Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

ABSTRACT: The tumor suppressor p53 plays a unique role as a central hub of numerous cell proliferation and apoptotic pathways and its malfunction due to mutations is a major cause of various malignancies. Therefore, it serves as an attractive target for developing novel anti-cancer therapeutics. Due to its intrinsically unstable DNA-binding domain, p53 unfolds rapidly at physiological temperature. Certain mutants shift the equilibrium towards the unfolded state and yield high-molecular-weight, non-functional, and cytotoxic β -sheet-rich aggregates that share tinctorial and conformational similarities with amyloid deposits found in various protein-misfolding diseases. Here, we examined the effect of a novel protein-assembly modulator, the lysine (Lys)-specific molecular tweezer, CLR01, on different aggregation stages of misfolded mutant p53 *in vitro* and on the cytotoxicity of the resulting p53 aggregates in cell culture. We found that CLR01 induced rapid formation of β -sheet-rich, intermediate-size p53 aggregates, yet inhibited further p53 aggregation and reduced cytotoxicity of the resulting aggregates. Our data suggest that aggregation modulators, such as CLR01, could prevent formation of toxic p53 aggregates.

INTRODUCTION:

p53 is a transcription factor that regulates cell cycle and plays a key role in the prevention of cancer development (1). The outstanding role of p53 as a tumor suppressor and its unique location as a hub of numerous cell pathways make it a prime target for developing novel anti-cancer therapeutics.

p53 functions as a homo-tetramer, comprising four polypeptide chains of 393 amino-acid residues each. The structure of p53 consists of two folded domains: the DNA binding domain (DBD) and the oligomerization domain (OD), which are flanked by intrinsically disordered domains – the trans-activation domain (TAD) in the N-terminus, and a regulatory domain at the extreme C-terminus (CTD). The p53DBD is intrinsically unstable and unfolds rapidly at body temperature (2, 3).

Folded and unfolded p53 are in equilibrium, but unfolded p53 can denature irreversibly and form small, soluble aggregates, which subsequently assemble irreversibly by classical nucleation-dependent polymerization, displaying typical kinetics characterized by a lag phase, followed by a rapid growth and finally a plateau (Fig. 1) (3-5). This process is facilitated by multiple distinct mutations and eventually yields high molecular weight, β -sheet-rich aggregates that are conformationally and tinctorially similar to the amyloid deposits characterizing many protein-misfolding diseases, although their morphology tends to be amorphous rather than fibrillar (5-7).

Because the DBD governs the stability of the entire protein and is responsible for its transcriptional transactivation, >90% of the oncogenic mutations in p53 have been found to be located in this domain (8). Of all p53-associated cancer mutations, 30–40% perturb the structure of the protein (conformational mutations), resulting in

1
2
3 reduced thermo-stability and leading to increased aggregation rate (3, 9). Two such
4
5 examples are the mutations leading to G245S and R249S substitutions in the p53
6
7 DBD, which are two of the six most frequent conformational mutations in human
8
9 cancers (9). These two mutants and other conformational mutants of p53 largely are
10
11 unfolded under physiological conditions, thus displaying a loss of transcription
12
13 transactivation capacity (10). The G245S and R249S substitutions induce
14
15 conformational changes in the DBD and destabilize the protein moderately by only 1-
16
17 2 kcal/mol (8).
18
19

20
21 The G245S and R249S structural variants of p53 result from two of the most frequent
22
23 mutation in the p53 cognate gene found in cancer patients. These mutations are
24
25 located in the L3 loop, which binds to the minor groove of DNA-response elements
26
27 (11). The crystal structure of p53DBD-G245S revealed distinct structural changes in
28
29 the immediate environment of the mutation site. Observed conformational changes in
30
31 certain surface loops (e.g., the L1 and S7–S8 loops) can be attributed to differences in
32
33 crystallization conditions and crystal packing for WT p53DBD and p53DBD-G245S.
34
35 In contrast, the R249S mutation, substantially perturbs the L3 loop, induces high
36
37 flexibility, and favors alternative conformations with substantially more severe
38
39 consequences for the overall protein stability and DNA binding (11). These structural
40
41 changes in p53DBD also result in high propensity of G245S and R249S to aggregate
42
43
44
45 (3).
46
47

48
49 Although a large body of structural information is available on the transition of p53
50
51 mutants from the folded to the unfolded state, much less is known about the shift from
52
53 the unfolded to the "small aggregated" state. It is thus reasonable to believe that
54
55 because p53DBD-G245S and p53DBD-R249S adopt alternative conformation in the
56
57 unfolded state they also possess different structures at the initiation of aggregation.
58
59
60

