHYAN 13M searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing an isolated electron or muon, a hadronically decaying τ lepton and two b-quark jets. No excess above the Standard Model expectations is observed. Limits are set on stop masses in $R\!\!\!/$ SUSY models with $L_3Q_3D_3$ couplings, see Fig. 2. In a simplified model where the decay $\tilde{t}_1 \to \tau b$ takes place with a branching ratio of 100%, stop masses below 525 GeV are excluded at 95% C.L.

[23] HAN 13 used combined ATLAS results based on 20.1 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV to derive 95% C.L. exclusion limits on the stop mass in the framework of natural SUSY in the MSSM, after considering the constraints from the Higgs mass, B-physics, and electroweak precision measurements.

[24] CHATRCHYAN 12AN looked in 4.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with pair production of long-lived stops. The hadronization of the stops leads to R-hadrons which may stop inside the detector and later decay via $\tilde{t} \to t\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of $m_{\tilde{t}}$ is derived, see Fig. 4. The mass limit is valid for lifetimes between 10^{-5} and 10^3 seconds, for what they call "the daughter top energy E_t >" 125 GeV and assuming the *cloud* interaction model for R-hadrons. Supersedes KHACHATRYAN 11.

[25] CHATRCHYAN 12L looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{t}_1$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of stops as a function of mass (see Fig. 3). In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 626 GeV. Supersedes KHACHATRYAN 11C.

[26] AAD 11K looked in 34 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of $\tilde{t}$. No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of stop, see Fig. 4.

[27] KHACHATRYAN 11C looked in 3.1 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the muon chambers, from pair production of $\tilde{t}_1$. No evidence for an excess over the expected background is observed. Limits are derived for pair production of stop as a function of mass, see Fig. 3, and compared to the production cross section in a benchmark scenario.

[28] AALTONEN 10O searched in 2.7 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with a charged lepton pair (e or μ), $\not{E}_T$ and at least two jets. A fit of the data is made to the $\tilde{t}_1\,\overline{\tilde{t}}_1$ hypothesis. Assuming a 100% branching ratio of $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$, the exclusion is independent of the value of the $\tilde{\chi}_1^\pm \to \ell\tilde{\chi}_1^0\nu$ branching ratio.

[29] ABAZOV 09N looked in 0.9 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with $\geq$ 3 jets, at least one being b-tagged, one electron or muon and $\not{E}_T$ originating from associated production $\tilde{t}\,\overline{\tilde{t}}$, with one $\tilde{t}$ decaying leptonically, the other hadronically. The branching ratios for $\tilde{t}_1 \to b\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^\pm \to \tilde{\chi}_1^0 W^\pm$ are assumed to be 100%. The separation from the dominant $t\overline{t}$ background is based on a multivariate likelihood discriminant analysis. The tested mass range is 130 GeV $\leq m_{\tilde{t}} \leq$ 190 GeV, 90 GeV $\leq m_{\tilde{\chi}_1^\pm} \leq$ 150 GeV and $m_{\tilde{\chi}_1^0}$ = 50 GeV fixed. The excluded cross section is a factor 2–13 larger than the theoretical expectation in the considered MSSM scenarios, see their Fig. 3.

[30] ABAZOV 09O looked in 1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with two electrons or one electron and one muon and $\not{E}_T$ originating from associated production $\tilde{t}\,\overline{\tilde{t}}$, followed by the three-body decays $\tilde{t} \to b\ell\tilde{\nu}$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{\nu}}$ versus $m_{\tilde{t}}$, see their Fig. 3. The largest excluded $\tilde{t}$ mass is 175 GeV for a $\tilde{\nu}$ mass of 45 GeV, and the largest excluded $\tilde{\nu}$ mass is 96 GeV for a $\tilde{t}$ mass of 140 GeV. Superseded by ABAZOV 11N.

[31] AALTONEN 08Z searched in 322 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for dijet events with a lepton (e or μ) and a hadronic τ decay produced via R-parity violating couplings $LQ\overline{D}$. No heavy flavour-tagged jets are requested. No significant excess was found compared to the background expectation. Upper limits on the cross-section times the square of the branching ratio B($\tilde{t}_1 \to b\tau$) are extracted, and a limit is derived on the stop mass assuming B($\tilde{t}_1 \to b\tau$) = 1, see their Fig. 2. Supersedes the results of ACOSTA 04B.

[32] ABAZOV 08 looked at approximately 400 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with $b\overline{b}\ell\ell'\not{E}_T$ with $\ell\ell' = e^\pm\mu^\mp$ or $\ell\ell' = \mu^+\mu^-$, originating from associated production $\tilde{t}\,\overline{\tilde{t}}$. Branching ratios are assumed to be 100% for both $\tilde{\chi}_1^\pm \to \ell\tilde{\nu}$ and $\tilde{\nu} \to \nu\tilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\tilde{\nu}}$ versus $m_{\tilde{t}}$, see their Fig.3. Superseded by ABAZOV 09O.

[33] AALTONEN 07E searched in 295 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for multijet events with large $\not{E}_T$. They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\tilde{t}_1 \to c\tilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of stop versus $\tilde{\chi}_1^0$, see their Fig. 4.

[34] ABAZOV 07B looked in 360 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with a pair of acoplanar heavy-flavor jets with $\not{E}_T$. No excess is observed relative to the SM background expectations. Limits are set on the production of $\tilde{t}_1$ under the assumption that the only decay mode is into $c\tilde{\chi}_1^0$, see their Fig. 4 for the limit in the ($m_{\tilde{t}}$,

$m_{\widetilde{\chi}^0_1}$) plane. No limit can be obtained for $m_{\widetilde{\chi}^0_1} > 54$ GeV. Supersedes the results of ABAZOV 04B.

[35] CHEKANOV 07 search for the $LQ\overline{D}$ R-parity violating process $e^+p \to \widetilde{t}_1$ in 65 pb^{-1} at 318 GeV. Final states may originate from $LQ\overline{D}$ couplings $\widetilde{t} \to e^+d$ and from the R-parity conserving decay $\widetilde{t} \to \widetilde{\chi}^+b$, giving rise to e + jet, e + multi-jet, and ν + multi-jet. The excluded region in an MSSM scenario is presented for λ'_{131} as a function of the stop mass in Fig. 6. Other excluded regions in a more restricted mSUGRA model are shown in Fig. 7 and 8.

[36] ABBIENDI 04F use data from $\sqrt{s} = 189$–209 GeV. They derive limits on the stop mass under the assumption of $\not{R}$ with $LQ\overline{D}$ or $\overline{UDD}$ couplings. The limit quoted applies to direct decays with $\overline{UDD}$ couplings when the stop decouples from the Z^0 and improves to 88 GeV for $\theta_t = 0$. For $LQ\overline{D}$ couplings, the limit improves to 98 (100) GeV for λ'_{13k} or λ'_{23k} couplings and all θ_t ($\theta_t = 0$). For λ'_{33k} couplings it is 96 (98) GeV for all θ_t ($\theta_t = 0$). Supersedes the results of ABBIENDI 00.

[37] ABDALLAH 04M use data from $\sqrt{s} = 192$–208 GeV to derive limits on sparticle masses under the assumption of $\not{R}$ with $LL\overline{E}$ or $\overline{UDD}$ couplings. The results are valid for $\mu = -200$ GeV, $\tan\beta = 1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for decoupling of the stop from the Z^0 and indirect $\overline{UDD}$ decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for $\overline{UDD}$ couplings, also derived in ABDALLAH 04M. For no mixing (decoupling) and indirect decays via $LL\overline{E}$ the limit improves to 92 (87) GeV if the constraint from the neutralino is used and to 88 (81) GeV if it is not used. For indirect decays via $\overline{UDD}$ couplings it improves to 87 GeV for no mixing and using the constraint from the neutralino, whereas it becomes 81 GeV (67) GeV for no mixing (decoupling) if the neutralino constraint is not used. Supersedes the result of ABREU 01D.

[38] AKTAS 04B looked in 106 pb^{-1} of $e^\pm p$ collisions at $\sqrt{s} = 319$ GeV and 301 GeV for resonant production of $\widetilde{t}_1$ by R-parity violating $LQ\overline{D}$ couplings couplings with λ'_{131}, others being zero. They consider the decays $\widetilde{t}_1 \to e^+d$ and $\widetilde{t}_1 \to W\widetilde{b}$ followed by $\widetilde{b} \to \overline{\nu}_e d$ and assume gauginos too heavy to participate in the decays. They combine the channels $je\not{p}_T$, $j\mu\not{p}_T$, $jj\not{p}_T$ to derive limits in the plane ($m_{\widetilde{t}}$, λ'_{131}), see their Fig. 5.

[39] DAS 04 reanalyzes AFFOLDER 00G data and obtains constraints on $m_{\widetilde{t}_1}$ as a function of B($\widetilde{t} \to b\ell\nu\chi^0$)×B($\widetilde{t} \to b\overline{q}q'\chi^0$), B($\widetilde{t} \to c\chi^0$) and m_{χ^0}. Bound weakens for larger B($\widetilde{t} \to c\chi^0$) and m_{χ^0}.

[40] ABDALLAH 03C looked for events of the type $q\overline{q}R^\pm R^\pm$, $q\overline{q}R^\pm R^0$ or $q\overline{q}R^0R^0$ in e^+e^- interactions at $\sqrt{s} = 189$–208 GeV. The $R^\pm$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. Excluded mass regions in the ($m(\widetilde{t})$, $m(\widetilde{g})$) plane for $m(\widetilde{g}) > 2$ GeV are obtained for several values of the probability for the gluino to fragment into $R^\pm$ or R^0, as shown in their Fig. 18. The limit improves to 90 GeV for $\theta_t = 0$.

[41] ACOSTA 03C searched in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for pair production of $\widetilde{t}$ followed by the decay $\widetilde{t} \to b\ell\widetilde{\nu}$. They looked for events with two isolated leptons (e or μ), at least one jet and $\not{E}_T$. The excluded mass range is reduced for larger $m_{\widetilde{\nu}}$, and no limit is set for $m_{\widetilde{\nu}} > 88.4$ GeV (see Fig. 2). Superseded by AALTONEN 10Y.

[42] Theoretical analysis of e^+e^-+2 jet final states from the RPV decay of $t\overline{t}^*$ pairs produced in $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. 95%CL limits of 220 (165) GeV are derived for B($\widetilde{t} \to eq$)=1 (0.5).

[43] HEISTER 03G searches for the production of $\widetilde{t}$ pairs in the case of $\not{R}$ prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or $\overline{UDD}$ couplings at $\sqrt{s} = 189$–209 GeV. The limit holds for indirect decays mediated by $\not{R}$ $\overline{UDD}$ couplings. It improves to 91 GeV for indirect decays mediated by $\not{R}$ $LL\overline{E}$ couplings, to 97 GeV for direct (assuming B($\widetilde{t}_L \to q\tau$) = 100%) and to 85 GeV for indirect decays mediated by $\not{R}$ $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B.

[44] HEISTER 03H use e^+e^- data from 183–208 GeV to look for the production of stop decaying into a c quark and a stable gluino hadronizing into charged or neutral R-hadrons. Combining these results with bounds on stable squarks and on a stable gluino LSP from the same paper yields the quoted limit. See their Fig. 13 for the dependence of the mass limit on the gluino mass and on θ_t.

[45] ABAZOV 02C looked in 108.3pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with $e\mu\not{E}_T$, originating from associated production $\widetilde{t}\,\overline{\widetilde{t}}$. Branching ratios are assumed to be 100%. The bound for the $b\ell\widetilde{\nu}$ decay weakens for large $\widetilde{\nu}$ mass (see Fig. 3), and no limit is set when $m_{\widetilde{\nu}} > 85$ GeV. See Fig. 4 for the limits in case of decays to a real $\widetilde{\chi}^\pm_1$, followed by $\widetilde{\chi}^\pm_1 \to \ell\widetilde{\nu}$, as a function of $m_{\widetilde{\chi}^\pm_1}$.

[46] ACHARD 02 searches for the production of squarks in the case of $\not{R}$ prompt decays with $\overline{UDD}$ couplings at $\sqrt{s}$=189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for both direct and indirect decays.

[47] AFFOLDER 01B searches for decays of the top quark into stop and LSP, in $t\overline{t}$ events. Limits on the stop mass as a function of the LSP mass and of the decay branching ratio are shown in Fig. 3. They exclude branching ratios in excess of 45% for SLP masses up to 40 GeV.

[48] ABREU 00I searches for the production of stop in the case of R-parity violation with $LL\overline{E}$ couplings, for which only indirect decays are allowed. They investigate topologies with jets plus leptons in data from $\sqrt{s}$=183 GeV. The lower bound on the stop mass assumes a neutralino mass limit of 27 GeV, also derived in ABREU 00I.

[49] AFFOLDER 00D search for final states with 2 or 3 jets and $\not{E}_T$, one jet with a c tag. See their Fig. 2 for the mass exclusion in the ($m_{\widetilde{t}}$,$m_{\widetilde{\chi}^0_1}$) plane. The maximum excluded $m_{\widetilde{t}}$ value is 119 GeV, for $m_{\widetilde{\chi}^0_1}$= 40 GeV.

[50] AFFOLDER 00G searches for $\widetilde{t}_1\,\overline{\widetilde{t}}^*_1$ production, with $\widetilde{t}_1 \to b\ell\widetilde{\nu}$, leading to topologies with ≥ 1 isolated lepton (e or μ), $\not{E}_T$, and ≥ 2 jets with ≥ 1 tagged as b quark by a secondary vertex. See Fig. 4 for the excluded mass range as a function of $m_{\widetilde{\nu}}$. Cross-section limits for $\widetilde{t}_1\,\overline{\widetilde{t}}^*_1$, with $\widetilde{t}_1 \to b\chi^\pm_1$ ($\chi^\pm_1 \to \ell^\pm\nu\widetilde{\chi}^0_1$), are given in Fig. 2. Superseded by AALTONEN 10Y.

[51] ABE 99M looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\widetilde{q} \to q\widetilde{\chi}^0_1$ and $\widetilde{\chi}^0_1 \to eq\overline{q}'$, assuming $\not{R}$ coupling $L_1Q_jD^c_k$, with j=2,3 and k=1,2,3. They assume B($\widetilde{t}_1 \to c\widetilde{\chi}^0_1$)=1, B($\widetilde{\chi}^0_1 \to eq\overline{q}'$)=0.25 for both e^+ and e^-, and $m_{\widetilde{\chi}^0_1} \geq m_{\widetilde{t}_1}/2$. The limit improves for heavier $\widetilde{\chi}^0_1$.

[52] AID 96 considers photoproduction of $\widetilde{t}\,\overline{\widetilde{t}}$ pairs, with 100% R-parity violating decays of $\widetilde{t}$ to eq, with q=d, s, or b quarks.

[53] AID 96 considers production and decay of $\widetilde{t}$ via the R-parity violating coupling $\lambda' L_1 Q_3 d^c_1$.

[54] CHO 96 studied the consistency among the B^0-$\overline{B}^0$ mixing, ϵ in K^0-$\overline{K}^0$ mixing, and the measurements of V_{cb}, V_{ub}/V_{cb}. For the range 25.5 GeV<$m_{\widetilde{t}_1}$ <$m_Z/2$ left by AKERS 94K for $\theta_t = 0.98$, and within the allowed range in M_2-μ parameter space from chargino, neutralino searches by ACCIARRI 95E, they found the scalar top contribution to B^0-$\overline{B}^0$ mixing and ϵ to be too large if $\tan\beta$ <2. For more on their assumptions, see the paper and their reference 10.

[55] BUSKULIC 95E looked for $Z \to \widetilde{t}\,\overline{\widetilde{t}}$, where $\widetilde{t} \to c\chi^0_1$ and χ^0_1 decays via R-parity violating interactions into two leptons and a neutrino.

[56] SHIRAI 94 bound assumes the cross section without the s-channel Z-exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume m_c=1.5 GeV.

Heavy $\widetilde{g}$ (Gluino) MASS LIMIT

For $m_{\widetilde{g}} > 60$–70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included. Limits made obsolete by the most recent analyses of $p\overline{p}$ collisions can be found in previous Editions of this *Review*.

[1] AAD 13AV searched in 20.3 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events containing large number of jets (7 or more), with missing transverse momentum and no isolated electrons or muons. The sensitivity of the search is enhanced by considering the number of b-tagged jets and the scalar sum of masses of large-radius jets in an event. No evidence was found for excesses above the expected level of Standard Model background.

[2] Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays exclusively via an off-shell top squark, $\widetilde{g}\to t\bar{t}\widetilde{\chi}_1^0$, see their Fig. 9.

[3] Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays exclusively via an on-shell top quark, $\widetilde{g}\to\bar{t}\,t$, with consecutively $t\to t\widetilde{\chi}_1^0$, assuming $m_{\widetilde{\chi}_1^0}$ = 60 GeV, see their Fig. 10.

[4] Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays exclusively via an on-shell top quark, $\widetilde{g}\to\bar{t}\,t$, with the stop consecutively decaying via the R-parity- and baryon-number-violating decay $\bar{t}\to\bar{s}\bar{b}$, see Fig. 14.

[5] Exclusion limits at 95% C.L. are set on the gluino mass assuming the gluino decays exclusively via an on-shell quark and a chargino, $\widetilde{g}\to\overline{q}q'\widetilde{\chi}_1^\pm$, with consecutively $\widetilde{\chi}_1^\pm\to W^\pm\widetilde{\chi}_1^0$, see their Fig. 11. An alternative interpretation in the case where the gluino can decay via $\widetilde{\chi}_1^\pm$ or $\widetilde{\chi}_2^0$ is given in Fig. 12.

[6] Exclusion limits at the 95% C.L. are derived in the mSUGRA/CMSSM model with parameters tanβ = 30, $A_0=-2\,m_0$ and μ > 0, see their Fig. 13. For large universal scalar masses m_0, gluino masses smaller than 1.1 TeV are excluded at 95% C.L.

[7] CHATRCHYAN 13G searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing 0,1,2, $\geq$ 3 b-jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0, and μ > 0, gluinos with masses below 700 GeV are excluded at 95% C.L. Squarks and gluinos of equal mass are excluded for masses below 1250 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 7.

[8] CHATRCHYAN 13P searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing a single isolated electron or muon, energetic jets and large $\not{E}_T$. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 17. The results are also interpreted in a simplified model, see Fig. 19.

[9] CHATRCHYAN 13R searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing one or more hadronically decaying τ leptons, energetic jets and large $\not{E}_T$. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ=10, A_0=0 and μ >0, see Fig. 7. The results are also interpreted in various simplified models, see Fig. 9.

[10] CHATRCHYAN 13T searched in 11.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with at least two energetic jets and significant $\not{E}_T$, using the α_T variable to discriminate between processes with genuine and misreconstructed $\not{E}_T$. No significant excess above the Standard Model expectations is observed.

[11] CHATRCHYAN 13T limits are set on gluino masses in simplified models where the decay $\widetilde{g}\to b\bar{b}\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

[12] CHATRCHYAN 13T limits are set on gluino masses in simplified models where the decay $\widetilde{g}\to q\bar{q}\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

[13] CHATRCHYAN 13T limits are set on gluino masses in simplified models where the decay $\widetilde{g}\to t\bar{t}\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, see Fig. 8 and Table 9.

[14] CHATRCHYAN 13V searched in 10.5 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with two isolated same-sign dileptons and at least two b-jets in the final state. No significant excess above the Standard Model expectations is observed. Limits are set on the gluino mass in simplified models where the decay $\widetilde{g}\to t\bar{t}\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, or where the decay $\widetilde{g}\to\bar{t}\,t$, $\bar{t}\to t\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\widetilde{\chi}_1^0$, or where the decay $\widetilde{g}\to\bar{b}b$, $\bar{b}\to t\widetilde{\chi}_1^\pm$, $\widetilde{\chi}_1^\pm\to W^\pm\widetilde{\chi}_1^0$ takes place with a branching ratio of 100%, with varying mass of the $\widetilde{\chi}_1^\pm$, see Fig. 4.

[15] AAD 12AP searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for gluinos decaying via the scalar partner of the top quark into events with two same-sign leptons, jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 4, and in simplified models, see Figs. 2 and 3.

[16] AAD 12AX searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for supersymmetry in events containing jets, missing transverse momentum and one isolated electron or muon. No excess over the expected SM background is observed and model-independent limits are set on the cross section of new physics contributions to the signal regions. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks and gluinos of equal mass are excluded for masses below 820 GeV at 95% C.L. Limits are also set on simplified models for gluino production and decay via an intermediate chargino and on supersymmetric models with bilinear R-parity violation. Supersedes AAD 11G.

[17] AAD 12BI looked in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 6 to $\geq$ 9 jets plus $\not{E}_T$. No excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 10, A_0 = 0 and μ > 0, see their Fig. 7. Limits are also set in the ($m_{\widetilde{g}}$,$m_{\widetilde{\chi}^0_1}$) plane in a simplified supersymmetric model with four tops + $\not{E}_T$ in the final state. Supersedes AAD 11AF.

[18] AAD 12BY searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with large missing transverse momentum and at least three b-jets in the final state. The data are found to be consistent with the Standard Model expectations. In a simplified supersymmetric scenario where $\widetilde{g} \rightarrow \widetilde{b}_1 b$ and $\widetilde{b}_1 \rightarrow b\widetilde{\chi}^0_1$, with branching ratios of 100% for both decays, a 95% C.L. limit on the gluino mass of 1000 GeV is set for $m_{\widetilde{b}_1} < 870$ GeV and $m_{\widetilde{\chi}^0_1} = 60$ GeV. In a scenario where the sbottom is heavier than the gluino and the gluino decays through a three-body decay into bottom quarks 100% of the time, $\widetilde{g} \rightarrow bb\widetilde{\chi}^0_1$, the limit on the gluino mass becomes 1020 GeV, provided $m_{\widetilde{\chi}^0_1} < 400$ GeV. In a scenario where $\widetilde{g} \rightarrow \widetilde{t}_1 t$ and $\widetilde{t}_1 \rightarrow t\widetilde{\chi}^0_1$, with branching ratios of 100% for both decays, a 95% C.L. limit on the gluino mass of 820 GeV is set for $m_{\widetilde{t}_1} < 640$ GeV and $m_{\widetilde{\chi}^0_1} = 60$ GeV. In a scenario where the stop is heavier than the gluino and the gluino decays through a three-body decay into top quarks 100% of the time, $\widetilde{g} \rightarrow tt\widetilde{\chi}^0_1$, the limit on the gluino mass becomes 940 GeV, provided $m_{\widetilde{\chi}^0_1} < 50$ GeV.

[19] AAD 12CJ searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing one or more isolated leptons (electrons or muons), jets and $\not{E}_T$. The observations are in good agreement with the SM expectations and exclusion limits have been set in number of SUSY models. In the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0, and μ > 0, 95% C.L. exclusion limits have been derived for $m_{\widetilde{g}} < 1200$ GeV, assuming equal squark and gluino masses. In minimal GMSB, values of the effective SUSY breaking scale Λ < 50 TeV are excluded at 95% C.L. for tanβ < 45. Also exclusion limits in a number of simplified models have been presented, see Figs. 10 and 11.

[20] AAD 12CU searched in 4.6 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for pair production of gluinos decaying into six-quark final states in an R-parity violating supersymmetric model. The data are found to be consistent with the Standard Model expectations. Based on an analysis where all six jets in the final state are resolved, a 95% C.L. limit of 666 GeV is placed on the gluino mass. The gluino decay is assumed to be prompt.

[21] CHATRCHYAN 12AT searched in 4.73 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, gluinos with masses below 800 GeV are excluded at 95% C.L. Squarks and gluinos of equal mass are excluded for masses below 1180 GeV at 95% C.L. Exclusions are also derived in various simplified models, see Fig. 6.

[22] CHATRCHYAN 12U looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two same-sign leptons (e, μ, τ) not necessarily the same flavor, jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0, and μ > 0, see Fig. 3. The limit is independent of the squark masses. The exclusion includes a $-$ 1 σ_{th} reduction to account for the theory uncertainty on the cross section.

[23] AAD 11G looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with a single lepton (e or μ), jets and $\not{E}_T$ from the production of squarks and gluinos. No evidence for an excess over the SM expectation is observed, and a limit is derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 3, see Fig. 2.

[24] AAD 11N looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 2 jets and $\not{E}_T$. Four signal regions were defined, and the background model was found to be in good agreement with the data. Limits are derived in the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane (see Fig. 2) for a simplified model where degenerate masses of the squarks of the first two generations are assumed, $m_{\widetilde{\chi}^0_1} = 0$, and all other masses including third generation squarks are set to 5 TeV. Limits are also derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 3) for tanβ = 3.

[25] AAD 11O looked in 35 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with jets, of which at least one is a b-jet, and $\not{E}_T$. No excess above the Standard Model was found. Limits are derived in the ($m_{\widetilde{g}}$, $m_{\widetilde{b}_1}$) plane (see Fig. 2) under the assumption of 100% branching ratios and $\widetilde{b}_1$ being the lightest squark. The quoted limit is valid for $m_{\widetilde{b}_1} <$ 500 GeV. A similar approach for $\widetilde{t}_1$ as the lightest squark with $\widetilde{g} \rightarrow \widetilde{t}_1 t$ and $\widetilde{t}_1 \rightarrow b\widetilde{\chi}^{\pm}_1$ with 100% branching ratios leads to a gluino mass limit of 520 GeV for 130 < $m_{\widetilde{t}_1}$ < 300 GeV. Limits are also derived in the CMSSM (m_0, $m_{1/2}$) plane for tanβ = 40, see Fig. 4, and in scenarios based on the gauge group SO(10).

[26] CHATRCHYAN 11AC looked in 36 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with $\geq$ 3 jets, a large total transverse energy, and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane and the ($m_{\widetilde{g}}$, $m_{\widetilde{q}}$) plane for tanβ = 10 (see Fig. 10). Limits are also obtained for Simplified Model Spectra.

[27] AALTONEN 09S searched in 2 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for events with at least 2 jets and $\not{E}_T$. No evidence for a signal is observed. A limit is derived for a mSUGRA scenario in the $m_{\widetilde{q}}$ versus $m_{\widetilde{g}}$ plane, see their Fig. 2.

[28] ABAZOV 08G looked in 2.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV for events with acoplanar jets or multijets with large $\not{E}_T$. No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific MSUGRA parameter values, see Figure 3. Similar results would be obtained for a large class of parameter sets. Supersedes the results of ABAZOV 06C.

[29] ABULENCIA 06I searched in 156 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV for multijet events with large $\not{E}_T$. They request at least 2 b-tagged jets and no isolated leptons. They investigate the production of gluinos decaying into $\widetilde{b}_1 b$ followed by $\widetilde{b}_1 \rightarrow b\widetilde{\chi}^0_1$. Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and gluinos, see their Fig.3.

[30] AFFOLDER 02 searched in $\sim$ 84 pb^{-1} of $p\overline{p}$ collisions for events with $\geq$ 3 jets and $\not{E}_T$, arising from the production of gluinos and/or squarks. Limits are derived by scanning the parameter space, for $m_{\widetilde{q}} \geq m_{\widetilde{g}}$ in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and for $m_{\widetilde{q}} < m_{\widetilde{g}}$ in the framework of constrained MSSM, assuming conservatively four flavors of degenerate squarks. See Fig. 3 for the variation of the limit as function of the squark mass. Supersedes the results of ABE 97K.

[31] ABBOTT 01D looked in $\sim$ 108 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with ee, $\mu\mu$, or $e\mu$ accompanied by at least 2 jets and $\not{E}_T$. Excluded regions are obtained in the MSUGRA framework from a scan over the parameters 0<m_0 <300 GeV, 10<$m_{1/2}$ <110 GeV, and 1.2 <tanβ <10.

