69 Abstract

70

71 We conducted a cluster randomized hybrid Effectiveness-Implementation study of
72 *CyberRwanda*, a digital family planning and reproductive health intervention for Rwandan
73 adolescents. Sixty schools were randomized 1:1:1 to control or to one of two implementation
74 models: self-service (self-guided access on tablets) or facilitated (peer-led clubs plus tablet
75 access) with no masking. Eligible participants were aged 12–19 years, in secondary school
76 levels 1 or 2, and willing to provide consent or assent/parental consent and contact information
77 for follow-up. In 2021, 6,078 randomly selected adolescents were enrolled. At 24 months, 91.3%
78 of participants were retained and included in the primary intention-to-treat analyses (control:
79 n=1,845; self-service: n=1,849; facilitated: n=1,858). There were no adverse events related to
80 the study. *CyberRwanda* did not affect the primary outcomes of modern contraceptive use
81 (prevalence ratio [PR]: 1.04; 95% confidence interval [CI]: 0.76, 1.42), childbearing (PR: 1.33;
82 95% CI: 0.71, 2.50), and HIV testing (PR: 1.00; 95% CI: 0.91, 1.11) in the full sample.
83 Significantly higher modern contraceptive use observed in the *CyberRwanda* facilitated arm in a
84 pre-specified analysis of sexually active participants suggests that longer-term evaluation is
85 needed to examine effects as more of the study population becomes sexually active and has
86 increased demand for contraception. **ClinicalTrials.gov registration:** NCT04198272.

88
89 **Introduction**

90
91 Digital health interventions are a promising approach for improving adolescent family planning
92 and reproductive health (FP/RH) outcomes in low-resource settings. By increasing access to
93 accurate health information and comprehensive health products and services through direct-to-
94 consumer channels, digital health interventions have potential to mitigate health misinformation
95 and extend quality healthcare coverage. Several studies in sub-Saharan Africa (SSA) have
96 found that digital FP/RH interventions can improve FP/RH knowledge¹⁻⁴, increase contraceptive
97 use^{2,5}, and reduce adolescent pregnancy.¹ Consequently, the United Nations promotes access
98 to equitable, rights-based digital health technologies to reduce information disparities and
99 increase sexual health literacy to meet the Sustainable Development Goals.^{6,7}

100
101 Digital health interventions may be particularly well-suited for many adolescents, given their
102 preference for private information channels and early technology adoption. In SSA, a paucity of
103 youth-friendly FP/RH information and services contributes to low knowledge and use of
104 contraception,^{8,9} high rates of unintended pregnancy, and persistently high HIV incidence
105 among young people who account for ~30% of all new HIV infections,¹⁰ despite significant
106 progress towards global HIV goals in the general population.¹¹ These detrimental FP/RH
107 outcomes are bidirectionally linked to school dropout, which is pervasive in SSA.¹²⁻¹⁵ Together
108 with harmful gender norms and lack of access to quality FP/RH information, services, and
109 products, these obstacles prevent many young people from completing school HIV-free and
110 avoiding unintended pregnancy.¹⁶⁻¹⁸ However, to date, few rigorous impact evaluations have
111 examined the effectiveness of digital FP/RH interventions designed for adolescents or
112 compared the effectiveness of different implementation models developed using community-led
113 approaches.

114
115 CyberRwanda is an innovative digital FP/RH intervention that was developed using a multi-year,
116 participatory, human-centered design (HCD) process to address gaps in FP/RH care in
117 Rwanda.¹⁹ It was designed as an online platform with three main features (Fig. 1): **STORIES**,
118 webcomics on navigating relationships and sex, including sexual consent, contraceptive use,
119 adolescent pregnancy, and HIV/sexually transmitted infections; **LEARN**, informational guides,
120 videos, audio-recordings, and frequently asked questions focused on menstruation, puberty,

121 gender equality, relationships, consent, education, careers, money, and goal setting; and
122 **SHOP**, a direct-to-consumer online store for discreet ordering of health products (e.g.,
123 condoms, emergency contraception, oral contraception, pads, paracetamol) from nearby
124 pharmacies, health posts, and health facilities trained in youth-friendly services. Products at
125 health posts and facilities were available for free, while products at pharmacies were offered at
126 market rate with periodic promotional discounts to motivate SHOP use. The platform also
127 included a facility finder to assist adolescents in finding nearby health facilities.

128
129 CyberRwanda was implemented in schools and youth centers; however, the present study
130 evaluated school-based implementation only. Schools received one of two implementation
131 models: self-service (self-guided access to the CyberRwanda platform on tablets provided to
132 schools, school computers, or personal devices) or facilitated (self-guided and group access to
133 the CyberRwanda platform along with peer-led weekly clubs to reinforce its content). In both
134 models, CyberRwanda was accessible in Kinyarwanda and English with its content updated
135 regularly based on student feedback and Google Analytics data on usage. A mixed-methods
136 pilot study conducted in secondary schools revealed the acceptability and feasibility of both
137 implementation models and the high demand and enthusiasm for the intervention among
138 adolescents.²⁰

139
140 Following the pilot, we initiated a 24-month Hybrid Effectiveness-Implementation trial in 60
141 secondary schools across eight districts of Rwanda. The aim of our study was to evaluate the
142 effectiveness of the CyberRwanda intervention on individual-level FP/RH outcomes, including
143 modern contraceptive use, childbearing, and HIV testing, and to compare the relative
144 effectiveness of each implementation model to understand whether there are additional benefits
145 from pairing digital interventions with in-person activities and how different implementation
146 models translate into impact. We also assessed student engagement with each implementation
147 model and secondary outcomes related to FP/RH knowledge, attitudes and beliefs, self-efficacy,
148 and behavior.

149

150 **Results**

151

152 ***Participant characteristics***

153

154 All sixty schools approached about the study agreed to participate. Of 10,107 students in study
155 schools who were screened for enrollment and determined to be preliminarily eligible, 7,425
156 were randomly invited to participate and 6,078 enrolled between February 20 and May 29,
157 2021. School and participant characteristics were balanced across study arms at baseline
158 (Table 1). At enrollment, participants were 15 years old on average, and 51.5% were female.
159 Overall, 49.4% of study participants had access to a tablet or computer and 4.8% had their own
160 smartphone.

161
162 Of 6,078 participants enrolled at baseline, 5,552 (91.3%) completed endline surveys at 24
163 months (Fig. 2). Participants who were lost to follow-up at 24 months were more likely to be
164 older, male, have a parent with lower levels of education, and have a lower wealth index than
165 participants who completed endline surveys (Supplementary Table S1). The endline sample
166 (mean age: 18 years) included 29.2% who had transferred schools and 12.8% who had dropped
167 out of school. Among female participants who reported having initiated childbearing (n=69),
168 85.5% had dropped out of school.

