SPARSE APPROXIMATE MULTIFRONTAL FACTORIZATION WITH BUTTERFLY COMPRESSION FOR HIGH FREQUENCY WAVE EQUATIONS

YANG LIU*, PIETER GHYSELS*, LISA CLAUS*, AND XIAOYE SHERRY LI*

Abstract. We present a fast and approximate multifrontal solver for large-scale sparse linear systems arising from finite-difference, finite-volume or finite-element discretization of high-frequency wave equations. The proposed solver leverages the butterfly algorithm and its hierarchical matrix extension for compressing and factorizing large frontal matrices via graph-distance guided entry evaluation or randomized matrix-vector multiplication-based schemes. Complexity analysis and numerical experiments demonstrate $\mathcal{O}(N \log^2 N)$ computation and $\mathcal{O}(N)$ memory complexity when applied to an $N \times N$ sparse system arising from 3D high-frequency Helmholtz and Maxwell problems.

1. Introduction. Direct solution of large sparse linear systems arising from e.g., finite-difference, finite-element or finite-volume discretization of partial differential equations (PDE) is crucial for many high-performance scientific and engineering simulation codes. Efficient solution of these sparse systems often requires reordering the matrix to improve numerical stability and fill-in ratios, and performing the computations on smaller but dense submatrices to improve flop performance. Examples include supernodal and multifrontal methods [12] that perform operations on so-called supernodes and frontal matrices, respectively. For multifrontal methods, the size n of the frontal matrices can grow as $n = \mathcal{O}(N^{1/2})$ and $n = \mathcal{O}(N^{2/3})$ for typical 2D and 3D PDEs with N denoting the system size. Performing dense factorization and solution on the frontal matrices requires $\mathcal{O}(n^3)$ operations, yielding the overall complexities of $\mathcal{O}(N^{3/2})$ in 2D and $\mathcal{O}(N^2)$ in 3D. The same complexities also apply to supernodal methods.

For many applications arising from wide classes of PDEs, these complexities can be reduced by leveraging algebraic compression tools to exploit rank structures in blocks of the matrix inverse. For example, it can be rigorously shown that, for elliptical PDEs with constant or smooth coefficients, certain off-diagonal blocks in a frontal matrix exhibit low-rankness [11]. Low-rank based fast direct solvers, including \mathcal{H} [23, 18] and \mathcal{H}^2 matrices [24], hierarchically off-diagonal low-rank (HOD-LR) formats [1], sequentially semi-separable formats [47], hierarchically semi-separable (HSS) formats [47], and block low-rank (BLR) formats [44, 2], represent off-diagonal blocks as low-rank products and leverage fast algebras to perform efficient matrix factorization. These methods were first developed for solving dense systems, e.g., arising from boundary element methods, in quasi-linear complexity and have been recently adapted for sparse systems. Examples include solvers coupling \mathcal{H} [53], HOD-LR [3], HSS [49, 48, 16] or BLR [2] with multifrontal methods, which we will refer to as rank structured multifrontal methods, and solvers coupling HOD-LR [10] or BLR [39] with supernodal methods, and solvers based on the inverse fast multipole method [43]. Available software packages include STRUMPACK [16], MUMPS [2], and PaStiX [28, 39]. It is worth mentioning that many of these methods rely on fast

*Computational Research Division, Lawrence Berkeley National Laboratory, Berkeley, CA, USA. ({liuyangzhuan, pghysels, lclaus, xsli}@lbl.gov)

entry evaluation or randomized matrix vector multiplication (matvec) to compress the frontal matrices, without explicitly forming them. Despite differences in the leading constants, implementation details and applicability of these compression formats, in general they lead to quasi-linear complexity direct solvers and preconditioners when applied to many elliptical PDEs. Unfortunately, when applied to wave equations, such as Helmholtz, Maxwell, or Schrödinger equations with constant or non-constant coefficients, the frontal matrices exhibit much higher numerical ranks due to the highly oscillatory nature of the numerical Green’s function [15] and consequently no asymptotic complexity reduction compared to the exact sparse solvers can be attained. That said, the low-rank based sparse direct solver packages (e.g., STRUMPACK and MUMPS) oftentimes significantly reduce the costs (up to a constant factor) of exact sparse solvers for practical wave equation systems [41].

In contrast to low-rank-based algorithms, we consider another algebraic compression tool called butterfly [37, 34, 32, 31, 42], for constructing fast multifrontal methods for wave equations. Butterfly is a multilevel matrix decomposition algorithm well-suited for representing highly oscillatory operators such as Fourier transforms and integral operators [9, 51, 50] and special function transforms [46, 6, 40]. When combined with hierarchical matrix techniques, butterfly can also serve as the building block for accelerating iterative methods [38], direct solvers [19, 20, 22, 33] and preconditioners [35] for boundary element methods for high-frequency wave equations. These techniques essentially replace low-rank products in the \mathcal{H} [20], \mathcal{H}^2 [52, 8] and HOD-LR formats [33] with butterflies, and leverage fast and randomized butterfly algebra to compute the matrix inverse (for direct solvers and preconditioners). We particularly focus on the butterfly extension of the HOD-LR format [33], called HOD-BF in this paper. The HOD-BF format yields smaller leading constants and better parallel performance compared to other butterfly-enhanced hierarchical matrix formats. Moreover, HOD-BF can attain an $\mathcal{O}(n \log^2 n)$ compression complexity and an empirical $\mathcal{O}(n^{3/2} \log n)$ inversion complexity given a $n \times n$ HOD-BF compressible dense matrix. HOD-BF has been previously applied to both 2D [33] and 3D boundary element methods.

In this paper, we leverage the HOD-BF format for compressing the frontal matrices in the multifrontal method. Specifically, any non-root frontal matrix has a 2×2 blocked partition, and each block represents numerical Green’s function interactions between unknowns residing on planar or crossing planes (or lines). These blocks are compressed as butterfly or HOD-BF by extracting selected matrix entries [37, 42] guided by graph distance, from the children frontal matrices and the original sparse matrix. Moreover, the method factorizes the leading diagonal block using the HOD-BF inversion technique [33] and compute its Schur complement with the randomized butterfly construction algorithm [34]. Given a frontal matrix of size $n \times n$, the construction and factorization can be performed in $\mathcal{O}(n^{3/2} \log n)$ complexity. Consequently, for a sparse matrix resulting from 2D and 3D wave equations, the solver can attain an overall complexity of $\mathcal{O}(N)$ and $\mathcal{O}(N \log^2 N)$, respectively. It is worth mentioning the same complexities can be attained for 2D and 3D low-frequency or static PDEs such as the Poisson equation as well. To the best of our knowledge, the proposed solver represents the first-ever quasi-linear complexity multifrontal solver for high-frequency wave equations.

As a related work, the sweeping preconditioner-based domain decomposition solvers [45] represent another quasi-linear complexity technique for wave equations and impressive numerical results have been reported for both 2D and 3D cases. However, sweeping preconditioners only apply to regular grids and domains and do not

work well for domains containing resonant cavities. In comparison, the proposed solver does not suffer from these constraints and applies to wider classes of applications. In addition, the proposed solver can be used inside domain decomposition solvers, which often use multifrontal solvers for their local sparse systems.

The rest of the paper is organized as follows. The multifrontal method is presented in [section 2](#). The butterfly format, construction and entry extraction algorithms are described in [section 3](#), followed by their generalization to the HOD-BF format in [section 4](#). The proposed rank structured multifrontal method is detailed in [section 5](#), including complexity analysis. Numerical results demonstrating the efficiency and applicability of the proposed solver for the 3D Helmholtz, Maxwell, and Poisson equations are presented in [section 6](#).

2. Sparse Multifrontal LU Factorization. We consider the LU factorization of a sparse matrix $A \in \mathbb{C}^{N \times N}$, as $P(D_r A D_c Q_c)P^\top = LU$, where P and Q_c are permutation matrices, D_r and D_c are diagonal row and column scaling matrices and L and U are sparse lower and upper-triangular respectively. D_r , D_c and Q_c are optional and are applied for numerical stability. Q_c aims to maximize the magnitude of the elements on the matrix diagonal. D_r and D_c scale the matrix such that the diagonal entries are one in absolute value and all off-diagonal entries are less than one. This step is implemented using the sequential MC64 code [\[13\]](#) or the parallel method – without the diagonal scaling – described in [\[5\]](#). The permutation P is applied symmetrically and is used to minimize the fill, i.e., the number of non-zero entries in the sparse factors L and U . This permutation is computed from the symmetric sparsity structure of $A + A^\top$. For large problems the preferred ordering is typically based on the nested dissection heuristic, as implemented in METIS [\[30\]](#) or Scotch.

The multifrontal method [\[14\]](#) relies on a graph called the assembly tree to guide the computation. Each node τ of the assembly tree corresponds to a dense frontal matrix, with the following 2×2 block structure: $F_\tau = \begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}$, with F_{11} of dimension $\#I_\tau^s$ and F_{22} of dimension $\#I_\tau^u$. Let $n_\tau = \#I_\tau^s + \#I_\tau^u$ denote the dimension of F_τ . A frontal matrix is an intermediate dense submatrix in sparse Gaussian elimination. The rows and columns corresponding to the F_{11} block are called the fully-summed variables because when the front is constructed, these variables have received all their Schur complement updates. The fully-summed variables correspond to I_τ^s , which are mutually exclusive, with $\bigcup_\tau I_\tau^s = \{1, \dots, N\}$. In the context of nested dissection, the sets I_τ^s correspond to individual vertex separators. The I_τ^u index sets define the temporary Schur complement update blocks. Note that the frontal matrices tend to get bigger toward the root of the assembly tree. Furthermore, if ν is a child of τ in the assembly tree, then $I_\nu^u \subset \{I_\tau^s \cup I_\tau^u\}$. For the root node t , $I_t^u \equiv \emptyset$. When considering a single front, we will omit the τ subscript.

The multifrontal method casts the factorization of a sparse matrix into a series of partial factorizations of many smaller dense matrices and Schur complement updates. It consists in a bottom-up traversal of the assembly tree following a topological order. Processing a node consists of four steps:

1. Assembling the frontal matrix F_τ , i.e., combining elements from the sparse matrix A with the children's (ν_1 and ν_2) Schur complement updates F_{22} into the (larger) F_τ . This involves a scatter operations and is called extend-add, denoted by $\leftarrow \! \! \! \leftarrow$:

$$F_\tau = \begin{bmatrix} A(I_\tau^s, I_\tau^s) & A(I_\tau^s, I_\tau^u) \\ A(I_\tau^u, I_\tau^s) & A(I_\tau^u, I_\tau^u) \end{bmatrix} \leftarrow \! \! \! \leftarrow F_{22;\nu_1} \leftarrow \! \! \! \leftarrow F_{22;\nu_2} = \begin{bmatrix} \text{---} & \text{---} \\ \cdot & \cdot \\ \cdot & \cdot \end{bmatrix} \leftarrow \! \! \! \leftarrow \begin{bmatrix} \text{---} \\ \cdot \\ \cdot \end{bmatrix} \leftarrow \! \! \! \leftarrow \begin{bmatrix} \text{---} \\ \cdot \\ \cdot \end{bmatrix}$$

2. Elimination of the fully-summed variables in the F_{11} block, i.e., dense LU factorization with partial pivoting of F_{11} .
3. Updating the off-diagonal blocks F_{12} and F_{21} .
4. Compute the Schur complement update: $F_{22} \leftarrow F_{22} - F_{21}F_{11}^{-1}F_{12}$. We will also denote the Schur updated F_{22} for front τ as the contribution block CB_τ . F_{22} is temporary storage (pushed on a stack), and can be released as soon as it has been used in the front assembly (step (1)) of the parent node.