[32] AFFOLDER 01J searched in $\sim$ 106 pb^{-1} of $p\overline{p}$ collisions for events with 2 like-sign leptons (e or μ), $\geq$ 2 jets and $\not{E}_T$, expected to arise from the production of gluinos and/or squarks with cascade decays into $\widetilde{\chi}^{\pm}$ or $\widetilde{\chi}^0_2$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks and a pseudoscalar Higgs mass m_A=500 GeV. The limits are derived for tanβ=2, μ=$-$800 GeV, and scanning over $m_{\widetilde{g}}$ and $m_{\widetilde{q}}$. See Fig. 2 for the variation of the limit as function of the squark mass. These limits supersede the results of ABE 96D.

[33] ABBOTT 99L consider events with three or more jets and large $\not{E}_T$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino ($m_{1/2}$) and scalar (m_0) masses See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\widetilde{q}}$ and $m_{\widetilde{g}}$.

[34] AAD 13AB searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing 0,1 or 2 high-p_T leptons and with or without jets identified as originating from b-quarks. No excess over the expected SM background is observed. Limits are derived in mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, see their Fig. 12. Also, exclusion limits in simplified models containing gluinos, squarks, charginos, and stops are set, see their Figures 10 and 11.

[35] AAD 13L searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no high-p_T electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with tanβ = 10, A_0 = 0 and μ > 0, squarks and gluinos of equal mass are excluded for masses below 1360 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, gluino masses below 860 GeV are excluded at 95% C.L, for squark masses below 2 TeV. See their Figures 10–15 for more precise bounds.

[36] AAD 13Q searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events containing a high-p_T isolated photon, at least one jet identified as originating from a bottom quark, and high missing transverse momentum. Such signatures may originate from supersymmetric models with gauge-mediated supersymmetry breaking in events in which one of a pair of higgsino-like neutralinos decays into a photon and a gravitino while the other decays into a Higgs boson and a gravitino. No significant excess above the expected background was found and limits were set on the gluino mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a higgsino-like neutralino NLSP, see their Fig. 4. For neutralino masses greater than 220 GeV, gluino masses below 900 GeV are excluded at 95% C.L.

[37] CHATRCHYAN 13 looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two opposite-sign leptons (e, μ, τ), jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 6.

[38] CHATRCHYAN 13AK searched in 19.4 fb^{-1} of pp collisions at $\sqrt{s}$ = 8 TeV for events with large $\not{E}_T$, no isolated electron or muon, and at least three jets with one or more identified as a b-quark jet. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of gluinos are set as a function of the gluino and neutralino mass in a scenario where $\widetilde{g} \rightarrow b\overline{b}\widetilde{\chi}^0_1$ with a 100% branching ratio, see Fig. 7 left, and in a scenario where $\widetilde{g} \rightarrow t\overline{t}\widetilde{\chi}^0_1$ with a 100% branching ratio, see Fig. 7, right. Supersedes CHATRCHYAN 12AH.

[39] CHATRCHYAN 13AM searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with large $\not{E}_T$, a single isolated electron or muon, and multiple jets including some identified as a b-quark jet. No significant excesses over the expected SM backgrounds are observed and 95% C.L.

[40] CHATRCHYAN 13AM limits on the production cross section of gluinos are set as a function of the gluino and neutralino mass in a scenario where $\widetilde{g} \rightarrow t\overline{t}\widetilde{\chi}^0_1$ with a 100% branching ratio, see Fig. 10.

[41] CHATRCHYAN 13AM exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 8.

[42] CHATRCHYAN 2013AO searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for events with two opposite-sign isolated leptons accompanied by hadronic jets and $\not{E}_T$. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 8. The results are also interpreted in an asymmetric simplified model of gluino pair production, see Fig. 7.

[43] CHATRCHYAN 13AT provides interpretations of various searches for supersymmetry by the CMS experiment based on 4.73–4.98 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV in the framework of simplified models. Limits are set on the gluino mass in a simplified models where gluinos are pair-produced and the decay $\widetilde{g} \rightarrow q\overline{q}\widetilde{\chi}^0_1$ takes place with a branching ratio of 100%, see Fig. 4.

[44] CHATRCHYAN 13AV searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV for new heavy particle pairs decaying into jets (possibly b-tagged), leptons and $\not{E}_T$ using the Razor variables. No significant excesses over the expected SM backgrounds are observed and 95% C.L. exclusion limits are derived in the mSUGRA/CMSSM model with tanβ = 10, A_0 = 0 and μ > 0, see Fig. 3. The results are also interpreted in various simplified models, see Fig. 4.

[45] CHATRCHYAN 13W searched in 4.93 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with one or more photons, hadronic jets and $\not{E}_T$. No significant excess above the Standard Model expectations is observed. Limits are set on gluino masses in the general gauge-mediated SUSY breaking model (GGM), for both a wino-like and bino-like neutralino NLSP scenario, see Fig. 5.

[46] AAD 12BA searched in 2.05 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with heavy flavor jets and large $\not{E}_T$ due to $\tilde{g}\to\tilde{t}_1 b$ or $\tilde{g}\to\tilde{t}_1 t$ decays. No significant excess above the expected background was found and limits were set on the gluino mass in simplified R-parity conserving models in which only scalar bottoms and tops appear in the gluino decay and in an SO(10) model framework.

[47] AAD 12CP searched in 4.8 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with two photons and large $\not{E}_T$ due to $\tilde{\chi}_1^0\to\gamma\tilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the gluino mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP. The other sparticle masses were decoupled, $\tan\beta=2$ and $c\tau_{NLSP}<0.1$ mm. Also, in the framework of the SPS8 model, a 95% C.L. lower limit was set on the breaking scale Λ of 196 TeV.

[48] AAD 12W searched in 1.04 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for the production of squarks and gluinos in events containing jets, missing transverse momentum and no electrons or muons. No excess over the expected SM background is observed. In mSUGRA/CMSSM models with $\tan\beta=10$, $A_0=0$ and $\mu>0$, squarks and gluinos of equal mass are excluded for masses below 950 GeV at 95% C.L. In a simplified model containing only squarks of the first two generations, a gluino octet and a massless neutralino, gluino masses below 700 GeV are excluded at 95% C.L.

[49] AAD 12X searched in 1.07 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with two photons and large $\not{E}_T$ due to $\tilde{\chi}_1^0\to\gamma\tilde{G}$ decays in a GMSB framework. No significant excess above the expected background was found and limits were set on the gluino mass as a function of the neutralino mass in a generalized GMSB model (GGM) with a bino-like neutralino NLSP. The other sparticle masses were set to 1.5 TeV, $\tan\beta=2$ and $c\tau_{NLSP}<0.1$ mm. Also, in the framework of the SPS8 model, a 95% C.L. lower limit was set on the breaking scale Λ of 145 TeV. Superseded by AAD 12CP.

[50] CHATRCHYAN 12 looked in 35 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with e and/or μ and/or jets, a large total transverse energy, and $\not{E}_T$. The event selection is based on the dimensionless razor variable R, related to the $\not{E}_T$ and M_R, an indicator of the heavy particle mass scale. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for $\tan\beta=3$, 10 and 50 (see Fig. 7 and 8). Limits are also obtained for Simplified Model Spectra.

[51] CHATRCHYAN 12AE searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with at least three jets and large missing transverse momentum. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of gluinos in a scenario where $\tilde{g}\to q q\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 3. For $m_{\tilde{\chi}_1^0}<200$ GeV, values of $m_{\tilde{g}}$ below 1000 GeV are excluded at 95% C.L. Also limits in the CMSSM are presented, see Fig. 2.

[52] CHATRCHYAN 12AH searched in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with large $\not{E}_T$, at least three jets, and at least one, two or three b-quark jets. No significant excesses over the expected SM backgrounds are observed and 95% C.L. limits on the production cross section of gluinos are set as a function of the gluino and neutralino mass in a scenario where $\tilde{g}\to b b\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 14, and in a scenario where $\tilde{g}\to t t\tilde{\chi}_1^0$ with a 100% branching ratio, see Fig. 15.

[53] CHATRCHYAN 12AI looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with two same-sign leptons (e, μ), but not necessarily same flavor, at least 2 b-jets and missing transverse energy. No excess beyond the Standard Model expectation is observed. Exclusion limits are derived in simplified models where gluinos are pair produced and decay through $\tilde{g}\to t\bar{t}\tilde{\chi}_1$ (intermediate stop, real or virtual), see Fig. 6, or through $\tilde{g}\to b\bar{t}W^+\tilde{\chi}_1$ (intermediate sbottom), see Fig. 8.

[54] CHATRCHYAN 12AL looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for anomalous production of events with three or more isolated leptons. Limits on squark and gluino masses are set in $R\!\!\!/$ SUSY models with leptonic $LL\bar{E}$ couplings, $\lambda_{123}>0.05$, and hadronic $\overline{UDD}$ couplings, $\lambda''_{112}>0.05$, see their Fig. 5. In the $\overline{UDD}$ case the leptons arise from supersymmetric cascade decays. A very specific supersymmetric spectrum is assumed. All decays are prompt.

[55] CHATRCHYAN 12BD searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for three-jet resonances produced in the decay of a gluino in R-parity violating supersymmetric models. No excess over the expected SM background is observed. Assuming a branching ratio for gluino decay into three jets of 100%, limits are set on the cross section of gluino pair production, see Fig. 4. Gluino masses between 280 GeV and 460 GeV are excluded at 95% C.L.

[56] CHATRCHYAN 12Q looked in 4.98 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for anomalous production of events with a Z-boson, jets and significant $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are set in a simplified supersymmetric model where the $\tilde{\chi}_2^0\to Z\tilde{\chi}_1^0$ decay is dominant, see Figs. 5 and 6.

[57] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the gluino and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

[58] DREINER 12A reassesses constraints from CMS (at 7 TeV, $\sim$ 4.4 fb^{-1}) under the assumption that the first and second generation squarks, the gluino, and the lightest SUSY particle are quasi-degenerate in mass (compressed spectrum).

[59] AAD 11AF looked in 1.34 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with 6 up to 8 jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for $\tan\beta=10$ (see Fig. 5). The limit improves to $m_{\tilde{g}}>680$ GeV for $m_{\tilde{q}}=2\,m_{\tilde{g}}$.

[60] AAD 11X looked in 36 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 photons and $\not{E}_T$ from the pair production of gluinos with cascade decays to $\tilde{\chi}_1^0$ followed by $\tilde{\chi}_1^0\to\gamma\tilde{G}$ prompt decay. No evidence for an excess over the SM expectation is observed, and a limit on the number of new physics events is set. Limits are derived in a Generalized Gauge Mediated model in the ($m_{\tilde{g}}$, $m_{\tilde{\chi}_1^0}$) plane (see Fig. 5) under the assumptions $\tan\beta=2$ and all sparticle masses at 1.5 TeV, except the $\tilde{g}$, $\tilde{\chi}_1^0$, and $\tilde{G}$. Superseded by AAD 12X.

[61] AALTONEN 11Q searched in 3.2 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 6 jets from the pair production of gluinos and squarks with the subsequent decays $\tilde{g}\to$ 3jets in the MSSM framework with $R\!\!\!/$. No statistically significant bumps in the 3-jet systems are observed over the SM background. Limits on the cross section times branching ratio are derived as a function of the gluino mass, displayed in Fig. 3. For decoupled squarks in the range $0.5<m_{\tilde{q}}<0.7$ TeV gluinos are excluded below 144 GeV. The quoted limit is for near degeneracy of squark and gluino masses.

[62] CHATRCHYAN 11AB looked in 35 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 same charge isolated leptons (e, μ or τ), jets and $\not{E}_T$. Such events might be produced from $\tilde{g}\tilde{g}$ or $\tilde{g}\tilde{q}$ decaying via charginos into leptons. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for $\tan\beta=3$ (see Fig. 10).

[63] CHATRCHYAN 11G looked in 36 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 isolated photons, ≥ 1 jet and $\not{E}_T$, which may arise in a generalized gauge mediated model from the decay of a $\tilde{\chi}_1^0$ NLSP. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark versus gluino mass (see Fig. 4) for several values of $m_{\tilde{\chi}_1^0}$.

[64] CHATRCHYAN 11Q looked in 36 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with a single isolated lepton (e or μ), ≥ 4 jets and $\not{E}_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane for $\tan\beta=10$ (see Fig. 7).

[65] CHATRCHYAN 11V looked in 35 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 3 isolated leptons (e, μ or τ), with or without jets and $\not{E}_T$. Multi-lepton final states originate from $\tilde{q}\to\tilde{\chi}^0+X$, followed by $\tilde{\chi}^0\to\tilde{\ell}^{\pm}\ell^{\mp}$ and $\tilde{\ell}\to\ell\tilde{G}$. No evidence for an excess over the expected background is observed. Limits are derived (see Fig. 4) for a GMSB-type scenario with mass-degenerate right-handed sleptons (slepton co-NLSP scenario).

[66] CHATRCHYAN 11W looked in 1.14 fb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets, large total jet energy, and $\not{E}_T$. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T=E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. Given the lack of an excess over the SM backgrounds, limits are derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 4) for $\tan\beta=10$. The limits are only weakly dependent on $\tan\beta$ and A_0.

[67] KHACHATRYAN 11I looked in 35 pb^{-1} of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets and $\not{E}_T$. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T=E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM (m_0, $m_{1/2}$) plane (see Fig. 5) for $\tan\beta=3$. Superseded by CHATRCHYAN 11W.

[68] ABAZOV 02F looked in 77.5 pb^{-1} of $p\bar{p}$ collisions at 1.8 TeV for events with $\geq 2\mu+\geq$ 4jets, originating from associated production of squarks followed by an indirect R decay (of the $\tilde{\chi}_1^0$) via $LQ\overline{D}$ couplings of the type λ'_{2jk} where j=1,2 and k=1,2,3. Bounds are obtained in the MSUGRA scenario by a scan in the range $0\leq M_0\leq 400$ GeV, $60\leq m_{1/2}\leq 120$ GeV for fixed values A_0=0, $\mu<0$, and $\tan\beta$=2 or 6. The bounds are weaker for $\tan\beta$=6. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for $\tan\beta$=2 and 6, respectively.

[69] ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s}$=1.8 TeV, using events with one electron, ≥ 4 jets, and large $\not{E}_T$. The results are compared to a MSUGRA scenario with $\mu<0$, A_0=0, and $\tan\beta$=3 and allow to exclude a region of the (m_0,$m_{1/2}$) shown in Fig. 11.

[70] CHEUNG 02B studies the constraints on a $\tilde{b}_1$ with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.

[71] BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m\sim$ 12–16 GeV) with subsequent 2-body decay into a light sbottom ($m\sim$ 2–5.5 GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R-parity- and B-violating interaction, or be long-lived.

[72] ABBOTT 99 searched for $\gamma\not{E}_T+\geq 2$ jet final states, and set limits on $\sigma(p\bar{p}\to\tilde{g}\tilde{g}+X)\cdot B(\tilde{g}\to\gamma\not{E}_T X)$. The quoted limits correspond to $m_{\tilde{q}}\geq m_{\tilde{g}}$, with $B(\tilde{\chi}_2^0\to\tilde{\chi}_1^0\gamma)$=1 and $B(\tilde{\chi}_1^0\to\tilde{G}\gamma)$=1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma\tilde{G}$ decay) for $m_{\tilde{g}}=m_{\tilde{q}}$.

[73] ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via $R\!\!\!/\,LQ\overline{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the (m_0,$m_{1/2}$) plane under the assumption that A_0=0, $\mu<0$, $\tan\beta$=2 and any one of the couplings $\lambda'_{1jk}>10^{-3}$ (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0, but the limit deteriorates rapidly with increasing $\tan\beta$ or $\mu>0$.

[74] ABACHI 95C assume five degenerate squark flavors with with $m_{\tilde{q}_L}=m_{\tilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta=2.0$ $\mu=-250$ GeV, and m_{H^+}=500 GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.

[75] ABE 95T looked for a cascade decay of gluino into $\tilde{\chi}_2^0$ which further decays into $\tilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu=-40$ GeV, $\tan\beta=1.5$, and heavy squarks, the range $50<m_{\tilde{g}}$ (GeV)<140 is excluded at 90% CL. See the paper for details.

[76] HEBBEKER 93 combined jet analyses at various e^+e^- colliders. The 4-jet analyses at TRISTAN/LEP and the measured α_s at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks $N=6.3\pm1.1$ is obtained, which is compared to that with a light gluino, N=8.

[77] ABE 92L bounds are based on similar assumptions as ABACHI 95C. Not sensitive to $m_{\text{gluino}}<40$ GeV (but other experiments rule out that region).

[78] ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g}\to q\bar{q}\tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q\overline{d}$ or $\ell\ell\overline{e}$ is assumed.

[79] NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.

[80] The limits of ALBAJAR 87D are from $p\overline{p} \to \tilde{g}\tilde{g}X$ ($\tilde{g} \to q\overline{q}\tilde{\gamma}$) and assume $m_{\tilde{q}} > m_{\tilde{g}}$. These limits apply for $m_{\tilde{\gamma}} \lesssim 20$ GeV and $\tau(\tilde{g}) < 10^{-10}$ s.

[81] The limit of ANSARI 87D assumes $m_{\tilde{q}} > m_{\tilde{g}}$ and $m_{\tilde{\gamma}} \approx 0$.

Long-lived/light $\tilde{g}$ (Gluino) MASS LIMIT

Limits on light gluinos ($m_{\tilde{g}} < 5$ GeV), or gluinos which leave the detector before decaying.

[1] AAD 13AA searched in 4.7 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events containing colored long-lived particles that hadronize forming R-hadrons. No significant excess above the expected background was found. Long-lived R-hadrons containing a $\tilde{g}$ are excluded for masses up to 985 GeV at 95% C.L in a general interaction model. Also, limits independent of the fraction of R-hadrons that arrive charged in the muon system were derived, see Fig. 6.

[2] AAD 13BC searched in 5.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV and in 22.9 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for bottom squark R-hadrons that have come to rest within the ATLAS calorimeter and decay at some later time to hadronic jets and a neutralino. In absence of an excess of events above the expected backgrounds, limits are set on gluino masses for different decays, lifetimes, and neutralino masses, see their Table 6 and Fig. 10.

[3] CHATRCHYAN 13AB looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV and in 18.8 fb^{-1} of pp collisions at $\sqrt{s} = 8$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 8 and Table 5), depending on the fraction, f, of formation of $\tilde{g}$–g (R-gluonball) states. The quoted limit is for f = 0.1, while for f = 0.5 it degrades to 1276 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for f = 0.1.

[4] AAD 12P looked in 31 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of $m_{\tilde{g}}$ is derived for $m_{\tilde{\chi}_1^0} = 100$ GeV, see Fig. 4. The limit is valid for lifetimes between 10^{-5} and 10^3 seconds and assumes the *Generic* matter interaction model for the production cross section.

[5] CHATRCHYAN 12AN looked in 4.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section as a function of $m_{\tilde{g}}$ is derived, see Fig. 3. The mass limit is valid for lifetimes between 10^{-5} and 10^3 seconds, for what they call "the daughter gluon energy $E_g >$" 100 GeV and assuming the *cloud* interaction model for R-hadrons. Supersedes KHACHATRYAN 11.

[6] CHATRCHYAN 12L looked in 5.0 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$'s. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction, f, of formation of $\tilde{g}$–g (R-glueball) states. The quoted limit is for f = 0.1, while for f = 0.5 it degrades to 1046 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 928 GeV for f=0.1. Supersedes KHACHATRYAN 11C.

[7] AAD 11K looked in 34 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of $\tilde{g}$. No evidence for an excess over the SM expectation is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 4), for a fraction, f = 10%, of formation of $\tilde{g} - g$ (R-gluonball). If instead of a phase space driven approach for the hadronic scattering of the R-hadrons, a triple-Regge model or a bag-model is used, the limit degrades to 566 and 562 GeV, respectively.

[8] AAD 11P looked in 37 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with heavy stable particles, reconstructed and identified by their time of flight in the Muon System. There is no requirement on their observation in the tracker to increase the sensitivity to cases where gluinos have a large fraction, f, of formation of neutral $\tilde{g} - g$ (R-gluonball). No evidence for an excess over the SM expectation is observed. Limits are derived as a function of mass (see Fig. 4), for f=0.1. For fractions f = 0.5 and 1.0 the limit degrades to 537 and 530 GeV, respectively.

[9] KHACHATRYAN 11 looked in 10 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons which may stop inside the detector and later decay via $\tilde{g} \to g\tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section times branching ratio is derived for $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} > 100$ GeV, see their Fig. 2. Assuming 100% branching ratio, lifetimes between 75 ns and 3×10^5 s are excluded for $m_{\tilde{g}} = 300$ GeV. The $\tilde{g}$ mass exclusion is obtained with the same assumptions for lifetimes between 10 μs and 1000 s, but shows some dependence on the model for R-hadron interactions with matter, illustrated in Fig. 3. From a time-profile analysis, the mass exclusion is 382 GeV for a lifetime of 10 μs under the same assumptions as above.

[10] KHACHATRYAN 11C looked in 3.1 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally requiring that it be identified as muon in the muon chambers, from pair production of $\tilde{g}$. No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction, f, of formation of $\tilde{g} - g$ (R-gluonball). The quoted limit is for f=0.1, while for f=0.5 it degrades to 357 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 311 GeV for f=0.1.

[11] BERGER 10 updated the results of BERGER 05. They fit parton distribution functions including the effects of a light gluino as an extra parton. Different data on α_s is also included. A fit for $\alpha_s(M_Z)$ is performed as a function of the gluino mass. The bound is determined by comparing the quality of the fit to the CT10 fit, and the CT10 tolerance criterion is used to define the significance. The lower bound is 25 GeV for fixed $\alpha_s(M_Z) = 0.118$.

[12] KAPLAN 08 reanalysed jet event shape data from LEP 1 and LEP 2 using soft collinear effective theory methods. These data are sensitive to the effects of new degrees of freedoms, including a relatively light gluino, at different energy scales, roughly between 5 and 50 GeV. The analysis relies on theoretical modeling of and approximations for non-perturbative effects and matching between different scales.

[13] ABAZOV 07L looked in approximately 410 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with a long-lived gluino from split supersymmetry, decaying after stopping in the detector into $g\tilde{\chi}_1^0$ with lifetimes from 30 μs to 100 h. The signal signature is a largely empty event with a single large transverse energy deposit in the calorimeter. The main

background is due to cosmic muons interacting in the calorimeter. The data agree with the estimated background and allow the authors to estimate a limit on the rate of an out-of-time monojet signal of a given energy. Assuming the branching ratios $\tilde{g} \to g\tilde{\chi}_1^0$ to be 100% the results can be translated to limits on the gluino cross section versus the gluino mass for fixed $\tilde{\chi}_1^0$ mass. After comparing to the expected gluino cross sections, the excluded region of gluino masses can be obtained, see examples in their Fig. 3.

[14] BERGER 05 include the light gluino in proton PDF and perform global analysis of hadronic data. Effects on the running of α_s also included. Strong dependency on $\alpha_s(m_Z)$. Bound quoted for $\alpha_s(m_Z) = 0.118$. Superseded by BERGER 10.

[15] ABDALLAH 03C looked for events of the type $q\overline{q}R^{\pm}R^{\pm}$, $q\overline{q}R^{\pm}R^{0}$ or $q\overline{q}R^{0}R^{0}$ in e^+e^- interactions at 91.2 GeV collected in 1994. The $R^{\pm}$ bound states are identified by anomalous dE/dx in the tracking chambers and the R^0 by missing energy, due to their reduced energy loss in the calorimeters. The upper value of the excluded range depends on the probability for the gluino to fragment into $R^{\pm}$ or R^0, see their Fig. 17. It improves to 23 GeV for 100% fragmentation to $R^{\pm}$.

[16] ABDALLAH 03G used e^+e^- data at and around the Z^0 peak, above the Z^0 up to $\sqrt{s}$ = 202 GeV and events from radiative return to cover the low energy region. They perform a direct measurement of the QCD beta-function from the means of fully inclusive event observables. Compared to the energy range, gluinos below 5 GeV can be considered massless and are firmly excluded by the measurement.

[17] HEISTER 03 use e^+e^- data from 1994 and 1995 at and around the Z^0 peak to measure the 4-jet rate and angular correlations. The comparison with QCD NLO calculations allow $\alpha_S(M_Z)$ and the color factor ratios to be extracted and the results are in agreement with the expectations from QCD. The inclusion of a massless gluino in the beta functions yields T_R / C_F = 0.15 ± 0.06 ± 0.06 (expectation is T_R / C_F = 3/8), excluding a massless gluino at more than 95% CL. As no NLO calculations are available for massive gluinos, the earlier LO results from BARATE 97L for massive gluinos remain valid.

[18] HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for stable gluinos hadronizing into charged or neutral R-hadrons with arbitrary branching ratios. Combining these results with bounds on the Z^0 hadronic width from electroweak measurements (JANOT 03) to cover the low mass region the quoted lower limit on the mass of a long-lived gluino is obtained.

[19] JANOT 03 excludes a light gluino from the upper limit on an additional contribution to the Z hadronic width. At higher confidence levels, $m_{\tilde{g}} > 5.3(4.2)$ GeV at $3\sigma(5\sigma)$ level.

[20] MAFI 00 reanalyzed CDF data assuming a stable heavy gluino as the LSP, with model for R-hadron-nucleon scattering. Gluino masses between 35 GeV and 115 GeV are excluded based on the CDF Run I data. Combined with the analysis of BAER 99, this allows a LSP gluino mass between 25 and 35 GeV if the probability of fragmentation into charged R-hadron P>1/2. The cosmological exclusion of such a gluino LSP are assumed to be avoided as in BAER 99. Gluino could be NLSP with $\tau_{\tilde{g}} \sim 100$ yrs, and decay to gluon gravitino.

[21] ALAVI-HARATI 99E looked for R^0 bound states, yielding $\pi^+\pi^-$ or π^0 in the final state. The experiment is sensitive to values of $\Delta m = m_{R^0} - m_{\tilde{\gamma}}$ larger than 280 MeV and 140 MeV for the two decay modes, respectively, and to R^0 mass and lifetime in the ranges 0.8–5 GeV and 10^{-10}–10^{-3} s. The limits obtained depend on B($R^0 \to \pi^+\pi^-$photino) and B($R^0 \to \pi^0$photino) on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_L^0)$. See Figures in the paper for the excluded R^0 production rates as a function of Δm, R^0 mass and lifetime. Using the production rates expected from perturbative QCD, and assuming dominance of the above decay channels over the suitable phase space, R^0 masses in the range 0.8–5 GeV are excluded at 90%CL for a large fraction of the sensitive lifetime region. ALAVI-HARATI 99E updates and supersedes the results of ADAMS 97B.

[22] BAER 99 set constraints on the existence of stable $\tilde{g}$ hadrons, in the mass range $m_{\tilde{g}} > 3$ GeV. They argue that strong-interaction effects in the low-energy annihilation rates could leave small enough relic densities to evade cosmological constraints up to $m_{\tilde{g}} < 10$ TeV. They consider jet+$\not{E}_T$ as well as heavy-ionizing charged-particle signatures from production of stable $\tilde{g}$ hadrons at LEP and Tevatron, developing modes for the energy loss of $\tilde{g}$ hadrons inside the detectors. Results are obtained as a function of the fragmentation probability P of the $\tilde{g}$ into a charged hadron. For P< 1/2, and for various energy-loss models, OPAL and CDF data exclude gluinos in the 3 <$m_{\tilde{g}}$(GeV)< 130 mass range. For P> 1/2, gluinos are excluded in the mass ranges 3 <$m_{\tilde{g}}$(GeV)< 23 and 50 <$m_{\tilde{g}}$(GeV)< 200.

[23] FANTI 99 looked for R^0 bound states yielding high P_T $\eta \to 3\pi^0$ decays. The experiment is sensitive to a region of R^0 mass and lifetime in the ranges of 1–5 GeV and 10^{-10}–10^{-3} s. The limits obtained depend on B($R^0 \to \eta\tilde{\gamma}$), on the value of $m_{R^0}/m_{\tilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_L^0)$. See Fig. 6–7 for the excluded production rates as a function of R^0 mass and lifetime.

[24] ACKERSTAFF 98V excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\tilde{\chi}_1^{\pm}$,$\tilde{\chi}_2^0 \to q\overline{q}\tilde{g}$ from total hadronic cross sections at $\sqrt{s}$=130–172 GeV. See paper for the case of nonuniversal gaugino mass.