169
170 At endline, 26.6% of participants reported that they had ever had sexual intercourse (34.7% of
171 males, 19.0% of females), with only 11.1% reporting sexual intercourse in the past year. Most
172 sexually active participants reported having sexual intercourse less than three times in their
173 lifetime (81.7%).

174

175 *Implementation fidelity and engagement*

176

177 Most indicators of school-level fidelity to and individual-level engagement with the
178 CyberRwanda intervention were similar across models but modestly higher in the facilitated arm
179 compared to the self-service arm (Table 2). At the school level, an average of 98.4% of
180 participants per intervention school had heard of CyberRwanda. Among participants who had
181 tried to access CyberRwanda, participants rated the ease of accessing CyberRwanda as a 4 out
182 of 5 on average. Limited tablet availability and/or internet connectivity challenges were reported
183 by an average of 39.2% of participants per school.

184

185 At the individual level, 75.9% of participants in CyberRwanda schools reported ever using the
186 platform, and participants in CyberRwanda schools had used the platform once in the past
187 month on average. Most CyberRwanda users had accessed CyberRwanda in schools (99.0%);

188 few reported accessing CyberRwanda outside of school (3.6%). Tablets were the main device
189 used to access the platform (reported by 99.2% of users), while smartphones were rarely used
190 (1.9%). Most users (85.2%) reported that they shared a tablet with others at last use.

191
192 STORIES was the most used CyberRwanda feature (used by 65.7% of all participants in
193 CyberRwanda schools overall and 86.5% of participants who had ever used the platform),
194 followed by LEARN (39.7% overall, 52.3% of users) and SHOP (30.1% overall, 39.6% of users).
195 Most users (78.7%) reported that STORIES was the most useful feature on the platform, with
196 90.9% of users agreeing that the content was relevant to their life, needs, and interests. Many
197 users agreed that the LEARN feature provided helpful information (91.8%) and that the SHOP
198 feature made it easier for them to purchase health products (62.3%). Nonetheless, few
199 participants (12.9%) had ever placed an online order using the SHOP feature, and 37.6% of
200 users said they did not want to use the SHOP. The most common reason for not using the
201 SHOP was not needing or wanting any of the products offered (70.8%).

202

203 ***Primary outcomes***

204

205 Among all female participants, 10.6% reported using a modern method of contraception overall
206 (intraclass correlation coefficient [ICC] = 0.02). Current modern contraceptive use did not differ
207 by study arm (CyberRwanda combined vs. control: 10.7% vs. 10.6%, prevalence ratio [PR]:
208 1.04, 95% confidence interval [CI]: 0.76–1.42) (Table 3). Few female participants (2.4%)
209 reported a previous pregnancy (ICC = 0.02). There were no differences in childbearing by study
210 arm (CyberRwanda combined vs. control: 2.6% vs. 2.0%, PR: 1.33, 95% CI: 0.71–2.50). Half of
211 all participants (51.6%) reported ever HIV testing (ICC = 0.12), with no differences by study arm
212 (CyberRwanda combined vs. control: 51.6% vs. 51.4%, PR: 1.00, 95% CI: 0.91–1.11).

213

214 ***Secondary outcomes***

215

216 *Knowledge*

217

218 Knowledge of the fertile window in a woman's menstrual cycle and HIV-related knowledge
219 (among all participants) and knowledge of menstrual tracking tools (among females only) did not
220 differ between study arms (Table 3, Extended Data Fig. 1). Participants in both the facilitated
221 arm (57.5%) and the self-service arm (54.2%) had significantly higher knowledge of when

222 emergency contraception can be taken after unprotected sex to prevent a pregnancy compared
223 to control (CyberRwanda combined vs. control: 55.9% vs. 49.2%, PR: 1.14, 95% CI: 1.04–1.24).

224

225 *Attitudes and beliefs*

226

227 Views on FP/RH service utilization were similar across study arms. Participants in the combined
228 CyberRwanda arm and the facilitated arm were significantly more likely to have favorable beliefs
229 about condom use compared to control (facilitated vs. control: 78.6% vs. 75.1%, PR: 1.06, 95%
230 CI: 1.01–1.12).

231

232 *Self-efficacy*

233

234 There were no differences in self-efficacy for giving sexual consent or obtaining HIV testing
235 across study arms. Participants in both the facilitated arm (94.5%) and the self-service arm
236 (94.7%) were significantly more confident that they could get a partner to use contraceptives or
237 condoms if desired compared to control (CyberRwanda combined vs. control: 94.6% vs. 92.7%,
238 PR: 1.02, 95% CI: 1.00–1.03). Confidence in the ability to access and use contraceptive
239 services among female participants was significantly higher in the facilitated arm compared to
240 control (97.6% vs. 95.5%, PR: 1.02, 95% CI: 1.00–1.04).

241

242 *Behavior*

243

244 There were no differences in participants' reporting of previous sexual activity or receipt of FP
245 counseling or HIV testing in the past 12 months by study arm. In addition to the primary
246 outcome of current use of modern contraceptive methods among females, we also examined
247 current modern contraceptive method use among male participants. Modern method use was
248 significantly higher among male participants in the combined CyberRwanda arm and the
249 facilitated arm compared to control (facilitated vs. control: 22.6% vs. 17.5%, PR: 1.31, 95% CI:
250 1.04–1.65).

251

252 Past condom use and partner contraceptive discussions were assessed among sexually active
253 participants only. Sexually active participants in facilitated schools were significantly more likely
254 to report having used a condom (ever condom use) compared to those in control (61.9% vs.
255 53.3%, PR: 1.19, 95% CI: 1.05–1.35). Sexually active participants in the combined

256 CyberRwanda arm and the facilitated arm were also significantly more likely to report discussing
257 contraception with their most recent sexual partner (facilitated vs. control: 59.5% vs. 52.9%, PR:
258 1.15, 95% CI: 1.03–1.30).

259

260 **Safety**

261

262 There were seven participant deaths (unrelated to the study) over the study period. There were
263 no adverse events related to the CyberRwanda intervention or impact evaluation reported.

264

265 **Sensitivity analyses**

266

267 Sensitivity analyses were conducted to compare outcomes in the full sample with the sexually
268 active subgroup and by sex among sexually active participants only. Among sexually active
269 participants overall (n=1,477), current modern contraceptive use was significantly higher in the
270 combined CyberRwanda arm and the facilitated arm compared to control (facilitated vs. control:
271 63.0% vs. 52.7%, PR: 1.24, 95% CI: 1.12–1.38) (Fig. 3, Supplementary Table S2). This
272 association was in part driven by higher *current* condom use among sexually active male
273 participants in the facilitated arm (facilitated vs. control: 62.6% vs. 49.7%, PR: 1.28, 95% CI:
274 1.11–1.48).