After the numerical factorization, the lower triangular sparse factor is available in the F_{21} and F_{11} blocks and the upper triangular factor in the F_{11} and F_{12} blocks. These can then be used to very efficiently solve linear systems, using forward and backward substitution. A high-level overview is given in [Algorithm 2.1](#).

We implemented the multifrontal method in the STRUMPACK library¹, using C++, MPI and OpenMP, supporting real/complex arithmetic, single/double precision and 32/64-bit integers.

For any frontal matrix F_τ of size n_τ , its LU factorization (only on F_{11}) and storage costs scale as $\mathcal{O}(n_\tau^3)$ and $\mathcal{O}(n_\tau^2)$, severely limiting the applicability of the multifrontal method to large-scale PDE problems. In what follows, we leverage the butterfly algorithm and its hierarchical matrix extension for representing frontal matrices and constructing fast sparse direct solvers, particularly for high-frequency wave equations.

Algorithm 2.1 Sparse multifrontal factorization and solve.

Input: $A \in \mathbb{R}^{N \times N}$, $b \in \mathbb{R}^N$

Output: $x \approx A^{-1}b$

- 1: $A \leftarrow D_r A D_c Q_c$ ▷ (optional) col perm & scaling
 - 2: $A \leftarrow P A P^\top$ ▷ symm fill-reducing reordering
 - 3: Build assembly tree: define I_τ^s and I_τ^u for every frontal matrix F_τ
 - 4: **for** nodes τ in assembly tree in topological order **do**
 - 5: ▷ sparse with the children updates extended and added
 - 6: $F_\tau \leftarrow \begin{bmatrix} A(I_\tau^s, I_\tau^s) & A(I_\tau^s, I_\tau^u) \\ A(I_\tau^u, I_\tau^s) & 0 \end{bmatrix} \diamond F_{\nu_1;22} \diamond F_{\nu_2;22}$
 - 7: $P_\tau L_\tau U_\tau \leftarrow F_{\tau;11}$ ▷ LU with partial pivoting
 - 8: $F_{\tau;12} \leftarrow L_\tau^{-1} P_\tau^\top F_{\tau;12}$
 - 9: $F_{\tau;21} \leftarrow F_{\tau;21} U_\tau^{-1}$
 - 10: $F_{\tau;22} \leftarrow F_{\tau;22} - F_{\tau;21} F_{\tau;12}$ ▷ Schur update
 - 11: **end for**
 - 12: $x \leftarrow D_c Q_c P^\top$ bwd-solve (fwd-solve ($P D_\tau b$))

3. Butterfly Algorithms. As the building block of our butterfly algorithms, we first present some background regarding the interpolative decomposition (ID). Given a matrix $A \in \mathbb{R}^{m \times n}$, a row ID represents or approximates A in the low-rank form $U A_{I,:}$, where $U \in \mathbb{R}^{m \times r}$ has bounded entries, $A_{I,:} \in \mathbb{R}^{r \times n}$ contains k rows of A , and r is the rank. Symmetrically, a column ID can represent or approximate A column-wise as $A_{:,J} V^\top$ where $V \in \mathbb{R}^{n \times r}$ and $A_{:,J}$ contains r columns of A .

Using an algebraic approach, an ID approximation with a given rank or a given error threshold can be computed using for instance the strong rank-revealing or column-pivoted QR decomposition with typical complexity $\mathcal{O}(rmn)$ (or $\mathcal{O}(rmn \log m)$ in rare cases). Note that we use base 2 for the logarithm throughout this paper. The matrix

¹<http://portal.nersc.gov/project/sparse/strumpack/>

U obtained by rank-revealing QR can have all its entries bounded by a prespecified parameter $C_{qr} \geq 1$. In practice, pivoted QR decomposition is more commonly used while entries of the obtained U are mostly also bounded (but without theoretical guarantee). Specifically, an ID approximation is calculated as follows. Calculate a QR decomposition of A^\top and truncate it with a given error threshold as

$$A^\top P = [A_1^\top \quad A_2^\top] = [Q_1 \quad Q_2] \begin{bmatrix} R_{11} & R_{12} \\ & R_{22} \end{bmatrix} \approx Q_1 [R_{11} \quad R_{12}] = A_1^\top [I \quad R_{11}^{-1} R_{12}],$$

where P is a permutation matrix that indicates the important rows (oftentimes referred to as row skeletons) of A . The ID approximation is $A \approx P \begin{bmatrix} I \\ (R_{11}^{-1} R_{12})^\top \end{bmatrix} A_1 = UA_1$ where U is the interpolation matrix.

In addition to the above-described deterministic algorithm, an ID approximation can also be constructed in a randomized fashion, via random matrix-vector products as described in [27]. Both the deterministic and randomized ID algorithms will be used in our butterfly algorithms below. Unless otherwise stated, all the ID algorithms in this paper are deterministic algorithms.

3.1. Complementary Low-Rank Property and Butterfly Decomposition. We consider the butterfly compression of a matrix $A = K(O, S) \in \mathbb{R}^{m \times n}$ defined by a highly-oscillatory operator $K(\cdot, \cdot)$ and point sets S and O . For example, one can think of K as the free-space Green's function for 3D Helmholtz equations, and S and O as sets of Cartesian coordinates representing source and observer points in the Green's function. However, we do not restrict ourselves to analytical functions and geometrical points in this paper. For simplicity, we assume $m = \mathcal{O}(n)$ and we partition S and O using bisection, resulting in the binary trees \mathcal{T}_S and \mathcal{T}_O . We number the levels of \mathcal{T}_O and \mathcal{T}_S from the root to the leaves. The root node, denoted by t in \mathcal{T}_O and s in \mathcal{T}_S , is at level 0; its children are at level 1, etc. All the leaf nodes are at level L . At each level l , \mathcal{T}_O and \mathcal{T}_S both have 2^l nodes. Let O_τ be the subset of points in O corresponding to node τ in \mathcal{T}_O . Furthermore, for any non-leaf node $\tau \in \mathcal{T}_O$ with children τ_1 and τ_2 , $O_{\tau_1} \cup O_{\tau_2} = O_\tau$ and $O_{\tau_1} \cap O_{\tau_2} = \emptyset$. With a slight abuse of notation, we also use τ_i , $i = 1, \dots, 2^l$ to denote all nodes at level l of \mathcal{T}_O . The same properties hold true for the partitioning of S .

$A = K(O, S)$ satisfies the *complementary low-rank property* if for any level $0 \leq l \leq L$, node τ at level l of \mathcal{T}_O and a node ν at level $(L - l)$ of \mathcal{T}_S , the subblock $K(O_\tau, S_\nu)$ is numerically low-rank with rank $r_{\tau, \nu}$ bounded by a small number r ; r is called the (maximum) butterfly rank. For simplicity, we assume constant butterfly ranks $r = \mathcal{O}(1)$ throughout sections 3 and 4. As explained in Section 4.5 of [34], low complexities for butterfly construction, multiplication, inversion and storage can still be achieved even for certain cases of non-constant ranks, e.g., $r = \mathcal{O}(\log n)$ or $r = \mathcal{O}(n^{1/4})$. We will further discuss the non-constant rank case in subsection 5.3. The complementary low-rank property is illustrated in Figure 3.1. At any level l of \mathcal{T}_O , $K(O_\tau, S_\nu)$ with all nodes τ at level l of \mathcal{T}_O and nodes ν at level $(L - l)$ of \mathcal{T}_S (referred to as the blocks at level l) form a non-overlapping partitioning of $K(O, S)$.

For any level l , we can compress $K(O_\tau, S_\nu)$ via row-wise and column-wise ID as

$$(3.1) \quad K(O_\tau, S_\nu) \approx U_{\tau, \nu} K(\bar{O}_\tau, \bar{S}_\nu) V_{\tau, \nu}^\top = U_{\tau, \nu} B_{\tau, \nu} V_{\tau, \nu}^\top.$$

Here, \bar{O}_τ represents skeleton rows (constructed from O_τ), \bar{S}_ν represents skeleton columns (constructed from S_ν), and $B_{\tau, \nu}$ is the *skeleton matrix*. The row and column

Fig. 3.1: For a 4-level butterfly decomposition, the complementary low-rank property states that each of the illustrated sub-blocks $K(O_\tau, S_\nu)$, $\tau \in \mathcal{T}_O, \nu \in \mathcal{T}_S$ are low-rank.

interpolation matrices $U_{\tau,\nu}$ and $V_{\tau,\nu}$ are defined as

$$(3.2) \quad U_{\tau,\nu} = \begin{bmatrix} U_{\tau_1, p_\nu} & \\ & U_{\tau_2, p_\nu} \end{bmatrix} R_{\tau,\nu}, \quad V_{\tau,\nu}^\top = W_{\tau,\nu} \begin{bmatrix} V_{p_\tau, \nu_1}^\top & \\ & V_{p_\tau, \nu_2}^\top \end{bmatrix}.$$

where $R_{\tau,\nu}$ and $W_{\tau,\nu}$ are referred to as the *transfer matrices*, and p_τ, p_ν denote the parent nodes of τ, ν . Oftentimes we choose a center level $l = l_c = L/2$, and the butterfly representation of $K(O, S)$ is constructed as,

$$(3.3) \quad K(O, S) = \begin{bmatrix} K(O_{\tau_1}, S_{\nu_1}) & K(O_{\tau_1}, S_{\nu_2}) & \cdots & K(O_{\tau_1}, S_{\nu_q}) \\ K(O_{\tau_2}, S_{\nu_1}) & K(O_{\tau_2}, S_{\nu_2}) & \cdots & K(O_{\tau_2}, S_{\nu_q}) \\ \vdots & \vdots & \ddots & \vdots \\ K(O_{\tau_p}, S_{\nu_1}) & K(O_{\tau_p}, S_{\nu_2}) & \cdots & K(O_{\tau_p}, S_{\nu_q}) \end{bmatrix}$$

where $\tau_1, \tau_2, \dots, \tau_p$ are the $p = 2^{l_c}$ nodes at level l_c of \mathcal{T}_O , and $\nu_1, \nu_2, \dots, \nu_q$ are the $q = 2^{L-l_c}$ nodes at level $(L - l_c)$ of \mathcal{T}_S .