[25] ADAMS 97B looked for $\rho^0 \to \pi^+\pi^-$ as a signature of R^0=($\tilde{g}g$) bound states. The experiment is sensitive to an R^0 mass range of 1.2–4.5 GeV and to a lifetime range of 10^{-10}–10^{-3} sec. Precise limits depend on the assumed value of $m_{R^0}/m_{\tilde{\gamma}}$. See Fig. 7 for the excluded mass and lifetime region.

[26] ALBUQUERQUE 97 looked for weakly decaying baryon-like states which contain a light gluino, following the suggestions in FARRAR 96. See their Table 1 for limits on the production fraction. These limits exclude gluino masses in the range 100–600 MeV for the predicted lifetimes (FARRAR 96) and production rates, which are assumed to be comparable to those of strange or charmed baryons.

[27] BARATE 97L studied the QCD color factors from four-jet angular correlations and the differential two-jet rate in Z decay. Limit obtained from the determination of n_f = 4.24 ± 0.29 ± 1.15, assuming T_F/C_F=3/8 and C_A/C_F=9/4.

[28] CSIKOR 97 combined the α_s from $\sigma(e^+e^- \to$ hadron), τ decay, and jet analysis in Z decay. They exclude a light gluino below 5 GeV at more than 99.7%CL.

[29] DEGOUVEA 97 reanalyzed AKERS 95A data on Z decay into four jets to place constraints on a light stable gluino. The mass limit corresponds to the pole mass of 2.8 GeV. The analysis, however, is limited to the leading-order QCD calculation.

[30] FARRAR 96 studied the possible R^0=($\tilde{g}g$) component in Fermilab E799 experiment and used its bound B($K_L^0 \to \pi^0\nu\overline{\nu}$) $\leq 5.8 \times 10^{-5}$ to place constraints on the combination of R^0 production cross section and its lifetime.

[31] AKERS 95R looked for Z decay into $q\overline{q}\tilde{g}\tilde{g}$, by searching for charged particles with dE/dx consistent with $\tilde{g}$ fragmentation into a state $(\tilde{g}q\overline{q})^{\pm}$ with lifetime $\tau > 10^{-7}$ sec. The fragmentation probability into a charged state is assumed to be 25%.

[32] CLAVELLI 95 updates the analysis of CLAVELLI 93, based on a comparison of the hadronic widths of charmonium and bottomonium S-wave states. The analysis includes a parametrization of relativistic corrections. Claims that the presence of a light gluino improves agreement with the data by slowing down the running of α_s.

[33] CAKIR 94 reanalyzed TUTS 87 and later unpublished data from CUSB to exclude pseudo-scalar gluinonium $\eta_{\tilde{g}}(\tilde{g}\tilde{g})$ of mass below 7 GeV. it was argued, however, that the perturbative QCD calculation of the branching fraction $\Upsilon \to \eta_{\tilde{g}}\gamma$ is unreliable for $m_{\eta_{\tilde{g}}} < 3$ GeV. The gluino mass is defined by $m_{\tilde{g}}$=($m_{\eta_{\tilde{q}}}$)/2. The limit holds for any gluino lifetime.

[34] LOPEZ 93C uses combined restraint from the radiative symmetry breaking scenario within the minimal supergravity model, and the LEP bounds on the (M_2,μ) plane. Claims that the light gluino window is strongly disfavored.

[35] CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between α_s at LEP and at quarkonia (Υ), since a light gluino slows the running of the QCD coupling.

[36] ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of α_s between 5 GeV and m_Z. The significance is less than 2 s.d.

[37] ANTONIADIS 91 interpret the search for missing energy events in 450 GeV/c pN collisions, AKESSON 91, in terms of light gluinos.

[38] NAKAMURA 89 searched for a long-lived ($\tau \gtrsim 10^{-7}$ s) charge-(±2) particle with mass $\lesssim$ 1.6 GeV in proton-Pt interactions at 12 GeV and found that the yield is less than 10^{-8} times that of the pion. This excludes R-Δ^{++} (a $\tilde{g}uuu$ state) lighter than 1.6 GeV.

[39] The limits assume $m_{\tilde{q}} = 100$ GeV. See their figure 3 for limits vs. $m_{\tilde{q}}$.

[40] The gluino mass is defined by half the bound $\tilde{g}\tilde{g}$ mass. If zero gluino mass gives a $\tilde{g}\tilde{g}$ of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.

[41] ALBRECHT 86C search for secondary decay vertices from $\chi_{b1}(1P) \to \tilde{g}\tilde{g}g$ where $\tilde{g}$'s make long-lived hadrons. See their figure 4 for excluded region in the $m_{\tilde{g}} - m_{\tilde{g}}$ and $m_{\tilde{g}} - m_{\tilde{q}}$ plane. The lower $m_{\tilde{g}}$ region below $\sim$ 2 GeV may be sensitive to fragmentation effects. Remark that the $\tilde{g}$-hadron mass is expected to be $\sim$ 1 GeV (glueball mass) in the zero $\tilde{g}$ mass limit.

[42] BADIER 86 looked for secondary decay vertices from long-lived $\tilde{g}$-hadrons produced at 300 GeV π^- beam dump. The quoted bound assumes $\tilde{g}$-hadron nucleon total cross section of 10μb. See their figure 7 for excluded region in the $m_{\tilde{g}} - m_{\tilde{q}}$ plane for several assumed total cross-section values.

[43] BARNETT 86 rule out light gluinos (m = 3–5 GeV) by calculating the monojet rate from gluino gluino gluon events (and from gluino gluino events) and by using UA1 data from $p\overline{p}$ collisions at CERN.

[44] VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron $\tilde{g}uud$. Quasi-stable ($\tau > 1.\times10^{-7}$s) light gluino of $m_{\tilde{g}}$ <3 GeV is also ruled out by nonobservation of the stable charged particles, $\tilde{g}uud$, in high energy hadron collisions.

[45] COOPER-SARKAR 85B is BEBC beam-dump. Gluinos decaying in dump would yield $\tilde{\gamma}$'s in the detector giving neutral-current-like interactions. For $m_{\tilde{q}}$ >330 GeV, no limit is set.

[46] DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam dump experiment.

[47] FARRAR 85 points out that BALL 84 analysis applies only if the $\tilde{g}$'s decay before interacting, i.e. $m_{\tilde{q}}$ <80$m_{\tilde{g}}^{1.5}$. FARRAR 85 finds $m_{\tilde{g}}$ <0.5 not excluded for $m_{\tilde{q}}$ = 30–1000 GeV and $m_{\tilde{g}}$ <1.0 not excluded for $m_{\tilde{q}}$ = 100–500 GeV by BALL 84 experiment.

[48] GOLDMAN 85 use nonobservation of a pseudoscalar $\tilde{g}$-$\tilde{g}$ bound state in radiative ψ decay.

[49] HABER 85 is based on survey of all previous searches sensitive to low mass $\tilde{g}$'s. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersymmetric particle.

[50] BALL 84 is FNAL beam dump experiment. Observed no interactions of $\tilde{\gamma}$ in the calorimeter, where $\tilde{\gamma}$'s are expected to come from pair-produced $\tilde{g}$'s. Search for long-lived $\tilde{\gamma}$ interacting in calorimeter 56m from target. Limit is for $m_{\tilde{q}}$ = 40 GeV and production cross section proportional to A$^{0.72}$. BALL 84 find no $\tilde{g}$ allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on $m_{\tilde{q}}$ and A. See also KANE 82.

[51] BRICK 84 reanalyzed FNAL 147 GeV HBC data for R-$\Delta(1232)^{++}$ with $\tau > 10^{-9}$ s and p_{lab} >2 GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in pp, π^+p, K^+p collisions respectively. R-Δ^{++} is defined as being $\tilde{g}$ and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.

[52] FARRAR 84 argues that $m_{\tilde{g}}$ <100 MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than $\tilde{\gamma}$'s or if $m_{\tilde{q}}$ >100 GeV.

[53] BERGSMA 83C is reanalysis of CERN-SPS beam-dump data. See their figure 1.

[54] CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if $m_{\tilde{g}}$ <1 GeV. This is important since tracks from decay of neutral s-hadron cannot be reconstructed to primary vertex because of missed $\tilde{\gamma}$. Charged s-hadron leaves track from vertex.

[55] KANE 82 inferred above $\tilde{g}$ mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if $\tilde{g}$ decays inside detector.

LIGHT $\tilde{G}$ (Gravitino) MASS LIMITS FROM COLLIDER EXPERIMENTS

The following are bounds on light ($\ll$ 1 eV) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy ($\not{E}$) signature.

[1] ABDALLAH 05B use data from $\sqrt{s} = 180$–208 GeV. They look for events with a single photon + $\not{E}$ final states from which a cross section limit of $\sigma < 0.18$ pb at 208 GeV is obtained, allowing a limit on the mass to be set. Supersedes the results of ABREU 00Z.

[2] ACHARD 04E use data from $\sqrt{s} = 189$–209 GeV. They look for events with a single photon + $\not{E}$ final states from which a limit on the Gravitino mass is set corresponding to $\sqrt{F} > 238$ GeV. Supersedes the results of ACCIARRI 99R.

[3] HEISTER 03C use the data from $\sqrt{s} = 189$–209 GeV to search for $\gamma\not{E}_T$ final states.

[4] ACOSTA 02H looked in 87 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with a high-E_T photon and $\not{E}_T$. They compared the data with a GMSB model where the final state could arise from $q\overline{q} \to \widetilde{G}\widetilde{G}\gamma$. Since the cross section for this process scales as $1/|F|^4$, a limit at 95% CL is derived on $|F|^{1/2} > 221$ GeV. A model independent limit for the above topology is also given in the paper.

[5] ABBIENDI,G 00D searches for $\gamma\not{E}$ final states from $\sqrt{s}$=189 GeV.

[6] ABREU 00Z search for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. Superseded by ABDALLAH 05B.

[7] AFFOLDER 00J searches for final states with an energetic jet (from quark or gluon) and large $\not{E}_T$ from undetected gravitinos.

[8] ACCIARRI 99R search for $\gamma\not{E}$ final states using data from $\sqrt{s}$=189 GeV. Superseded by ACHARD 04E.

[9] Searches for $\gamma\not{E}$ final states at $\sqrt{s}$=183 GeV.

[1] AAD 13P searched in 5 fb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for single lepton-jets with at least four muons; pairs of lepton-jets, each with two or more muons; and pairs of lepton-jets with two or more electrons. All of these could be signatures of Hidden Valley supersymmetric models. No statistically significant deviations from the Standard Model expectations are found. 95% C.L. limits are placed on the production cross section times branching ratio of dark photons for several parameter sets of a Hidden Valley model.

[2] AALTONEN 12AB looked in 5.1 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for anomalous production of multiple low-energy leptons in association with a W or Z boson. Such events may occur in hidden valley models in which a supersymmetric Higgs boson is produced in association with a W or Z boson, with $H \to \widetilde{\chi}_1^0\widetilde{\chi}_1^0$ pair and with the $\widetilde{\chi}_1^0$ further decaying into a dark photon (γ_D) and the unobservable lightest SUSY particle of the hidden sector. As the γ_D is expected to be light, it may decay into a lepton pair. No significant excess over the SM expectation is observed and a limit at 95% C.L. is set on the cross section for a benchmark model of supersymmetric hidden-valley Higgs production.

[3] AAD 11AA looked in 34 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with ≥ 4 jets originating from pair production of scalar gluons, each decaying to two gluons. No two-jet resonances are observed over the SM background. Limits are derived on the cross section times branching ratio (see Fig. 3). Assuming 100% branching ratio for the decay to two gluons, the quoted exclusion range is obtained, except for a 5 GeV mass window around 140 GeV.

[4] CHATRCHYAN 11E looked in 35 pb^{-1} of pp collisions at $\sqrt{s} = 7$ TeV for events with collimated μ pairs (leptonic jets) from the decay of hidden sector states. No evidence for new resonance production is found. Limits are derived and compared to various SUSY models (see Fig. 4) where the LSP, either the $\widetilde{\chi}_1^0$ or a $\widetilde{q}$, decays to dark sector particles.

[5] ABAZOV 10N looked in 5.8 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events from hidden valley models in which a $\widetilde{\chi}_1^0$ decays into a dark photon, γ_D, and the unobservable lightest SUSY particle of the hidden sector. As the γ_D is expected to be light, it may decay into a tightly collimated lepton pair, called lepton jet. They searched for events with $\not{E}_T$ and two isolated lepton jets observable by an opposite charged lepton pair ee, $e\mu$ or $\mu\mu$. No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Table I. They also examined the invariant mass of the lepton jets for a narrow resonance, see their Fig. 4, but found no evidence for a signal.

[6] LOVE 08A searched for decays of Y(nS) with n = 1, 2, 3 into $\mu\tau$ in 1.1, 1.3, 1.4 fb^{-1}, respectively, in the CLEO III detector at CESR. The signature is a muon with ≈ 97 % of the beam energy and an electron from the decay of τ. No evidence for lepton flavour violation is found and 95% CL limits on the branching ratio are estimated to be 6.0, 14.4 and 20.3×10^{-6} for n = 1, 2, 3, respectively.

[7] ABULENCIA 06P searched in 305 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for an excess of events with $\ell\gamma\not{E}_T$ and $\ell\ell\gamma$ ($\ell = e, \mu$). No significant excess was found compared to the background expectation. No events are found such as the $ee\gamma\gamma\not{E}_T$ event observed in ABE 99I.

[8] ACOSTA 04E looked in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV for events with two same sign leptons without selection of other objects nor $\not{E}_T$. No significant excess is observed compared to the Standard Model expectation and constraints are derived on the parameter space of MSUGRA models, see Figure 4.

[9] Looked for the scalar partner of a goldstino in decays $K^- \to \pi^-\pi^0 P$ from a 25 GeV K^- beam produced at the IHEP 70 GeV proton synchrotron. The sgoldstino is assumed to be sufficiently long-lived to be invisible. A 90% CL upper limit on the decay branching ratio is set at $\sim 9.0 \times 10^{-6}$ for a sgoldstino mass range from 0 to 200 MeV, excluding the interval near $m(\pi^0)$, where the limit is $\sim 3.5 \times 10^{-5}$.

[10] AFFOLDER 02D looked in 85 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV for events with a high-E_T photon, and a b-tagged jet with or without $\not{E}_T$. They compared the data with models where the final state could arise from cascade decays of gluinos and/or squarks into $\widetilde{\chi}^\pm$ and $\widetilde{\chi}_2^0$ or direct associated production of $\widetilde{\chi}_2^0\widetilde{\chi}_2^\pm$, followed by $\widetilde{\chi}_2^0 \to \gamma\widetilde{\chi}_1^0$ or a GMSB model where $\widetilde{\chi}_1^0 \to \gamma\widetilde{G}$. It is concluded that the experimental sensitivity is insufficient to detect the associated production or the GMSB model, but some sensitivity may exist to the cascade decays. A model independent limit for the above topology is also given in the paper.

[11] AFFOLDER 01H searches for $p\overline{p} \to \gamma\gamma$X events, where the di-photon system originates from sgoldstino production, in 100 pb^{-1} of data. Upper limits on the cross section times branching ratio are shown as function of the di-photon mass >70 GeV in Fig. 5. Excluded regions are derived in the plane of the sgoldstino mass versus the supersymmetry breaking scale for two representative sets of parameter values, as shown in Figs. 6 and 7.

[12] ABBOTT 00G searches for trilepton final states (ℓ=e,μ) with $\not{E}_T$ from the indirect decay of gauginos via $LL\overline{E}$ couplings. Efficiencies are computed for all possible production and decay modes of SUSY particles in the framework of the Minimal Supergravity scenario. See Figs. 1–4 for excluded regions in the $m_{1/2}$ versus m_0 plane.

[13] ABREU,P 00C look for the CP-even (S) and CP-odd (P) scalar partners of the goldstino, expected to be produced in association with a photon. The S/P decay into two photons or into two gluons and both the tri-photon and the photon + two jets topologies are investigated. Upper limits on the production cross section are shown in Fig. 5 and the excluded regions in Fig. 6. Data collected at $\sqrt{s}$= 189–202 GeV.

[14] ABACHI 97 searched for $p\overline{p} \to \gamma\gamma\not{E}_T + X$ as supersymmetry signature. It can be caused by selectron, sneutrino, or neutralino production with a radiative decay of their decay products. They placed limits on cross sections.

[15] BARBER 84B consider that $\widetilde{\mu}$ and $\widetilde{e}$ may mix leading to $\mu \to e\widetilde{\gamma}\widetilde{\gamma}$. They discuss mass-mixing limits from decay dist. asym. in LBL-TRIUMF data and e^+ polarization in SIN data.

[16] HOFFMAN 83 set CL = 90% limit $d\sigma/dt$ B$(e^+e^-) < 3.5 \times 10^{-32}$ cm^2/GeV^2 for spin-1 partner of Goldstone fermions with 140 $< m <$160 MeV decaying $\to e^+e^-$ pair.

DYNAMICAL ELECTROWEAK SYMMETRY BREAKING: IMPLICATIONS OF THE H

Written October 2013 by R.S. Chivukula (Michigan State University), M. Narain (Brown University), and J. Womersley (STFC, Rutherford Appleton Laboratory).

1. Introduction and Phenomenology

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a composite operator, typically a fermion bilinear. In these theories, the longitudinal components of the massive weak bosons are identified with composite Nambu-Goldstone bosons arising from dynamical symmetry breaking in a strongly-coupled extension of the standard model. Viable theories of dynamical electroweak symmetry breaking must also explain (or at least accommodate) the presence of an additional composite scalar state to be identified with the H scalar boson [1,2] – a state unlike any other observed to date.

Theories of dynamical electroweak symmetry breaking can be classified by the nature of the composite singlet state to be associated with the H, and the corresponding dimensional scales f, the analog of the pion decay-constant in QCD, and Λ, the scale of the underlying strong dynamics.[1] Of particular importance is the ratio v/f, where $v^2 = 1/(\sqrt{2}G_F) \approx (246\,\mathrm{GeV})^2$, since this ratio measures the expected size of the deviations of the couplings of a composite Higgs boson from those expected in the standard model. The basic possibilities, and the additional states that they predict, are described below.

1.1 Technicolor, $v/f \simeq 1$, $\Lambda \simeq 1$ TeV:

Technicolor models [8–10] incorporate a new asymptotically free gauge theory ("technnicolor") and additional massless fermions ("technifermions" transforming under a vectorial representation of the gauge group). The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral symmetry in QCD is broken down to isospin by the formation of a quark condensate. The $SU(2)_W \times U(1)_Y$ interactions are embedded in the global technifermion chiral symmetries in such a way that the only unbroken gauge symmetry after chiral symmetry breaking is $U(1)_{em}$.[2] These theories naturally provide the Nambu-Goldstone bosons "eaten" by the W and Z boson, and there are various possibilities for the scalar H as described below.

In these theories there would typically be additional states (e.g. vector mesons, analogous to the ρ and ω mesons in QCD) with TeV masses [14,15], and the WW and ZZ scattering amplitudes would expected to be strong at energies of order 1 TeV. In all of these cases, however, to the extent that the H has couplings consistent with those of the standard model, these theories are very highly constrained.

a) **H as a singlet scalar resonance:** The strongly-interacting fermions which make up the Nambu-Goldstone bosons eaten by the weak bosons would naturally be expected to also form an isoscalar neutral bound state, analogous to the σ particle expected in pion-scattering in QCD [16]. However, in this case, there is no symmetry protecting the mass of such a particle – which would therefore generically be of order the energy scale of the underlying strong dynamics Λ. In the simplest theories of this kind – those with a global $SU(2)_L \times SU(2)_R$ chiral symmetry which is spontaneously broken to $SU(2)_V$ – the natural dynamical scale Λ would be of order a TeV, resulting in a particle too heavy to be identified with the H. The scale of

[1] In a strongly interacting theory "Naive Dimensional Analysis" [3,4] implies that, in the absence of fine-tuning, $\Lambda \simeq g^* f$ where $g^* \simeq 4\pi$ is the typical size of a strong coupling in the low-energy theory [5,6]. This estimate is modified in the presence of multiple flavors or colors [7].

[2] For a review of technicolor models, see [11–13].

the underlying interactions could naturally be smaller than 1 TeV if the global symmetries of the theory are larger than $SU(2)_L \times SU(2)_R$, but in this case there would be additional (pseudo-)Nambu-Goldstone bosons (more on this below). A theory of this kind would only be viable, therefore, if some choice of the parameters of the high energy theory could give rise to sufficiently light state without the appearance of additional particles that should have already been observed. Furthermore, while a particle with these quantum numbers could have Higgs-like couplings to any electrically neutral spin-zero state made of quarks, leptons, or gauge-bosons, there is no symmetry insuring that the coupling strengths of such a composite singlet scalar state would be precisely the same as those of the standard model Higgs.

b) **H as a dilaton:** It is possible that the underlying strong dynamics is approximately scale-invariant, as inspired by theories of "walking technicolor" [17–21], and that both the scale and electroweak symmetries are spontaneously broken at the TeV energy scale [22]. In this case, due to the spontaneous breaking of approximate scale invariance, one might expect a corresponding (pseudo-) Nambu-Goldstone boson with a mass less than a TeV, the dilaton [18]. [3] A dilaton couples to the trace of the energy momentum tensor, which leads to a simllar pattern of two-body couplings as the couplings of the standard model Higgs boson [27–29]. Scale-invariance is a space-time symmetry, however, and by the Coleman-Mandula theorem [30], we know that space-time symmetries cannot be embedded in a larger symmetry which includes the global symmetries that we can identify with the electroweak group. Therefore the decay-constants associated with the breaking of the scale and electroweak symmetries will not, in general, be precisely the same.[4] In other words, if there are no large anomalous dimensions associated with the W- and Z-bosons or the top- or bottom-quarks, the ratios of the couplings of the dilaton to these particles would be the same as the ratios of the same couplings for the standard model Higgs boson, but the overall strength of the dilaton couplings would be expected to be different [31,32]. Furthermore, the couplings of the dilaton to gluon- and photon-pairs can be related to the beta functions of the corresponding gauge interactions in the underlying high-energy theory, and will not in general yield couplings with the exactly the same strengths as the standard model.

c) **H as a singlet Pseudo-Nambu-Goldstone Boson:** If the global symmetries of the technicolor theory are larger than $SU(2)_L \times SU(2)_R$, there can be extra singlet (pseudo-) Nambu-Goldstone bosons which could be identified with the H. In this case, however, the coupling strength of the singlet state to WW and ZZ pairs would be comparable to the couplings to gluon and photon pairs, and these would all arise from loop-level couplings in the underlying technicolor theory [33]. This pattern of couplings is not supported by the data.

1.2 The Higgs doublet as a pseudo-Nambu-Goldstone Boson, $v/f < 1$, $\Lambda > 1$ TeV:

In technicolor models, the symmetry-breaking properties of the underlying strong dynamics necessarily breaks the electroweak gauge symmetries. An alternative possibility is that the underlying strong dynamics itself does not break the electroweak interactions, and that the entire quartet of bosons in the Higgs doublet (including the state associated with the H) are composite (pseudo-) Nambu-Goldstone particles [34–37]. In this case, the underlying dynamics can occur at energies larger than 1 TeV and additional interactions with the top-quark mass generating sector (and possibly with additional weakly-coupled gauge bosons) cause the vacuum energy to be minimized when the composite Higgs doublet gains a vacuum expectation value [38]. In these theories, the couplings of the remaining singlet scalar state would naturally be equal to that of the standard model Higgs boson up to corrections of order $(v/f)^2$ and, therefore, constraints on the size of deviations of the H couplings from that of the standard model Higgs give rise to lower bounds on the scales f and Λ.

The electroweak gauge interactions, as well as the interactions responsible for the top-quark mass, explicitly break the chiral symmetries of the composite Higgs model, and lead generically to sizable corrections to the mass-squared of the Higgs-doublet – the so-called "Little Hierarchy Problem" [39]. "Little Higgs" theories [40–43] are examples of composite Higgs models in which the (collective) symmetry-breaking structure is selected so as to suppress these contributions to the Higgs mass-squared, while allowing for a sufficiently large Higgs-boson self-coupling. The collective symmetry breaking required in Little Higgs models typically requires a larger global symmetry of the underlying theory, and hence additional relatively light (compared to Λ) scalar particles, extra electroweak vector bosons (e.g. an additional $SU(2) \times U(1)$ gauge group), and vector-like partners of the top-quark of charge $+2/3$ and possibly also $+5/3$ [44]. Finally, in addition to these states, one would expect the underlying dynamics to yield additional scalar and vector resonances with masses of order Λ.

[3] Even in this case, however, a dilaton associated with electroweak symmetry breaking will likely not *generically* be as light as the H [23–26].

[4] If both the electroweak symmetry and the approximate scale symmetry are broken only by electroweak doublet condensate(s), then the decay-constants for scale and electroweak symmetry breaking may be approximately equal – differing only by terms formally proportional to the amount of explicit scale-symmetry breaking.

1.3 Top-Condensate, Top-Color, Top-Seesaw and related theories, $v/f < 1$, $\Lambda > 1$ TeV:

A final alternative is to consider a strongly interacting theory with a high (compared to a TeV) underlying dynamical scale that *would* naturally break the electroweak interactions, but whose strength is adjusted ("fine-tuned") to produce electroweak symmetry breaking at 1 TeV. This alternative is possible if the electroweak (quantum) phase transition is continuous (second order) in the strength of the strong dynamics [45]. If the fine tuning can be achieved, the underlying strong interactions will produce a light composite Higgs bound state with couplings equal to that of the standard model Higgs boson up to corrections of order $(1\ \mathrm{TeV}/\Lambda)^2$. As in theories in which electroweak symmetry breaking occurs through vacuum alignment, therefore, constraints on the size of deviations of the H couplings from that of the standard model Higgs give rise to lower bounds on the scale Λ. Formally, in the limit $\Lambda \to \infty$ (a limit which requires arbitrarily fine adjustment of the strength of the high-energy interactions), these theories are equivalent to a theory with a fundamental Higgs boson – and the fine adjustment of the coupling strength is a manifestation of the hierarchy problem of theories with a fundamental scalar particle.

In many of these theories the top-quark itself interacts strongly (at high energies), potentially through an extended color gauge sector [46–49]. In these theories, top-quark condensation (or the condensation of an admixture of the top with additional vector-like quarks) is responsible for electroweak symmetry breaking, and the H is identified with a bound state involving the third generation of quarks. These theories typically include an extra set of massive color-octet vector bosons (top-gluons), and an extra $U(1)$ interaction (giving rise to a top-color Z') which couple preferentially to the third generation and whose masses define the scale Λ of the underlying physics.

In addition to the electroweak symmetry breaking dynamics described above, which gives rise to the masses of the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. Two general avenues have been suggested for these new interactions. In one case, e.g. "extended technicolor" theories [50,51], the gauge interactions in the underlying strongly interacting theory are extended to incorporate flavor. This extended gauge symmetry is broken down (possibly sequentially, at several different mass scales) to the residual strongly-interacting interaction responsible for electroweak symmetry breaking. The massive gauge-bosons corresponding to the broken symmetries then mediate interactions between mass operators for the quarks/leptons and the corresponding bilinears of the strongly-interacting fermions, giving rise to the masses of the ordinary fermions after electroweak symmetry breaking. An alternative proposal, "partial compositeness" [52], postulates additional interactions giving rise to mixing between the ordinary quarks and leptons and massive composite fermions in the strongly-interacting underlying theory. Theories incorporating partial compositeness include additional vector-like partners of the ordinary quarks and leptons, typically with masses of order a TeV or less.