275

276 There were no significant differences in *current* condom use among sexually active female
277 participants in the facilitated arm compared to control (51.1% vs. 45.8%). However, sexually
278 active female participants in both the facilitated arm (13.6%) and the self-service arm (15.1%)
279 were more likely to report *current* use of modern contraceptive methods *other than* male
280 condoms compared to control (CyberRwanda combined vs. control: 14.4% vs. 7.8%, PR: 2.06,
281 95% CI: 1.18–3.60).

282

283 The observed increases in *ever* condom use and contraceptive discussions among sexually
284 active CyberRwanda participants were also driven by male participants; *ever* condom use was
285 higher among sexually active males in the facilitated arm compared to control (64.8% vs.
286 53.0%, PR: 1.24, 95% CI: 1.08–1.41) (Fig. 3), and contraceptive discussions were higher
287 among sexually active males in both arms compared to control (59.8% vs. 49.3%, PR: 1.23,
288 95% CI: 1.07–1.40) (Supplementary Table S2).

289

290 There were no differences in initiation of childbearing by study arm when limiting analyses to
291 sexually active female participants; HIV testing was also similar across study arms among
292 sexually active participants overall and of either sex (Supplementary Table S2).

293

294 **Discussion**

295

296 This manuscript presents results from a 24-month, Type 2 Hybrid Effectiveness-Implementation
297 study in 60 schools evaluating CyberRwanda, a digital, school-based intervention designed by
298 and for adolescents using an HCD approach to improve FP/RH outcomes. CyberRwanda was
299 perceived favorably and widely accessed by students in participating schools. However, the
300 majority of the study population reported that they were not yet sexually active, and we did not
301 find significant impacts of CyberRwanda on the primary outcomes of modern contraceptive use
302 and childbearing among all female adolescents and HIV testing in the full sample. Among all
303 *sexually active* adolescents, CyberRwanda significantly increased modern contraceptive use
304 among participants in intervention schools compared to those in control schools. Hypothesis-
305 generating analyses revealed that this finding was driven by increased condom use among
306 sexually active male participants (CyberRwanda combined arms and facilitated arm) and
307 increased use of modern contraceptive method(s) other than male condoms among sexually
308 active female participants (CyberRwanda combined, facilitated, and self-service arms)
309 compared to the control arm.

310

311 CyberRwanda was also associated with positive shifts in other secondary, intermediate
312 outcomes, including increased emergency contraceptive knowledge (combined, facilitated, and
313 self-service arms), more favorable condom beliefs (combined and facilitated arms), greater
314 confidence in getting a partner to use contraception (combined, facilitated, and self-service
315 arms), greater confidence in accessing/using contraceptive services (facilitated arm), and
316 increased partner contraceptive discussions (combined and facilitated arms) compared to
317 control. Although some of these effect sizes were modest in magnitude, the intermediate
318 impacts we observed align with the changes anticipated in the hypothesized impact pathway¹⁹
319 and are consistent with the increased contraceptive use observed among sexually active
320 participants.

321

322 This study contributes to a small but growing evidence base of studies evaluating digital FP/RH
323 interventions delivered to adolescents in SSA, which have demonstrated improvements in

324 FP/RH and HIV outcomes.^{1-4,21} Our findings add to this evidence and suggest that
325 CyberRwanda has potential to achieve its intended FP/RH impacts and reinforce efforts and
326 progress made by the Rwandan government to improve adolescent FP/RH. An innovative
327 aspect of this study is our examination of the relative effectiveness of two CyberRwanda
328 implementation models: a self-guided, digital-only delivery model (self-service) and a more
329 resource-intensive delivery model with complementary in-person, peer-led group activities
330 (facilitated). The facilitated implementation model demonstrated stronger benefits on FP/RH-
331 related attitudes and behaviors among adolescents compared to the self-service model,
332 although in most cases the width of the confidence intervals could not rule out that the two
333 models performed similarly. We hypothesize that the in-person element and group setting of the
334 facilitated model (i.e., peer-led club sessions which reached large numbers of students) may be
335 important to foster deeper engagement with the digital content, increase exposure to sexual
336 health education, and ultimately influence FP/RH behavior. Still, it remains uncertain as to
337 whether these potential benefits are strong enough to warrant the added complexity and costs
338 of the facilitated model compared to self-service. The effectiveness of peer-led education in
339 reinforcing positive reproductive health beliefs and practices is supported by implementation
340 research and adolescent neuro-developmental studies.²²⁻²⁴ While implementation fidelity was
341 high across both models, adolescents in facilitated schools had slightly higher engagement
342 when comparing metrics related to use of the platform, lending some support to this hypothesis.
343 However, we lacked sufficient quantitative metrics to adequately measure engagement with the
344 in-person component of the facilitated model (i.e., weekly club meetings), a limitation of our
345 evaluation.

346

347 A unique component of CyberRwanda is the direct-to-consumer SHOP feature through which
348 adolescents can discreetly order FP/RH products from nearby youth-friendly pharmacies, health
349 posts, and health facilities. Despite nearly two-thirds of participants reporting that the SHOP
350 made it easier for them to purchase health products, SHOP orders were unexpectedly
351 infrequent. While supply-side challenges may have deterred SHOP use, the most common
352 explanation provided by participants was that they did not need or want any products. This
353 lower-than-expected demand for contraceptives may relate to the low prevalence and frequency
354 of sexual activity among the cohort; only one quarter of participants reported previous sexual
355 activity at endline (mean age: 18 years), with only 11% reporting sex in the past year,
356 suggesting that “sexually active” participants were not engaging in intercourse frequently.
357 Longer-term follow up with study participants would provide us with more statistical power to

358 examine CyberRwanda's impact on these outcomes in the overall sample as more participants
359 become sexually active and have increased need for FP/RH products. Nevertheless, the
360 positive impacts we observed on contraceptive use among sexually active participants and on
361 intermediate outcomes in the full sample suggest that CyberRwanda is working as intended,
362 and we anticipate that early exposure to the platform's youth-friendly, age-appropriate FP/RH
363 information for adolescents who are not yet sexually active may improve outcomes when they
364 engage in sexual behavior in the future.