$$(3.4) \quad K(O, S) \approx \begin{bmatrix} U_{\tau_1, \nu_1} B_{\tau_1, \nu_1} V_{\tau_1, \nu_1}^\top & U_{\tau_1, \nu_2} B_{\tau_1, \nu_2} V_{\tau_1, \nu_2}^\top & \cdots & U_{\tau_1, \nu_q} B_{\tau_1, \nu_q} V_{\tau_1, \nu_q}^\top \\ U_{\tau_2, \nu_1} B_{\tau_2, \nu_1} V_{\tau_2, \nu_1}^\top & U_{\tau_2, \nu_2} B_{\tau_2, \nu_2} V_{\tau_2, \nu_2}^\top & \cdots & U_{\tau_2, \nu_q} B_{\tau_2, \nu_q} V_{\tau_2, \nu_q}^\top \\ \vdots & \vdots & \ddots & \vdots \\ U_{\tau_p, \nu_1} B_{\tau_p, \nu_1} V_{\tau_p, \nu_1}^\top & U_{\tau_p, \nu_2} B_{\tau_p, \nu_2} V_{\tau_p, \nu_2}^\top & \cdots & U_{\tau_p, \nu_q} B_{\tau_p, \nu_q} V_{\tau_p, \nu_q}^\top \end{bmatrix}$$

$$(3.5) \quad = (U^L R^{L-1} R^{L-2} \dots R^{l_c}) B^{l_c} (W^{l_c} W^{l_c-1} \dots W^1 V^0)$$

where $U^L = \text{diag}(U_{\tau_1, s}, \dots, U_{\tau_{2^L}, s})$ consists of column basis matrices at level L , and each factor $R^l, l = L-1, \dots, l_c$ is block diagonal consisting of diagonal blocks R_ν for all nodes ν at level $L-l-1$ of \mathcal{T}_S

$$(3.6) \quad R_\nu = [\text{diag}(R_{\tau_1, \nu_1}, \dots, R_{\tau_{2^l}, \nu_1}) \quad \text{diag}(R_{\tau_1, \nu_2}, \dots, R_{\tau_{2^l}, \nu_2})].$$

Here, $\tau_1, \tau_2, \dots, \tau_{2^l}$ are the nodes at level l of \mathcal{T}_O and ν_1, ν_2 are children of ν . Similarly, $V^0 = \text{diag}(V_{t, \nu_1}^\top, \dots, V_{t, \nu_{2^L}}^\top)$ with t denoting the root of \mathcal{T}_O , and the block-diagonal inner factors $W^l, l = 1, \dots, l_c$ have blocks W_τ for all nodes τ at level $l-1$ of \mathcal{T}_T

$$(3.7) \quad W_\tau = \begin{bmatrix} \text{diag}(W_{\tau_1, \nu_1}, \dots, W_{\tau_1, \nu_{2^{L-l}}}) \\ \text{diag}(W_{\tau_2, \nu_1}, \dots, W_{\tau_2, \nu_{2^{L-l}}}) \end{bmatrix}$$

Here, $\nu_1, \nu_2, \dots, \nu_{2^{L-l}}$ are the nodes at level $L-l$ of \mathcal{T}_S and τ_1, τ_2 are children of τ . Moreover, the inner factor B^{l_c} consists of blocks $B_{\tau,\nu}$ at level l_c in (3.4). For simplicity assuming $r_{\tau,\nu} = r$, B^{l_c} is a $p \times q$ block-partitioned matrix with each block of

Fig. 3.2: Illustration of a 4-level butterfly representation. For a butterfly representation, we typically put the inner factor B^l at the center level ($l = l_c = L/2$).

size $qr \times pr$; the (i, j) block is a $q \times p$ block-partitioned matrix with each block of size $r \times r$, among which the only nonzero block is the (j, i) block and equals B_{τ_i, ν_j} . We call (3.5) a butterfly representation of $K(O, S)$, or simply, a butterfly. These structures are illustrated in Figure 3.2. Once factorized in the form of (3.5), the storage and application costs of a matrix-vector product scale as $\mathcal{O}(n \log n)$. Naive butterfly construction of (3.5) requires $\mathcal{O}(n^2)$ operations. However, we consider two scenarios that allow fast butterfly construction: when individual elements of the matrix can be quickly computed, subsection 3.2, or when the matrix can be applied efficiently to a set of random vectors, subsection 3.3.

3.2. Butterfly Construction using Matrix Entry Evaluation. Oftentimes fast access to any matrix entry is available, e.g., when the matrix entry has a closed-form expression, or the matrix has been stored in full or compressed forms. If any entry of the matrix can be computed in less than e.g., $\mathcal{O}(\log n)$ operations, the butterfly construction cost can be reduced to quasi-linear.

Starting from level L of \mathcal{T}_O , we need to compute the interpolation matrices $U_{\tau_i, s}$ via row ID such that $K(O_{\tau_i}, S_s) = U_{\tau_i, s} K(\bar{O}_{\tau_i}, S_s)$, $i = 1, \dots, 2^L$ for the root node s of \mathcal{T}_S . Note that it is expensive to perform such direct computation as there are $2^L = \mathcal{O}(n)$ IDs each requiring at least $\mathcal{O}(m)$ operations. Instead, we consider using proxy columns to reduce the ID costs. Specifically, we choose $\mathcal{O}(r)$ columns $S_{\tau_i, s}$ from S_s and compute $U_{\tau_i, s}$ from $K(O_{\tau_i}, S_{\tau_i, s}) = U_{\tau_i, s} K(\bar{O}_{\tau_i}, S_{\tau_i, s})$. There exists several options on how to choose the proxy columns, including uniform, random or Chebyshev samples [31]. However, uniform or random samples often yield inaccuracies when the operator represents interactions between close-by spatial domains, and Chebyshev samples only apply to regular spatial domains. Instead we pick $(\alpha + k_{\text{nn}})|O_{\tau_i}|$ columns with $\alpha|O_{\tau_i}|$ uniform samples (α is an oversampling factor) and k_{nn} nearest points per row using a certain distance metric, see also subsection 5.2 for its application to frontal matrix compression.

At any level $l = L - 1, \dots, l_c$, we can compute the transfer matrix $R_{\tau, \nu}$ for node τ at level l of \mathcal{T}_O and node ν at level $L - l$ of \mathcal{T}_S , from

$$(3.8) \quad K(O_\tau, S_\nu) = \begin{bmatrix} U_{\tau_1, p_\nu} & \\ & U_{\tau_2, p_\nu} \end{bmatrix} \begin{bmatrix} K(\bar{O}_{\tau_1}, S_\nu) \\ K(\bar{O}_{\tau_2}, S_\nu) \end{bmatrix} = \begin{bmatrix} U_{\tau_1, p_\nu} & \\ & U_{\tau_2, p_\nu} \end{bmatrix} R_{\tau, \nu} K(\bar{O}_\tau, S_\nu).$$

From (3.8), the transfer matrix $R_{\tau, \nu}$ can be computed as the interpolation matrix in the row ID of $K(\bar{O}_{\tau_1} \cup \bar{O}_{\tau_2}, S_\nu)$. Just like level L , we choose $(\alpha + k_{\text{nn}})|\bar{O}_{\tau_1} \cup \bar{O}_{\tau_2}|$ columns $S_{\tau, \nu}$ from S_ν as the proxy columns to compute $R_{\tau, \nu}$.

Similarly, we compute the interpolation matrices $V_{\tau, \nu}$ at level 0 and transfer

matrices $W_{\tau,\nu}$ at levels $l = 1, \dots, l_c$ using column IDs with uniform and nearest neighboring sampling. Finally, the skeleton matrices $B_{\tau,\nu}$ are directly assembled at center level l_c .

The above-described process is summarized as `BF_entry_eval(A)` (Algorithm 3.1). Note that at each level $l = 0, \dots, L$ one needs to extract $\mathcal{O}(n)$ submatrices of size $\mathcal{O}(r) \times \mathcal{O}(r)$ using the element extraction function `extract(L, A)` at lines 12, 28, 34. This function can efficiently compute a list of submatrices indexed by a list of (rows, columns) index sets $\mathcal{L} = \{(X_1, Y_1), (X_2, Y_2), \dots\}$. When A has a closed-form expression or has been stored in full, `extract(L, A)` takes $\mathcal{O}(n)$ time and the butterfly construction requires $\mathcal{O}(n \log n)$ time; when A has been computed in some compressed form (e.g., as summation of two butterflies), `extract(L, A)` often takes $\mathcal{O}(n \log n)$ time and the butterfly construction requires $\mathcal{O}(n \log^2 n)$ time. As we will see, the latter case appears when compressing the frontal matrices and we describe the `extract` function with compressed A in subsection 3.4.

Algorithm 3.1 `BF_entry_eval(A)`: Butterfly construction of matrix A with entry evaluation.

Input: A routine `extract(L, A)` to extract a list of sub-matrices of A with \mathcal{L} denoting the list of (rows, columns) index sets, an over-sampling parameter α , nearest neighbor parameter k_{nn} , ID with a tolerance ε named ID_ε , and binary partitioning trees \mathcal{T}_S and \mathcal{T}_O of L levels.

Output: $A = K(O, S) \approx (U^L R^{L-1} R^{L-2} \dots R^{l_c}) B^{l_c} (W^{l_c} W^{l_c-1} \dots W^1 V^0)$ with $l_c = L/2$

<pre> 1: for $l = L$ to l_c do $\triangleright U_{\tau,\nu}, R_{\tau,\nu}$ 2: $\mathcal{L} \leftarrow \{\}$ 3: for (τ, ν) at $(l, L-l)$ of $(\mathcal{T}_O, \mathcal{T}_S)$ do 4: if $l = L$ then 5: $\mathcal{L} \leftarrow \{\mathcal{L}, (O_{\tau}, S_{\tau,\nu})\}$ with 6: $S_{\tau,\nu} = (\alpha + k_{\text{nn}}) O_{\tau}$ 7: else 8: $\mathcal{L} \leftarrow \{\mathcal{L}, (\bar{O}_{\tau_1} \cup \bar{O}_{\tau_2}, S_{\tau,\nu})\}$ with 9: $S_{\tau,\nu} = (\alpha + k_{\text{nn}}) \bar{O}_{\tau_1} \cup \bar{O}_{\tau_2}$ 10: end if 11: end for 12: $\{\forall (X, Y) \in \mathcal{L} : K(X, Y)\} \leftarrow \text{extract}(\mathcal{L}, A)$ 13: for $(X, Y) \in \mathcal{L}$ (corresp. (τ, ν)) do 14: $U_{\tau,\nu}$ (or $R_{\tau,\nu}$), $\bar{O}_{\tau} \leftarrow \text{ID}_\varepsilon$ of $K(X, Y)$ 15: end for 16: end for </pre>	<pre> 17: for $l = 0$ to l_c do $\triangleright V_{\tau,\nu}, W_{\tau,\nu}$ 18: $\mathcal{L} \leftarrow \{\}$ 19: for (τ, ν) at $(l, L-l)$ of $(\mathcal{T}_O, \mathcal{T}_S)$ do 20: if $l = 0$ then 21: $\mathcal{L} \leftarrow \{\mathcal{L}, (O_{\tau,\nu}, S_\nu)\}$ with 22: $O_{\tau,\nu} = (\alpha + k_{\text{nn}}) S_\nu$ 23: else 24: $\mathcal{L} \leftarrow \{\mathcal{L}, (O_{\tau,\nu}, \bar{S}_{\nu_1} \cup \bar{S}_{\nu_2})\}$ with 25: $O_{\tau,\nu} = (\alpha + k_{\text{nn}}) \bar{S}_{\nu_1} \cup \bar{S}_{\nu_2}$ 26: end if 27: end for 28: $\{\forall (X, Y) \in \mathcal{L} : K(X, Y)\} \leftarrow \text{extract}(\mathcal{L}, A)$ 29: for $(X, Y) \in \mathcal{L}$ (corresp. (τ, ν)) do 30: $V_{\tau,\nu}$ (or $W_{\tau,\nu}$), $\bar{S}_\nu \leftarrow \text{ID}_\varepsilon$ of $K(X, Y)$ 31: end for 32: end for 33: $\mathcal{L} \leftarrow \{\forall \tau, \nu \text{ at level } l_c : (\bar{O}_\tau, \bar{S}_\nu)\}$ 34: $\{\forall \tau, \nu \text{ at level } l_c : B_{\tau,\nu}\} \leftarrow \text{extract}(\mathcal{L}, A)$ </pre>
--	--