In both cases, the effects of these flavor interactions on the electroweak properties of the ordinary quarks and leptons are likely to be most pronounced in the third generation of fermions.[5] The additional particles present, especially the additional scalars, often couple more strongly to heavier fermions. Moreover, since the flavor interactions must give rise to quark mixing, we expect that a generic theory of this kind could give rise to large flavor-changing neutral-currents [51]- - though these constraints are typically somewhat relaxed if the theory "walks" [17–21] or if $\Lambda > 1$ TeV [53]. For these reasons, most authors assume that the underlying flavor dynamics respects flavor symmetries ("minimal" [54,55] or "next-to-minimal" [56] flavor violation) which suppress flavor-changing neutral currents in the two light generations.[6] Additional considerations apply when extending these considerations to potential explanation of neutrino masses (see, for example, [59,60]) .

Since the underlying high-energy dynamics in these theories are strongly coupled, there are no reliable calculation techniques that can be applied to analyze their properties. Instead, most phenomenological studies depend on the construction of a "low-energy" effective theory describing additional scalar, fermion, or vector boson degrees of freedom, which incorporates the relevant symmetries and, when available, dynamical principles. In some cases, motivated by the AdS/CFT correspondence [61], the strongly-interacting theories described above have been investigated by analyzing a dual compactified five-dimensional gauge theory. In these cases, the AdS/CFT "dictionary" is used to map the features of the underlying strongly coupled high-energy dynamics onto the low-energy weakly coupled dual theory [62].

More recently, progress has been made in investigating strongly-coupled models using lattice gauge theory [63,64]. These calculations offer the prospect of establishing which strongly coupled theories of electroweak symmetry breaking have a particle with properties consistent with those observed for the H – and for establishing concrete predictions for these theories at the LHC [65].

2. Experimental Searches

As discussed above, the extent to which the couplings of the H conform to the expectations for a standard model Higgs boson constrains the viability of each of these models.

[5] Indeed, from this point of view, the vector-like partners of the top-quark in top-seesaw and little Higgs models can be viewed as incorporating partial compositeness to explain the origin of the top quark's large mass.

[6] In theories of partial compositeness, the masses of the ordinary fermions depend on the scaling-dimension of the operators corresponding to the composite fermions with which they mix. This leads to a new mechanism for generating the mass-hierarchy of the observed quarks and leptons that, potentially, incorporates minimal or next-to-minimal flavor violation [57,58].

Measurements of the H couplings, and their interpretation in terms of effective field theory, are summarized in the H review in this volume. In what follows, we will focus on searches for the additional particles that might be expected to accompany the singlet scalar: extra scalars, fermions, and vector bosons. In some cases, detailed model-specific searches have been made for the particles described above (though generally not yet taking account of the demonstrated existence of the H boson).

In most cases, however, generic searches (e.g. for extra W' or Z' particles, extra scalars in the context of multi-Higgs models, or for fourth-generation quarks) are quoted that can be used – when appropriately translated – to derive bounds on a specific model of interest.

The mass scale of the new particles implied by the interpretations of the low mass of H discussed above, and existing studies from the Tevatron and lower-energy colliders, suggests that only the Large Hadron Collider has any real sensitivity. A number of analyses already carried out by ATLAS and CMS use relevant final states and might have been expected to observe a deviation from standard model expectations – in no case so far has any such deviation been reported. The detailed implications of these searches in various model frameworks are described below.

2.1 W' or Z' Bosons

Massive vector bosons or particles with similar decay channels would be expected to arise in Little Higgs theories, in theories of Technicolor, or models involving a dilaton, adjusted to produce a light Higgs boson, consistent with the observed H. These particles would be expected to decay to pairs of vector bosons, to third generation quarks, or to leptons. The generic searches for W' and Z' vector bosons listed below can, therefore, be used to constrain models incorporating a composite Higgs-like boson. ATLAS [74] and CMS [75] have searched for Z' production with $Z' \to ee$ or $\mu\mu$ in collision data recorded at $\sqrt{s} = 8$ TeV during the 2012 run of the LHC. These searches are carried out using a integrated luminosity of 20 fb^{-1} and 20.6 fb^{-1} by ATLAS and CMS respectively. The main backgrounds to these analyses arise from Drell-Yan, $t\bar{t}$, and diboson production and are estimated using Monte Carlo, with the cross sections scaled by next-to-next-to-leading-order k-factors. Instrumental backgrounds from QCD multijet and W+jet events are estimated using control data samples. One of the challenges of this analysis is the modeling of the dilepton pair invariant mass resolution. The dielectron channel has higher sensitivity due to the superior mass resolution compared to the dimuon channel. No deviation from the standard model prediction is seen in the dielectron and dimuon invariant mass spectra, by either the ATLAS or the CMS analysis, and lower limits on possible Z' boson masses are set. A $Z'_{\rm SSM}$ with couplings equal to the standard model Z (a "sequential standard model" Z') and a mass below 2.86 TeV is excluded by ATLAS, while CMS sets a 95% C.L. lower mass limit of 2.96 TeV. The ATLAS analysis rules out various $E6$-motivated bosons (Z'_ψ, Z'_χ) with masses lower than $2.38 - 2.54$ TeV. A Z'_ψ with a mass below 2.6 TeV is excluded by CMS. ATLAS searches are also interpreted to obtain a lower mass limit of 2.47 TeV for a Randall-Sundrum graviton with coupling parameter $k/\overline{M}_{Pl} = 0.1$. In addition, ATLAS has performed a search for Z' decaying to a ditau final state [76]. An excess in this signature could have interesting implications for models in which lepton universality is not a necessary requirement and enhanced couplings to the third generation are allowed. This analysis leads to a lower limit on the mass of $Z'_{\rm SSM}$ of 1.9 TeV.

ATLAS [77] has also searched for Z' bosons decaying into top quark pairs using 14 fb^{-1} of collision data collected at $\sqrt{s} = 8$ TeV. The lepton plus jets final state is used, where the top quark pair decays as $t\bar{t} \to WbWb$ with one W boson decaying leptonically and the other hadronically. CMS [70] has carried out a similar search for Z' resonances decaying to $t\bar{t}$ pairs, using "semi-leptonic" and "all-hadronic" decays of the top quarks. The data sample analyzed corresponds to an integrated luminosity of 19.7 fb^{-1}. Both analyses consider $t\bar{t}$ events at the kinematic production threshold, and those produced with high Lorentz boosts. In addition to a conventional resolved-jet analysis, large radius jet-substructure identification techniques are used to reconstruct the $t\bar{t}$ resonance. The $t\bar{t}$ invariant mass spectrum is analyzed for any local excess, and no evidence for any resonance is seen.

Upper limits are set by ATLAS on the cross section times branching ratio of a narrow Z' boson decaying to top quark pairs ranging from 5.3 pb for a Z' mass of 0.5 TeV to 0.08 pb for a mass of 3 TeV. A narrow leptophobic topcolor Z' boson, with $\Gamma/m = 1.2\%$, and a mass below 1.8 TeV is excluded, and upper limits are also set on the cross section times branching ratio for a broad Kaluza Klein excitation of the gluon (g_{KK}) with $\Gamma/m = 15.3\%$ decaying to $t\bar{t}$ which range from 9.6 pb for a mass of 0.5 TeV to 0.152 pb for a mass of 2.5 TeV.

CMS sets upper limits on the production cross section times branching ratio for narrow (wide) resonances at 1.94(1.71) pb for a mass of 0.5 TeV, and 0.029(0.045) pb for a mass of 2 TeV. Topcolor Z' bosons with masses below 2.1 TeV and 2.7 TeV are excluded for $\Gamma/m = 1.2\%$ and 10%, respectively. In the Randall-Sundrum model, g_{KK} masses below 2.5 TeV are excluded.

The semi-leptonic analysis is sensitive to a spin-zero resonance with narrow width, produced via gluon fusion without interference with the standard model background. For heavy Higgs-like particles decaying into $t\bar{t}$, CMS obtains upper limits on the cross sections of 0.8 pb and 0.3 pb for spin-zero resonances with masses of 500 and 750 GeV, respectively [70].

CMS [94] has additionally searched for heavy Z' resonances decaying to the $b\bar{b}$ final state by selecting event with dijets with one or both of the jets tagged as a b-jet. The search is performed using 19.6 fb^{-1} of data collected at $\sqrt{s}$=8 TeV and excludes a sequential standard model Z' with a mass between 1.20 and 1.68 TeV, when the decay branching ratio of $Z' \to b\bar{b}$ relative to $Z' \to jj$ is taken to be 0.22.

Both ATLAS and CMS have also searched for massive charged vector bosons. ATLAS [88] and CMS [89] have searched for a resonant W' state decaying to WZ in the fully-leptonic channel, $\ell\nu\ell'\ell'$ (where $\ell, \ell' = e, \mu$). The WZ invariant mass distribution reconstructed from the observed lepton and neutrino momenta and L_T, the scalar sum of the charged lepton p_Ts, are used as the discriminating variables to identify the W' signal and reject the backgrounds. The backgrounds are mainly from standard model WZ production. No significant localized excess is observed in the reconstructed WZ invariant mass distribution. Using a sample of 19.6 fb^{-1} of data recorded at $\sqrt{s} = 8$ TeV, CMS excludes a W' with masses between 0.17 and 1.45 TeV. The analysis by ATLAS, based on 13 fb^{-1} collected at $\sqrt{s} = 8$ TeV, derives upper limits on the production cross section times branching ratio and obtains a bound on the W' mass of 1.18 TeV in the context of benchmark Extended Gauge models.

CMS [90] also performed a search for $W' \to WZ$ using dijet events, with one or both of the jets identified as a W or a Z boson using jet-substructure techniques. In the absence of any excess, a W' decaying into WZ is excluded up to 1.73 TeV at 95% C.L.

Searches by CMS [91] for a heavy W' decaying to $e\nu$ or $\mu\nu$ again yield a null signal, allowing a standard model-like W' with masses up to 3.35 TeV to be excluded. This result can be re-interpreted to rule out a split UED Kaluza-Klein W^2_{KK} excitation below 3.7 TeV for the mass parameter μ=10 TeV, and in addition set a limit on the scale of a new helicity non-conserving four-fermion contact interaction Λ of 13.0 (10.9) TeV for the electron (muon) channel.

Heavy new gauge bosons can couple to left-handed fermions like the W boson or to right-handed fermions. W' bosons that couple only to right-handed fermions may not have leptonic decay modes, depending on the mass of the right-handed neutrino. For these W' bosons, the tb decay mode is especially important because it is the hadronic decay mode with the best signal-to-background. CMS [92] has carried out a search for $W' \to tb$ decays followed by $t \to bW$ and $W \to \ell\nu$. The analysis relies on the invariant mass of the W', using $\ell\nu$+jets events with one or more b-tags and uses multivariate techniques to improve signal to background separation. The measurement is carried out for arbitrary combinations of the coupling strengths of the W' to left- and right-handed fermions. Based on an analysis of 19.6 fb^{-1} of data, W' bosons with purely left-handed (right-handed) couplings to fermions are excluded for masses below 2.09 (2.03) TeV. ATLAS [93] has also searched for W' bosons in single-top quark production, using 14.3 fb^{-1} of data recorded at $\sqrt{s} = 8$ TeV. The analysis looks at the $\ell\nu b\bar{b}$ final state ($\ell = e, \mu$) again using a multivariate method. No significant deviation from the standard model expectation is observed and for a left-handed (right-handed) W' boson, masses below 1.74 (1.84) TeV are excluded at the 95% confidence level.

2.2 Technicolor Resonances

While the W' and Z' searches listed above have not been interpreted in terms of specific technicolor models, the technicolor-inspired searches listed here have been carried out at the LHC.

ATLAS has searched for a dijet resonance [86] with an invariant mass in the range $130 - 300$ GeV, produced in association with a W or a Z boson. The analysis used 20.3 fb^{-1} of data recorded at $\sqrt{s} = 8$ TeV. The W or Z boson is required to decay leptonically ($\ell = e, \mu$). No significant deviation from the standard model prediction is observed and limits are set on the production cross section times branching ratio for a hypothetical technipion produced in association with a W or Z boson from the decay of a technirho particle in the context of Low Scale Technicolor models.

Both ATLAS and CMS searches for a resonant W' state decaying to WZ in the fully-leptonic channel, $\ell\nu\ell'\ell'(\ell, \ell' = e, \mu)$, described earlier [88,89], have also been used to place limits on a technirho decaying to WZ in similar models.

2.3 Vector-like third generation quarks

Vector-like quarks have non-chiral couplings to W bosons, i.e. their left- and right-handed components couple in the same way. They therefore have vectorial couplings to W bosons. Vector-like quarks arise in Little Higgs theories and theories of a composite Higgs with partial compositeness. In the following the notation T quark refers to a vector-like quark with charge 2/3 and the notation B quark refers to a vector-like quark with charge $-1/3$. T quarks can decay to bW, tZ, or tH. Weak isospin singlets are expected to decay to all three final states with branching fractions of 50%, 25%, 25%, respectively. Weak isospin doublets are expected to decay exclusively to tZ and to tH [67]. Analogously, B quarks can decay to tW, bZ, or bH. All limits in this section are quoted at a confidence level of 95%.

Searches for T quarks that decay to W bosons

CMS has searched for pair production of heavy T quarks that decay exclusively to bW [71] based on the data collected at $\sqrt{s} = 7$ TeV in 2011 with an integrated luminosity of 5 fb^{-1}. The analysis selects events with exactly one charged lepton, assuming that the W boson from the second T quark decays hadronically. Under this hypothesis, a 2C kinematic fit can be performed to reconstruct the mass of the T quark. The two-dimensional distribution of reconstructed mass vs H_T is used to test for the signal. H_T is the scalar sum of the missing p_T and the transverse momenta of the lepton and the leading four jets. No excess over standard model backgrounds is observed. This analysis excludes new quarks that decay 100% to bW for masses below 570 GeV.

A search by ATLAS for the production of a heavy T quark together with its antiparticle, assumes a significant branching ratio for subsequent decay into a W boson and a b quark [78]. The search is based on 14.3 fb^{-1} of data recorded at $\sqrt{s} = 8$ TeV. It uses the lepton+jets final state with an isolated electron or muon and at least four jets, at least one of which

must be tagged as a b-jet. The selection is optimized for T quark masses above about 400 GeV by requiring a high boost of the W decay products. No significant excess of events above standard model expectation is observed. For a chiral fourth generation quark with branching ratio $BR(T \to Wb) = 1$, masses lower than 740 GeV are excluded.

Searches for T and B quarks that decay to Z bosons

CMS has performed a search targeted on T quarks that decay exclusively to tZ based on an integrated luminosity of 1.1 fb^{-1} from pp collisions at $\sqrt{s} = 7$ TeV [68]. Selected events must have three isolated charged leptons, two of which must be consistent with a leptonic Z-boson decay. No significant excess was observed. T quark masses below 485 GeV are excluded.

CMS has also searched for the pair-production of a heavy B quark and its antiparticle, one of which decays to bZ based on 19.6 fb^{-1} of data collected at $\sqrt{s} = 8$ TeV. Events with a Z-boson decay to e^+e^- or $\mu^+\mu^-$ and a jet identified as originating from a b quark are selected. The signal from $B \to bZ$ decays would appear as a local enhancement in the bZ mass distribution. No such enhancement is found and B quarks that decay 100% into bZ are excluded below 700 GeV. This analysis also sets upper limits on the branching fraction for $B \to bZ$ decays of 30-100% in the B quark mass range 450-700 GeV.

A complementary search has been carried out by ATLAS for new heavy quarks decaying into a Z boson and a third generation quark [79]. The analysis targets both a new charge +2/3 quark T, with $T \to Zt$, and a new charge -1/3 quark B, with $B \to bZ$. The search uses 14.3 fb^{-1} of data recorded at $\sqrt{s}$=8 TeV. Selected events contain a high transverse momentum Z boson that decays leptonically, together with two b-jets. No significant excess of events above the standard model expectation is observed, and mass limits are set depending on the assumed branching ratios, see Fig. 1. In a weak-isospin singlet scenario, a T (B) quark with mass lower than 585 (645) GeV is excluded, while for a particular weak-isospin doublet scenario, a T (B) quark with mass lower than 680 (725) GeV is excluded.

Searches for T quarks that decay to H bosons

ATLAS has performed a search for $T\overline{T}$ production with an appreciable T quark branching fraction into tH, followed by $H \to b\overline{b}$. These events are characterized by a large number of jets, many of which are b-jets. Thus the event selection requires one isolated electron or muon and at least six jets, two of which must be tagged as b-jets. The data are classified according to their b-jet multiplicity and the distribution of H_T, the scalar sum of the lepton and jet p_Ts and the missing p_T, is used to search for the signal. No excess of events is found. Weak isospin doublet T quarks are excluded below 790 GeV and weak isospin singlet T quarks are excluded below 640 GeV. This search is orthogonal to the search for T quarks that decay to bW and the results of the two searches are combined.

Searches for T and B quarks in multiple final states

Pair-production of T or B quarks with their antiparticles can result in events with like-sign leptons, for example if the decay $T \to tH \to bWW^+W^-$ is present, followed by leptonic decays of two same-sign W bosons. ATLAS and CMS have searched for this final state. The CMS search is part of the analysis described in the following paragraph. The ATLAS search [73] requires exactly two leptons, both with the same electric charge, at least two jets of which at least one must be tagged as a b-jet, and missing p_T. ATLAS quotes exclusions of some possible branching fraction combinations depending on the mass of the new quarks. T quarks that are electroweak singlets are excluded below 540 GeV and the sensitivity is largest for T quarks that decay exclusively to tH. B quarks that are electroweak singlets are excluded below 590 GeV and the sensitivity for B quarks is maximal if they exclusively decay to tW. The limits set by all the ATLAS searches are superimposed in Fig. 1 and Fig. 2.

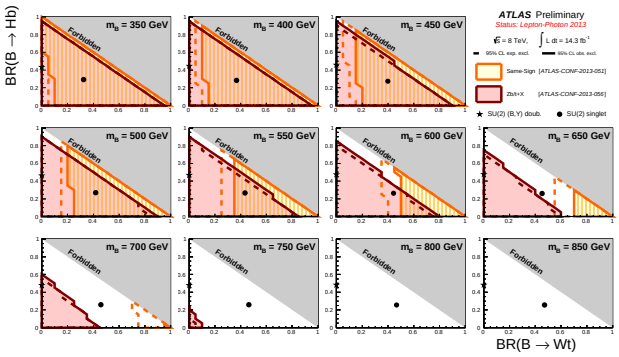

Figure 1: Exclusion limits for BB pair production in the $BR(B \to Wt)$ versus $BR(B \to Ht)$ plane. The limits of the two ATLAS searches are superimposed on the plots. The circle and star symbols denote the default branching ratios for the weak-isospin singlet and doublet cases.

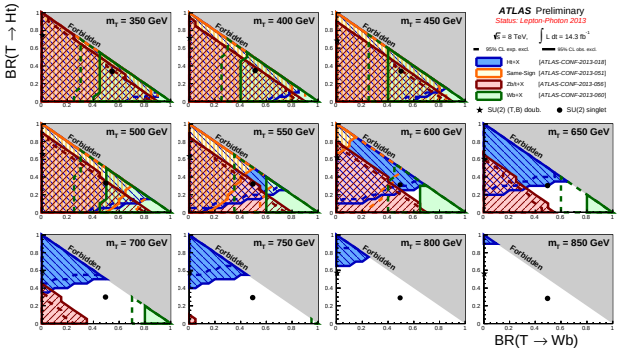

Figure 2: Exclusion limits for TT pair production in the $B(T \to Wb)$ versus $B(T \to Ht)$ plane. The limits of the four ATLAS searches are superimposed on the plots. The circle and star symbols denote the default branching ratios for the weak-isospin singlet and doublet cases.

An inclusive search by CMS targeted at heavy T quarks decaying to any combination of bW, tZ, or tH is described in Ref. [80]. This analysis is based on the data collected at $\sqrt{s}$ = 8 TeV in 2012 with an integrated luminosity of 19.5 fb^{-1}. Selected events have at least one isolated charged lepton. Events are categorized according to number and flavour of the leptons, the number of jets, and the presence of hadronic vector boson and top quark decays that are merged into a single jet. The use of jet substructure to identify hadronic decays significantly increases the acceptance for high T quark masses. The analysis of the high-background single lepton channels is based on a multivariate algorithm using Boosted Decision Trees. The analysis of the low background multilepton channels is based on the event counts in the individual channels. No excess above standard model backgrounds is observed. Limits on the pair production cross section of the new quarks are set, combining all event categories, for all combinations of branching fractions into the three final states. For T quarks that exclusively decay to $bW/tZ/tH$, masses below 700/782/706 GeV are excluded. Electroweak singlet vector-like T quarks which decay 50% to bW, 25% to tZ, and 25% to tH are excluded for masses below 696 GeV. The CMS analysis also quotes limits between 690 and 782 GeV on the mass of the T quark for all possible values of the branching fractions into the three different final states bW, tZ and tH. The observed limit for all combination of the three branching fractions is shown in Fig. 3 (left panel). Every point in the triangle corresponds to a particular set of branching fraction values for $T \to bW$, tZ and tH, such that all three add up to one. In Fig. 3 (right panel) the cross section limit is plotted for the nominal combination of branching fractions (50% to bW, 25% to tZ, and 25% to tH).

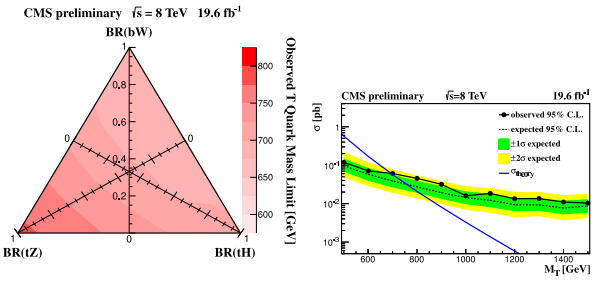

Figure 3: The branching fraction triangle with observed limits for the T quark mass are shown in the left panel. The upper limit on the T quark production cross section for branching fractions into bW, tH, tZ of 50%, 25%, 25% is shown in the right panel [80].

CMS has also carried out a similar inclusive search for the pair production of B quarks that decay into tW, bZ, or bH based on 19.8 fb^{-1} of data collected at $\sqrt{s}$ = 8 TeV [81]. Events must have one isolated electron or muon, at least four jets of which at least one is tagged as a b-jet, and missing p_T. Events are classified according to the number of highly boosted W, Z, or H boson decays. No significant excess of events is observed and B quarks below 582 and 732 GeV are excluded, depending on the B quark decay branching fractions. B quarks that decay exclusively into tW are excluded below 732 GeV. The observed limits for all combinations of branching fractions are shown in Fig. 4, together with the cross section limit plotted for the nominal combination of branching fractions (50% to tW, 25% to bZ, and 25% to bH).

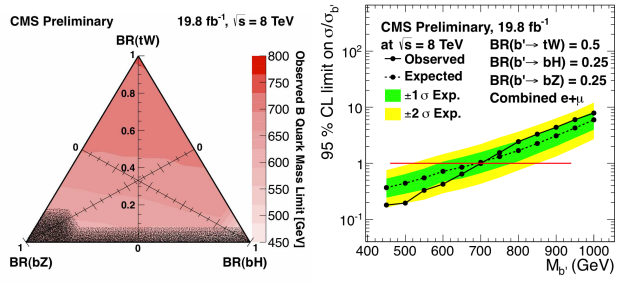

Figure 4: The branching fraction triangle with observed limits for the B quark mass is shown in the left panel. The shaded area at the bottom was not probed by the analysis. The upper limit on the B quark production cross section for branching fractions into mtW, bH, bZ modes of 50%, 25%, 25% respectively, is shown in the right panel [81].

2.4 A charge +5/3 top-partner quark

In models of dynamical electroweak symmetry breaking, the same interactions which give rise to the mass of the top-quark can give unacceptably large corrections to the branching ratio of the Z boson to $b\bar{b}$ [66]. These corrections can be substantially reduced, however, in theories with an extended "custodial symmetry" [44]. This symmetry requires the existence of a charge +5/3 vector-like partner of the top quark.

CMS has performed a search for heavy top with exotic charge 5/3, $T_{5/3}$ vector-like quark following the models in Refs. [82,83]. CMS has searched for the pair-production of $T_{5/3}$ with $T_{5/3}$ decays to tW with a 100% branching fraction. It is assumed that $T_{5/3}$ is heavier than the B quark. The analysis is based on searching for same-sign leptons, from the two W bosons from one of the $T_{5/3}$. Requiring same-sign leptons eliminates most of the standard model background processes, leaving those with smaller cross sections: $t\bar{t}$, W, $t\bar{t}Z$, WWW, and same-sign WW. In addition backgrounds from instrumental effects due to charge misidentification are considered. The CMS search also utilizes jet substructure techniques to identify boosted $T_{5/3}$ topologies. These searches restrict the $T_{5/3}$ mass to be higher than 770 GeV [84].

The single $T_{5/3}$ production cross section depends on the coupling constant λ of the $tWT_{5/3}$ vertex. ATLAS has performed an analysis of same-sign dileptons for the cases where $\lambda = 1$, $\lambda = 3$ which includes both the single and pair production, and for $\lambda \ll 1$, which corresponds to pair production only. This

analysis leads to a 95% C.L. lower limit on the mass of the $T_{5/3}$ of 680, 700, and 670 GeV for $\lambda = 1, 3$ and $\ll 1$, respectively.

2.5 Colorons, Z' and Colored Scalars

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets, $t\bar{t}$, and $b\bar{b}$.

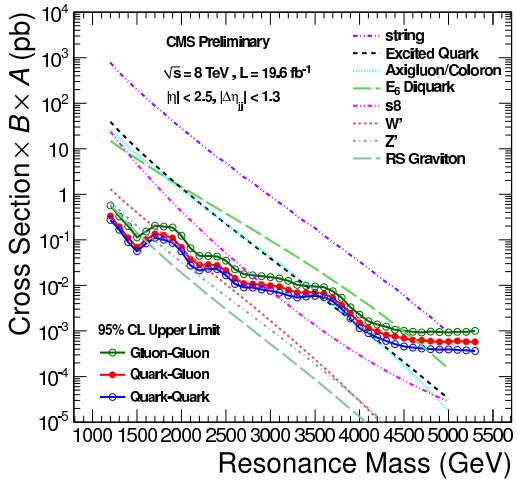

Figure 5: Observed 95% C.L. limits on $\sigma \times B \times A$ for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances, W' and Z' bosons, and Randall-Sundrum gravitons [85].

Direct searches for colorons, W', Z', color-octect scalars and other heavy objects decaying to $q\overline{q}$, qg, qq, or gg has been performed using LHC data from pp collisions at $\sqrt{s}$ =7 and 8 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of 19.6 fb^{-1}, the CMS experiment excludes pair production of colorons with mass between $1.20 - 3.60$ and $3.90 - 4.08$ TeV at 95% C.L., color-octet scalars (s8) with masses between $1.20 - 2.79$ TeV, W' bosons with masses below 2.29 TeV, and Z' Boson with masses below 1.68 TeV, as shown in Fig. 5 [85].

A search for pair-produced colorons based on an integrated luminosity of 5.0 fb^{-1} at $\sqrt{s} = 7$ TeV by CMS excludes colorons with masses between 250 GeV and 740 GeV, assuming colorons decay 100% into $q\overline{q}$ [87]. This analysis is based on events with at least four jets and two dijet combinations with similar dijet mass.

3. Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the H in dynamical frameworks of electroweak symmetry breaking. No hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to 1 TeV are set.

Given the need to better understand the H and to pin down how it behaves, we expect that such analyses will be a major theme of the next run of the LHC, and we look forward to increased sensitivity as a result of the higher luminosity and increased centre of mass energy of collisions.

[1] AAD 13AN search for vector techni-resonance a_T decaying into $W\gamma$.

[2] AAD 13AN search for vector techni-resonance ω_T decaying into $Z\gamma$.

[3] Search for top-color Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[4] CHATRCHYAN 13AP search for top-color leptophobic Z' decaying to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[5] BAAK 12 give electroweak oblique parameter constraints on the QCD-like technicolor models. See their Fig. 28.

[6] CHATRCHYAN 12AF search for a vector techni-resonance decaying to WZ. The limit assumes $M_{\pi_T} = (3/4)\ M_{\rho_T} - 25$ GeV. See their Fig. 3 for the limit in $M_{\pi_T} - M_{\rho_T}$ plane of the low scale technicolor model.