365

366 This study has notable strengths as well as some limitations. With a sample of >6,000
367 adolescents across 60 schools in eight districts of Rwanda, this is among the few trials of this
368 size and scope conducted in SSA and, to our knowledge, the first in Rwanda to examine the
369 effectiveness of a large-scale digital health intervention on youth sexual health outcomes. The
370 results advance knowledge on youth sexual behavior and the utility of digital tools with and
371 without in-person facilitation to improve knowledge, attitudes, self-efficacy, and behavior during
372 a critical and sensitive development stage of adolescence. Through rigorous follow-up
373 procedures, we successfully retained 91% of the enrolled study population at 24 months,
374 including 29% of endline participants who had transferred schools and 13% who had dropped
375 out of school yet remained in the study. Despite these efforts, there remains the possibility that
376 participants who were lost to follow-up were unreachable due to pregnancy-related drop out
377 from school and/or were less likely to use a contraceptive method than their in-school peers;
378 thus, we cannot rule out the potential for selection bias in our analytic sample. In addition, while
379 the survey was designed to maximize privacy and data quality for highly sensitive questions
380 related to sexual behavior, there may have been social desirability bias for self-reported
381 outcomes which, if similar across study arms, is likely to bias effect estimates towards the
382 null.^{25,26} While it is possible that such response bias was differential by study arm (e.g., if
383 participants exposed to CyberRwanda were more or less likely to disclose and/or overreport
384 certain FP/RH outcomes), participants were equally as likely to report past sexual activity across
385 study arms, which mitigates concerns of differential reporting for sensitive questions about
386 sexual behavior. Lastly, we enrolled adolescents attending secondary schools at baseline;
387 therefore, our results may have limited generalizability for out-of-school youth who may be more
388 likely to engage in higher-risk sexual behaviors.

389

390 We identified opportunities for improving intervention implementation, including increasing the
391 amount of school time allocated to accessing CyberRwanda, addressing the high student-tablet

392 ratio, and mitigating technological challenges, which likely impeded access and engagement in
393 both implementation models. Frequent tablet sharing may have been especially limiting for the
394 SHOP feature, as some students may not have been able to access it privately. Other studies
395 highlight internet connectivity as a common issue in the delivery of digital interventions²⁷ and
396 recommend offline content as an alternative to improve access and engagement with digital
397 tools, particularly in low-resource settings. CyberRwanda's STORIES and LEARN features
398 could be accessed offline via the app during the study, and since study completion, the platform
399 has incorporated USSD ordering of products via feature phones to support offline access to the
400 SHOP feature. Taken together, this suggests that small investments in more tablets, offline
401 access to the platform, and ongoing technological support in schools could further strengthen
402 the benefits of CyberRwanda observed in this study.

403
404 In conclusion, the CyberRwanda intervention did not significantly impact the primary outcomes
405 of modern contraceptive method use and initiation of childbearing among females and HIV
406 testing overall. Despite this, we found significantly higher modern method use among sexually
407 active CyberRwanda participants compared to the control arm. The intervention was
408 implemented with high fidelity across 40 schools in Rwanda; had strong participant acceptability
409 and engagement; and was also associated with positive shifts in some intermediate, secondary
410 outcomes on the hypothesized impact pathway including FP/RH-related knowledge, attitudes,
411 and behaviors among adolescents. The stronger shifts in intermediate outcomes observed in
412 the facilitated model suggest that digital interventions may benefit from in-person education to
413 reinforce digital content. Further research is warranted to compare the relative cost-
414 effectiveness of the two implementation models and to examine CyberRwanda's longer-term
415 effectiveness as more of the study population becomes sexually active and has increased
416 demand for contraception.

417 **Acknowledgements**

418 The authors thank the study participants, the local research team at YLabs Rwanda, and the
419 Society for Family Health Rwanda for their contributions to this research. The Effectiveness-
420 Implementation study was supported by the David & Lucile Packard Foundation and the United
421 States Agency for International Development (USAID). The analysis and interpretation of the
422 data is solely the responsibility of the authors and does not represent the official views of the
423 funder.

424

425 **Author Contributions Statement**

426 RH(1), LP, SB(2), RH(2), and SM conceptualized the study. RH(1), EG, LH, LP, FS, MM, SB(2),
427 RH(2), and SM designed the study's methodology. EG, LK, and NI performed data collection.
428 RH(1) and LH conducted data analyses. RH(1), LH, and SM drafted the manuscript. RH(1), EG,
429 LK, LH, LP, NI, DC, DCL, PG, SB(1), FS, MM, SB(2), RH(2), and SM contributed to data
430 interpretation and revised and approved the submitted manuscript.

431

432 **Competing Interests Statement**

433 The authors have no conflicts of interest to declare.

455 CR: CyberRwanda, SRH: sexual and reproductive health.

456 *Calculated using principal components analysis of the participant's household dwelling materials and assets with the
457 first factor categorized into quartiles.

458 Data reported as mean ± standard deviation for continuous variables or n (column %) for categorical variables.

459 Missing responses: number of students (n=2), number of teachers (n=1), student-teacher ratio (n=3), computers
460 (n=2), SRH curriculum (n=1), partnered (n=5), parental education (n=755), wealth index (n=2), religion (n=3).

461 **Table 2.** School-level fidelity and individual-level engagement with the CyberRwanda
 462 intervention, overall and by CyberRwanda implementation model.

School-level fidelity*	CR combined (n=40)	CR facilitated (n=20)	CR self-service (n=20)
Heard of CR	98.4% ± 2.2%	98.5% ± 1.4%	98.2% ± 2.8%
Ease of access score (range: 0–5)	4.0 ± 0.3	4.0 ± 0.4	3.9 ± 0.3
No tablet/internet challenges**	60.8% ± 9.0%	61.6% ± 7.9%	60.0% ± 10.1%
No issues with tablet access	61.7% ± 10.2%	63.9% ± 8.4%	59.6% ± 11.5%
Individual-level engagement	CR combined (n=3707)	CR facilitated (n=1858)	CR self-service (n=1849)
Ever used CR	2815 (75.9%)	1435 (77.2%)	1380 (74.6%)
Used CR “many times”	1175 (31.7%)	618 (33.3%)	557 (30.1%)
Times used CR in past month	1.0 ± 3.3	1.1 ± 2.8	0.9 ± 3.7
Number of STORIES seasons read	1.3 ± 1.2	1.3 ± 1.2	1.3 ± 1.2
Times used SHOP	0.8 ± 2.2	0.8 ± 2.4	0.8 ± 2.0
Ever placed SHOP order	479 (12.9%)	247 (13.3%)	232 (12.5%)

463 CR: CyberRwanda.

464 Data reported as mean ± standard deviation for continuous variables or n (column %) for categorical variables.

465 *School-level proportions or means among endline participants (n=3707 CR combined), excluding participants who
 466 had never heard of (n=34) or tried to access (n=520) CR.