3.3. Randomized Matrix-Free Butterfly Construction. When fast matrix entry evaluation is not available, but the matrix can be applied to arbitrary vectors in quasi-linear time, typically $\mathcal{O}(n \log n)$, the randomized matrix-free butterfly methods from [21] and [34] can be used. We use a slight modification based on the method from [34], which, given a $\mathcal{O}(n \log n)$ matrix-vector product, requires $\mathcal{O}(n^{3/2} \log n)$ operations and $\mathcal{O}(n \log n)$ storage.

The algorithm works as follows. First, multiply $A = K(O, S) \in \mathbb{C}^{m \times n}$, from the

right, with a random matrix $\Gamma_s \in \mathbb{R}^{|S_s| \times (r+p)}$, where r is an estimate of the butterfly rank and p is a small oversampling parameter: $K(O, S_s)\Gamma_s$ with s denoting the root node of \mathcal{T}_S . From this product, one can easily extract the submatrix $K(O_\tau, S_s)\Gamma_s$ and construct $U_{\tau,s}$ for all τ at level L of \mathcal{T}_O using a randomized low-rank approximation algorithm, as described in detail in [27]. This can be repeated with increasing r until convergence, see for instance [17] for a detailed discussion of the adaptive rank determination. Similarly, $V_{t,\nu}$ with t the root node of \mathcal{T}_O and ν all the nodes at level L of \mathcal{T}_S , can be obtained by multiplying $K(O_t, S)$ from the left with a random matrix.

In the following phases, the individual block diagonal matrices of R^l can be reconstructed by multiplication with random matrices structured as

$$(3.9) \quad \Gamma^0 = \Gamma_s, \quad \Gamma^1 = \begin{bmatrix} \Gamma_{\nu_1} & \\ & \Gamma_{\nu_2} \end{bmatrix}, \dots, \quad \Gamma^l = \begin{bmatrix} \Gamma_{\nu_1} & & \\ & \ddots & \\ & & \Gamma_{\nu_{2^l}} \end{bmatrix}$$

where Γ^l , $l \leq l_c$ is used to construct the R^l factors. Specifically, from the product $K(O, S_{\nu_j})\Gamma_{\nu_j}$, $j = 1, \dots, 2^l$, we can extract the product $K(O_\tau, S_{\nu_j})\Gamma_{\nu_j}$ for any node τ at level $L-l$ of \mathcal{T}_O . One can further extract the product $K(\bar{O}_{\tau_1} \cup \bar{O}_{\tau_2}, S_{\nu_j})\Gamma_{\nu_j}$ (recall that \bar{O}_{τ_1} and \bar{O}_{τ_2} are previously computed row skeletons as in (3.8)) and compute its interpolation matrix as R_{τ,ν_j} using the randomized ID algorithm [27]. Note that here the column dimension of Γ_{ν_j} , i.e., $r+p$, can be estimated since the upper bound on the rank r can be directly computed from the constructed factors at the previous level. Throughout this paper, we name this randomized algorithm as `BF_random_matvec(A)`. Similarly, the W^l and B^l factors can be reconstructed by multiplying K from the left with structured random vectors similar to (3.9). We refer the reader to [34] for the details of this algorithm.

Algorithm 3.2 `extract_BF(L, A)`: Extraction of a list \mathcal{L} of sub-matrices of a butterfly-compressed matrix A .

Input: $A = (U^L R^{L-1} R^{L-2} \dots R^{l_c}) B^{l_c} (W^{l_c} W^{l_c-1} \dots W^1 V^0) \approx K(O, S)$. A list of (rows, columns) index sets $\mathcal{L} = \{(X_1, Y_1), \dots\}$.

Output: $\forall (X, Y) \in \mathcal{L} : K(X, Y)$.

<pre> 1: for (X, Y) in \mathcal{L} do 2: for $l = 0$ to L do 3: Generate a list \mathcal{L}_l of (τ, ν) at level $(l, L-l)$ of $(\mathcal{T}_O, \mathcal{T}_S)$ with $X \cap$ $O_\tau \neq \emptyset$ and $Y \cap S_\nu \neq \emptyset$ 4: end for 5: for $l = L$ to l_c do 6: for (τ, ν) in \mathcal{L}_l do 7: if $l = L$ then 8: $E_{\tau,\nu}^l = U_{\tau,\nu}(I, :)$ 9: I corresponds to points in $X \cap O_\tau$ 10: else 11: $E_{\tau,\nu}^l = [E_{\tau_1, p\nu}^{l+1}, E_{\tau_2, p\nu}^{l+1}] R_{\tau,\nu}$ 12: end if 13: end for 14: end for </pre>	<pre> 15: for $l = 0$ to l_c do 16: for (τ, ν) in \mathcal{L}_l do 17: if $l = 0$ then 18: $F_{\tau,\nu}^l = V_{\tau,\nu}^\top(:, J)$ 19: J corresponds to points in $Y \cap S_\nu$ 20: else 21: $F_{\tau,\nu}^l = W_{\tau,\nu}[F_{p\tau, \nu_1}^{l-1}; F_{p\tau, \nu_2}^{l-1}]$ 22: end if 23: end for 24: end for 25: $K(X, Y) \leftarrow E_{\tau,\nu}^{l_c} B_{\tau,\nu}^{l_c} F_{\tau,\nu}^{l_c} \forall (\tau, \nu) \in \mathcal{L}_{l_c}$ 26: end for </pre>
---	--

Fig. 3.3: The extract routine, see Algorithm 3.2, to compute a list of submatrices from a 2-level butterfly matrix. (a) This shows the center level partitioning of the 2-level butterfly matrix and the two submatrices (with sizes 1×1 and 1×2 , colored green and blue respectively) to be extracted. (b) The transfer, interpolation and skeleton matrices required for the extraction of the two subblocks are highlighted.

3.4. Extracting Elements from a Butterfly Matrix. As explained in more detail in section 5, incorporating butterfly compression in the sparse solver requires both the `BF_entry_eval` and `BF_random_matvec` algorithms. In one step of the multifrontal algorithm, a subblock of a frontal matrix will be constructed as a butterfly matrix using the `BF_entry_eval` Algorithm 3.1. Since fronts are constructed as a combination (extend-add) of other smaller fronts, the extract routine used in `BF_entry_eval` will need to extract a list of submatrices from other fronts which might already be compressed using butterfly. Therefore it is critical for performance to have an efficient algorithm to extract a list of submatrices from a butterfly matrix. This is presented as `extract_BF` in Algorithm 3.2.

Given an $m \times n$ butterfly matrix $A \approx K(O, S)$ and a list of (rows, columns) index sets \mathcal{L} inquiring a total of $n_e = \sum_{(X,Y) \in \mathcal{L}} |X||Y|$ matrix entries, Algorithm 3.2 extracts all required elements in $\mathcal{O}(n_e \log n)$ operations. In other words, this algorithm requires $\mathcal{O}(\log n)$ operations per entry regardless of the number of entries needed. Consider for example the case where one wants to construct a butterfly matrix from the sum of two butterfly matrices. This can be done by calling `BF_entry_eval` with an extract routine, implemented using two calls to `extract_BF`.

In a nutshell, extracting a submatrix from a butterfly can be performed via *EAF* with selection matrices E and F that pick the rows and columns of the submatrix. However, an efficient algorithm requires multiplying only selected transfer, interpolation and skeleton matrices. Specifically, Algorithm 3.2 computes, for each $(X, Y) \in \mathcal{L}$, lists \mathcal{L}_l of (τ, ν) pairs indicating the required butterfly blocks (see Algorithm 3.2). These blocks are then multiplied together to compute the submatrix $K(X, Y)$ (see lines 11, 21, 25), which requires $\mathcal{O}(n_e \log n)$ operations. For example, Figure 3.3 shows an extraction of two submatrices (with sizes 1×1 and 1×2 and colored green and blue) from a 2-level butterfly, with the required transfer, interpolation and skeleton matrices also highlighted. To further improve the performance, we modify Algorithm 3.2 by moving the outermost loop into the innermost loops at lines 6 and 16. This way any butterfly block is multiplied at most once, and the communication is minimized when A is distributed over multiple processes.

4. Hierarchically Off-Diagonal Butterfly Matrix Representation. The hierarchically off-diagonal low-rank (HOD-LR) matrix representation is a special case of the more general class of \mathcal{H} matrices. For HOD-LR every off-diagonal block is assumed to be low-rank, which corresponds to so-called \mathcal{H} -matrix weak admissibil-

ity [25]. The hierarchically off-diagonal butterfly (HOD-BF) format, however, is a generalization of HOD-LR where low-rank approximation is replaced by butterfly decomposition [33].

For dense linear systems arising from high-frequency wave equations, the HOD-BF format is a suitable matrix representation, since butterfly compression applied to the off-diagonal blocks reduces storage and solution complexity, as opposed to \mathcal{H} or HOD-LR matrices which do not reduce complexity for such problems. The HOD-BF matrix format was first developed to solve 2D high-frequency Helmholtz equations with $\mathcal{O}(n \log^2 n)$ memory and $\mathcal{O}(n^{3/2} \log n)$ time [33]. Recent work shows that the same complexity can also be obtained for 3D Helmholtz equations despite the non-constant butterfly rank due to weak-admissibility [34]. It is also worth mentioning that compared to butterfly-based \mathcal{H} matrix compression with strong admissibility [21, 22], HOD-BF enjoys simpler butterfly arithmetic, smaller leading constants in complexity, and significantly better parallelization performance. In what follows, we briefly describe the HOD-BF format, which is used in section 5 to construct the quasi-linear complexity multifrontal solver.