[7] Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11 obtain a limit on the top-Higgs mass > 300 GeV at 95% CL assuming 150 GeV top-pion mass.

[8] Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11A obtain a limit on the techinipion mass ruling out the region 110 GeV $< m_P < 2m_t$. Existence of color techni-fermions, top-color mechanism, and $N_{TC} \geq 3$ are assumed.

[9] AALTONEN 10I search for the vector techni-resonances (ρ_T, ω_T) decaying into $W\pi_T$ with $W \to \ell\nu$ and $\pi_T \to b\overline{b}$, $b\overline{c}$, or $b\overline{u}$. See their Fig. 3 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$ plane.

[10] ABAZOV 10A search for a vector techni-resonance decaying into WZ. The limit assumes $M_{\rho_T} < M_{\pi_T} + M_W$.

[11] ABAZOV 07I search for the vector techni-resonances (ρ_T, ω_T) decaying into $W\pi_T$ with $W \to e\nu$ and $\pi_T \to b\overline{b}$ or $b\overline{c}$. See their Fig. 2 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$ plane.

[12] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions. at $\sqrt{s} = 1.96$ TeV. The limit assumes Technicolor-scale mass parameters $M_V = M_A = 500$ GeV.

[13] CHEKANOV 02B search for color octet techni-π P decaying into dijets in ep collisions. See their Fig. 5 for the limit on $\sigma(ep \to ePX)\cdot B(P \to 2j)$.

[14] ABAZOV 01B searches for vector techni-resonances (ρ_T,ω_T) decaying to e^+e^-. The limit assumes $M_{\rho_T} = M_{\omega_T} < M_{\pi_T} + M_W$.

[15] The limit is independent of the π_T mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the M_{ρ_T}–M_{π_T} plane. ABDALLAH 01 limit on the techni-pion mass is $M_{\pi_T} > 79.8$ GeV for N_D=2, assuming its point-like coupling to gauge bosons.

[16] AFFOLDER 00F search for ρ_T decaying into $W\pi_T$ or $\pi_T\pi_T$ with $W \to \ell\nu$ and $\pi_T \to \overline{b}b$, $\overline{b}c$. See Fig. 1 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the M_{ρ_T}–M_{π_T} plane.

[17] AFFOLDER 00K search for the ρ_{T8} decaying into $\pi_{LQ}\pi_{LQ}$ with $\pi_{LQ} \to b\nu$. For $\pi_{LQ} \to c\nu$, the limit is $M_{\rho_{T8}}$ >510 GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the $M_{\rho_{T8}}$–$M_{\pi_{LQ}}$ plane.

[18] ABE 99F search for a new particle X decaying into $b\overline{b}$ in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to b\overline{b})$. ABE 99F also exclude top gluons of width Γ=0.3M in the mass interval 280 <M< 670 GeV, of width Γ=0.5M in the mass interval 340 <M< 640 GeV, and of width Γ=0.7M in the mass interval 375 <M< 560 GeV.

[19] ABE 99N search for the techni-ω decaying into $\gamma\pi_T$. The technipion is assumed to decay $\pi_T \to b\overline{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the M_{ω_T}–M_{π_T} plane.

[20] ABE 97G search for a new particle X decaying into dijets in $p\overline{p}$ collisions at E_{cm}= 1.8 TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p} \to X)\times B(X \to 2j)$.

The latest unpublished results are described in the "Quark and Lepton Compositeness" review.

SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

Revised 2001 by K. Hagiwara (KEK), and K. Hikasa and M. Tanabashi (Tohoku University).

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ. The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2}\Big[\eta_{LL}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_L\gamma^\mu\psi_L + \eta_{RR}\,\overline{\psi}_R\gamma_\mu\psi_R\,\overline{\psi}_R\gamma^\mu\psi_R + 2\eta_{LR}\,\overline{\psi}_L\gamma_\mu\psi_L\,\overline{\psi}_R\gamma^\mu\psi_R\Big]\ . \tag{1}$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned}
&\Lambda = \Lambda^\pm_{LL} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, 0, 0)\ ,\\
&\Lambda = \Lambda^\pm_{RR} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0, \pm1, 0)\ ,\\
&\Lambda = \Lambda^\pm_{VV} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \pm1)\ ,\\
&\Lambda = \Lambda^\pm_{AA} \ \text{ for } \ (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm1, \pm1, \mp1)\ ,
\end{aligned} \tag{2}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, *e.g.*, for $ee \to ee$) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass and the success of QED prediction for g–2 suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by SU(2)×U(1) quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L\ , \qquad [\nu^*_R]\ , \qquad \ell^*_R\ .$$

ν^*_R is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[\nu_L^*]\,, \qquad \ell_L^*\,, \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\,.$$

3. Homodoublet type

$$\begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_L\,, \qquad \begin{pmatrix}\nu^*\\ \ell^*\end{pmatrix}_R\,.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions"):

	Sequential type	Mirror type	Homodoublet type
V^{ℓ^*}	$-\frac{1}{2}+2\sin^2\theta_W$	$-\frac{1}{2}+2\sin^2\theta_W$	$-1+2\sin^2\theta_W$
A^{ℓ^*}	$-\frac{1}{2}$	$+\frac{1}{2}$	0
$V^{\nu_D^*}$	$+\frac{1}{2}$	$+\frac{1}{2}$	$+1$
$A^{\nu_D^*}$	$+\frac{1}{2}$	$-\frac{1}{2}$	0
$V^{\nu_M^*}$	0	0	—
$A^{\nu_M^*}$	$+1$	-1	—

Here ν_D^* (ν_M^*) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned}\mathcal{L} = &\frac{\lambda_\gamma^{(f^*)} e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f F_{\mu\nu}\\ &+\frac{\lambda_Z^{(f^*)} e}{2m_{f^*}}\,\overline{f}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})f Z_{\mu\nu}\\ &+\frac{\lambda_W^{(\ell^*)} g}{2m_{\ell^*}}\,\overline{\ell}^*\sigma^{\mu\nu}\tfrac{1-\gamma_5}{2}\nu W_{\mu\nu}\\ &+\frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}}\,\overline{\nu}^*\sigma^{\mu\nu}(\eta_L\tfrac{1-\gamma_5}{2}+\eta_R\tfrac{1+\gamma_5}{2})\ell\, W^\dagger_{\mu\nu}\\ &+\text{h.c.}\,, \end{aligned} \tag{3}$$

where $g = e/\sin\theta_W$, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.* The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1\,.$$

Chirality conservation requires

$$\eta_L \eta_R = 0\,. \tag{4}$$

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1, 0)$ or $(0, 1)$ after rescaling λ.

These couplings in Eq. (3) can arise from SU(2)×U(1)-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda}\overline{L}^*\sigma^{\mu\nu}(g f\tfrac{\tau^a}{2}W^a_{\mu\nu} + g' f' Y B_{\mu\nu})\tfrac{1-\gamma_5}{2}L + \text{h.c.}\,, \tag{5}$$

where L denotes the lepton doublet (ν, ℓ), Λ is the compositeness scale, g, g' are SU(2) and $\mathrm{U}(1)_Y$ gauge couplings, and $W^a_{\mu\nu}$ and $B_{\mu\nu}$ are the field strengths for SU(2) and $\mathrm{U}(1)_Y$ gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of $(250\,\text{GeV})/\Lambda$ or m_{L^*}/Λ. In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z\cot\theta_W + \lambda_\gamma)\,. \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned}\mathcal{L} = &\frac{1}{2\Lambda}\overline{Q}^*\sigma^{\mu\nu}\left(g_s f_s\tfrac{\lambda^a}{2}G^a_{\mu\nu} + g\, f\tfrac{\tau^a}{2}W^a_{\mu\nu} + g'\, f' Y B_{\mu\nu}\right)\\ &\times\tfrac{1-\gamma_5}{2}Q + \text{h.c.}\,, \end{aligned} \tag{7}$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G^a_{\mu\nu}$ the gluon field strength.

It should be noted that the electromagnetic radiative decay of $\ell^*(\nu^*)$ is forbidden if $f = -f'$ ($f = f'$). These two possibilities ($f = f'$ and $f = -f'$) are investigated in many analyses of the LEP experiments above the Z pole.

Several different conventions are used by LEP experiments on Z pole to express the transition magnetic couplings. To facilitate comparison, we re-express these in terms of λ_Z and λ_γ using the following relations and taking $\sin^2\theta_W = 0.23$. We assume chiral couplings, *i.e.*, $|c| = |d|$ in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2}\lambda_Z \quad (1990\text{ papers}) \tag{8a}$$

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}[\text{or } m_{\nu^*}]} \quad (\text{for } |c| = |d|) \tag{8b}$$

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin\theta_W\cos\theta_W}{\sqrt{\frac{1}{4}-\frac{2}{3}\sin^2\theta_W+\frac{8}{9}\sin^4\theta_W}}\,\lambda_Z = 1.11\lambda_Z \tag{9}$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot\theta_W - \tan\theta_W}\,\lambda_Z = -1.10\lambda_Z \tag{10}$$

4. L3 (neutrino)

$$f_Z^{\text{L3}} = \sqrt{2}\lambda_Z \tag{11}$$

5. OPAL (charged lepton)

$$\frac{f^{\rm OPAL}}{\Lambda} = -\frac{2}{\cot\theta_W - \tan\theta_W}\,\frac{\lambda_Z}{m_{\ell^*}} = -1.56\,\frac{\lambda_Z}{m_{\ell^*}} \qquad (12)$$

6. OPAL (quark)

$$\frac{f^{\rm OPAL}c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|) \qquad (13)$$

7. DELPHI (charged lepton)

$$\lambda_\gamma^{\rm DELPHI} = -\frac{1}{\sqrt{2}}\,\lambda_\gamma \qquad (14)$$

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda}\sum_\ell \left\{ \overline{\ell}_8^{\,\alpha}\; g_S\, F_{\mu\nu}^{\alpha}\, \sigma^{\mu\nu}\left(\eta_L\, \ell_L + \eta_R\, \ell_R\right) + h.c. \right\} \qquad (15)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L\, \eta_R = 0$ as before.

MASS LIMITS for Excited e (e*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits from some e^+e^- experiments which depend on λ have assumed transition couplings which are chirality violating ($\eta_L = \eta_R$). However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e*) from Pair Production

These limits are obtained from $e^+e^- \to e^{*+}e^{*-}$ and thus rely only on the (electroweak) charge of e^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^* coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume a dominant $e^* \to e\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

>102.8	95	[2] ACHARD	03B	L3	$e^+e^- \to e^*e^*$ Homodoublet type

[1] From e^+e^- collisions at $\sqrt{s}$ = 183–209 GeV. $f = f'$ is assumed.
[2] From e^+e^- collisions at $\sqrt{s}$ = 189–209 GeV. $f = f'$ is assumed. ACHARD 03B also obtain limit for $f = -f'$: $m_{e^*} > 96.6$ GeV.

Limits for Excited e (e*) from Single Production

These limits are from $e^+e^- \to e^*e$, $W \to e^*\nu$, or $ep \to e^*X$ and depend on transition magnetic coupling between e and e^*. All limits assume $e^* \to e\gamma$ decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L = \eta_R = 1$. In most papers, the limit is expressed in the form of an excluded region in the λ–m_{e^*} plane. See the original papers.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

[1] AAD 13BB search for single e^* production in pp collisions with $e^* \to e\gamma$ decay. $f = f' = 1$, and e^* production via contact interaction with $\Lambda = m_{e^*}$ are assumed.
[2] CHATRCHYAN 13AE search for single e^* production in pp collisions with $e^* \to e\gamma$ decay. $f = f' = 1$, and e^* production via contact interaction with $\Lambda = m_{e^*}$ are assumed.
[3] AAD 12AZ search for e^* production via four-fermion contact interaction in pp collisions with $e^* \to e\gamma$ decay. The quoted limit assumes $\Lambda = m_{e^*}$. See their Fig. 8 for the exclusion plot in the mass-coupling plane.
[4] CHATRCHYAN 11X search for single e^* production in pp collisions with the decay $e^* \to e\gamma$. $f = f' = \Lambda/m_{e^*}$ is assumed. See their Fig. 2 for the exclusion plot in the mass-coupling plane.
[5] AARON 08A search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. The quoted limit assumes $f = f' = \Lambda/m_{e^*}$. See their Fig. 3 and Fig. 4 for the exclusion plots in the mass-coupling plane.
[6] ABAZOV 08H search for single e^* production in $p\overline{p}$ collisions with the decays $e^* \to e\gamma$. The e^* production is assumed to be described by an effective four-fermion interaction. See their Fig. 5 for the exclusion plot in the mass-coupling plane.
[7] ACOSTA 05B search for single e^* production in $p\overline{p}$ collisions with the decays $e^* \to e\gamma$. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig.3 for the exclusion limit in the mass-coupling plane.
[8] ACHARD 03B result is from e^+e^- collisions at $\sqrt{s}$ = 189–209 GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.
[9] ABBIENDI 02G result is from e^+e^- collisions at $\sqrt{s}$ = 183–209 GeV. $f = f' = \Lambda/m_{e^*}$ is assumed for e^* coupling. See their Fig. 4c for the exclusion limit in the mass-coupling plane.
[10] CHEKANOV 02D search for single e^* production in ep collisions with the decays $e^* \to e\gamma$, eZ, νW. $f = f' = \Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 5a for the exclusion plot in the mass-coupling plane.

Limits for Excited e (e*) from $e^+e^- \to \gamma\gamma$

These limits are derived from indirect effects due to e^* exchange in the t channel and depend on transition magnetic coupling between e and e^*. All limits are for $\lambda_\gamma = 1$. All limits except ABE 89J and ACHARD 02D are for nonchiral coupling with $\eta_L = \eta_R = 1$. We choose the chiral coupling limit as the best limit and list it in the Summary Table.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

>310	95	ACHARD	02D	L3	$\sqrt{s}$= 192–209 GeV

[1] ABDALLAH 04N also obtain a limit on the excited electron mass with ee^* chiral coupling, $m_{e^*} > 295$ GeV at 95% CL.

Indirect Limits for Excited e (e^*)

These limits make use of loop effects involving e^* and are therefore subject to theoretical uncertainty.

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] DORENBOS...	89	CHRM	$\overline{\nu}_\mu e \to \overline{\nu}_\mu e$, $\nu_\mu e \to \nu_\mu e$
	[2] GRIFOLS	86	THEO	$\nu_\mu e \to \nu_\mu e$
	[3] RENARD	82	THEO	$g-2$ of electron

[1] DORENBOSCH 89 obtain the limit $\lambda_\gamma^2 \Lambda_{cut}^2 / m_{e^*}^2 < 2.6$ (95% CL), where Λ_{cut} is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that $\Lambda_{cut} = 1$ TeV and $\lambda_\gamma = 1$, one obtains $m_{e^*} > 620$ GeV. However, one generally expects $\lambda_\gamma \approx m_{e^*}/\Lambda_{cut}$ in composite models.

[2] GRIFOLS 86 uses $\nu_\mu e \to \nu_\mu e$ and $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

[3] RENARD 82 derived from $g-2$ data limits on mass and couplings of e^* and μ^*. See figures 2 and 3 of the paper.

MASS LIMITS for Excited μ (μ^*)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+e^- \to \mu^{*+}\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^*. Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume a dominant $\mu^* \to \mu\gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review **D45** S1 (1992)).

Extra Dimensions

For explanation of terms used and discussion of significant model dependence of following limits, see the "Extra Dimensions" review. Footnotes describe originally quoted limit. δ indicates the number of extra dimensions.

Limits not encoded here are summarized in the "Extra Dimensions" review, where the latest unpublished results are also described.

EXTRA DIMENSIONS

Updated October 2013 by John Parsons (Columbia University) and Alex Pomarol (Universitat Autònoma de Barcelona)

I Introduction

Proposals for a spacetime with more than three spatial dimensions date back to the 1920's, mainly through the work of Kaluza and Klein, in an attempt to unify the forces of nature [1]. Although their initial idea failed, the formalism that they and others developed is still useful nowadays. Around 1980, string theory proposed again to enlarge the number of space dimensions, this time as a requirement for describing a consistent theory of quantum gravity. The extra dimensions were supposed to be compactified at a scale close to the Planck scale, and thus not testable experimentally in the near future.

A different approach was given by Arkani-Hamed, Dimopoulos and Dvali (ADD) in their seminal paper in 1998 [2], where they showed that the weakness of gravity could be explained by postulating two or more extra dimensions in which only gravity could propagate. The size of these extra dimensions should range between roughly a millimeter and $\sim$1/TeV, leading to possible observable consequences in current and future experiments. A year later, Randall and Sundrum (RS) [3] found a new possibility using a warped geometry, postulating a five-dimensional Anti-de Sitter (AdS) spacetime with a compactification scale of order TeV. The origin of the smallness of the electroweak scale versus the Planck scale was explained by the gravitational redshift factor present in the warped AdS metric. As in the ADD model, originally only gravity was assumed to propagate in the extra dimensions, although it was soon clear that this was not necessary in warped extra-dimensions and also the SM gauge fields [4] and SM fermions [5,6] could propagate in the five-dimensional space.

The physics of warped extra-dimensional models has an alternative interpretation by means of the AdS/CFT correspondence [7]. Models with warped extra dimensions are related to four-dimensional strongly-interacting theories, allowing an understanding of the properties of five-dimensional fields as those of four-dimensional composite states [8]. This approach has opened new directions for tackling outstanding questions in particle physics, such as the flavor problem, grand unification, and the origin of electroweak symmetry breaking or supersymmetry breaking.

Kaluza-Klein Theories: Field theories with compact extra dimensions can be written as theories in ordinary four dimensions (4D) by performing a Kaluza-Klein (KK) reduction. As an illustration, consider a simple example, namely a field theory of a complex scalar in flat five-dimensional (5D) spacetime. The action will be given by †

$$S_5 = -\int d^4x\, dy\, M_5 \left[|\partial_\mu \phi|^2 + |\partial_y \phi|^2 + \lambda_5 |\phi|^4\right] , \qquad (1)$$

where y refers to the extra (fifth) dimension. A universal scale M_5 has been extracted in front of the action in order to keep the 5D field with the same mass-dimension as in 4D. This theory is perturbative for energies $E \lesssim \ell_5 M_5/\lambda_5$ where $\ell_5 = 24\pi^3$ [9].

Let us now consider that the fifth dimension is compact with the topology of a circle S^1 of radius R, which corresponds to the identification of y with $y + 2\pi R$. In such a case, the 5D complex scalar field can be expanded in a Fourier series:

$$\phi(x,y) = \frac{1}{\sqrt{2\pi R M_5}} \sum_{n=-\infty}^{\infty} e^{iny/R} \phi^{(n)}(x) ,$$

that, inserted in Eq. (1) and integrating over y, gives

$$S_5 = S_4^{(0)} + S_4^{(n)} ,$$

where

$$S_4^{(0)} = -\int d^4x \left[|\partial_\mu \phi^{(0)}|^2 + \lambda_4 |\phi^{(0)}|^4\right] , \text{ and} \qquad (2)$$

$$S_4^{(n)} = -\int d^4x \sum_{n\neq 0} \left[|\partial_\mu \phi^{(n)}|^2 + \left(\frac{n}{R}\right)^2 |\phi^{(n)}|^2\right] + \text{quartic int.}$$

The $n = 0$ mode self-coupling is given by

$$\lambda_4 = \frac{\lambda_5}{2\pi R M_5} . \qquad (3)$$

The above action corresponds to a 4D theory with a massless scalar $\phi^{(0)}$, referred to as the zero-mode, and an infinite tower of massive modes $\phi^{(n)}$, known as KK modes. The KK reduction thus allows a treatment of 5D theories as 4D field theories with an infinite number of fields. At energies smaller than $1/R$, the KK modes can be neglected, leaving the zero-mode action of Eq. (2). The strength of the interaction of the zero-mode, given by Eq. (3), decreases as R increases. Thus, for a large extra dimension $R \gg 1/M_5$, the massless scalar is weakly coupled.

II Large Extra Dimensions for Gravity

II.1 The ADD Scenario

The ADD scenario [2,10,11] assumes a $D = 4 + \delta$ dimensional spacetime, with δ compactified spatial dimensions. The weakness of gravity arises since it propagates in the higher-dimensional space. The SM is assumed to be localized in a 4D subspace, a 3-brane, as can be found in certain string constructions [12]. Gravity is described by the Einstein-Hilbert action in $D = 4 + \delta$ spacetime dimensions

$$S_D = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x d^\delta y \sqrt{-g}\mathcal{R} + \int d^4x \sqrt{-g_{\rm ind}}\, \mathcal{L}_{\rm SM} , \qquad (4)$$

where x labels the ordinary four coordinates, y the δ extra coordinates, g refers to the determinant of the D-dimensional

† Our convention for the metric is $\eta_{MN} = \text{Diag}(-1,1,1,1,1)$.

metric whose Ricci scalar is defined by $\mathcal{R}$, and $\bar{M}_D$ is the reduced Planck scale of the D-dimensional theory. In the second term of Eq. (4), which gives the gravitational interactions of SM fields, the D-dimensional metric reduces to the induced metric on the 3-brane where the SM fields propagate. The extra dimensions are assumed to be flat and compactified in a volume V_δ. As an example, consider a toroidal compactification of equal radii R and volume $V_\delta = (2\pi R)^\delta$. After a KK reduction, one finds that the fields that couple to the SM are the spin-2 gravitational field $G_{\mu\nu}(x,y)$ and a tower of spin-1 KK graviscalars [13]. The graviscalars, however, only couple to SM fields through the trace of the energy-momentum tensor, resulting in weaker couplings to the SM fields. The Fourier expansion of the spin-2 field is given by

$$G_{\mu\nu}(x,y) = G^{(0)}_{\mu\nu}(x) + \frac{1}{\sqrt{V_\delta}} \sum_{\vec{n}\neq 0} e^{i\vec{n}\cdot\vec{y}/R} G^{(\vec{n})}_{\mu\nu}(x)\,, \qquad (5)$$

where $\vec{y} = (y_1, y_2, ..., y_\delta)$ are the extra-dimensional coordinates and $\vec{n} = (n_1, n_2, ..., n_\delta)$. Eq. (5) contains a massless state, the 4D graviton, and its KK tower with masses $m^2_{\vec{n}} = |\vec{n}|^2/R^2$. At energies below $1/R$ the action is that of the zero-mode

$$S^{(0)}_4 = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x\, V_\delta \sqrt{-g^{(0)}}\mathcal{R}^{(0)} + \int d^4x \sqrt{-g^{(0)}_{\rm ind}}\,\mathcal{L}_{\rm SM}\,,$$

where we can identify the 4D reduced Planck mass, $M_P \equiv G_N/\sqrt{8\pi} \simeq 2.4\times 10^{18}$ GeV, as a function of the D-dimensional parameters:

$$M_P^2 = V^\delta \bar{M}_D^{2+\delta} \equiv R^\delta M_D^{2+\delta}\,. \qquad (6)$$

Fixing M_D at around the electroweak scale $M_D \sim$ TeV to avoid introducing a new mass-scale in the model, Eq. (6) gives a prediction for R:

$$\delta = 1, 2, ..., 6 \;\rightarrow\; R \sim 10^9 \text{ km}\,, 0.5 \text{ mm}\,, ...\,, 0.1 \text{ MeV}^{-1}\,. \qquad (7)$$

The option $\delta = 1$ is clearly ruled out. However this is not the case for $\delta \geq 2$, and possible observable consequences can be sought in present and future experiments.

Consistency of the model requires a stabilization mechanism for the radii of the extra dimensions, to the values shown in Eq. (7). The fact that we need $R \gg 1/M_D$ leads to a new hierarchy problem, the solution of which might require imposing supersymmetry in the extra-dimensional bulk [14].

II.2 Tests of the Gravitational Force Law at Sub-mm Distances

The KK modes of the graviton give rise to deviations from Newton's law of gravitation for distances $\gtrsim 1/R$. Such deviations are usually parametrized by a modified Newtonian potential of the form

$$V(r) = -G_N \frac{m_1 m_2}{r}\left[1 + \alpha\, e^{-r/\lambda}\right]\,. \qquad (8)$$

For a 2-torus compactification, $\alpha = 16/3$ and $\lambda = R$. Searches for deviations from Newton's law of gravitation have been performed in several experiments. Ref. [15] gives the present constraints: $R < 37\mu$m at 95% CL for $\delta = 2$, corresponding to $M_D > 3.6$ TeV.

II.3 Astrophysical and Cosmological Constraints

The light KK gravitons could be copiously produced in stars, carrying away energy. Ensuring that the graviton luminosity is low enough to preserve the agreement of stellar models with observations provides powerful bounds on the scale M_D. The most stringent arises from supernova SN1987A, giving $M_D > 27$ (2.4) TeV for $\delta = 2$ (3) [16]. After a supernova explosion, most of the KK gravitons stay gravitationally trapped in the remnant neutron star. The requirement that neutron stars are not excessively heated by KK decays into photons leads to $M_D > 1700$ (76) TeV for $\delta = 2$ (3) [17].

Cosmological constraints are also quite stringent [18]. To avoid overclosure of the universe by relic gravitons one needs $M_D > 7$ TeV for $\delta = 2$. Relic KK gravitons decaying into photons contribute to the cosmic diffuse gamma radiation, from which one can derive the bound $M_D > 100$ TeV for $\delta = 2$.

We must mention however that bounds coming from the decays of KK gravitons into photons can be reduced if we assume that KK gravitons decay mainly into other non-SM states. This could happen, for example, if there were other 3-branes with hidden sectors residing on them [10].

II.4 Collider Signals

Collider limits on extra-dimensional models are dominated by Run I LHC results, which are based on total integrated luminosities of $\sim$5 fb^{-1} ($\sim$20 fb^{-1}) collected in 2011 (2012) at a center-of-mass energy of 7 (8) TeV. This review focuses on the most recent limits, most of which are 8 TeV preliminary results which can be found on the WWW pages of public results of the ATLAS [19] and CMS [20] experiments; a more complete record of published results can be found in the PDG Listings.

II.4a Graviton and Other Particle Production

Although each KK graviton has a purely gravitational coupling, suppressed by $1/M_P$, inclusive processes in which one sums over the almost continuous spectrum of available gravitons have cross sections suppressed only by powers of M_D. Processes involving gravitons are therefore detectable in collider experiments if $M_D \sim$ TeV. A number of experimental searches for evidence of large extra dimensions have been performed at colliders, and interpreted in the context of the ADD model.

One signature arises from direct graviton emission. By making a derivative expansion of Einstein gravity, one can construct an effective theory, valid for energies much lower than M_D, and use it to make predictions for graviton-emission processes at colliders [13,21,22]. Gravitons produced in the final state would escape detection, giving rise to missing transverse energy ($\not\!\!E_T$). The results quoted below are 95% CL lower limits on M_D for a range of values of δ between 2 and 6, with more stringent limits corresponding to lower δ values.

At hadron colliders, experimentally sensitive channels include the $j + \not\!\!E_T$ and $\gamma + \not\!\!E_T$ final states. At the LHC, using the full 20 fb^{-1} dataset at 8 TeV and assuming k-factors of

1.5 (1.4) for $\delta = 2, 3$ ($\delta = 4 - 6$) to account for next-to-leading order (NLO) contributions to the signal cross sections, CMS sets limits of $M_D > 3.12 - 5.67$ TeV [23] from analyzing the $j + \not{E}_T$ final state. ATLAS $j + \not{E}_T$ results with 10 fb^{-1} of 8 TeV data provide limits of $M_D > 2.58 - 3.88$ TeV [24], using leading order (LO) cross sections. For these $j + \not{E}_T$ analyses, the LHC experiments handle somewhat differently the issue that the effective theory is only valid for energies much less than M_D: CMS suppresses the graviton cross section by a factor $M_D^4/\hat{s}^2$ for $\sqrt{\hat{s}} > M_D$, where $\sqrt{\hat{s}}$ is the parton-level center-of-mass energy of the hard collision. ATLAS considers the impact of simply truncating the differential cross section to remove the contribution from events where $\sqrt{\hat{s}} > M_D$, and shows that the effect of the truncation grows from a negligible impact for $\delta = 2$ up to a 50% reduction in the total cross section for $\delta = 6$. The ATLAS limits are quoted using the full phase space. Less stringent limits are obtained from analyses of the $\gamma + \not{E}_T$ final state, where both ATLAS [25] and CMS [26] have published results using their full 7 TeV datasets of $\sim$5 fb^{-1}.