467 **Challenges include restricted tablet access, too few tablets available, broken tablets, internet connection issues,
 468 and/or not enough time with tablet.

469 Missing responses: n=33 times used CR, n=183 STORIES seasons, n=20 times used SHOP, n=28 SHOP order.

470

471

472 **Table 3.** Effects of CyberRwanda on primary outcomes and secondary outcomes of knowledge, attitudes and beliefs, self-efficacy,
 473 and behavior at 24 months.

	Control (n=1845)	CR combined (n=3707)	PR (95% CI), CR combined vs. control	CR facilitated (n=1858)	PR (95% CI), CR facilitated vs. control	CR self- service (n=1849)	PR (95% CI), CR self-service vs. control
Primary outcomes†							
Current modern contraceptive use by self or partner (females)*	101 (10.6%)	205 (10.7%)	1.04 (0.76, 1.42)	106 (11.2%)	1.10 (0.76, 1.58)	99 (10.2%)	0.98 (0.68, 1.41)
Ever pregnancy (females)*	19 (2.0%)	50 (2.6%)	1.33 (0.71, 2.50)	20 (2.1%)	1.03 (0.49, 2.16)	30 (3.1%)	1.65 (0.82, 3.29)

583 **Methods**

584

585 ***Study design and participant selection***

586

587 We conducted a three-arm, parallel-group cluster randomized, Type 2 Hybrid Effectiveness-
588 Implementation trial in eight Rwandan districts.¹ The study design and analysis plan were pre-
589 registered (clinicaltrials.gov [NCT04198272](https://clinicaltrials.gov/ct2/show/study/NCT04198272)),² and the study is reported per CONSORT
590 guidelines.^{3,4} Secondary schools located within 4.5 kilometers of a pharmacy, ≥ 1.5 kilometers
591 from another secondary school, and with ≥ 150 students were eligible. Boarding schools were
592 excluded. Within participating schools, students ages 12–19 years, in school levels S1 and S2
593 (the first two years of high school), and who were willing to provide contact information and
594 informed consent (participants 18–19 years) or assent and parental consent (participants <18
595 years) were eligible to enroll. There were no exclusion criteria for participants.

596

597 Of 383 secondary schools in these districts, 61 met eligibility criteria; 60 were randomly selected
598 to participate. Headteachers provided informed consent for their schools' participation. We
599 generated a list of all S1–S2 students who had returned signed parental consent forms
600 (distributed to students <18 years) and/or were ages 18–19 years based on school registers.
601 We used sex-stratified random selection to reach our target enrollment of 100 students per
602 school (50 males, 50 females), inviting an average of 124 students per school to participate,
603 including randomly selected replacements for students who were no longer attending the school
604 or did not enroll. Selected students were invited by teachers to attend weekend data collection
605 events at their school.

606

607 ***Study arms***

608

609 Schools assigned to both CyberRwanda implementation models and the control arm received
610 Comprehensive Sexuality Education as part of the Competence-based Curriculum implemented
611 by the Rwanda Education Board.⁵

612

613 In addition, CyberRwanda schools received one of two implementation models: self-service or
614 facilitated (Fig 1). The self-service model offered self-guided access to the CyberRwanda
615 platform and included tablets with instructional set-up guides (8 tablets per school), internet
616 connection via hotspots, and marketing materials. Trained student ambassadors promoted

617 CyberRwanda in schools and supported peers in using the platform as needed. The facilitated
618 model included all components of the self-service model, with the addition of peer facilitators (in
619 lieu of student ambassadors) who guided interactive sessions at in-person weekly
620 CyberRwanda clubs using an activity booklet with learning modules corresponding to the
621 CyberRwanda content offered on the digital platform. The club sessions (1–2 hours in duration,
622 50–150 students per week) were voluntary and included group tablet access and activities such
623 as skits, role-plays, and group discussions. The intervention was available to all students in
624 CyberRwanda schools throughout the 24-month study period.

625

626 Student ambassadors (self-service model), peer facilitators (facilitated model), and lead
627 teachers (both models) participated in a 1.5-day training on how to use CyberRwanda. Peer
628 facilitators participated in an additional one-day training on facilitating clubs and using the
629 activity booklet.

630

631 ***Theoretical framework and hypothesized impact pathway***

632

633 The study design was guided by the Theory of Planned Behavior, which states that attitudes,
634 beliefs, and perceived behavioral control are intermediate steps that can shift subjective norms
635 and influence intentions, leading to behavior change.^{6,7} CyberRwanda is hypothesized to create
636 an impact by engaging adolescents with interactive sexual health edutainment content through
637 the STORIES and LEARN features to improve knowledge, beliefs, attitudes, and self-efficacy
638 related to reproductive empowerment and autonomy, and through increasing access to
639 contraception and FP/RH information via the youth-friendly online SHOP with the overall goal of
640 increasing contraceptive use and HIV testing and delaying initiation of childbearing among
641 adolescents. The 12-month midline data demonstrated significant shifts in intermediate
642 outcomes on the impact pathway (e.g., knowledge, beliefs, self-efficacy) among CyberRwanda
643 participants.⁸ The present analysis of endline data will determine whether these shifts were
644 sustained and whether the intervention had any effect on the primary outcomes at 24 months.

645

646 ***Randomization***

647

648 Randomization was conducted at the school (cluster) level, stratified by district, using a
649 participatory two-stage approach. To ensure that global balance was achieved across all
650 districts (i.e., 20 schools per arm), the study team randomly allocated the number of schools per

651 study arm in a 1:1:1 ratio within each district using Stata.⁹ In cases when the number of schools
652 in a district was not a multiple of three, “misfit” schools were grouped into a new stratum and
653 randomly allocated across study arms.¹⁰ Schools were then randomly assigned to study arms
654 during community participatory randomization events held in each district. At each event, school
655 representatives who consented to participate in the study were selected in a random order to
656 choose colored balls (corresponding to their district’s predetermined study arm assignments)
657 from an opaque bag. After all balls were selected, the colors corresponding to each study arm
658 were announced to the participating schools. This transparent, participatory approach was
659 viewed favorably by participants and perceived to facilitate trust among stakeholders.¹¹ Due to
660 the nature of the intervention, participants and research assistants who collected outcomes data
661 were not blinded. The investigators were also not blinded to allocation during the intervention
662 and outcome assessment.