As illustrated in Figure 4.1, in the HOD-BF format diagonal blocks are recursively refined until a certain minimum size is reached. For a square matrix $A \in \mathbb{R}^{n \times n}$, this partitioning defines a single binary tree \mathcal{T}_H , as shown on the right in Figure 4.1. The root node is at level 0; its children are at level 1, etc. All the leaf nodes are at level L . Each node τ at level l in the HOD-BF tree has an index set $T_\tau^l \subset T_H = \{1, \dots, n\}$, where T_H is the index set corresponding to all rows and columns of the matrix. For an internal node τ at level l with children τ_1 and τ_2 , $T_\tau^l = T_{\tau_1}^{l+1} \cup T_{\tau_2}^{l+1}$. At the lowest level of the hierarchy, the leaves of the HOD-BF tree, the diagonal blocks $D_\tau = A(T_\tau^L, T_\tau^L)$ are stored as regular dense matrices, while off-diagonal blocks are approximated using butterfly decomposition. Let τ_1 and τ_2 be two siblings in \mathcal{T}_H on level l with the two trees $\mathcal{T}_{\tau_1}^l$ and $\mathcal{T}_{\tau_2}^l$, subtrees of \mathcal{T}_H , rooted at nodes τ_1 and τ_2 respectively. These two sibling nodes correspond to two off-diagonal blocks $B_{\tau_1} = A(T_{\tau_1}^l, T_{\tau_2}^l)$ and $B_{\tau_2} = A(T_{\tau_2}^l, T_{\tau_1}^l)$, approximated using butterfly decomposition. One of those butterfly blocks is defined by $\mathcal{T}_O = \mathcal{T}_{\tau_1}^l$ and $\mathcal{T}_S = \mathcal{T}_{\tau_2}^l$, while the other is defined by $\mathcal{T}_O = \mathcal{T}_{\tau_2}^l$ and $\mathcal{T}_S = \mathcal{T}_{\tau_1}^l$.

4.1. HOD-BF Construction Using Entry Evaluation. An HOD-BF matrix representation based on sampling matrix entries can be constructed upon applying the BF_entry_eval algorithm (Algorithm 3.1) to all off-diagonal blocks of the HOD-BF matrix. The construction can be done in $\mathcal{O}(n \log^2 n)$, or in $\mathcal{O}(n \log^3 n)$ operations, if an individual matrix entry can be computed in $\mathcal{O}(1)$, or in $\mathcal{O}(\log n)$ time. We name the HOD-BF construction of a matrix A as HODBF_entry_eval(A), where A is passed in the form of a routine that extracts a list of (rows, columns) index sets from A .

Similar to the butterfly extract routine in subsection 3.4, we also implement a routine to extract a list \mathcal{L} of (rows, columns) index sets from an HOD-BF matrix A , called extract_HODBF(\mathcal{L}, A). This routine is implemented using extract_BF for the off-diagonal blocks of A .

4.2. Inversion of HOD-BF Matrices. Once constructed, the inverse of the HOD-BF matrix can be computed in $\mathcal{O}(n^{3/2} \log n)$ operations based on the randomized matrix-vector product algorithm BF_random_matvec described in subsection 3.3. The inversion algorithm has been previously described in [33] and is briefly summarized as HODBF_invert, Algorithm 4.1.

Let $D_\tau = A$ with τ denoting the root node of \mathcal{T}_H . The algorithm first computes $D_{\tau_1}^{-1}$ and $D_{\tau_2}^{-1}$ using two recursive calls. Then the two off-diagonal butterflies are

Fig. 4.1: Illustration of a 4-level hierarchically off-diagonal butterfly matrix. The root node is at level $l = 0$, all the leaf nodes are at level $L = 3$. The two largest off-diagonal blocks are approximated using 2-level butterfly matrices. The 4 off-diagonal blocks one level down in the hierarchy are approximated using a 1 level butterfly ($U^1 B^1 V^0$). Finally, the smallest off-diagonal blocks are approximated as low-rank, i.e., 0-level butterfly matrices. Note that these different butterfly blocks are not related. The hierarchy is illustrated using the tree on the right. Each leaf node stores a dense diagonal block D_τ , the parent nodes store 2 off-diagonal (butterfly) blocks.

updated as $B_{\tau_i} \leftarrow D_{\tau_i}^{-1} B_{\tau_i}$ using `BF_random_matvec` (at lines 7 and 8) as both $D_{\tau_i}^{-1}$ and B_{τ_i} are already compressed. Finally the updated matrix $[I, B_{\tau_1}; B_{\tau_2}, I]$ is inverted using the butterfly extension of the Sherman-Morrison-Woodbury formula [26], named `BF_SMW`, which in turn requires `BF_random_matvec` (at lines 16 and 18) to facilitate the computation.

5. Rank Structured Multifrontal Factorization. It has been studied by several authors that although the frontal matrices are dense, they are data-sparse for many applications and can often be well approximated using rank-structured matrix formats. Algorithm 5.1 outlines the rank-structured preconditioner using HOD-BF compression for the fronts. However since the more complicated HOD-BF matrix format has overhead for smaller matrices – compared to the highly optimized BLAS and LAPACK routines – HOD-BF compression is only used for fronts larger than a certain threshold n_{\min} . Typically, the larger fronts are found closer to the root of the multifrontal assembly tree. This is illustrated in Figure 5.1 for a small regular 11^2 mesh (Figure 5.1a), and Figure 5.1c shows the corresponding multifrontal assembly tree, where only the top 3 fronts are compressed using HOD-BF.

We now discuss the construction and partial factorization of the HOD-BF compressed fronts. To limit the overall complexity of the solver, a large front in the rank-structured multifrontal solver is never explicitly assembled fully as a large dense matrix. Instead, the solver relies on butterfly and HOD-BF construction using either element extraction, as described in subsection 3.2 and section 4 or randomized sampling, as in subsection 3.3. Recall that a front F_τ is built up from elements of the reordered sparse input matrix A , and contributions from the Schur complements, called the contribution blocks, of the children of the front in the assembly tree: $CB_{\nu_1} = F_{\nu_1;22}$ and $CB_{\nu_2} = F_{\nu_2;22}$, where ν_1 and ν_2 are the two children of τ . Since multifrontal factorization traverses the assembly tree from the leaves to the root, these children contribution blocks might already be compressed using the HOD-BF format. Hence, extracting frontal matrix elements requires getting them from fronts

Algorithm 4.1 HODBF_invert(A): Inversion of a square HOD-BF matrix.

Input: A in HOD-BF form with L levels

Output: A^{-1} in HOD-BF form

- 1: Let $D_\tau = A$ with τ denoting the root node.
 - 2: **if** D_τ dense **then**
 - 3: Directly compute D_τ^{-1}
 - 4: **else**
 - 5: $D_{\tau_1}^{-1} \leftarrow \text{HODBF_invert}(D_{\tau_1})$ $\triangleright D_{\tau_1}$ is HODBF with $L - 1$ levels
 - 6: $D_{\tau_2}^{-1} \leftarrow \text{HODBF_invert}(D_{\tau_2})$ $\triangleright D_{\tau_2}$ is HODBF with $L - 1$ levels
 - 7: $B_{\tau_1} \leftarrow \text{BF_random_matvec}(D_{\tau_1}^{-1} B_{\tau_1})$
 - 8: $B_{\tau_2} \leftarrow \text{BF_random_matvec}(D_{\tau_2}^{-1} B_{\tau_2})$
 - 9: $D_\tau^{-1} \leftarrow \text{BF_SMW}\left(\begin{bmatrix} I & B_{\tau_1} \\ B_{\tau_2} & I \end{bmatrix}\right) \begin{bmatrix} D_{\tau_1}^{-1} \\ D_{\tau_2}^{-1} \end{bmatrix}$
 - 10: **end if**
 - 11: **function** BF_SMW(A)
 - 12: **Input:** $A - I$ is a butterfly of L levels \triangleright If $L = 0$, the low-rank SMW [26] can be used instead.
 - 13: **Output:** A^{-1} as a butterfly of L levels added with the identity I
 - 14: Split A into four children butterflies of $L - 2$ levels: $A = [A_{11}, A_{12}; A_{21}, A_{22}]$ using \mathcal{T}_O and \mathcal{T}_S
 - 15: $A_{22}^{-1} \leftarrow \text{BF_SMW}(A_{22})$
 - 16: $A_{11} \leftarrow \text{BF_random_matvec}(A_{11} - A_{12}(I + A_{22})A_{21})$
 - 17: $A_{11}^{-1} \leftarrow \text{BF_SMW}(A_{11})$
 - 18: $A^{-1} \leftarrow I + \text{BF_random_matvec}\left(\begin{bmatrix} I & \\ -A_{22}^{-1}A_{21} & I \end{bmatrix} \begin{bmatrix} A_{11}^{-1} \\ A_{22}^{-1} \end{bmatrix} \begin{bmatrix} I & -A_{12}A_{22}^{-1} \\ I & \end{bmatrix} - I\right)$
 - 19: **end function**
-

Fig. 5.1: (a) The top three levels of nested dissection for an 11^2 mesh. (b) The root separator S^0 is a vertical 11 point line, which is recursively bisected to define the hierarchical matrix partitioning. The next level separators S_0^1 and S_1^1 , are similarly partitioned. (c) The root separator corresponds to the top level front, and its HOD-BF partitioning is defined by the recursive bisection of the root separator, as shown in (b), and similarly for the next level down in the assembly/frontal tree. For the lower levels, the fronts are regular dense matrices. Note that the fronts in (c) are to scale, but from this figure it is not obvious that the fronts typically get smaller lower in the tree (except for the root front, which has no Schur complement). Only the top 3 fronts are compressed using HOD-BF, while the others are treated as regular dense matrices.

previously compressed as HOD-BF. The end result looks like:

$$(5.1) \quad F_\tau = \begin{array}{|c|c|} \hline & F_{12} \\ \hline F_{21} & \\ \hline \end{array} = \begin{array}{|c|c|} \hline \text{sparse} & \cdot \cdot \\ \hline \cdot & \\ \hline \end{array} \leftrightarrow \begin{array}{|c|} \hline CB_{\nu_1} \\ \hline \end{array} \leftrightarrow \begin{array}{|c|} \hline CB_{\nu_2} \\ \hline \end{array},$$

with F_{11} and F_{22} compressed as HOD-BF, and F_{12} and F_{21} compressed as butterfly. For each front to be compressed, the following operations are in order:

1. At first, the F_{11} block of $F \equiv F_\tau$ is compressed as an HOD-BF matrix via `HODBF_entry_eval`, see [subsection 4.1](#), which calls `BF_entry_eval`, [Algorithm 3.1](#), for each of the off-diagonal blocks, using a routine `extract(\mathcal{L}, F_{11})` to extract elements from $F_{11} = A(I_\tau^s, I_\tau^s) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2}$, see line 8 in [Algorithm 5.1](#). Here CB_{ν_1} refers to the contribution block, the $F_{\nu_1;22}$ block including its Schur update, of the first child of node τ in the assembly tree. Note that in this case, the extend-add operation just requires checking whether the required matrix entries appear in the sparse matrix, or in the child contribution blocks, and then adding those different contributions together. Consider for example the extraction of a single 2×2 subblock from a front, i.e., $\mathcal{L} = \{(\{x_1, x_2\}, \{y_1, y_2\})\}$ is a list with a single (rows, columns) index set. Note that in general, the list can contain multiple index sets for extracting multiple subblocks. This might look as follows:

$$(5.2) \quad \begin{array}{|c|} \hline y_1 y_2 \\ \hline x_1 \\ x_2 \\ \hline \end{array} = \begin{array}{|c|c|} \hline y_1 y_2 & \cdot \cdot \\ \hline x_1 \\ x_2 \\ \hline \end{array} \leftrightarrow \begin{array}{|c|} \hline y_1 \ y_2 \\ \hline x_1 \\ x_2 \\ \hline \end{array} \leftrightarrow \begin{array}{|c|} \hline y_2 \\ \hline x_2 \\ \hline \end{array},$$

where one element (x_1, y_2) corresponds to a nonzero element in the sparse matrix, and all 2×2 elements also appear in CB_{ν_1} , but only one of them is part of CB_{ν_2} . In other words, the list \mathcal{L} is converted to three separate lists, one associated with the sparse matrix, and one with each of the two child contribution blocks CB_{ν_1} and CB_{ν_2} . The routine `extract_HODBF` (see [subsection 4.1](#)), used to extract a list of subblocks from an HOD-BF matrix, is then called twice, once as `extract_HODBF(\{(\{x_1, x_2\}, \{y_1, y_2\})\}, CB_{\nu_1})` for the first child contribution block (with the list for this specific example), and for the second child once as `extract_HODBF(\{(\{x_2\}, \{y_2\})\}, CB_{\nu_2})`. Extracting the 2×2 submatrix from the HOD-BF matrix CB_{ν_1} in this case requires extracting one element (x_1, y_1) from a low-rank product, one element (x_1, y_2) from a dense block (leaf of the HOD-BF matrix), and extracting a 1×2 submatrix $(x_2, \{y_1, y_2\})$ from a butterfly matrix (lower left main off-diagonal block of the CB_{ν_1} HOD-BF matrix). Extraction from a butterfly matrix is explained in [subsection 3.4](#), [Algorithm 3.2](#) and [Figure 3.3b](#).

2. Second, line 9 approximates F_{11}^{-1} from the butterfly representation of F_{11} , see [subsection 4.2](#).
3. Next, lines 10 and 11, the F_{12} and F_{21} front off-diagonal blocks are each approximated as a single butterfly matrix, using routines to extract elements from $A(I_\tau^s, I_\tau^u) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2}$ and $A(I_\tau^u, I_\tau^s) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2}$ respectively. For F_{12} , the tree \mathcal{T}_H corresponding to F_{11} is used as \mathcal{T}_O , and the tree corresponding to F_{22}

is used for \mathcal{T}_S , and vice versa for F_{21} . Note that we truncate the trees \mathcal{T}_H if needed to enforce that \mathcal{T}_S and \mathcal{T}_O have the same number of levels. [Subsection 5.1](#) discusses the generation of the hierarchical partitioning.

4. Next, see line 12 of [Algorithm 5.1](#), the Schur complement update $S = F_{21}F_{11}^{-1}F_{12}$ is computed as a single butterfly matrix using randomized matrix-vector products, see [subsection 3.3](#). The matrix vector products can be performed efficiently, since both F_{12} and F_{21} are already compressed as butterfly and F_{11}^{-1} is approximated as an HOD-BF matrix.
5. The final step for this front is to construct $F_{22} = CB$ as an HOD-BF matrix, again using element extraction, now from $CB_{\nu_1} \leftrightarrow CB_{\nu_2} - S$, where CB_{ν_1} and CB_{ν_2} are in HOD-BF form and S is a single butterfly matrix. S can be released as soon as the contribution block has been assembled, and the contribution block is kept in memory until it has been used to assemble the parent front.

Algorithm 5.1 Sparse rank-structured multifrontal factorization using hierarchically off-diagonal butterfly matrix compression, followed by a GMRES iterative solve using the multifrontal factorization as an efficient preconditioner.

Input: $A \in \mathbb{R}^{N \times N}$, $b \in \mathbb{R}^N$

Output: $x \approx A^{-1}b$

- 1: $\hat{A} \leftarrow P(D_r A D_c Q_c) P^\top$ \triangleright scaling, and permutation for stability and fill reduction
 - 2: $\hat{A} \leftarrow \hat{P} \hat{A} \hat{P}^\top$ \triangleright rank-reducing separator reordering, [subsection 5.1](#)
 - 3: build assembly tree: define I_τ^s and I_τ^u for every frontal matrix F_τ
 - 4: **for** nodes τ in assembly tree in topological order **do**
 - 5: **if** dimension(F_τ) $<$ n_{\min} **then**
 - 6: construct F_τ as a dense matrix \triangleright [Algorithm 2.1](#)
 - 7: **else**
 - 8: $F_{11} \leftarrow \text{HODBF_entry_eval}(\hat{A}(I_\tau^s, I_\tau^s) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2})$ \triangleright [subsection 4.1](#)
 - 9: $F_{11}^{-1} \leftarrow \text{HODBF_invert}(F_{11})$ \triangleright [Algorithm 4.1](#)
 - 10: $F_{12} \leftarrow \text{BF_entry_eval}(\hat{A}(I_\tau^s, I_\tau^u) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2})$ \triangleright [Algorithm 3.1](#)
 - 11: $F_{21} \leftarrow \text{BF_entry_eval}(\hat{A}(I_\tau^u, I_\tau^s) \leftrightarrow CB_{\nu_1} \leftrightarrow CB_{\nu_2})$ \triangleright [Algorithm 3.1](#)
 - 12: $S \leftarrow \text{BF_random_matvec}(F_{21} F_{11}^{-1} F_{12})$ \triangleright [subsection 3.3](#)
 - 13: $CB_\tau \leftarrow \text{HODBF_entry_eval}(CB_{\nu_1} \leftrightarrow CB_{\nu_2} - S)$ \triangleright [subsection 4.1](#)
 - 14: **end if**

 - 16: $x \leftarrow \text{GMRES}(A, b, M : u \leftarrow D_c Q_c P^\top \hat{P}^\top \text{bwd-solve}(\text{fwd-solve}(\hat{P} P D_r v)))$
-

The final sparse rank-structured factorization can be used as an efficient preconditioner M in GMRES for example, line 16 in [Algorithm 5.1](#). Preconditioner application requires forward and backward solve phases. The forward solve traverses the assembly tree from the leafs to the root and applies $F_{\tau;11}^{-1}$ followed by $F_{\tau;21}$, and then the backward solve traverses back from the root to the leafs, applying $F_{\tau;12}$. Currently, we do not guarantee that the preconditioner is symmetric (or positive definite) for a symmetric (or positive definite) input matrix A .

5.1. Hierarchical Partitioning from Recursive Separator Bisection. The butterfly partitioning, illustrated in [Figure 3.1](#), can typically be constructed by a hierarchical clustering of the source and observer point sets, S and O , and similarly, point set coordinates can be used in clustering to define the HOD-BF partitioning hi-

erarchy. However, in the purely algebraic setting considered here, geometry or point coordinates are not available. Instead we define the HOD-BF hierarchy of F_{11} by performing a recursive bisection (using METIS) of the graph corresponding to $A(I_\tau^s, I_\tau^s)$. This defines the HOD-BF tree and a corresponding permutation of the rows/columns of F_{11} , and hence also the partitioning of the butterfly off-diagonal blocks of F_{11} . This permutation – globally denoted as \hat{P} , see line 2 in [Algorithm 5.1](#) – drastically reduces the ranks encountered in the off-diagonal low-rank and butterfly blocks. See [Figure 5.1b](#) for the recursive bisection, and [Figure 5.1c](#) for the corresponding HOD-BF partitioning. For the F_{22} block, no such recursive bisection is performed, but the indices in I_τ^u are sorted and partitioned using a balanced binary tree.

5.2. Graph Nearest Neighbor Search. During the graph bisection from [subsection 5.1](#), to define the hierarchical matrix structure, edges in the graph of $A(I_\tau^s, I_\tau^s)$ will be cut by the partitioning. These edges correspond to nonzero entries in the off-diagonal blocks of the F_{11} HOD-BF matrix. For a 2D problem, with 1D separators, there are $\mathcal{O}(1)$ such entries, while for a 3D problem there are $\mathcal{O}(k)$ with k denoting the number of grid points along each dimension. As shown in [\(5.1\)](#), these nonzeros are combined with the dense contribution blocks from the children fronts. However, these nonzero entries which come directly from the sparse matrix contribute significantly to the off-diagonal blocks, and to the numerical rank of these blocks. Based on the graph distance, we select for each point the k_{nn} nearest neighbors and pass them to the butterfly matrix construction, see [subsection 3.2](#) and [Algorithm 3.1](#). Recall that we use nearest neighbors in addition to uniform points as proxy points to accelerate the ID in [Algorithm 3.1](#).

More specifically, we consider the graph of $\hat{A}(I_\tau^s, I_\tau^s)$, and for each vertex in this graph we search, using a breadth-first search, for the k_{nn} nearest-neighbors in any of the off-diagonal blocks of the HOD-BF representation of F_{11} . This means we look at all length- k_{nn} connections in the graph. Similarly, for F_{22} we look for the k_{nn} nearest neighbors in the graph $\hat{A}(I_\tau^u, I_\tau^u)$. For the main off-diagonal blocks F_{12} (and F_{21}), we look for the nearest neighbors in the graph $\hat{A}(I_\tau^s, I_\tau^u)$ (and $\hat{A}(I_\tau^u, I_\tau^s)$) by performing a breadth-first search in the graph $\hat{A}(I_\tau^s, I_\tau^s) \cup \hat{A}(I_\tau^s, I_\tau^u) \cup \hat{A}(I_\tau^u, I_\tau^s)$.

A similar pseudo-skeleton low-rank approximation scheme based on graph distances was proposed in [\[3\]](#), where it is referred to as the boundary distance low-rank approximation scheme.