In models in which the ADD scenario is embedded in a string theory at the TeV scale [12], we expect the string scale M_s to be smaller than M_D, and therefore expect production of string resonances at the LHC [27]. Analysis of the dijet invariant mass distribution has been interpreted by CMS for their 8 TeV data to exclude at 95% CL string excitations of quarks and gluons that decay predominantly to $q + g$ with masses in the range from 1.20 to 5.08 TeV [28]. An ATLAS dijet analysis [29] using a 13 fb^{-1} dataset of 8 TeV collisions provides its results in the context of model-independent limits on the cross section times acceptance for generic resonances of a variety of possible widths.

II.4b Virtual graviton effects

One can also search for virtual graviton effects, the calculation of which however depends on the ultraviolet cut-off of the theory and is therefore very model dependent. In the literature, several different formulations exist [13,22,30] for the dimension-eight operator for gravity exchange at tree level:

$$\mathcal{L}_8 = \pm\frac{4}{M_{TT}^4}\left(T_{\mu\nu}T^{\mu\nu} - \frac{1}{\delta+2}T^{\mu}_{\mu}T^{\nu}_{\nu}\right), \qquad (9)$$

where $T_{\mu\nu}$ is the energy-momentum tensor and M_{TT} is related to M_D by some model-dependent coefficient [31]. The relations with the parametrizations of Refs. [30] and [13] are, respectively, $M_{TT} = M_S$ and $M_{TT} = (2/\pi)^{1/4}\Lambda_T$. The experimental results below are given as 95% CL lower limits on M_{TT}, including in some cases the possibility of both constructive or destructive interference, depending on the sign chosen in Eq. (9).

The most stringent limits arise from the CMS analysis of the dielectron [32] and dimuon [33] final states, using their full sample of 8 TeV collisions; the combined result corresponds to an approximate limit of $M_{TT} > 3.7$ TeV, assuming constructive interference. Using its full dataset at 7 TeV to analyse the $\gamma\gamma$ final state, ATLAS provides limits [34] of $M_{TT} > 2.94$ TeV (2.52 TeV) for constructive (destructive) interference; the ATLAS limit improves to $M_{TT} > 3.14$ TeV for constructive interference when they combine this diphoton result with their 7 TeV dilepton analysis [35].

At the one-loop level, gravitons can also generate dimension-six operators with coefficients that are also model dependent. Experimental bounds on these operators can also give stringent constraints on M_D [31].

II.4c Black Hole Production

The physics at energies $\sqrt{s} \sim M_D$ is sensitive to the details of the unknown quantum theory of gravity. Nevertheless, in the transplanckian regime, $\sqrt{s} \gg M_D$, one can rely on a semiclassical description of gravity to obtain predictions. An interesting feature of transplanckian physics is the creation of black holes [36]. A black hole is expected to be formed in a collision in which the impact parameter is smaller than the Schwarzschild radius [37]:

$$R_S = \frac{1}{M_D}\left[\frac{2^{\delta}\pi^{(\delta-3)/2}}{\delta+2}\Gamma\left(\frac{\delta+3}{2}\right)\frac{M_{BH}}{M_D}\right]^{1/(\delta+1)}, \qquad (10)$$

where M_{BH} is the mass of the black hole, which would roughly correspond to the total energy in the collision. The cross section for black hole production can be estimated to be of the same order as the geometric area $\sigma \sim \pi R_S^2$. For $M_D \sim$ TeV, this gives a production of $\sim 10^7$ black holes at the $\sqrt{s} = 14$ TeV LHC with an integrated luminosity of 30 fb^{-1} [36]. A black hole would provide a striking experimental signature since it is expected to thermally radiate with a Hawking temperature $T_H = (\delta + 1)/(4\pi R_S)$, and therefore would evaporate democratically into all SM states. Nevertheless, given the present constraints on M_D, the LHC will not be able to reach energies much above M_D. This implies that predictions based on the semiclassical approximation could receive sizable modifications from model-dependent quantum-gravity effects.

The most stringent limits on microscopic black holes arise from LHC searches which observed no excesses above the SM background in high-multiplicity final states. The results are usually quoted as model-independent limits on the cross section for new physics in the final state and kinematic region analyzed. These results can then be used to provide constraints of models of low-scale gravity and weakly-coupled string theory. In addition, limits are sometimes quoted on particular implementations of models, which are used as benchmarks to illustrate the sensitivity. For example, the ATLAS analysis [38] of the track multiplicity in same-sign dimuon events, using their full 20 fb^{-1} sample at 8 TeV, excludes semiclassical black holes below masses in the range of 5.1 - 5.7 TeV, fixing $M_D = 1.5$ TeV and depending on details of the model and also the number of extra dimensions. A CMS analysis [39] of multi-object final states using 12 fb^{-1} of 8 TeV data provides similar limits, but extending out to values of $M_D \sim 5$ TeV.

For black hole masses near M_D, the semi-classical approximation is not valid, and one instead expects quantum black

holes that decay primarily into two-body final states [40]. LHC results provide lower limits on quantum black hole masses of order 5 TeV, depending on the details of the model, including from the CMS multi-object analysis [39] and from an ATLAS search in the photon+jet final state [41] using their full 8 TeV dataset.

In weakly-coupled string models the semiclassical description of gravity fails in the energy range between M_s and M_s/g_s^2 where stringy effects are important. In this regime one expects, instead of black holes, the formation of string balls, made of highly excited long strings, that could be copiously produced at the LHC for $M_s \sim$ TeV [42], and would evaporate thermally at the Hagedorn temperature giving rise to high-multiplicity events. The same analyses used to search for black holes can be interpreted in the context of string balls. For example, the ATLAS same-sign dimuon analysis [38] excludes string balls with minimal masses below 5.3 TeV, for the case of $\delta = 6$ and with model parameters fixed to values of $g_s = 0.4$, $M_D = 1.5$ TeV, and $M_s = M_D/1.26 = 1.2$ TeV. The CMS multi-object [39] analysis excludes the production of string balls with a minimum mass below ~ 5.5 TeV for $g_s = 0.4$, M_D in the range of $1.4 - 2.1$ TeV, and $M_s = M_D/1.25$.

III TeV-Scale Extra Dimensions

III.1 Warped Extra Dimensions

The RS model [3] is the most attractive setup of warped extra dimensions at the TeV scale, since it provides an alternative solution to the hierarchy problem. The RS model is based on a 5D theory with the extra dimension compactified in an orbifold, S^1/Z_2, a circle S^1 with the extra identification of y with $-y$. This corresponds to the segment $y \in [0, \pi R]$, a manifold with boundaries at $y = 0$ and $y = \pi R$. Let us now assume that this 5D theory has a cosmological constant in the bulk Λ, and on the two boundaries Λ_0 and $\Lambda_{\pi R}$:

$$S_5 = -\int d^4x\, dy \Big\{ \sqrt{-g} \left[\frac{1}{2} M_5^3 \mathcal{R} + \Lambda \right] + \sqrt{-g_0}\delta(y)\Lambda_0 + \sqrt{-g_{\pi \mathrm{R}}}\delta(y - \pi R)\Lambda_{\pi R} \Big\}, \tag{11}$$

where g_0 and $g_{\pi R}$ are the values of the determinant of the induced metric on the two respective boundaries. Einstein's equations can be solved, giving in this case the metric

$$ds^2 = a(y)^2 dx^\mu dx^\nu \eta_{\mu\nu} + dy^2 \,, \quad a(y) = e^{-ky} \,, \tag{12}$$

where $k = \sqrt{-\Lambda/6M_5^3}$. Consistency of the solution requires $\Lambda_0 = -\Lambda_{\pi R} = -\Lambda/k$. The metric in Eq. (12) corresponds to a 5D AdS space. The factor $a(y)$ is called the "warp" factor and determines how 4D scales change as a function of the position in the extra dimension. In particular, this implies that energy scales for 4D fields localized at the boundary at $y = \pi R$ are red-shifted by a factor $e^{-k\pi R}$ with respect to those localized at $y = 0$. For this reason, the boundaries at $y = 0$ and $y = \pi R$ are usually referred to as the ultraviolet (UV) and infrared (IR) boundaries, respectively.

As in the ADD case, we can perform a KK reduction and obtain the low-energy effective theory of the 4D massless graviton. In this case we obtain

$$M_P^2 = \int_0^{\pi R} dy\, e^{-2ky} M_5^3 = \frac{M_5^3}{2k} \left(1 - e^{-2k\pi R} \right) . \tag{13}$$

Taking $M_5 \sim k \sim M_P$, we can generate an IR-boundary scale of order $ke^{-k\pi R} \sim$ TeV for an extra dimension of radius $R \simeq 11/k$. Mechanisms to stabilize R to this value have been proposed [43] that, contrary to the ADD case, do not require introducing any new small or large parameter. Therefore a natural solution to the hierarchy problem can be achieved in this framework if the Higgs field, whose vacuum expectation value (VEV) is responsible for electroweak symmetry breaking, is localized at the IR-boundary where the effective mass scales are of order TeV.

In the RS model [3], all the SM fields were assumed to be localized on the IR-boundary. Nevertheless, for the hierarchy problem, only the Higgs field has to be localized there. SM gauge bosons and fermions can propagate in the 5D bulk [4,5,6,44]. By performing a KK reduction from the 5D action of a gauge boson, we find [4]

$$\frac{1}{g_4^2} = \int_0^{\pi R} dy\, \frac{1}{g_5^2} = \frac{\pi R}{g_5^2} \,,$$

where g_D ($D = 4, 5$) is the gauge coupling in D-dimensions. Therefore the 4D gauge couplings can be of order one, as is the case of the SM, if one demands $g_5^2 \sim \pi R$. Using $kR \sim 10$ and $g_4 \sim 0.5$, one obtains the 5D gauge coupling

$$g_5 \sim 4/\sqrt{k} \,. \tag{14}$$

Boundary kinetic terms for the gauge bosons can modify this relation, allowing for larger values of $g_5\sqrt{k}$.

Fermions propagating in a warped extra-dimension have 4D massless zero-modes with wavefunctions which vary as $f_0 \sim Exp[(1/2 - c_f)ky]$, where $c_f k$ is their 5D mass [45,6]. Depending on the free parameter $c_f k$, fermions can be localized either towards the UV-boundary ($c_f > 1/2$) or IR-boundary ($c_f < 1/2$). Since the Higgs is localized on the IR-boundary, one can generate exponentially suppressed Yukawa couplings by having the fermion zero-modes localized towards the UV-boundary, generating naturally the light SM fermion spectrum [6]. A large overlap with the wavefunction of the Higgs is needed for the top quark, in order to generate its large mass, thus requiring it to be localized towards the IR-boundary. In conclusion, the large mass hierarchies present in the SM fermion spectrum can be easily obtained in warped models via suitable choices of the order-one parameters c_f [46]. In these scenarios, deviations in flavor physics from the SM predictions are expected to arise from flavor-changing KK gluon couplings [47], putting certain constraints on the parameters of the models and predicting new physics effects to be observed in B-physics processes [48].

The masses of the KK states can also be calculated. One finds [6]

$$m_n \simeq \left(n + \frac{\alpha}{2} - \frac{1}{4}\right) \pi k e^{-\pi k R}, \qquad (15)$$

where $n = 1, 2, ...$ and $\alpha = \{|c_f - 1/2|, 0, 1\}$ for KK fermions, KK gauge bosons and KK gravitons, respectively. Their masses are of order $ke^{-\pi kR} \sim$ TeV; the first KK state of the gauge bosons would be the lightest, while gravitons are expected to be the heaviest.

III.1a Models of Electroweak Symmetry Breaking

Theories in warped extra dimensions can be used to implement symmetry breaking at low energies by boundary conditions [49]. For example, for a $U(1)$ gauge symmetry in the 5D bulk, this can be easily achieved by imposing a Dirichlet boundary condition on the IR-boundary for the gauge-boson field, $A_\mu|_{y=\pi R} = 0$. This makes the zero-mode gauge boson get a mass, given by $m_A = g_4\sqrt{2k/g_5^2}e^{-\pi kR}$. A very different situation occurs if the Dirichlet boundary condition is imposed on the UV-boundary, $A_\mu|_{y=0} = 0$. In this case the zero-mode gauge boson disappears from the spectrum. Finally, if a Dirichlet boundary condition is imposed on the two boundaries, one obtains a massless 4D scalar corresponding to the fifth component of the 5D gauge boson, A_5. Thus, different scenarios can be implemented by appropriately choosing the 5D bulk gauge symmetry, $\mathcal{G}_5$, and the symmetries to which it reduces on the UV and IR-boundary, $\mathcal{H}_{UV}$ and $\mathcal{H}_{IR}$ respectively. In all cases the KK spectrum comes in representations of the group $\mathcal{G}_5$.

The recent discovery of a light Higgs with $m_H \sim 125$ GeV [50] rules out Higgsless 5D models for electroweak symmetry breaking [51]. This discovery however is consistent with 5D composite Higgs model where a light Higgs is present in the spectrum.

Composite Higgs models: Warped extra dimensions can give rise to scenarios, often called gauge-Higgs unified models, where the Higgs appears as the fifth component of a 5D gauge boson, A_5. The Higgs mass is protected by the 5D gauge invariance and can only get a nonzero value from non-local one-loop effects [52]. To guarantee the relation $M_W^2 \simeq M_Z^2 \cos^2\theta_W$, a custodial $SU(2)_V$ symmetry is needed in the bulk and IR-boundary [53]. The simplest realization [54] has

$$\mathcal{G}_5 = SU(3)_c \times SO(5) \times U(1)_X\,,$$
$$\mathcal{H}_{IR} = SU(3)_c \times SO(4) \times U(1)_X\,,$$
$$\mathcal{H}_{UV} = G_{SM}\,.$$

The Higgs gets a potential at the one-loop level that triggers a VEV, breaking the electroweak symmetry. In these models there is a light Higgs whose mass can be around 125 GeV, as required by the recently discovered Higgs boson [50]. This state, as will be explained in Sec. III.2, behaves as a composite pseudo-Goldstone boson with couplings that deviate from the SM Higgs [55]. The lightest KK modes of the model are color fermions with charges $Q = -1/3, 2/3$ and $5/3$ [56].

III.1b Constraints from Electroweak Precision Tests

Models in which the SM gauge bosons propagate in 1/TeV-sized extra dimensions give generically large corrections to electroweak observables. When the SM fermions are confined on a boundary these corrections are universal and can be parametrized by four quantities: $\widehat{S}$, $\widehat{T}$, W and Y, as defined in Ref. [57]. For warped models, where the 5D gauge coupling of Eq. (14) is large, the most relevant parameter is $\widehat{T}$, which gives the bound $m_{KK} \gtrsim 10$ TeV [44]. When a custodial symmetry is imposed [53], the main constraint comes from the $\widehat{S}$ parameter, requiring $m_{KK} \gtrsim 3$ TeV, independent of the value of g_5. Corrections to the $Zb_L\bar{b}_L$ coupling can also be important [44], especially in warped models for electroweak symmetry breaking as the ones described above.

III.1c Kaluza-Klein Searches

The main prediction of 1/TeV-sized extra dimensions is the presence of a discretized KK spectrum, with masses around the TeV scale, associated with the SM fields that propagate in the extra dimension.

In the RS model [3], only gravity propagates in the 5D bulk. Experimental searches have been performed for the lightest KK graviton through its decay to a variety of SM particle-antiparticle pairs. The results are usually interpreted in the plane of the dimensionless coupling k/M_P versus m_1, where M_P is the reduced Planck mass defined previously and m_1 is the mass of the lightest KK excitation of the graviton. Since the AdS curvature $\sim k$ cannot exceed the cut-off scale of the model, which is estimated to be $\ell_5^{1/3}M_5$ [31], one must demand $k \ll \sqrt{2\ell_5}M_P$. The results quoted below are 95% CL lower limits on the KK graviton mass for a coupling $k/M_P = 0.1$.

The most stringent limits currently arise from searches for dilepton resonances, combining results from the ee and $\mu\mu$ final states. The ATLAS dilepton analysis [58] uses their full sample of 8 TeV collisions and excludes gravitons with masses below 2.47 TeV. The CMS dilepton analysis [59] combines the full 7 TeV dataset with the first 4 fb^{-1} of 8 TeV data to exclude graviton masses below 2.39 TeV. The $\gamma\gamma$ final state is quite powerful, with a branching ratio twice that of any individual lepton flavor, plus lower backgrounds. The ATLAS $\gamma\gamma$ analysis [34] using the full dataset at 7 TeV provides, in combination with $ee/\mu\mu$ results of the same 7 TeV dataset, a lower limit on the graviton mass of 2.23 TeV; this result is dominated by the $\gamma\gamma$ channel, which on its own provides a limit of 2.06 TeV. Less stringent limits on the KK graviton mass come from the WW [60,61] and ZZ [62] final states.

In warped extra-dimensional models in which the SM fields propagate in the 5D bulk, the couplings of the KK graviton to $ee/\mu\mu/\gamma\gamma$ are suppressed [63], and the above bounds do not apply. Furthermore, the KK graviton is the heaviest KK state (see Eq. (15)), and therefore experimental searches for KK gauge bosons and fermions are more appropriate discovery channels in these scenarios. For the scenarios discussed above in which only the Higgs and the top quark are localized close to the IR-boundary, the KK gauge bosons mainly decay

into top quarks, longitudinal W/Z bosons, and Higgs bosons. Couplings to light SM fermions are suppressed by a factor $g/\sqrt{g_5^2 k} \sim 0.2$ [6] for the value of Eq. (14) that is considered from now on. Searches have been made for evidence of the lightest KK excitation of the gluon, through its decay to $t\bar{t}$ pairs. The searches need to take into account the natural KK gluon width, which is typically $\sim 15\%$ of its mass. The decay of a heavy particle to $t\bar{t}$ would tend to produce highly boosted (anti-)top quarks in the final state. Products of the subsequent top decays would therefore tend to be close to each other in the detector. In the case of $t \to Wb \to jjb$ decays, the three jets could overlap one another and not be individually reconstructed with the standard jet algorithms, while $t \to Wb \to \ell\nu b$ decays could result in the lepton failing standard isolation cuts due to its proximity to the b-jet; in both cases, the efficiency for properly reconstructing the final state would fall as the mass of the original particle increases. To avoid the loss in sensitivity which would result, a number of techniques, known generally as "top tagging", have been developed to reconstruct and identify highly boosted top quarks, for example by using a single "fat" jet to contain all the decay products of a hadronic top decay. The large backgrounds from QCD jets can then be reduced by requiring the "jet mass" be consistent with that of a top quark, and also by examining the substructure of the large jet for indication that it resulted from the hadronic decay of a top quark. These techniques are key to extending to very high masses the range of accessible resonances decaying to $t\bar{t}$ pairs. The most stringent current limits result from analyses of the lepton-plus-jets channel, with less stringent limits from analyses of the fully hadronic channel. CMS analyses of the lepton-plus-jets [64](fully hadronic [65]) final state using the full 8 TeV dataset of 20 fb^{-1} exclude KK gluons with masses below 2.54 TeV (1.8 TeV), assuming a k-factor of 1.3 (without using the techniques for boosted top reconstruction, the lepton-plus-jets limit would be 1.7 TeV). An ATLAS analysis [66] of the lepton-plus-jets final state, using 14 fb^{-1} of 8 TeV data, excludes KK gluon masses below 2.0 TeV, whereas the ATLAS fully hadronic analysis [67], using the full 7 TeV dataset, yields a lower limit of 1.62 TeV; both of the ATLAS analyses assume LO cross section values. The results are not directly comparable between the two experiments, since they employ in their respective analyses different implementations of the theoretical model.

A gauge boson KK excitation could be also sought through its decay to longitudinal W/Z bosons. While searches for WZ resonances have been used to set limits on sequential SM W' bosons [68] or other models, as yet no WZ experimental results have been interpreted in the context of warped extra dimensions. The decay to a pair of intermediate vector bosons has, however, been exploited to search for KK gravitons in models in which the SM fields propagate in the 5D bulk. ATLAS analyses of the full 5 fb^{-1} dataset at 7 TeV searching for $G^* \to WW \to \ell\nu\ell\nu$ ($\ell\nu qq'$) [60]([61]) exclude gravitons with masses below 0.84 (0.71) TeV, both for $k/M_P = 1.0$ and using LO cross sections. Results from searches for $G^* \to ZZ \to \ell\ell\bar{q}q$ include CMS [69](ATLAS [70]) lower limits on the graviton mass of 0.71 TeV (0.85 TeV) for $k/M_P = 0.5$ (1.0), using 20 fb^{-1} (7 fb^{-1}) of 8 TeV data. CMS has searched, using their full 8 TeV dataset, for $G^* \to WW/ZZ$ in the fully hadronic decay mode [71], reconstructing each hadronic W/Z decay using the boosted techniques mentioned previously; the results, which are approximate since the finite graviton width is not taken into account, are exclusions of the graviton mass in the range between 1 TeV and 1.59 TeV (1.17 TeV) for decays to WW (ZZ), for $k/M_P = 0.1$.

The lightest KK states are, in certain models, the partners of the top quark. For example, in 5D composite Higgs models these are colored states with charges $Q = -1/3, 2/3$ and $5/3$, and masses expected to be below the TeV [56]. They can be either singly- or pair-produced, and mainly decay into a combination of W/Z with top/bottom [72]. Of particular note, the $Q = 5/3$ state decays mainly into $W^+t \to W^+W^+b$, giving a pair of same-sign leptons in the final state. CMS has used a same-sign dilepton analysis [73] of their full 20 fb^{-1} dataset at 8 TeV to search for pair-production of the $Q = 5/3$ state, excluding masses below 770 GeV. A search by ATLAS, using their full 7 TeV dataset and requiring in addition to a pair of same-sign leptons at least one b-tagged jet in the event [74], provides a lower mass limit on the $Q = 5/3$ state of 670 GeV from pair production, and up to 700 GeV from single production, the cross section for which is model-dependent [75]. Both LHC experiments have searched for pair-production of vector-like quarks T and B of charges $Q = 2/3$ and $-1/3$ respectively, assuming the allowable decays are $T \to Wb/Zt/Ht$ and $B \to Wt/Zb/Hb$. In each case, it is assumed the branching ratios of the three decay modes sum to unity, but the individual branching ratios, which are model-dependent, are allowed to vary within this constraint. CMS has performed inclusive searches, using their full 8 TeV data sample, for T [76] and B [77] pair-production, providing lower limits on the masses in the range of $687 - 782$ GeV ($582 - 732$ GeV) for T (B) vector-like quarks, depending on the values of the individual branching ratios. ATLAS has presented results from searches for pair-production of vector-like quarks, with 14 fb^{-1} of 8 TeV data, using same-sign dileptons with b-jets [78] as well as analyses targeting final states that include $Z + b/t$ [79], $H + t$ [80], and $W + b$ [81]; the first two analyses are relevant for both T and B searches, while the latter two apply only for T. The ATLAS results are similar to the CMS limits quoted above, though ATLAS does not provide a statistical combination of their results but has presented summary plots [19] which show the overlap of the separate results as a function of the individual branching ratio values.

III.2 Connection with Strongly-Coupled Models via the AdS/CFT Correspondence

The AdS/CFT correspondence [7] provides a connection between warped extra-dimensional models and strongly-coupled

theories in ordinary 4D. Although the exact connection is only known for certain cases, the AdS/CFT techniques have been very useful to obtain, at the qualitative level, a 4D holographic description of the various phenomena in warped extra-dimensional models [8].

The connection goes as follows. The physics of the bulk AdS_5 models can be interpreted as that of a 4D conformal field theory (CFT) which is strongly-coupled. The extra-dimensional coordinate y plays the role of the renormalization scale μ of the CFT by means of the identification $\mu \equiv ke^{-ky}$. Therefore the UV-boundary corresponds in the CFT to a UV cut-off scale at $\Lambda_{UV} = k \sim M_P$, breaking explicitly conformal invariance, while the IR-boundary can be interpreted as a spontaneous breaking of the conformal symmetry at energies $ke^{-k\pi R} \sim$ TeV. Fields localized on the UV-boundary are elementary fields external to the CFT, while fields localized on the IR-boundary and KK states corresponds to composite resonances of the CFT. Furthermore, local gauge symmetries in the 5D models, $\mathcal{G}_5$, correspond to global symmetries of the CFT, while the UV-boundary symmetry can be interpreted as a gauging of the subgroup $\mathcal{H}_{UV}$ of $\mathcal{G}_5$ in the CFT. Breaking gauge symmetries by IR-boundary conditions corresponds to the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT at energies $\sim ke^{-k\pi R}$. Using this correspondence one can easily derive the 4D massless spectrum of the compactified AdS_5 models. One also has the identification $k^3/M_5^3 \approx 16\pi^2/N^2$ and $g_5^2 k \approx 16\pi^2/N^r$ ($r = 1$ or 2 for CFT fields in the fundamental or adjoint representation of the gauge group), where N plays the role of the number of colors of the CFT. Therefore the weak-coupling limit in AdS_5 corresponds to a large-N expansion in the CFT.

Following the above AdS/CFT dictionary one can understand the RS solution to the hierarchy problem from a 4D viewpoint. The equivalent 4D model is a CFT with a TeV mass-gap and a Higgs emerging as a composite state. In the particular case where the Higgs is the fifth-component of the gauge-boson, A_5, this corresponds to models, similar to those proposed in Ref. [82], where the Higgs is a composite pseudo-Goldstone boson arising from the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT. The AdS/CFT dictionary tells us that KK states must behave as composite resonances. For example, if the SM gauge bosons propagate in the 5D bulk, the lowest KK $SU(2)_L$-gauge boson must have properties similar to those of the Techni-rho ρ_T [83] with a coupling to longitudinal W/Z bosons given by $g_5\sqrt{k} \approx g_{\rho_T}$, while the coupling to elementary fermions is $g^2/\sqrt{g_5^2 k} \approx g^2 F_{\rho_T}/M_{\rho_T}$.

Fermions in compactified AdS_5 also have a simple 4D holographic interpretation. The 4D massless mode described in Sec. III.1 corresponds to an external fermion ψ_i linearly coupled to a fermionic CFT operator $\mathcal{O}_i$: $\mathcal{L}_{\rm int} = \lambda_i \bar{\psi}_i \mathcal{O}_i + h.c.$. The dimension of the operator $\mathcal{O}_i$ is related to the 5D fermion mass according to $\mathrm{Dim}[\mathcal{O}_i] = |c_f + 1/2| - 1$. Therefore, by varying c_f one varies $\mathrm{Dim}[\mathcal{O}_i]$, making the coupling λ_i irrelevant ($c_f > 1/2$), marginal ($c_f = 1/2$) or relevant ($c_f < 1/2$). When irrelevant, the coupling is exponentially suppressed at low energies, and then the coupling of ψ_i to the CFT (and eventually to the composite Higgs) is very small. When relevant, the coupling grows in the IR and become as large as g_5 (in units of k), meaning that the fermion is as strongly coupled as the CFT states [54]. In this latter case ψ_i behaves as a composite fermion.

III.3 Flat Extra Dimensions

Models with quantum-gravity at the TeV scale, as in the ADD scenario, can have extra (flat) dimensions of 1/TeV size, as happens in string scenarios [84]. All SM fields may propagate in these extra dimensions, leading to the possibility of observing their corresponding KK states.

A simple example is to assume that the SM gauge bosons propagate in a flat five-dimensional orbifold S^1/Z_2 of radius R, with the fermions localized on a 4D boundary. The KK gauge bosons behave as sequential SM gauge bosons with a coupling to fermions enhanced by a factor $\sqrt{2}$ [84]. The experimental limits on such sequential gauge bosons could therefore be recast as limits on KK gauge bosons. Such an interpretation of the ATLAS 7 TeV dilepton analysis [85] yielded the bound $1/R > 4.16$ TeV. Indirect bounds from LEP2 require however $1/R \gtrsim 6$ TeV [57].