663

664 ***Procedures***

665

666 Enrollment and baseline data collection were conducted from February–May 2021. Midline and
667 endline data collection took place 12 months (February–August 2022) and 24 months (March–
668 August 2023) after baseline, respectively. After confirming students’ eligibility and obtaining
669 informed consent or assent plus parental consent, surveys (~45 minutes in length) were
670 administered by trained research assistants in Kinyarwanda on tablets using Qualtrics
671 software.¹² Participant sex was determined by research assistants based on the sex listed for
672 each student in their school register and their gender presentation. Participants were offered
673 3,000 Rwandan francs (~\$2.40) for transport reimbursement.

674

675 Sociodemographic and school characteristics were measured at baseline. The endline survey
676 included questions on CyberRwanda exposure; FP/RH knowledge, attitudes and beliefs, and
677 self-efficacy; sexual behavior; contraceptive use; pregnancy history; and HIV testing.

678

679 ***Outcomes***

680

681 The study had three pre-specified primary outcomes: 1) uptake of a modern contraceptive
682 method among females, defined as the proportion of all female participants who reported that
683 they or their partner were currently using a modern contraceptive method (i.e., male or female
684 condoms, oral contraceptive pills, injectable contraception, emergency contraceptive pills,

685 intrauterine devices [IUD], implants, diaphragms, spermicidal foam or jelly, male or female
686 sterilization, lactational amenorrhea method [LAM], and Standard Days Method^{13,14}); 2) initiation
687 of childbearing among females, defined as the proportion of all female participants who reported
688 ever having been pregnant regardless of the outcome; and 3) HIV testing among youth, defined
689 as the proportion of all participants who reported ever having an HIV test.

690
691 Secondary outcomes were categorized in four domains: 1) knowledge related to fertility,
692 emergency contraception, HIV, and menstrual tracking tools; 2) attitudes and beliefs related to
693 FP/RH service utilization and condom use; 3) FP/RH self-efficacy, namely confidence in one's
694 ability to give sexual consent, get a partner to use contraception, access and use contraceptive
695 services, and obtain an HIV test; and 4) FP/RH behaviors including past sexual activity, current
696 modern contraceptive use among males, current use of specific contraceptive methods (i.e.,
697 condoms vs. other modern methods), ever use of condoms, recent HIV testing, recent receipt of
698 FP counseling, and discussion of contraception with one's most recent sexual partner. All
699 secondary outcomes were pre-specified in a pre-registered analysis plan with the exception of
700 four outcomes (HIV knowledge, self-efficacy for giving sexual consent, recent receipt of FP
701 counseling, and partner contraceptive discussion), which were included to examine consistency
702 with previously reported 12-month findings.⁸

703
704 All primary and secondary outcomes were examined at the individual level. Details on their
705 operationalization can be found in Table S3.

706 707 ***Power and sample size***

708
709 Power calculations were conducted using a simulation-based approach based on the primary
710 outcome of modern contraceptive use among female participants.¹⁵ The simulations assumed
711 that the CyberRwanda intervention would not impact the rate at which participants become
712 sexually active. Schools were also assumed to be independent. Simulated data included
713 number of clusters (schools) and numbers of female participants per school, with a distribution
714 of contraceptive uptake by school to account for variability at the school-level. School-level
715 contraceptive uptake was based on the proportion of sexually active Rwandan youth currently
716 using modern contraception reported in the 2014–15 Rwanda Demographic and Health
717 Survey.¹⁶ The simulated data (2000 datasets) demonstrated that the study was powered at 80%
718 to detect an effect on modern contraceptive use when the facilitated model has an odds ratio,

719 approximating a relative risk, of ≥ 2.5 compared to control (i.e., an increase in modern
720 contraceptive use from 2%¹⁶ to 5%) with a target sample of 50 female participants per school
721 (n=3,000). We recruited an equal number of male participants per school for a total of 6,000
722 participants overall. Sample size calculations accounted for 10% attrition over the study period.
723

724 **Statistical Analyses**

725
726 Analyses were conducted in R version 4.3.1¹⁷ and Stata version 17.⁹ We generated descriptive
727 statistics to assess baseline balance of school and participant characteristics by study arm and
728 to qualitatively compare endline indicators of school-level implementation fidelity and individual-
729 level CyberRwanda engagement by intervention model. The intraclass correlation coefficient
730 (ICC) was calculated for the primary outcomes using one-way analysis of variance (ANOVA).
731

732 For all outcomes, we constructed generalized linear mixed models with either a three-level
733 explanatory variable for study arm (each CyberRwanda arm vs. control) or a two-level variable
734 (combined CyberRwanda arms vs. control). Prevalence ratios (PRs) and two-sided 95%
735 confidence intervals (CIs) were estimated using log-binomial regression or (when non-
736 convergent) log-Poisson regression with robust standard errors.¹⁸ All models were adjusted for
737 district with random intercepts to account for clustering by school.
738

739 A joint test of no difference was conducted for each primary outcome to determine whether at
740 least one of the CyberRwanda arms was significantly different than the control arm; likelihood
741 ratio tests compared null models to models with the three-level explanatory variable for study
742 arm. The study was designed as a non-inferiority trial. However, the likelihood ratio tests did not
743 show evidence of an intervention effect ($p \geq .05$), therefore we did not proceed with non-inferiority
744 testing.
745

746 Inverse probability of censoring weighting (IPCW) was used to account for loss to follow-up over
747 the study period in the modified intention-to-treat analyses for the primary outcomes. The
748 weighted analyses were compared to unweighted (complete case) models; models adjusted for
749 sociodemographic and school characteristics; and an instrumental variable analysis modeling
750 the intervention's impacts under conditions of high school-level implementation fidelity (model
751 specifications are detailed in Table S4). As the conclusions were unchanged, we present only
752 the primary analyses.

753

754 Complete case models were used to assess CyberRwanda's effects on the secondary
755 outcomes and to conduct pre-specified sensitivity analyses limited to participants who reported
756 past sexual intercourse at 24 months (both overall and stratified by sex).

757

758 ***Ethics and inclusion statement***

759

760 The CyberRwanda intervention was developed using HCD with more than 1,000 Rwandan
761 adolescents, parents, teachers, and healthcare providers to create a digital FP/RH intervention
762 that was well-suited for the Rwandan context, accessible to adolescents at all literacy levels,
763 and that addressed the most critical gaps in adolescent FP/RH in Rwanda. The impact
764 evaluation was designed and implemented in collaboration with Rwanda-based researchers and
765 government stakeholders. Best practices were used to ensure that all sensitive questions in
766 survey instruments minimize risks to participants and maximize privacy and confidentiality.
767 Ethical approval for this study was obtained from the Committee for Protection of Human
768 Subjects at UC Berkeley and the Rwanda National Ethics Committee.

769 **Data Availability**

770 De-identified participant data used in these analyses will be available on the Open Science
771 Framework (<https://osf.io/hdc6g/>) by September 2024. Approval to access or use the de-
772 identified data is not required; however, please contact the corresponding author prior to using
773 the data to inform the study team of the analyses to be performed.