5.3. Complexity Analysis. For the complexity analysis, we consider regular d -dimensional meshes with k gridpoints per dimension, for a total of $N = k^d$ degrees of freedom, with a stencil that is 3 points wide in each dimension. For the sparsity preserving ordering, we use nested dissection to recursively divide the mesh into $L = d \log k - \mathcal{O}(1)$ levels. At each level $\ell = 0, \dots, L$ there are 2^ℓ separators with geometric span of $\mathcal{O}(k/2^{\lfloor \ell/d \rfloor})$ and frontal matrices of size $\mathcal{O}(n) = \mathcal{O}((k/2^{\lfloor \ell/d \rfloor})^{d-1})$. For the analysis of the rank-structured solver, we split the fronts into dense and compressed fronts using a switching level $\ell_s = L - \mathcal{O}(1)$. Fronts closer to the top, i.e., at levels $\ell < \ell_s$, are typically larger and are thus compressed using the HOD-BF format, while all fronts at levels $\ell \geq \ell_s$ are stored as regular dense matrices. Note that in the implementation, we do not use a switching level, but instead decide only based on the actual size of the front. Hence, the total factorization flops $\mathcal{F}(k, d)$ and solution flops $\mathcal{S}(k, d)$ for the multifrontal solver are

$$(5.3) \quad \mathcal{F}(k, d) = \sum_{\ell=\ell_s+1}^L 2^\ell \mathcal{F}_D \left(\left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{d-1} \right) + \sum_{\ell=0}^{\ell_s} 2^\ell \mathcal{F}_{\text{BF}} \left(\left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{d-1} \right)$$

$$(5.4) \quad \mathcal{S}(k, d) = \sum_{\ell=\ell_s+1}^L 2^\ell \mathcal{S}_D \left(\left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{d-1} \right) + \sum_{\ell=0}^{\ell_s} 2^\ell \mathcal{S}_{BF} \left(\left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{d-1} \right).$$

Here $\mathcal{F}_D(n) = \mathcal{O}(n^3)$ and $\mathcal{S}_D(n) = \mathcal{O}(n^2)$ denote the costs of factorization (including construction) and solution of a dense front of size $\mathcal{O}(n)$, respectively. Similarly, $\mathcal{F}_{BF}(n)$ and $\mathcal{S}_{BF}(n)$ denote the cost of factorization (including construction) and solution of a HOD-BF compressed front of size $\mathcal{O}(n)$. In addition, it is straightforward to verify that the memory requirement of the multifrontal solver $\mathcal{M}(k, d) \sim \mathcal{S}(k, d)$ as the solution phase typically requires a single-pass of the memory storage. In addition, one can verify that setting $\ell_s = -1$ yields the exact multifrontal solver with $\mathcal{F} = \mathcal{O}(N^2)$, $\mathcal{S} = \mathcal{O}(N^{4/3})$ for $d = 3$ and $\mathcal{F} = \mathcal{O}(N^{3/2})$, $\mathcal{S} = \mathcal{O}(N \log N)$ for $d = 2$.

In what follows, we derive the complexity of the HOD-BF multifrontal solver and compare with the HSS multifrontal solver in [49] for both high-frequency and low-frequency wave equations. Note that the complexities of other rank structured multifrontal solvers are similar to or worse than those of the HSS multifrontal solver. Here “high-frequency” refers to linear systems whose size is proportional to certain power of the wavenumber (e.g., by fixing the number of grid points per wavelength to $\mathcal{O}(10)$), while “low-frequency” refers to linear systems whose size is, roughly speaking, independent of the wavenumber. We choose the high-frequency Helmholtz equation and the Poisson equation, both in homogeneous media, as two representative cases. Note that the proposed solver can be applied to a much wider range of wave equations and media with low complexities. Let $r(n)$ denote the maximum rank of the HOD-BF or HSS representation of a front of size $\mathcal{O}(n)$. As the front represents a numerical Green’s function that resembles the free-space Green’s function of the wave equations, we claim without proof that the rank $r(n)$ also behaves similarly to that arising from boundary element methods [35, 34]. For more rigorous proofs regarding ranks in multifrontal matrices, see [15]. We further assume (and observed) that the rank in HOD-BF or HSS representation of the front remains similar after the inversion process.

Helmholtz equation. Consider the F_{12} and F_{21} blocks of a front F of size $\mathcal{O}(n)$ which represent the numerical Green’s function interaction between two crossing separators. See Figure 5.1a for an illustration of such an interaction between two crossing separators, for instance S_0^1 and S^0 . By direct application of the results in Section 3.3.2 in [35] and Section 4.5.2 in [34] for 2D and 3D free-space Green’s functions, one can show that $r(n) = \mathcal{O}(\log n)$ for $d = 2$ and $r(n) = \mathcal{O}(n^{1/4})$ for $d = 3$. That said, the costs of construction from entry evaluation and randomized matvec still scale as $\mathcal{O}(n \log^2 n)$ and $\mathcal{O}(n^{3/2} \log n)$ just like the constant rank case in subsection 3.4 and subsection 3.3. We briefly summarize the computational complexities of lines 8 to 13 of Algorithm 5.1 here and leave their validations to the readers: BF_entry_eval at 10 and 11 requires $\mathcal{O}(n \log^2 n)$ operations, HODBF_entry_eval at 8 and 13 requires $\mathcal{O}(n \log^3 n)$ operations, BF_random_matvec at line 12 requires $\mathcal{O}(n^{3/2} \log n)$ operations, and HODBF_invert at line 9 requires $\mathcal{O}(n^{3/2} \log n)$ operations. In addition, the corresponding storage cost requires $\mathcal{O}(n \log^2 n)$ memory units. Therefore, the cost of factorization and solution of a HOD-BF compressed front is $\mathcal{F}_{BF}(n) = \mathcal{O}(n^{3/2} \log n)$ and $\mathcal{S}_{BF}(n) = \mathcal{O}(n \log^2 n)$. Plugging these estimates into (5.3) and (5.4) will yield the total factorization and solution cost of the HOD-BF multifrontal solver as

$$\mathcal{F}(k, 2) = \sum_{\ell=\ell_s+1}^L 2^\ell \left(\frac{k}{2^{\lfloor \ell/2 \rfloor}} \right)^3 + \sum_{\ell=0}^{\ell_s} 2^\ell \left(\frac{k}{2^{\lfloor \ell/2 \rfloor}} \right)^{3/2} \log \left(\frac{k}{2^{\lfloor \ell/2 \rfloor}} \right)$$

problem	dim	rank $r(n)$		factor flops \mathcal{F}		solve flops \mathcal{S}	
		HOD-BF	HSS	HOD-BF	HSS	HOD-BF	HSS

Table 5.1: Asymptotic complexity of the HOD-BF and HSS multifrontal solvers for 2D and 3D, Helmholtz and Poisson equations. The $\mathcal{O}(\cdot)$ has been dropped. Here n denotes the size of a front and N is the global number of degrees of freedom in the sparse system.

$$(5.5) \quad = \sum_{\ell=\ell_s+1}^L \frac{k^3}{2^{\lfloor \ell/2 \rfloor}} + \sum_{\ell=0}^{\ell_s} k^2 \frac{2^{\lfloor \ell/4 \rfloor}}{k^{1/2}} \log \left(\frac{k}{2^{\lfloor \ell/2 \rfloor}} \right) \stackrel{2^{\lfloor \ell/2 \rfloor} \rightarrow 2^t}{=} k^2 + \sum_{t=0}^{\log(k)} k^2 \frac{t}{2^{t/2}} = k^2$$

$$\mathcal{F}(k, 3) = \sum_{\ell=\ell_s+1}^L 2^\ell \left(\frac{k}{2^{\lfloor \ell/3 \rfloor}} \right)^6 + \sum_{\ell=0}^{\ell_s} 2^\ell \left(\frac{k}{2^{\lfloor \ell/3 \rfloor}} \right)^3 \log \left(\frac{k}{2^{\lfloor \ell/3 \rfloor}} \right)$$

$$(5.6) \quad = \sum_{\ell=\ell_s+1}^L \frac{k^6}{2^\ell} + \sum_{\ell=0}^{\ell_s} k^3 \log \left(\frac{k}{2^{\lfloor \ell/3 \rfloor}} \right) = k^3 + k^3 \log^2 k = k^3 \log^2 k$$

$$\mathcal{S}(k, d) = \sum_{\ell=\ell_s+1}^L 2^\ell \left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{2(d-1)} + \sum_{\ell=0}^{\ell_s} 2^\ell \left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)^{d-1} \log^2 \left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right)$$

$$(5.7) \quad = \sum_{\ell=\ell_s+1}^L \frac{k^{2(d-1)}}{2^{(1-2/d)\ell}} + \sum_{\ell=0}^{\ell_s} k^d \frac{2^{\lfloor \ell/d \rfloor}}{k} \log^2 \left(\frac{k}{2^{\lfloor \ell/d \rfloor}} \right) \stackrel{2^{\lfloor \ell/d \rfloor} \rightarrow 2^t}{=} k^d + \sum_{t=0}^{\log(k)} k^d \frac{t^2}{2^t} = k^d.$$

Note that $\mathcal{O}(\cdot)$ has been dropped in the above equations. Hence, the HOD-BF multifrontal solver can attain quasi-linear complexity for high-frequency Helmholtz equations. In contrast, one can show, based on the arguments in [7, 15], that the HSS rank $r(n) = \mathcal{O}(n)$ for both $d = 2$ and $d = 3$ due to the highly-oscillatory interaction between two crossing separators, which yields $\mathcal{O}(n^3)$ and $\mathcal{O}(n^2)$ factorization and solution complexity for one front and hence no asymptotic gains using the HSS multifrontal solver compared to exact multifrontal solvers. We summarize these complexities in Table 5.1.

Poisson equation. The complexity of the HOD-BF multifrontal solver for the Poisson equation can be estimated similarly to the Helmholtz equation. First, one can show that the butterfly rank $r(n) = \mathcal{O}(\log n)$ for $d = 2$ and $r(n) = \mathcal{O}(n^{1/4})$ for $d = 3$, just like the Helmholtz case. This yields similar complexities as those in (5.5)–(5.7) with smaller leading constants. For comparison, the HSS rank behaves as $r(n) = \mathcal{O}(\log n)$ for $d = 2$ and $r(n) = \mathcal{O}(n^{1/2})$ for $d = 3$ (see [29, 11, 15]), which yields fast HSS multifrontal solvers. We refer the readers to [49] for detailed analysis and list the complexities in Table 5.1. One can see that lower complexity can be attained using HOD-BF multifrontal ($\mathcal{O}(N \log^2 N)$) than HSS multifrontal ($\mathcal{O}(N^{4/3})$) for the factorization when $d = 3$; similar complexities are attained for all the other entries in the table, despite that HOD-BF multifrontal can yield larger leading constants than HSS multifrontal.

6. Experimental Results. Experiments reported here are all performed on the Haswell nodes of the Cori machine, a Cray XC40, at NERSC in Berkeley. Each of the 2,388 Haswell nodes has two 16-core Intel Xeon E5-2698v3 processors and 128GB of

2133MHz DDR4 memory. We developed a distributed memory code but we omit the description of the parallel algorithms here and will discuss this in a future paper.

The approximate multifrontal solver is used as a preconditioner for restarted GMRES(30) with modified Gram-Schmidt and a zero initial guess. All experiments are performed in double precision with absolute or relative stopping criteria $\|u_i\| \leq 10^{-10}$ or $\|u_i\|/\|u_0\| \leq 10^{-6}$, where $u_i = M^{-1}(Ax_i - b)$ is the preconditioned residual, with M the approximate multifrontal factorization of A . For the exact multifrontal solver, we use iterative refinement instead of GMRES. For the tests in subsections 6.1 and 6.3, the nested dissection ordering is constructed from planar separators. For the test in subsection 6.2 the nested dissection ordering from METIS [30] was used. For all the tests the column permutation and row/column scaling were disabled.