An alternative scenario, known as Universal Extra Dimensions (UED) [86], assumes that all SM fields propagate universally in a flat orbifold S^1/Z_2 with an extra Z_2 parity, called KK-parity, that interchanges the two boundaries. In this case, the lowest KK state is stable and is a Dark Matter candidate. At colliders, KK particles would have to be created in pairs, and would then cascade decay to the lightest KK particle (LKP), which would be stable and escape detection. Experimental signatures, such as jets or leptons and $\not{E}_T$, would be similar to those of typical R-parity conserving SUSY searches. Theoretical studies of the trilepton final state [87] suggest a potential bound from the LHC at 8 TeV with 20 fb^{-1} of $1/R \gtrsim 1.3$ TeV for $\Lambda R = 10$, where Λ is the cut-off scale of the model. The experimental searches have not yet been interpreted in the general UED scenario; for example, the ATLAS trilepton analysis [88] of their full 8 TeV dataset provides upper limits on the visible cross section for new physics that could be utilized to determine UED limits.

Experimental limits have been provided on two specific UED models which include KK parity violation. In one case, KK parity is violated by gravitational interactions [89], and the LKP can decay via $\gamma^* \to \gamma + G$. Beginning with strong production of a pair of KK quarks and/or gluons [90,91], the final state would be $\gamma\gamma + \not{E}_T + X$. Using their full 7 TeV datasets, ATLAS [92] and CMS [93] each determine a limit of $1/R \gtrsim 1.4$ TeV for $\Lambda R = 20$. In a second model, that involves two UEDs, the breaking of the KK parity allows the decay of the KK photon to $t\bar{t}$ [94]. The ATLAS same-sign lepton plus b-jet analysis [74], applied for searches of pair-produced KK photons, excludes KK masses below 0.9 TeV in this model.

Finally, realistic models of electroweak symmetry breaking can also be constructed with flat extra spatial dimensions,

similarly to those in the warped case, requiring, however, the presence of sizeable boundary kinetic terms [95]. There is also the possibility of breaking supersymmetry by boundary conditions [96]. Models of this type could explain naturally the presence of a Higgs boson lighter than $M_D \sim$ TeV [97].

CONTENTS:

Limits on R from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian ($1/r^2$) gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form $V = -(G\ m\ m'/r)\ [1 + \alpha\ \exp(-r/R)]$. For δ toroidal extra dimensions of equal size, $\alpha = 8\delta/3$. Quoted bounds are for $\delta = 2$ unless otherwise noted.

[1] KAPNER 07 search for new forces, probing a range of $\alpha \simeq 10^{-3}$–10^{5} and length scales $R \simeq$ 10–1000 μm. For $\delta = 1$ the bound on R is 44 μm. For $\delta = 2$, the bound is expressed in terms of M_*, here translated to a bound on the radius. See their Fig. 6 for details on the bound.

[2] XU 13 obtain constraints on non-Newtonian forces with strengths $|\alpha| \simeq 10^{34}$–10^{36} and length scales $R \simeq$ 1–10 fm. See their Fig. 4 for more details. These constraints do not place limits on the size of extra flat dimensions.

[3] BEZERRA 11 obtain constraints on non-Newtonian forces with strengths $10^{11} \lesssim |\alpha| \lesssim 10^{18}$ and length scales $R =$ 30–1260 nm. See their Fig. 2 for more details. These constraints do not place limits on the size of extra flat dimensions.

[4] SUSHKOV 11 obtain improved limits on non-Newtonian forces with strengths $10^{7} \lesssim |\alpha| \lesssim 10^{11}$ and length scales 0.4 μm $< R <$ 4 μm (95% CL). See their Fig. 2. These bounds do not place limits on the size of extra flat dimensions. However, a model dependent bound of $M_* > 70$ TeV is obtained assuming gauge bosons that couple to baryon number also propagate in $(4 + \delta)$ dimensions.

[5] BEZERRA 10 obtain improved constraints on non-Newtonian forces with strengths $10^{19} \lesssim |\alpha| \lesssim 10^{29}$ and length scales $R =$ 1.6–14 nm (95% CL). See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.

[6] MASUDA 09 obtain improved constraints on non-Newtonian forces with strengths $10^{9} \lesssim |\alpha| \lesssim 10^{11}$ and length scales $R =$ 1.0–2.9 μm (95% CL). See their Fig. 3. This bound does not place limits on the size of extra flat dimensions.

[7] GERACI 08 obtain improved constraints on non-Newtonian forces with strengths $|\alpha| >$ 14,000 and length scales $R =$ 5–15 μm. See their Fig. 9. This bound does not place limits on the size of extra flat dimensions.

[8] TRENKEL 08 uses two independent measurements of Newton's constant G to constrain new forces with strength $|\alpha| \simeq 10^{-4}$ and length scales $R =$ 0.02–1 m. See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.

[9] DECCA 07A search for new forces and obtain bounds in the region with strengths $|\alpha| \simeq 10^{13}$–10^{18} and length scales $R =$ 20–86 nm. See their Fig. 6. This bound does not place limits on the size of extra flat dimensions.

[10] TU 07 search for new forces probing a range of $|\alpha| \simeq 10^{-1}$–10^{5} and length scales $R \simeq$ 20–1000 μm. For $\delta = 1$ the bound on R is 53 μm. See their Fig. 3 for details on the bound.

[11] SMULLIN 05 search for new forces, and obtain bounds in the region with strengths $\alpha \simeq 10^{3}$–10^{8} and length scales $R =$ 6–20 μm. See their Figs. 1 and 16 for details on the bound. This work does not place limits on the size of extra flat dimensions.

[12] HOYLE 04 search for new forces, probing α down to 10^{-2} and distances down to 10μm. Quoted bound on R is for $\delta = 2$. For $\delta = 1$, bound goes to 160 μm. See their Fig. 34 for details on the bound.

[13] CHIAVERINI 03 search for new forces, probing α above 10^{4} and λ down to 3μm, finding no signal. See their Fig. 4 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

[14] LONG 03 search for new forces, probing α down to 3, and distances down to about 10μm. See their Fig. 4 for details on the bound.

[15] HOYLE 01 search for new forces, probing α down to 10^{-2} and distances down to 20μm. See their Fig. 4 for details on the bound. The quoted bound is for $\alpha \geq 3$.

[16] HOSKINS 85 search for new forces, probing distances down to 4 mm. See their Fig. 13 for details on the bound. This bound does not place limits on the size of extra flat dimensions.

Limits on R from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on R, the assumed common radius of the flat extra dimensions, for $\delta = 2$ extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons: $m_{\vec{n}} = |\vec{n}|/R$. See the Review on "Extra Dimensions" for details. Bounds are given in μm for $\delta = 2$.

[1] CHATRCHYAN 12AP search for $pp \to jG$, using 5.0 fb^{-1} of data at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to six extra dimensions, from which this bound on R is derived. See their Table 7 for bounds on all $\delta \leq 6$.

[2] AAD 13AD search for $pp \to jG$, using 4.7 fb^{-1} of data at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to six extra dimensions, from which this bound on R is derived. See their Table 8 for bounds on all $\delta \leq 6$.

[3] AAD 13C search for $pp \to \gamma G$, using 4.6 fb^{-1} of data at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to six extra dimensions, from which this bound on R is derived.

[4] AAD 13D search for the dijet decay of quantum black holes in 4.8 fb^{-1} of data produced in pp collisions at $\sqrt{s} = 7$ TeV to place bounds on M_D for two to seven extra dimensions, from which these bounds on R are derived. Limits on M_D for all $\delta \leq 7$ are given in their Table 3.

[5] AJELLO 12 obtain a limit on R from the gamma-ray emission of point γ sources that arise from the photon decay of KK gravitons which are gravitationally bound around neutron stars. Limits for all $\delta \leq 7$ are given in their Table 7.

[6] AAD 11S search for $pp \to jG$, using 33 pb^{-1} of data at $\sqrt{s} = 7$ TeV, to place bounds on M_D for two to four extra dimensions, from which these bounds on R are derived. See their Table 3 for bounds on all $\delta \leq 4$.

[7] CHATRCHYAN 11U search for $pp \to jG$, using 36 pb^{-1} of data at $\sqrt{s} = 7$ TeV, to place bounds on M_D for two to six extra dimensions, from which these bounds on R are derived. See their Table 3 for bounds on all $\delta \leq 6$.

[8] AALTONEN 08AC search for $p\overline{p} \to \gamma G$ and $p\overline{p} \to jG$ at $\sqrt{s} = 1.96$ TeV with 2.0 fb^{-1} and 1.1 fb^{-1} respectively, in order to place bounds on the fundamental scale and size of the extra dimensions. See their Table III for limits on all $\delta \leq 6$.

[9] ABAZOV 08S search for $p\overline{p} \to \gamma G$, using 1 fb^{-1} of data at $\sqrt{s} = 1.96$ TeV to place bounds on M_D for two to eight extra dimensions, from which these bounds on R are derived. See their paper for intermediate values of δ.

[10] DAS 08 obtain a limit on R from Kaluza-Klein graviton cooling of SN1987A due to plasmon-plasmon annihilation.

[11] ABULENCIA,A 06 search for $p\overline{p} \to jG$ using 368 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV. See their Table II for bounds for all $\delta \leq 6$.

[12] ABDALLAH 05B search for $e^+e^- \to \gamma G$ at $\sqrt{s} = 180$–209 GeV to place bounds on the size of extra dimensions and the fundamental scale. Limits for all $\delta \leq 6$ are given in their Table 6. These limits supersede those in ABREU 00Z.

[13] ACHARD 04E search for $e^+e^- \to \gamma G$ at $\sqrt{s} = 189$–209 GeV to place bounds on the size of extra dimensions and the fundamental scale. See their Table 8 for limits with $\delta \leq 8$. These limits supersede those in ACCIARRI 99R.

[14] ACOSTA 04C search for $\overline{p}p \to jG$ at $\sqrt{s} = 1.8$ TeV to place bounds on the size of extra dimensions and the fundamental scale. See their paper for bounds on $\delta = 4, 6$.

[15] CASSE 04 obtain a limit on R from the gamma-ray emission of point γ sources that arises from the photon decay of gravitons around newly born neutron stars, applying the technique of HANNESTAD 03 to neutron stars in the galactic bulge. Limits for all $\delta \leq 7$ are given in their Table I.

[16] ABAZOV 03 search for $p\overline{p} \to jG$ at $\sqrt{s}$=1.8 TeV to place bounds on M_D for 2 to 7 extra dimensions, from which these bounds on R are derived. See their paper for bounds on intermediate values of δ. We quote results without the approximate NLO scaling introduced in the paper.

[17] HANNESTAD 03 obtain a limit on R from graviton cooling of supernova SN1987a. Limits for all $\delta \leq 7$ are given in their Tables V and VI.

[18] HANNESTAD 03 obtain a limit on R from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic γ background. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.

[19] HANNESTAD 03 obtain a limit on R from gravitons emitted in two recent supernovae and which subsequently decay, creating point γ sources. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits are corrected in the published erratum.

[20] HANNESTAD 03 obtain a limit on R from the heating of old neutron stars by the surrounding cloud of trapped KK gravitons. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.

[21] HEISTER 03C use the process $e^+e^- \to \gamma G$ at $\sqrt{s} = 189$–209 GeV to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with $\delta \leq 6$ for derived limits on M_D.

[22] FAIRBAIRN 01 obtains bounds on R from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from $R < 0.13\ \mu$m to 0.001 μm for δ=2; bounds for δ=3,4 can be derived from Table 1 in the paper.

[23] HANHART 01 obtain bounds on R from limits on graviton cooling of supernova SN 1987a using numerical simulations of proto-neutron star neutrino emission.

[24] CASSISI 00 obtain rough bounds on M_D (and thus R) from red giant cooling for δ=2,3. See their paper for details.

[25] ACCIARRI 99S search for $e^+e^- \to ZG$ at $\sqrt{s}$=189 GeV. Limits on the gravity scale are found in their Table 2, for $\delta \leq 4$.

Mass Limits on M_{TT}

This section includes limits on the cut-off mass scale, M_{TT}, of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter λ, which is taken to be $\lambda = \pm 1$ in the following analyses. Bounds for $\lambda = -1$ are shown in parenthesis after the bound for $\lambda = +1$, if appropriate. Different papers use slightly different definitions of the mass scale. The definition used here is related to another popular convention by $M_{TT}^4 = (2/\pi)\,\Lambda_T^4$, as discussed in the above Review on "Extra Dimensions."

[1] AAD 13E use 4.9 and 5.0 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the dielectron and dimuon channels, respectively, to place lower limits on M_{TT} (equivalent to their M_S). The dielectron and dimuon channels are combined with previous results in the diphoton channel to set the best limit. Bounds on individual channels and different priors can be found in their Table VIII.

[2] AAD 13AS use 4.9 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to place lower limits on M_{TT} (equivalent to their M_S).

[3] AAD 12Y use 2.12 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to place lower limits on M_{TT} (equivalent to their M_S).

[4] BAAK 12 use electroweak precision observables to place bounds on the ratio Λ_T/M_D as a function of M_D. See their Fig. 22 for constraints with a Higgs mass of 120 GeV.

[5] CHATRCHYAN 12J use approximately 2 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV in the dielectron and dimuon channels to place lower limits on Λ_T, here converted to M_{TT}.

[6] CHATRCHYAN 12R use 2.2 fb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to place lower limits on M_{TT} (equivalent to their M_S).

[7] AARON 11C search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ in 446 pb^{-1} of data taken at $\sqrt{s} = 301$ and 319 GeV to place a bound on M_{TT}.

[8] CHATRCHYAN 11A use 36 pb^{-1} of data from pp collisions at $\sqrt{s} = 7$ TeV to place lower limits on Λ_T, here converted to M_{TT}.

[9] ABAZOV 09AE use dijet angular distributions in 0.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_S), here converted to M_{TT}.

[10] ABAZOV 09D use 1.05 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_s), here converted to M_{TT}.

[11] SCHAEL 07A use e^+e^- collisions at $\sqrt{s} = 189$–209 GeV to place lower limits on Λ_T, here converted to limits on M_{TT}.

[12] ABDALLAH 06C use e^+e^- collisions at $\sqrt{s} \sim 130$–207 GeV to place lower limits on M_{TT}, which is equivalent to their definition of M_S. Bound shown includes all possible final state leptons, $\ell = e, \mu, \tau$. Bounds on individual leptonic final states can be found in their Table 31.

[13] GERDES 06 use 100 to 110 pb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV, as recorded by the CDF Collaboration during Run I of the Tevatron. Bound shown includes a K-factor of 1.3. Bounds on individual e^+e^- and $\gamma\gamma$ final states are found in their Table I.

[14] ABAZOV 05V use 246 pb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV to search for deviations in the differential cross section to $\mu^+\mu^-$ from graviton exchange.

[15] CHEKANOV 04B search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ with 130 pb^{-1} of combined data and Q^2 values up to 40,000 GeV^2 to place a bound on M_{TT}.

[16] ABBIENDI 03D use e^+e^- collisions at $\sqrt{s}$=181–209 GeV to place bounds on the ultraviolet scale M_{TT}, which is equivalent to their definition of M_s.

[17] ACHARD 03D look for deviations in the cross section for $e^+e^- \to ZZ$ from $\sqrt{s} =$ 200–209 GeV to place a bound on M_{TT}.

[18] ADLOFF 03 search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ at $\sqrt{s}$=301 and 319 GeV to place bounds on M_{TT}.

[19] GIUDICE 03 review existing experimental bounds on M_{TT} and derive a combined limit.

[20] GIUDICE 03 place bounds on Λ_6, the coefficient of the gravitationally-induced dimension-6 operator $(2\pi\lambda/\Lambda_6^2)(\sum \overline{f}\gamma_\mu\gamma^5 f)(\sum \overline{f}\gamma^\mu\gamma^5 f)$, using data from a variety of experiments. Results are quoted for $\lambda = \pm 1$ and are independent of δ.

[21] HEISTER 03C use e^+e^- collisions at $\sqrt{s}$= 189–209 GeV to place bounds on the scale of dim-8 gravitational interactions. Their $M_s^\pm$ is equivalent to our M_{TT} with $\lambda = \pm 1$.

[22] ACHARD 02 search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm} = 192–209 GeV.
[23] ABBOTT 01 search for variations in differential cross sections to e^+e^- and $\gamma\gamma$ final states at the Tevatron.
[24] ABBIENDI 00R uses e^+e^- collisions at $\sqrt{s}$= 189 GeV.
[25] ABREU 00A search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}= 189–202 GeV.
[26] ABREU 00S uses e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV. Bounds on μ and τ individual final states given in paper.
[27] CHANG 00B derive 3σ limit on M_{TT} of (28,19,15) TeV for δ=(2,4,6) respectively assuming the presence of a torsional coupling in the gravitational action. Highly model dependent.
[28] CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for δ=4. However, unknown UV theory renders δ dependence unreliable. Original paper works in HLZ convention.
[29] GRAESSER 00 obtains a bound from graviton contributions to $g-2$ of the muon through loops of 0.29 TeV for δ=2 and 0.38 TeV for δ=4,6. Limits scale as $\lambda^{1/2}$. However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."
[30] HAN 00 calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using S and T. Bounds on M_{TT} range from 0.5 TeV (δ=6) to 1.1 TeV (δ=2); see text. Limits have strong dependence, $\lambda^{\delta+2}$, on unknown λ coefficient.
[31] MATHEWS 00 search for evidence of graviton exchange in CDF and DØ dijet production data. See their Table 2 for slightly stronger δ-dependent bounds. Limits expressed in terms of $\tilde{M}_S^4 = M_{TT}^4/8$.
[32] MELE 00 obtains bound from KK graviton contributions to $e^+e^- \to VV$ (V=γ,W,Z) at LEP. Authors use Hewett conventions.
[33] ABBIENDI 99P search for s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$ at E_{cm}=189 GeV. The limits $G_+ > 660$ GeV and $G_- > 634$ GeV are obtained from combined E_{cm}=183 and 189 GeV data, where $G_\pm$ is a scale related to the fundamental gravity scale.
[34] ACCIARRI 99M search for the reaction $e^+e^- \to \gamma G$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=183 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.
[35] ACCIARRI 99S search for the reaction $e^+e^- \to ZG$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^-, ZZ, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at E_{cm}=189 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.
[36] BOURILKOV 99 performs global analysis of LEP data on e^+e^- collisions at $\sqrt{s}$=183 and 189 GeV. Bound is on Λ_T.

Limits on $1/R = M_c$

This section includes limits on $1/R = M_c$, the compactification scale in models with one TeV-sized extra dimension, due to exchange of Standard Model KK excitations. Bounds assume fermions are not in the bulk, unless stated otherwise. See the "Extra Dimensions" review for discussion of model dependence.

[1] AAD 12CC use 4.9 and 5.0 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest KK Z/γ boson (equivalent to $1/R = M_c$). The limit quoted here assumes a flat prior corresponding to when the pure Z/γ KK cross section term dominates. See their Section 15 for more details.
[2] BARBIERI 04 use electroweak precision observables to place a lower bound on the compactification scale $1/R$. Both the gauge bosons and the Higgs boson are assumed to propagate in the bulk.
[3] CHATRCHYAN 13AQ use 5.0 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV and a further 3.7 fb^{-1} of data at $\sqrt{s}$ = 8 TeV to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 5 for the bound as a function of the universal bulk fermion mass parameter μ.
[4] CHATRCHYAN 13W use diphoton events with large missing transverse momentum in 4.93 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[5] EDELHAUSER 13 use 19.6 and 20.6 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 8 TeV analyzed by the CMS Collaboration in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the second lightest Kaluza-Klein Z/γ boson (converted to a limit on $1/R = M_c$). The bound assumes Standard Model fields propagating in the bulk and that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$.
[6] AAD 12CP use diphoton events with large missing transverse momentum in 4.8 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[7] AAD 12X use diphoton events with large missing transverse momentum in 1.07 fb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[8] ABAZOV 12M use same-sign dimuon events in 7.3 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions where all Standard Model fields propagate in the bulk.
[9] BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. Bound assumes a 125 GeV Higgs mass. See their Fig. 25 for the bound as a function of the Higgs mass.
[10] FLACKE 12 use electroweak precision observables to place a lower bound on the compactification scale $1/R$, in models with universal extra dimensions and Standard Model fields propagating in the bulk. See their Fig. 1 for the bound as a function of the universal bulk fermion mass parameter μ.
[11] NISHIWAKI 12 use up to 2 fb^{-1} of data from the ATLAS and CMS experiments that constrains the production cross section of a Higgs-like particle to place a lower bound on the compactification scale $1/R$ in universal extra dimension models. The quoted bound assumes Standard Model fields propagating in the bulk and a 125 GeV Higgs mass. See their Fig. 1 for the bound as a function of the Higgs mass.
[12] AAD 11F use diphoton events with large missing transverse energy in 3.1 pb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[13] AAD 11X use diphoton events with large missing transverse energy in 36 pb^{-1} of data produced from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_c = 20$. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[14] ABAZOV 10P use diphoton events with large missing transverse energy in 6.3 fb^{-1} of data produced from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ, for the radiative corrections to the Kaluza-Klein masses, satisfies Λ/M_c=20. The model parameters are chosen such that the decay $\gamma^* \to G\gamma$ occurs with an appreciable branching fraction.
[15] ABAZOV 09AE use dijet angular distributions in 0.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the compactification scale.
[16] HAISCH 07 use inclusive $\overline{B}$-meson decays to place a Higgs mass independent bound on the compactification scale $1/R$ in the minimal universal extra dimension model.
[17] GOGOLADZE 06 use electroweak precision observables to place a lower bound on the compactification scale in models with universal extra dimensions. Bound assumes a 115 GeV Higgs mass. See their Fig. 3 for the bound as a function of the Higgs mass.
[18] CORNET 00 translates a bound on the coefficient of the 4-fermion operator $(\overline{\ell}\gamma_\mu\tau^a\ell)(\overline{\ell}\gamma^\mu\tau^a\ell)$ derived by Hagiwara and Matsumoto into a limit on the mass scale of KK W bosons.
[19] RIZZO 00 obtains limits from global electroweak fits in models with a Higgs in the bulk (3.8 TeV) or on the standard brane (3.3 TeV).

Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

This sections places limits on the mass of the first Kaluza-Klein (KK) excitation of the graviton in the warped extra dimension model of Randall and Sundrum. Bounds in parenthesis assume Standard Model fields propagate in the bulk. Experimental bounds depend strongly on the warp parameter, k. See the "Extra Dimensions" review for a full discussion.

Here we list limits for the value of the warp parameter $k/\overline{M}_P = 0.1$.

[1] AAD 12CC use 4.9 and 5.0 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest KK graviton. See their Figure 5 for limits on the lightest KK graviton mass as a function of $k/\overline{M}_P$.

[2] AAD 13A use 4.7 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV to place a lower bound on the mass of the lightest KK graviton.

[3] AAD 13AS use 4.9 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. The diphoton channel is combined with previous results in the dielectron and dimuon channels to set the best limit. See their Table 2 for warp parameter values $k/\overline{M}_P$ between 0.01 and 0.1.

[4] CHATRCHYAN 13AF use 5.3 and 4.1 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV, respectively, in the dielectron and dimuon channels, to place a lower bound on the mass of the lightest KK graviton.

[5] CHATRCHYAN 13U use 5 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons. See their Figure 5 for limits on the lightest KK graviton mass as a function of $k/\overline{M}_P$.

[6] AAD 12AD use 1.02 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons in the $lljj$ and $llll$ channels (ℓ=e, μ). The limit is quoted for the combined $lljj + llll$ channels. See their Figure 5 for limits on the cross section $\sigma(G \rightarrow ZZ)$ as a function of the graviton mass.

[7] AAD 12Y use 2.12 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. The diphoton channel is combined with previous results in the dielectron and dimuon channels to set the best limit. See their Table 3 for warp parameter values $k/\overline{M}_P$ between 0.01 and 0.1.

[8] AALTONEN 12V use 6 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons in the $lljj$ and $llll$ channels (ℓ=e, μ). It provides improved limits over the previous analysis in AALTONEN 11G. See their Figure 16 for limits from all channels combined on the cross section times branching ratio $\sigma(p\overline{p} \rightarrow G^* \rightarrow ZZ)$ as a function of the graviton mass.

[9] BAAK 12 use electroweak precision observables to place a lower bound on the compactification scale $k\, e^{-\pi k R}$, assuming Standard Model fields propagate in the bulk and the Higgs is confined to the IR brane. See their Fig. 27 for more details.

[10] CHATRCHYAN 12R use 2.2 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the diphoton channel to place lower limits on the mass of the lightest KK graviton. See their Table III for warp parameter values $k/\overline{M}_P$ between 0.01 and 0.1.

[11] AAD 11AD use 1.08 and 1.21 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For warp parameter values $k/\overline{M}_P$ between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 0.71 and 1.63 TeV. See their Table IV for more details.

[12] AALTONEN 11G use 2.5–2.9 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons via the $eeee$, $ee\mu\mu$, $\mu\mu\mu\mu$, $eejj$, and $\mu\mu jj$ channels. See their Fig. 20 for limits on the cross section $\sigma(G \rightarrow ZZ)$ as a function of the graviton mass.

[13] AALTONEN 11R uses 5.7 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV in the dielectron channel to place a lower bound on the mass of the lightest graviton. It provides combined limits with the diphoton channel analysis of AALTONEN 11U. For warp parameter values $k/\overline{M}_P$ between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 612 and 1058 GeV. See their Table I for more details.

[14] ABAZOV 11H use 5.4 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the mass of the lightest graviton. Their 95% C.L. exclusion limit does not include masses less than 300 GeV.

[15] CHATRCHYAN 11 use 35 and 40 pb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For a warp parameter value $k/\overline{M}_P$ = 0.05, the lower limit on the mass of the lightest graviton is 0.855 TeV.

[16] AALTONEN 10N use 2.9 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the mass of the lightest graviton.

[17] ABAZOV 10F use 5.4 fb^{-1} of data from $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to place a lower bound on the mass of the lightest graviton. For warp parameter values of $k/\overline{M}_P$ between 0.01 and 0.1 the lower limit on the mass of the lightest graviton is between 560 and 1050 GeV. See their Fig. 3 for more details.

[18] AALTONEN 08S use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to four electrons via two Z bosons using 1.1 fb^{-1} of data. See their Fig. 8 for limits on $\sigma \cdot B(G \rightarrow ZZ)$ versus the graviton mass.

[19] ABAZOV 08J use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons and photons using 1 fb^{-1} of data. For warp parameter values of $k/\overline{M}_P$ between 0.01 and 0.1 the lower limit on the mass of the lightest excitation is between 300 and 900 GeV. See their Fig. 4 for more details.

[20] AALTONEN 07G use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to photons using 1.2 fb^{-1} of data. For warp parameter values of $k/\overline{M}_P$ = 0.1, 0.05, and 0.01 the bounds on the graviton mass are 850, 694, and 230 GeV, respectively. See their Fig. 3 for more details. See also AALTONEN 07H.

[21] AALTONEN 07H use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons using 1.3 fb^{-1} of data. For a warp parameter value of $k/\overline{M}_P$ = 0.1 the bound on the graviton mass is 807 GeV. See their Fig. 4 for more details. A combined analysis with the diphoton data of AALTONEN 07G yields for $k/\overline{M}_P$ = 0.1 a graviton mass lower bound of 889 GeV.

[22] ABAZOV 05N use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons, electrons or photons, using 260 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P$ = 0.1, 0.05, and 0.01, the bounds on the graviton mass are 785, 650 and 250 GeV respectively. See their Fig. 3 for more details.

[23] ABULENCIA 05A use $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons or electrons, using 200 pb^{-1} of data. For warp parameter values of $k/\overline{M}_P$ = 0.1, 0.05, and 0.01, the bounds on the graviton mass are 710, 510 and 170 GeV respectively.