774

775 **Code Availability**

776 R and Stata code files used in these analyses will be available on the Open Science Framework
777 (<https://osf.io/hdc6g/>) by September 2024.

WHAT IS CYBERRWANDA?

Intervention derived using human-centered design providing education on family planning and reproductive health, employment, and goal setting

Features

STORIES: Edutainment webcomics

LEARN: Educational videos and frequently asked questions

SHOP: Direct-to-consumer online store linked to youth-friendly pharmacies

IMPACT EVALUATION

60 schools
Cluster randomized 1:1:1

IMPLEMENTATION

Comparing two models

Self-service

- Self-guided access
- Tablets, hotspots
- School ambassadors

Facilitated

- Self-guided and group access
- Tablets, hotspots
- Peer facilitators with activity guide
- Weekly club sessions (1-2 hours) with 50-150 students

Control

Government approved Comprehensive Sexuality Education

PRIMARY OUTCOMES AT 24 MONTHS

- Use of a modern contraceptive method
- Initiation of childbearing
- HIV testing

Enrollment

Assessed for eligibility (n=383 schools)

Excluded (n=323 schools)
• n=322 did not meet eligibility criteria
• n=1 not randomly selected

Randomized (n=60 schools)
• n=10,107 students assessed for eligibility
• n=7,425 students randomly selected to participate

Excluded (n=0 schools)
• n=1,313 students did not attend data collection events
• n=34 students did not meet eligibility criteria

Enrolled (n=60 schools)
• n=6,078 participants

Allocation

Allocated to CyberRwanda self-service (n=20 schools)
• n=2,016 participants
Received allocated intervention (n=20 schools)

Allocated to CyberRwanda facilitated (n=20 schools)
• n=2,025 participants
Received allocated intervention (n=20 schools)

Allocated to control (n=20 schools)
• n=2,037 participants

Follow Up

24-month loss to follow-up (n=0 schools)
• n=167 participants

24-month loss to follow-up (n=0 schools)
• n=167 participants

24-month loss to follow-up (n=0 schools)
• n=192 participants

Analysis

Analyzed (n=20 schools)
• n=1,849 participants

Analyzed (n=20 schools)
• n=1,858 participants

Analyzed (n=20 schools)
• n=1,845 participants

Discussed contraception with most recent sexual partner	258 (52.9%)	583 (58.9%)	1.13 (1.02, 1.26)	294 (59.5%)	1.15 (1.03, 1.30)	289 (58.4%)	1.11 (0.99, 1.25)
- Females	112 (58.3%)	204 (57.5%)	1.00 (0.85, 1.17)	104 (59.1%)	1.03 (0.85, 1.25)	100 (55.9%)	0.97 (0.82, 1.15)
- Males	146 (49.3%)	379 (59.8%)	1.23 (1.07, 1.40)	190 (59.7%)	1.24 (1.07, 1.43)	189 (59.8%)	1.22 (1.05, 1.41)
Ever pregnancy (females)	19 (9.9%)	50 (14.1%)	1.42 (0.81, 2.48)	20 (11.4%)	1.14 (0.59, 2.19)	30 (16.8%)	1.69 (0.93, 3.06)
Ever HIV testing	303 (62.1%)	592 (59.9%)	0.97 (0.87, 1.07)	297 (60.1%)	0.99 (0.86, 1.13)	295 (59.6%)	0.95 (0.85, 1.05)
- Females	134 (69.8%)	235 (66.2%)	0.99 (0.90, 1.10)	114 (64.8%)	1.00 (0.88, 1.12)	121 (67.6%)	0.99 (0.88, 1.12)
- Males	169 (57.1%)	357 (56.3%)	0.98 (0.84, 1.14)	183 (57.5%)	1.00 (0.83, 1.21)	174 (55.1%)	0.95 (0.81, 1.12)

CR: CyberRwanda, PR: prevalence ratio estimated via generalized linear mixed model adjusted for district with school-level random intercepts; CI: confidence interval.

Bold values indicate $p < .05$ based on two-sided Wald test.

*Female participants: control n=192, CR combined n=355, CR facilitated n=176, CR self-service n=179; male participants: control n=296, CR combined n=634, CR facilitated n=318, CR self-service n=316.

Missing responses: current contraceptive use (any, condoms, or other methods) n=24, ever condom use n=30, partner contraceptive discussion n=15, ever pregnancy n=5.

Table S3. CyberRwanda survey questions and outcome definitions for primary and secondary outcomes at 24 months.

Outcome	Survey Question(s)	Response Option(s)
Uptake of modern contraception		
Current modern contraceptive use†*(a)	What contraceptive method(s) are you (or your partner) currently using? <i>Note: Question asked of participants who reported past sexual intercourse (participants who reported never having sexual intercourse were inferred as non-users in primary analyses). Participants could select multiple contraceptive methods.</i>	Pills OR Condoms OR Female condoms OR Intrauterine devices (IUD) OR Injectables OR Implants/Jadelle OR Emergency contraceptive pills OR Diaphragm OR Foam/jelly OR Standard Days Method OR Female sterilization OR Male sterilization OR Lactational amenorrhea method (LAM)
Current male condom use*	Same as previous	Condoms
Current use of method(s) other than male condoms*	Same as previous	Pills OR Female condoms OR Intrauterine devices (IUD) OR Injectables OR Implants/Jadelle OR Emergency contraceptive pills OR Diaphragm OR Foam/jelly OR Standard Days Method OR Female sterilization OR Male sterilization OR Lactational amenorrhea method (LAM)
Ever condom use*	Have you ever used a condom with a current or previous partner? <i>Note: Question asked of participants who reported past sexual intercourse.</i>	Yes
Initiation of childbearing		
Ever pregnancy†	Have you <u>ever</u> been pregnant, regardless of the outcome of the pregnancy or if no child was born? <i>Note: Question asked of female participants who reported past sexual intercourse (participants who reported never having sexual intercourse were inferred as non-childbearing in primary analyses).</i>	Yes
HIV testing		
Ever HIV testing†	I don't want to know the results, but have you ever been tested for HIV/AIDs?	Yes
HIV testing in past 12 months*	1. I don't want to know the results, but have you ever been tested for HIV/AIDS? IF YES: 2. How many months ago was your most recent HIV test?	Yes AND In the past 6 months OR 7 months–1 year ago