6.1. Visco-Acoustic Wave Propagation. We first consider the 3D visco-acoustic wave propagation governed by the Helmholtz equation

$$(6.1) \quad \left(\sum_i \rho(\mathbf{x}) \frac{\partial}{\partial x_i} \frac{1}{\rho(\mathbf{x})} \frac{\partial}{\partial x_i} \right) p(\mathbf{x}) + \frac{\omega^2}{\kappa^2(\mathbf{x})} p(\mathbf{x}) = -f(\mathbf{x}).$$

Here $\mathbf{x} = (x_1, x_2, x_3)$, $\rho(\mathbf{x})$ is the mass density, $f(\mathbf{x})$ is the acoustic excitation, $p(\mathbf{x})$ is the pressure wave field, ω is the angular frequency, $\kappa(\mathbf{x}) = v(\mathbf{x})(1 - i/(2q(\mathbf{x})))$ is the complex bulk modulus with the velocity $v(\mathbf{x})$ and quality factor $q(\mathbf{x})$. We solve (6.1) by a finite-difference discretization on staggered grids using a 27-point stencil and 8 PML absorbing boundary layers [41]. This requires direct solution of a sparse linear system where each matrix row contains 27 nonzeros, whose values depend on the coefficients and frequency in (6.1).

Table 6.1: Results for applying the HOD-BF and exact multifrontal solvers to (6.1) with constant coefficients and $N = 250^3$. For the top 3 fronts, we give the compression rate, maximum rank and time spent, separated by ”/”.

Homogeneous media. We consider a cubed domain with $v(\mathbf{x}) = 4000\text{m/s}$, $\rho(\mathbf{x}) = 1\text{kg/m}^3$, $q(\mathbf{x}) = 10^4$. The frequency is set to $\omega = 8\pi\text{Hz}$ and the grid spacing is set such that there are 15 grid points per wavelength. First, we consider a problem with size $N = k^3$, $k = 250$ and compare the performance of the HOD-BF multifrontal solver with the exact multifrontal solver by setting tolerances $\varepsilon = 10^{-1}, 10^{-2}$ and switching levels $\ell_s = 0, 1$ (corresponding to minimum compressed separators with sizes $n_{\min} =$

60K, 30K). In other words, there are at most three fronts compressed as HOD-BF. Here, ε refers to the ID tolerance used in `BF_entry_eval` and `BF_random_matvec`. [Table 6.1](#) lists the time, flop counts, memory and ranks for the factor and solve phases, as well as those for the fronts at $\ell = 0$ and $\ell = 1$, using 32 compute nodes, with 4 MPI ranks per node and 8 OpenMP threads per MPI process. Significant memory compression of up to 0.9% – meaning the HOD-BF compressed front only requires 0.9% of the memory that a dense front would use – and factor speedups up to $4\times$ are observed for the compressed fronts. Next, we validate the complexity estimates in [Table 5.1](#) when varying N from 100^3 to 250^3 , while compressing all fronts corresponding to separators larger than 7.5K. Compared to the $\mathcal{O}(N^2)$ computation and $\mathcal{O}(N^{4/3})$ memory complexities using the exact multifrontal solver, we observe the predicted $\mathcal{O}(N \log^2 N)$ computation and $\mathcal{O}(N)$ memory complexities using the HOD-BF multifrontal solver with $\varepsilon = 10^{-3}$ (see [Figures 6.1a](#) and [6.1b](#)). Finally, we investigate the effect of HOD-BF compression tolerance on the GMRES convergence using $N = 200^3$. The GMRES residual history with different ε are plotted in [Figure 6.1c](#).

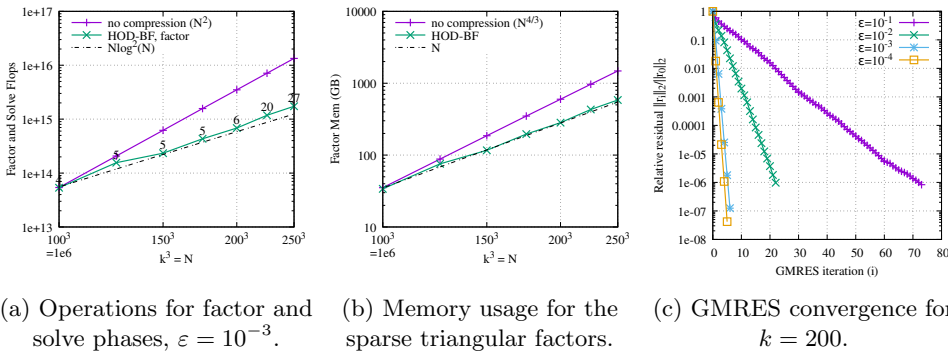

Fig. 6.1: Results for high frequency 3D Helmholtz. (a) The total number of operations, for both factorization and solve, using iterative refinement for the exact factorization and preconditioned GMRES for the HOD-BF approximate factorization. The number of GMRES iterations are shown by every datapoint for the experiments with HOD-BF compression. (b) Memory usage for the factors (not the peak working memory). (c) GMRES convergence using the multifrontal+HOD-BF preconditioner for $k = 200$, with different compression tolerances ε .

Heterogeneous media. Here we use the Marmousi2 [36] P-wave velocity model for $v(\mathbf{x})$, and set $\rho(\mathbf{x}) = 1\text{kg/m}^3$, $q(\mathbf{x}) = 10^4$. We generate a 174×500 grid in the x-z plane using the Marmousi2 model and duplicate the model 200 times in the y direction, yielding a mesh of $190 \times 216 \times 516$ with $N = 21,176,640$ and grid spacing 20m including the PMLs (see [Figure 6.2](#)). We set the frequency to $\omega = 20\pi$ corresponding to 7.5 grid points per minimum wavelength. The real part of the pressure field, induced by a point source located at the domain center, is computed by the proposed HOD-BF multifrontal solver with 32 compute nodes and plotted in [Figure 6.2](#). The technical data with different compression tolerance and switching levels is listed in [Figure 6.2](#). Significant memory compression ratios have been observed. Note that there is a trade-off between the factor and solve flops when using different tolerances and switching levels.

6.2. Indefinite Maxwell. We solve the electromagnetics problem corresponding to the second order Maxwell equation, $\nabla \times \nabla \times \mathbf{E} - \Omega^2 \mathbf{E} = \mathbf{f}$, which is given in the weak formulation as $(\nabla \times \mathbf{E}, \nabla \times \mathbf{E}') - (\Omega^2 \mathbf{E}, \mathbf{E}') = (\mathbf{f}, \mathbf{E}')$ with a testing function \mathbf{E}' . Here it is assumed a given tangential field as boundary condition for \mathbf{E} . More specifically, $\mathbf{f}(\mathbf{x}) = (\kappa^2 - \Omega^2)(\sin(\kappa x_2), \sin(\kappa x_3), \sin(\kappa x_1))$ on the domain boundaries. For large wavenumber Ω , the problem is highly indefinite and hard to precondition, so typically a direct solver is used. We discretize the weak form with first order Nédélec elements using MFEM [4]. We use a uniform tetrahedral finite element mesh on a unit cube, resulting in a linear system of size 14,827,904 and approximately 24 points per wavelength. The results for $\Omega = 16$ and $\kappa = \Omega/1.05$ are shown in Figure 6.3.

6.3. 3D Poisson. We solve the Poisson equation on a regular 3D k^3 mesh. Figure 6.4 shows comparison with the multifrontal solver with HSS compression [49, 16], also implemented in STRUMPACK. Figure 6.4a shows the number of floating point operations for the combination of the numerical factorization and solve (GMRES) phases – the number of operations for the solve phase is very small compared to those for the factorization phase. Figure 6.4b shows that the maximum ranks in the HOD-BF representation, as a function of the size n of the root front, remain much smaller

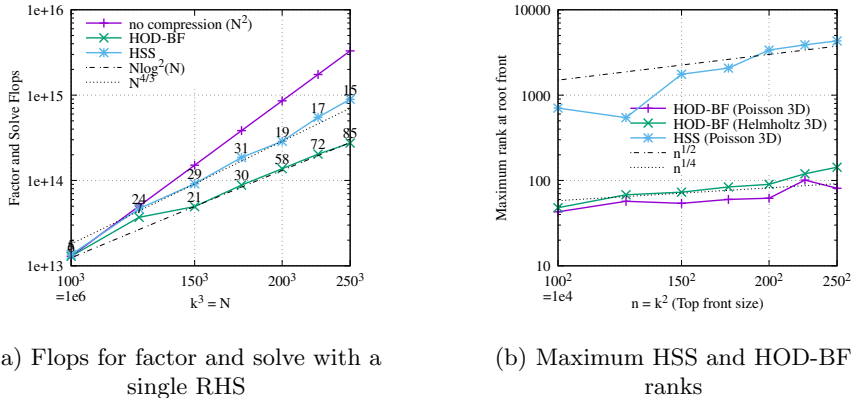

Fig. 6.4: Results for a 3D Poisson benchmark on a regular k^3 mesh, with $n_{\min} = 7500$ and $\varepsilon = 10^{-2}$. (a) Number of floating point operations for both the numerical factorization and the GMRES solve with a single right hand side. (b) The maximum ranks encountered in the HSS or HOD-BF representations at the root front, showing both 3D Poisson and Helmholtz.

than those in HSS. Note the agreement with Table 5.1, which predicts $\mathcal{O}(n^{1/2})$ and $\mathcal{O}(n^{1/4})$ for HSS and HOD-BF respectively. For the 250^3 problem, the top separator is a 250×250 plane, corresponding to a $62,500 \times 62,500$ frontal matrix. The largest front is found at the next level, $\ell = 1$, and is $93,750^2$ ($= 250 \times 250/2 + 250 \times 250$). Using HSS, this front is compressed to 11.3% of the dense storage with a maximum off-diagonal rank of 3754, while HOD-BF compresses this front to 0.76% with a maximum rank of 70.

7. Conclusion. This paper presents a fast multifrontal sparse solver for high-frequency wave equations. The solver leverages the butterfly algorithm and its hierarchical matrix extension, HOD-BF, to represent large frontal matrices. The butterfly representation is computed via fast entry evaluation based on the graph distance, and factorized with randomized matrix-vector multiplication-based algorithms. When compared to the exact solver, HOD-BF can reduce the storage and factorization costs respectively to 1% and 25% for the larger fronts. The resulting solver can attain quasi-linear computation and memory complexity when applied to high-frequency Helmholtz and Maxwell equations. Similar complexities have been analyzed and observed for Poisson equations as well. The code is made publicly available as an effort to integrate the dense solver package ButterflyPACK² into the sparse solver package STRUMPACK. The focus of this work is on asymptotic complexity reduction. However, for practical applications, a rank structured format with smaller leading constants in its complexity, such as for instance block low-rank, applied to medium sized fronts, could further reduce the overall number of operations and especially the factorization time.