Limits on Kaluza-Klein Gluons in Warped Extra Dimensions

This section places limits on the mass of the first Kaluza-Klein (KK) excitation of the gluon in warped extra dimension models with Standard Model fields propagating in the bulk. Bounds are given for a specific benchmark model with Γ/m = 15.3% where Γ is the width and m the mass of the KK gluon. See the "Extra Dimensions" review for more discussion.

VALUE (TeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>2.07	95	[1] AAD	13AQ	ATLS	$g_{KK} \rightarrow t\overline{t} \rightarrow \ell j$
>2.5	95	[2] CHATRCHYAN	13BM	CMS	$g_{KK} \rightarrow t\overline{t}$
		[3] CHEN	13A		$\overline{B} \rightarrow X_s\gamma$
>1.5	95	[4] AAD	12BV	ATLS	$g_{KK} \rightarrow t\overline{t} \rightarrow \ell j$

[1] AAD 13AQ use 4.7 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV.

[2] CHATRCHYAN 13BM use 19.7 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 8 TeV. Bound is for a width of approximately 15–20% of the KK gluon mass.

[3] CHEN 13A place limits on the KK mass scale for a specific warped model with custodial symmetry and bulk fermions. See their Figures 4 and 5.

[4] AAD 12BV use 2.05 fb^{-1} of data from pp collisions at $\sqrt{s}$ = 7 TeV.

WIMPs and Other Particles Searches for

OMITTED FROM SUMMARY TABLE

WIMPS AND OTHER PARTICLE SEARCHES

Revised August 2013 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

1. Galactic WIMP (weakly-interacting massive particle) searches
2. Concentration of stable particles in matter
3. General new physics searches
4. Limits on jet-jet resonance in hadron collisions
5. Limits on neutral particle production at accelerators
6. Limits on charged particles in e^+e^- collisions
7. Limits on charged particles in hadron reactions
8. Limits on charged particles in cosmic rays
9. Searches for quantum black hole production

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R, W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, *etc.*

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

GALACTIC WIMP SEARCHES

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of 0.3 GeV/cm^3 is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

Limits for Spin-Independent Cross Section of Dark Matter Particle (X^0) on Nucleon

Isoscalar coupling is assumed to extract the limits from those on X^0–nuclei cross section.

For m_{X^0} = 20 GeV

[1] AARTSEN 13 search for neutrinos from the Sun arising from the pair annihilation of X^0 trapped by the sun in data taken between June 2010 and May 2011. The annihilation channel $X^0X^0 \to \tau^+\tau^-$ is assumed.

[2] See their Fig. 8 for limits extending down to m_{X^0} = 7 GeV.

[3] AGNESE 13 use data taken between Oct. 2006 and July 2007. See their Fig. 4 for limits extending down to m_{X^0} = 7 GeV.

[4] AGNESE 13A use data taken between July 2007 and Sep. 2008. Three candidate events are seen. Assuming these events are real, the best fit parameters are m_{X^0} = 8.6 GeV and $\sigma = 1.9\times10^{-5}$ pb.

[5] Limit from combined data of AGNESE 13 and AGNESE 13A. See their Fig. 4 for limits extending down to m_{X^0} = 5.5 GeV.

[6] See their Fig. 4 for limits extending down to m_{X^0} = 4 GeV.

[7] See their Fig. 5 for limits for m_{X^0} = 4–12 GeV.

[8] ANGLOHER 12 observe excess events above the expected background which are consistent with X^0 with mass $\sim$ 25 GeV (or 12 GeV) and spin-independent X^0-nucleon cross section of 2×10^{-6} pb (or 4×10^{-5} pb).

[9] Reanalysis of ANGLOHER 09 data with all three nuclides. See also BROWN 12.

[10] See their Fig. 7 for cross section limits for m_{X^0} between 4 and 12 GeV.

[11] See their Fig. 4 for limits extending down to m_{X^0} = 7 GeV.

[12] See their Fig. 13 for cross section limits for m_{X^0} between 1.2 and 10 GeV.

[13] See also DAHL 12 for a criticism.

[14] See their Fig. 4 for limits extending to m_{X^0} = 3.5 GeV.

[15] AALSETH 11A find indications of annual modulation of the data, the energy spectrum being compatible with X^0 mass around 8 GeV. See also AALSETH 13.

[16] AHMED 11 search for X^0 inelastic scattering. See their Fig. 8–10 for limits.

[17] AHMED 11A combine CDMS and EDELWEISS data.

[18] AHMED 11B give limits on spin-independent X^0-nucleon cross section for m_{X^0} = 4–12 GeV in the range 10^{-3}–10^{-5} pb. See their Fig. 3.

[19] See their Fig. 3 for limits down to m_{X^0} = 4 GeV.

[20] APRILE 11 reanalyze APRILE 10 data.

[21] APRILE 11A search for X^0 inelastic scattering. See their Fig. 2 and 3 for limits.

[22] HORN 11 perform detector calibration by neutrons. Earlier results are only marginally affected.

[23] See their Fig. 10 and 12 for limits extending to X^0 mass of 1 GeV.

[24] Superseded by AHMED 10.

[25] See their Fig. 6(a) for cross section limits for m_{X^0} extending down to 2 GeV.

[26] See their Fig. 2 for cross section limits for m_{X^0} between 4 and 10 GeV.

For m_{X^0} = 100 GeV

[1] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[2] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[3] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}\mathrm{Ge} \rightarrow X^0\,^{73}\mathrm{Ge}^*$ (13.26 keV).
[4] BELLI 96 limit for inelastic scattering $X^0\,^{129}\mathrm{Xe} \rightarrow X^0\,^{129}\mathrm{Xe}^*$(39.58 keV).
[5] BELLI 96C use background subtraction and obtain $\sigma < 150$ pb (< 1.5 fb) (90% CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[6] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[7] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[8] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[9] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[10] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[11] REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 100 GeV

[1] ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
[2] BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.
[3] BERNABEI 02C analyze the DAMA data in the scenario in which X^0 scatters into a slightly heavier state as discussed by SMITH 01.
[4] GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.
[5] ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.
[6] BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay NaI experiments.
[7] BERNABEI 00D limit is for inelastic scattering $X^0\,^{129}\mathrm{Xe} \rightarrow X^0\,^{129}\mathrm{Xe}$ (39.58 keV).
[8] AMBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.
[9] BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.
[10] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}\mathrm{Ge} \rightarrow X^0\,^{73}\mathrm{Ge}^*$ (13.26 keV).
[11] KLIMENKO 98 limit is for inelastic scattering $X^0\,^{73}\mathrm{Ge} \rightarrow X^0\,^{73}\mathrm{Ge}^*$ (66.73 keV).
[12] BELLI 96 limit for inelastic scattering $X^0\,^{129}\mathrm{Xe} \rightarrow X^0\,^{129}\mathrm{Xe}^*$(39.58 keV).
[13] BELLI 96C use background subtraction and obtain $\sigma < 0.35$ pb (< 0.15 fb) (90% CL) for spin-dependent (independent) X^0-proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
[14] BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
[15] SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
[16] SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm^{-3} is assumed.
[17] GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
[18] SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ^{27}Al and ^{28}Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
[19] BECK 94 uses enriched ^{76}Ge (86% purity).
[20] REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For m_{X^0} = 1 TeV

$<10^{-25}$	95	[10] ACKERMANN	11	FLAT	Satellite galaxy, m=100 GeV
$<10^{-24}$	95	[10] ACKERMANN	11	FLAT	Satellite galaxy, m=1 TeV

[1] AARTSEN 13C search for neutrinos from X^0 annihilation in nearby galaxies and galaxy clusters. See their Figs. 5–7 for limits on $\sigma\cdot v$ for $X^0X^0 \rightarrow \nu\overline{\nu}$, $\mu^+\mu^-$, $\tau^+\tau^-$, and W^+W^- for X^0 mass between 300 GeV and 100 TeV.
[2] ABRAMOWSKI 13 search for monochromatic γ from X^0 annihilation in the Milky Way halo in the central region. Limit on $\sigma\cdot v$ between 10^{-28} and 10^{-25} cm^3 s^{-1} (95% CL) is obtained for X^0 mass between 500 GeV and 20 TeV for $X^0X^0 \rightarrow \gamma\gamma$. X^0 density distribution in the Galaxy by Einasto is assumed. See their Fig. 4.
[3] ACKERMANN 13A search for monochromatic γ from X^0 annihilation in the Milky Way. Limit on $\sigma\cdot v$ for the process $X^0X^0 \rightarrow \gamma\gamma$ in the range 10^{-29}–10^{-27} cm^3 s^{-1} (95% CL) is obtained for X^0 mass between 5 and 300 GeV. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Tables VII–X and Fig.10. Supersedes ACKERMANN 12.
[4] ABRAMOWSKI 12 search for γ's from X^0 annihilation in the Fornax galaxy cluster. See their Fig. 7 for limits on $\sigma\cdot v$ for X^0 mass between 0.1 and 100 TeV for the annihilation channels $\tau^+\tau^-$, $b\overline{b}$, and W^+W^-.
[5] ACKERMANN 12 search for monochromatic γ from X^0 annihilation in the Milky Way. Limit on $\sigma\cdot v$ in the range 10^{-28}–10^{-26} cm^{3}s^{-1} (95% CL) is obtained for X^0 mass between 7 and 200 GeV if X^0 annihilates into $\gamma\gamma$. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Table III and Fig. 15.
[6] ACKERMANN 12 search for γ from X^0 annihilation in the Milky Way in the diffuse γ background. Limit on $\sigma\cdot v$ of 10^{-24} cm^{3}s^{-1} or larger is obtained for X^0 mass between 5 GeV and 10 TeV for various annihilation channels including W^+W^-, $b\overline{b}$, gg, e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$. The limit depends slightly on the assumed density profile of X^0 in the Galaxy. See their Figs. 17–20.
[7] ALIU 12 search for γ's from X^0 annihilation in the dwarf spheroidal galaxy Segue 1. Limit on $\sigma\cdot v$ in the range 10^{-24}–10^{-20} cm^{3}s^{-1} (95% CL) is obtained for X^0 mass between 10 GeV and 2 TeV for annihilation channels e^+e^-, $\mu^+\mu^-$, $\tau^+\tau^-$, $b\overline{b}$, and W^+W^-. See their Fig. 3.
[8] ABBASI 11C search for ν_μ from X^0 annihilation in the outer halo of the Milky Way. The limit assumes annihilation into $\nu\nu$. See their Fig. 9 for limits with other annihilation channels.
[9] ABRAMOWSKI 11 search for γ from X^0 annihilation near the Galactic center. The limit assumes Einasto DM density profile.
[10] ACKERMANN 11 search for γ from X^0 annihilation in ten dwarf spheroidal satellite galaxies of the Milky Way. The limit for $m = 10$ GeV assumes annihilation into $b\overline{b}$, the others W^+W^-. See their Fig. 2 for limits with other final states. See also GERINGER-SAMETH 11 for a different analysis of the same data.

Dark Matter Particle (X^0) Production in Hadron Collisions

Searches for X^0 production in association with observable particles (γ, jets, ...) in high energy hadron collisions. If a specific form of effective interaction Lagrangian is assumed, the limits may be translated into limits on X^0-nucleon scattering cross section.

Searches Particle Listings

WIMPs and Other Particle Searches

[1] JAVORSEK 01 search for (neutral) SIMPs (strongly interacting massive particles) bound to Au nuclei. Here M is the effective SIMP mass.
[2] JAVORSEK 01B search for (neutral) SIMPs (strongly interacting massive particles) bound to Au and Fe nuclei from various origins with exposures on the earth's surface, in a satellite, heavy ion collisions, etc. Here M is the mass of the anomalous nucleus. See also JAVORSEK 02.
[3] See HEMMICK 90 Fig. 7 for other masses 100–10000 m_p.
[4] Bound valid up to $m_{X^-} \sim 100$ TeV.

GENERAL NEW PHYSICS SEARCHES

This subsection lists some of the search experiments which look for general signatures characteristic of new physics, independent of the framework of a specific model.

The observed events are compatible with Standard Model expectation, unless noted otherwise.

[1] AAD 13D search for dijet resonances in pp collisions at $E_{cm} = 7$ TeV with $L = 4.8$ fb^{-1}. The observed events are compatible with Standard Model expectation. See their Fig. 6 and Table 2 for limits on resonance cross section in the range $m = 1.0$–4.0 TeV.
[2] AALTONEN 13R search for production of a pair of jet-jet resonances in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV with $L = 6.6$ fb^{-1}. See their Fig. 5 and Tables I, II for cross section limits.
[3] CHATRCHYAN 13A search for qq, qg, and gg resonances in pp collisions at $E_{cm} = 7$ TeV with $L = 4.8$ fb^{-1}. See their Fig. 3 and Table 1 for limits on resonance cross section in the range $m = 1.0$–4.3 TeV.
[4] CHATRCHYAN 13A search for $b\bar{b}$ resonances in pp collisions at $E_{cm} = 7$ TeV with $L = 4.8$ fb^{-1}. See their Fig. 8 and Table 4 for limits on resonance cross section in the range $m = 1.0$–4.0 TeV.
[5] AAD 12S search for dijet resonances in pp collisions at $E_{cm} = 7$ TeV with $L = 1.0$ fb^{-1}. See their Fig. 3 and Table 2 for limits on resonance cross section in the range $m = 0.9$–4.0 TeV.
[6] CHATRCHYAN 12BL search for $t\bar{t}$ resonances in pp collisions at $E_{cm} = 7$ TeV with $L = 4.4$ fb^{-1}. See their Fig. 4 for limits on resonance cross section in the range $m = 0.5$–3.0 TeV.
[7] AAD 11AG search for dijet resonances in pp collisions at $E_{cm} = 7$ TeV with L = 36 pb^{-1}. Limits on number of events for $m = 0.6$–4 TeV are given in their Table 3.
[8] AALTONEN 11M find a peak in two jet invariant mass distribution around 140 GeV in $W + 2$ jet events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV with L = 4.3 fb^{-1}.
[9] ABAZOV 11I search for two-jet resonances in $W + 2$ jet events in $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV with L = 4.3 fb^{-1} and give limits $\sigma <$ (2.6–1.3) pb (95% CL) for $m =$ 110–170 GeV. The result is incompatible with AALTONEN 11M.
[10] AAD 10 search for narrow dijet resonances in pp collisions at $E_{cm} = 7$ TeV with L = 315 nb^{-1}. Limits on the cross section in the range 10–10^3 pb is given for $m =$ 0.3–1.7 TeV.
[11] KHACHATRYAN 10 search for narrow dijet resonances in pp collisions at $E_{cm} = 7$ TeV with L = 2.9 pb^{-1}. Limits on the cross section in the range 1–300 pb is given for $m =$ 0.5–2.6 TeV separately in the final states qq, qg, and gg.
[12] ABE 99F search for narrow $b\bar{b}$ resonances in $p\bar{p}$ collisions at E_{cm}=1.8 TeV. Limits on $\sigma(p\bar{p} \to X+$ anything)×B($X \to b\bar{b}$) in the range 3–10^3 pb (95%CL) are given for m_X=200–750 GeV. See their Table I.
[13] ABE 97G search for narrow dijet resonances in $p\bar{p}$ collisions with 106 pb^{-1} of data at $E_{cm} = 1.8$ TeV. Limits on $\sigma(p\bar{p} \to X +$ anything)·B($X \to jj$) in the range 10^4–10^{-1} pb (95%CL) are given for dijet mass m=200–1150 GeV with both jets having $|\eta| < 2.0$ and the dijet system having $|\cos\theta^*| < 0.67$. See their Table I for the list of limits. Supersedes ABE 93G.
[14] ABE 93G give cross section times branching ratio into light (d, u, s, c, b) quarks for $\Gamma = 0.02\,M$. Their Table II gives limits for $M =$ 200–900 GeV and $\Gamma = (0.02$–$0.2)\,M$.

[3] ACKERSTAFF 97B associated production limit is for m_{X^0} = 80–160 GeV, m_{Y^0}=0 from 10.0 pb^{-1} at $E_{cm} = 161$ GeV. See their Fig. 3(a).
[4] ACKERSTAFF 97B pair production limit is for m_{X^0} = 40–80 GeV, m_{Y^0}=0 from 10.0 pb^{-1} at $E_{cm} = 161$ GeV. See their Fig. 3(b).

Heavy Particle Production Cross Section

VALUE (cm^2/N)	CL%	EVTS	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •						
			[1] ADAMS	97B	KTEV	m= 1.2–5 GeV
$< 10^{-36}$–10^{-33}	90		[2] GALLAS	95	TOF	m= 0.5–20 GeV
$<(4$–$0.3)\times10^{-31}$	95		[3] AKESSON	91	CNTR	m = 0–5 GeV
$<2 \times 10^{-36}$	90	0	[4] BADIER	86	BDMP	$\tau = (0.05$–$1.)\times10^{-8}$ s
$<2.5 \times 10^{-35}$		0	[5] GUSTAFSON	76	CNTR	$\tau > 10^{-7}$ s

[1] ADAMS 97B search for a hadron-like neutral particle produced in pN interactions, which decays into a ρ^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_L production for the mass range 1.2–5 GeV and lifetime 10^{-9}–10^{-4} s. See also our Light Gluino Section.

[2] GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c pN interactions decaying with a lifetime of 10^{-4}–10^{-8} s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section 10^{-29}–10^{-33} cm^2. See Fig. 10.

[3] AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERN SPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau > 10^{-7}$ s. For $\tau > 10^{-9}$ s, $\sigma < 10^{-30}$ cm^{-2}/nucleon is obtained.

[4] BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass >2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-$X, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass-τ plane for each mode.

[5] GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy (m >2 GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for $m = 3$ GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2.

Production of New Penetrating Non-ν Like States in Beam Dump

[1] ACKERSTAFF 98P search for pair production of long-lived charged particles at E_{cm} between 130 and 183 GeV and give limits $\sigma <$(0.05–0.2) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–89.5 GeV, charge 1 and 2/3. The limit is translated to the cross section at E_{cm}=183 GeV with the s dependence described in the paper. See their Figs. 2–4.

[2] ABREU 97D search for pair production of long-lived particles and give limits $\sigma <$(0.4–2.3) pb (95%CL) for various center-of-mass energies E_{cm}=130–136, 161, and 172 GeV, assuming an almost flat production distribution in cosθ.

[3] BARATE 97K search for pair production of long-lived charged particles at E_{cm} = 130, 136, 161, and 172 GeV and give limits $\sigma <$(0.2–0.4) pb (95%CL) for spin-0 and spin-1/2 particles with m=45–85 GeV. The limit is translated to the cross section at E_{cm}=172 GeV with the E_{cm} dependence described in the paper. See their Figs. 2 and 3 for limits on $J = 1/2$ and $J = 0$ cases.

[4] AKERS 95R is a CERN-LEP experiment with $W_{cm} \sim m_Z$. The limit is for the production of a stable particle in multihadron events normalized to $\sigma(e^+e^- \to$ hadrons). Constant phase space distribution is assumed. See their Fig. 3 for bounds for $Q = \pm 2/3$, $\pm 4/3$.

[5] BUSKULIC 93C is a CERN-LEP experiment with $W_{cm} = m_Z$. The limit is for a pair or single production of heavy particles with unusual ionization loss in TPC. See their Fig. 5 and Table 1.

[6] ADACHI 90C is a KEK-TRISTAN experiment with W_{cm} = 52–60 GeV. The limit is for pair production of a scalar or spin-1/2 particle. See Figs. 3 and 4.

[7] ADACHI 90E is KEK-TRISTAN experiment with W_{cm} = 52–61.4 GeV. The above limit is for inclusive production cross section normalized to $\sigma(e^+e^- \to \mu^+\mu^-)\cdot\beta(3-\beta^2)/2$, where $\beta = (1 - 4m^2/W_{cm}^2)^{1/2}$. See the paper for the assumption about the production mechanism.

[8] KINOSHITA 82 is SLAC PEP experiment at W_{cm} = 29 GeV using lexan and ^{39}Cr plastic sheets sensitive to highly ionizing particles.

[9] BARTEL 80 is DESY-PETRA experiment with W_{cm} = 27–35 GeV. Above limit is for inclusive pair production and ranges between 1. $\times 10^{-1}$ and 1. $\times 10^{-2}$ depending on mass and production momentum distributions. (See their figures 9, 10, 11).

Branching Fraction of Z^0 to a Pair of Stable Charged Heavy Fermions

$<1 \times 10^{-3}$	95	AKRAWY	90O	OPAL	m = 29–40 GeV

[1] AKERS 95R give the 95% CL limit $\sigma(X\overline{X})/\sigma(\mu\mu) < 1.8\times10^{-4}$ for the pair production of singly- or doubly-charged stable particles. The limit applies for the mass range 40.4–45.6 GeV for $X^\pm$ and < 45.6 GeV for $X^{\pm\pm}$. See the paper for bounds for $Q = \pm 2/3$, $\pm 4/3$.

LIMITS ON CHARGED PARTICLES IN HADRONIC REACTIONS

MASS LIMITS for Long-Lived Charged Heavy Fermions

Limits are for spin 1/2 particles with no color and SU(2)$_L$ charge. The electric charge Q of the particle (in the unit of e) is therefore equal to its weak hypercharge. Pair production by Drell-Yan like γ and Z exchange is assumed to derive the limits.

[1] AAD 13AH search for production of long-lived particles with $|q|$=(2–6)e in pp collisions at E_{cm} = 7 TeV with 4.4 fb^{-1}. See their Fig. 8 for cross section limits.

[2] AAD 11I search for production of highly ionizing massive particles in pp collisions at E_{cm} = 7 TeV with L = 3.1 pb^{-1}. See their Table 5 for similar limits for $|q| = 6e$ and $17e$, Table 6 for limits on pair production cross section.

[3] AALTONEN 09Z search for long-lived charged particles in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.0 fb^{-1}. The limits are on production cross section for a particle of mass above 100 GeV in the region $|\eta| \lesssim 0.7$, $p_T > 40$ GeV, and $0.4 < \beta < 1.0$.

[4] Limit for weakly interacting charge-1 particle.

[5] Limit for up-quark like particle.

[6] ABAZOV 09M search for pair production of long-lived charged particles in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV with L = 1.1 fb^{-1}. Limit on the cross section of (0.31–0.04) pb (95% CL) is given for the mass range of 60–300 GeV, assuming the kinematics of stau pair production.

[7] AKTAS 04C look for charged particle photoproduction at HERA with mean c.m. energy of 200 GeV.

[8] ABE 92J look for pair production of unit-charged particles which leave detector before decaying. Limit shown here is for m=50 GeV. See their Fig. 5 for different charges and stronger limits for higher mass.

[9] CARROLL 78 look for neutral, $S = -2$ dihyperon resonance in $pp \to 2K^+$X. Cross section varies within above limits over mass range and p_{lab} = 5.1–5.9 GeV/c.

[10] LEIPUNER 73 is an NAL 300 GeV p experiment. Would have detected particles with lifetime greater than 200 ns.

$<3.0 \times 10^{-36}$		[8] DORFAN	65	CNTR		Fe target m=3–7 GeV

[1] BALDIN 76 is a 70 GeV Serpukhov experiment. Value is per Al nucleus at $\theta = 0$. For other charges in range -0.5 to -3.0, CL = 90% limit is $(2.6 \times 10^{-36})/|(\text{charge})|$ for mass range (2.1–9.4 GeV) $\times$ $|(\text{charge})|$. Assumes stable particle interacting with matter as do antiprotons.

[2] ALBROW 75 is a CERN ISR experiment with E_{cm} = 53 GeV. θ = 40 mr. See figure 5 for mass ranges up to 35 GeV.

[3] JOVANOVICH 75 is a CERN ISR 26+26 and 15+15 GeV pp experiment. Figure 4 covers ranges $Q = 1/3$ to 2 and m = 3 to 26 GeV. Value is per GeV momentum.

[4] APPEL 74 is NAL 300 GeV pW experiment. Studies forward production of heavy (up to 24 GeV) charged particles with momenta 24–200 GeV (−charge) and 40–150 GeV (+charge). Above typical value is for 75 GeV and is per GeV momentum per nucleon.

[5] ALPER 73 is CERN ISR 26+26 GeV pp experiment. p >0.9 GeV, $0.2 < \beta < 0.65$.

[6] ANTIPOV 71B is from same 70 GeV p experiment as ANTIPOV 71C and BINON 69.

[7] ANTIPOV 71C limit inferred from flux ratio. 70 GeV p experiment.

[8] DORFAN 65 is a 30 GeV/c p experiment at BNL. Units are per GeV momentum per nucleus.

Long-Lived Heavy Particle Invariant Cross Section

$<3.0\times10^{-37}$	90	[6] VIDAL	78	CNTR		m=4.5–6 GeV

[1] BERNSTEIN 88 limits apply at $x = 0.2$ and $p_T = 0$. Mass and lifetime dependence of limits are shown in the regions: m = 1.5–7.5 GeV and $\tau = 10^{-8}$–2×10^{-6} s. First number is for hadrons; second is for weakly interacting particles.
[2] THRON 85 is FNAL 400 GeV proton experiment. Mass determined from measured velocity and momentum. Limits are for $\tau > 3\times10^{-9}$ s.
[3] ARMITAGE 79 is CERN-ISR experiment at $E_{cm} = 53$ GeV. Value is for $x = 0.1$ and $p_T = 0.15$. Observed particles at $m = 1.87$ GeV are found all consistent with being antideuterons.
[4] BOZZOLI 79 is CERN-SPS 200 GeV pN experiment. Looks for particle with τ larger than 10^{-8} s. See their figure 11–18 for production cross-section upper limits vs mass.
[5] CUTTS 78 is pBe experiment at FNAL sensitive to particles of $\tau > 5\times10^{-8}$ s. Value is for $-0.3 < x < 0$ and $p_T = 0.175$.
[6] VIDAL 78 is FNAL 400 GeV proton experiment. Value is for $x = 0$ and $p_T = 0$. Puts lifetime limit of $< 5\times10^{-8}$ s on particle in this mass range.

$<5.0\times10^{-11}$	90	0	JONES	67	ELEC		m=5–15 GeV

[1] SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis.
[2] MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Calibration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake effect.
[3] SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10^{17} eV may indicate production of very heavy parent at top of atmosphere.
[4] BHAT 82 observed 12 events with delay $> 2.\times10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
[5] MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
[6] YOCK 81 saw another 3 events with $Q = \pm1$ and m about $4.5m_p$ as well as 2 events with $m > 5.3m_p$, $Q = \pm0.75 \pm 0.05$ and $m > 2.8m_p$, $Q = \pm0.70 \pm 0.05$ and 1 event with $m = (9.3 \pm 3.)m_p$, $Q = \pm0.89 \pm 0.06$ as possible heavy candidates.
[7] YOCK 80 events are with charge exactly or approximately equal to unity.
[8] BHAT 78 is at Kolar gold fields. Limit is for $\tau > 10^{-6}$ s.
[9] YOCK 74 events could be tritons.

[1] AMBROSIO 00B searched for quark matter ("nuclearites") in the velocity range $(10^{-5}$–$1)$ c. The listed limit is for 2×10^{-3} c.
[2] ASTONE 93 searched for quark matter ("nuclearites") in the velocity range $(10^{-3}$–$1)$ c. Their Table 1 gives a compilation of searches for nuclearites.
[3] AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity $< 2.5\times10^{-3}$ c. See their Fig. 3 for other velocity/c and heavier mass range.
[4] NAKAMURA 91 searched for quark matter in the velocity range $(4\times10^{-5}$–$1)$ c.
[5] ORITO 91 searched for quark matter. The limit is for the velocity range $(10^{-4}$–$10^{-3})$ c.
[6] LIU 88 searched for quark matter ("nuclearites") in the velocity range $(2.5\times10^{-3}$–$1)c$. A less stringent limit of 5.8×10^{-11} applies for $(1$–$2.5)\times10^{-3}c$.
[7] BARISH 87 searched for quark matter ("nuclearites") in the velocity range $(2.7\times10^{-4}$–$5\times10^{-3})c$.
[8] NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of u, d, s quarks. These lumps or nuclearites were assumed to have velocity of $(10^{-4}$–$10^{-3})$ c.
[9] ULLMAN 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100–350 km/s.