Outcome	Survey Question(s)	Response Option(s)
Knowledge		
Knowledge of the fertile window*	<p>1. From one menstrual period to the next, are there certain days when a woman is more likely to become pregnant?</p> <p>IF YES:</p> <p>2. Is this time just before her period begins, during her period, right after her period has ended, or half-way between two periods?</p>	<p>Yes</p> <p>AND</p> <p>Half-way between two periods</p>
Knowledge of emergency contraception*	Emergency contraception can be taken up to one month after having unprotected sex to prevent a pregnancy.	False
HIV knowledge ^(b)	<p>1. Can a person reduce the risk of getting HIV/AIDS by having sex with only one uninfected partner who has no other partners?</p> <p>2. Can a person who is living with HIV/AIDS transmit the virus to another person during sex if they are taking their medication every day?</p> <p>3. Can a person get HIV/AIDS by having sex with a partner who has HIV/AIDS but is taking their medication every day?</p> <p>4. Can a person reduce the risk of getting HIV/AIDS virus by using a condom every time they have sex?</p> <p>5. Can a healthy-looking person have HIV/AIDS virus?</p> <p>6. Can people get the HIV/AIDS virus because of witchcraft or other supernatural means?</p> <p>7. Can a person get HIV/AIDS virus by sharing food with someone who is infected?</p> <p>8. Can people get the HIV/AIDS virus from mosquito bites?</p> <p>9. Can men reduce their risk of getting the HIV/AIDS virus by getting circumcised?</p> <p>10. Can men reduce their risk of getting the HIV/AIDS virus by taking a prevention pill every day?</p>	≥7 of 10 questions answered correctly
Knowledge of menstrual tracking tool(s)*	<p>I know what tools are available to track my menstrual cycle.</p> <p><i>Note: Question asked of female participants.</i></p>	Strongly agree OR Agree
Attitudes and beliefs		
Favorable views on family planning service utilization*	Family planning services are only for married men and women or women who have already had children.	Disagree OR Strongly disagree

Outcome	Survey Question(s)	Response Option(s)
Beliefs conducive to condom use*	If a girl suggested using condoms to her partner, it would mean that she didn't trust him. <i>Note: Question asked of participants who reported having heard of condoms.</i>	Disagree
Self-efficacy		
Self-efficacy for giving sexual consent ^(b)	I feel confident that I could verbally state my consent to someone I want to have sex with.	Agree
Self-efficacy for contraceptive/condom communication with partners*	How confident are you that you could get your partner(s) to use contraceptives/condoms if you desired it?	Confident OR Somewhat confident
Self-efficacy for access and utilization of contraceptive services*	I am confident that I can access and use contraceptive services if I need them.	Strongly agree OR Agree
Self-efficacy for HIV testing*	How confident are you that you can get tested for HIV if you need it?	Confident OR Somewhat confident
Other behavior		
Ever sexually active*	1. How old were you the first time you had vaginal sex/sexual intercourse? IF RESPONDED "Never had sex": 2. I want to make certain that I have the correct information. Have you ever had sex?	Selected an age at first sex OR I don't know the age, but have had sex OR Yes
Received family planning counseling in past 12 months ^(b)	Have you received family planning counseling services in the past 12 months? Family planning includes providing information on and access to contraceptive services to help with avoiding, delaying, or planning for pregnancy.	Yes
Partner contraceptive communication ^(b)	Now I'm going to ask you to think about your current partner, or if you don't currently have a partner, the most recent person you have had sexual intercourse with. [...] Did you ever discuss using contraception with this person? <i>Note: Question asked of participants who reported past sexual intercourse.</i>	Yes

†Pre-specified primary outcome in the pre-registered analysis plan.

*Pre-specified secondary outcome in the pre-registered analysis plan.

^(a)Current modern contraceptive use was pre-specified as a primary outcome among female participants and as a secondary outcome among male participants.

^(b)Secondary outcome retained from 12-month interim analysis (Hémono et al. *J Adolesc Health* 2024).

Table S4. Regression model specifications for analyses comparing primary and secondary outcomes by study arm at 24 months.

Modeling Approach	Analyses	Model Specifications
Unadjusted inverse-probability-of-censoring weighted (IPCW)	Primary outcomes†	<p>1. Logistic regression to predict probability of censoring at endline, including the following independent variables:</p> <ul style="list-style-type: none"> • <u>Baseline</u>: district, school, age, sex, school level, partnership status, religion, parental education, wealth index, food insecurity, sexual activity • <u>Midline</u>: sexual activity, participation at midline • <u>Combined baseline/midline</u>: ever pregnant, ever reported modern contraceptive use <p>2. Log-binomial generalized linear mixed models to estimate prevalence ratios comparing outcomes by study arm. Models were reweighted using inverse of probability of censoring predicted in previous step, included random intercepts for school, and adjusted for district.</p>
Complete case	Sensitivity analyses of primary outcomes† Secondary outcomes Subgroup analyses of primary and secondary outcomes	<p>Log-binomial* generalized linear mixed models to estimate prevalence ratios comparing outcomes by study arm. Models were unweighted (complete case), included random intercepts for school, and adjusted for district.</p> <p>*If non-convergent, log-Poisson with robust standard errors.</p>
Adjusted IPCW	Sensitivity analyses of primary outcomes†	<p>Logistic generalized linear mixed models to estimate odds ratios comparing outcomes by study arm. Models were reweighted using inverse probability of censoring weights (defined above), included random intercepts for school, and adjusted for covariates measured at baseline:</p> <ul style="list-style-type: none"> • <u>Participant level</u>: age, sex, religion, household wealth • <u>School level</u>: district, enrollment, student-teacher ratio, sexual health curriculum, computers

Modeling Approach	Analyses	Model Specifications
Instrumental variable	Sensitivity analyses of primary outcomes†	<p>1. Created composite fidelity score (range: 0–8) as the sum of four indicators of school-level fidelity measured at endline (set to 0 for control arm participants):</p> <ul style="list-style-type: none"> • Heard of CR (binary): 0 if no, 1 if yes • Ease of CR access (range: 0–5): 0 if had not heard of or tried to access CR, 1–5 based on ease of access rating (1 hardest, 5 easiest) • Did not report internet or table challenges (binary): 0 if reported tablet or internet challenges, 1 if did not report challenges • Did not report tablet access issues (binary): 0 if reported tablet access issues, 1 if did not report issues <p>Calculated average fidelity score for each school.</p> <p>2. Linear regression to predict participants' average school-level fidelity score including study arm and district as independent variables.</p> <p>3. Logistic regression to estimate the association between predicted average school-level fidelity score and the outcomes. Models were adjusted for district, and standard errors were adjusted for school-level clustering.</p>

CR: CyberRwanda.

†Primary outcomes: modern contraceptive use among all female participants, childbearing among all female participants, ever HIV testing among all participants.