1
2
3
4
5 In addition to being non-functional, structural p53 mutants also have been reported to
6
7 impart a dominant-negative effect over the wild-type protein. A recent landmark
8
9 paper has uncovered a novel mechanism for this dominant-negative effect. Rousseau,
10
11 Schymkowitz and coworkers found that the structural mutations expose an
12
13 aggregation-nucleating sequence, which normally is buried in the hydrophobic core of
14
15 the DBD of p53. As a result, these mutant proteins have an increased propensity to
16
17 form amyloid-like aggregates (12). In addition, these aggregates recruit wild-type p53
18
19 into cellular inclusions thereby decreasing the normal p53 availability and accounting
20
21 for the dominant-negative effect of the mutant. Moreover, structurally destabilized
22
23 p53 mutants also co-aggregate with the p53 family members p63 and p73, thereby
24
25 accounting for their loss of function (12).
26
27
28

29
30 Interestingly, it has been shown recently that pre-formed p53 aggregates enter HeLa
31
32 cells via macropinocytosis, a non-specific pathway, and induce intracellular
33
34 aggregation of endogenous p53 (13). Although the clinical significance of this
35
36 observation remains to be elucidated, these data suggest a possible role for p53
37
38 aggregation in cancer development that is distinct from direct loss of function of p53
39
40 by mutation. Thus, interfering with the aggregation of p53 mutants by small-molecule
41
42 modulators may prevent the harmful effects of the resulting aggregates and co-
43
44 aggregation with WT p53, p63, and p73. However, rescuing folding and function of
45
46 p53 mutants by a specific ligand represents a great challenge because only few of
47
48 these mutants (e.g., Y220C) possess a cleft or a crevice that can be targeted by a small
49
50 molecule without interfering with the ability of p53 to bind its DNA response element
51
52 (11). An alternative strategy is to modulate the aggregation itself. Theoretically, if a
53
54 small molecule could prevent the formation of the amyloid-like aggregates, it might
55
56
57
58
59
60

1
2
3 both prevent the potential toxicity of these aggregates and inhibit the recruitment of
4
5 wild-type p53, p63 and p73 into the aggregates.
6

7
8 Recently, a novel family of protein-assembly modulators, namely Lysine (Lys)-
9
10 specific molecular tweezers (MTs), was found to be highly efficient inhibitors of
11
12 amyloid assembly and toxicity (14). These small molecules are horseshoe-shaped,
13
14 artificial Lys receptors composed of two hydrocarbon arms capable of hydrophobic
15
16 interactions with the alkyl side chains of Lys residues, and negatively charged head
17
18 groups that form electrostatic interactions with the NH_3^+ group of Lys (Fig. 2).
19

20
21 Inhibition of aggregation by MTs is selective for amyloidogenic proteins but is not
22
23 specific to a particular protein (15). For example, the MT, CLR01 (Fig. 2a), disrupted
24
25 *in vitro* the aggregation and toxicity of multiple disease-related proteins, such as
26
27 amyloid β -protein ($\text{A}\beta$), tau and α -synuclein at equimolar or sub-equimolar
28
29 concentration ratios (14), whereas disruption of tubulin polymerization required ~55-
30
31 fold excess of CLR01 (15) and inhibition of enzymatic activity, e.g., of alcohol
32
33 dehydrogenase, required ~850-fold excess CLR01 (16). In agreement with these
34
35 observations, *in vivo* CLR01 suppressed α -synuclein aggregation in neurons and
36
37 rescued the phenotype and survival of zebrafish embryos (17), cleared existing $\text{A}\beta$
38
39 and tau aggregates in the brain of Alzheimer's disease transgenic mice, and decreased
40
41 transthyretin aggregation in a mouse model of familial amyloidotic polyneuropathy,
42
43 without any side effects (17-19). Moreover, CLR01 was found to have a high safety
44
45 margin in mice (15), supporting its selective action as an inhibitor of abnormal protein
46
47 aggregation.
48
49
50

51
52 Here, we examined the effect of CLR01 on different stages of aggregation of the p53
53
54 mutants G245S and R249S *in vitro* and on the harmful effect of their pre-formed
55
56 aggregates in cultured lung carcinoma cells. We found that CLR01 induced rapid
57
58
59
60

1
2
3 formation of β -sheet-rich, intermediate-size aggregates by each p53DBD mutant,
4
5 inhibited formation of later aggregates, and reduced the cytotoxicity of the resulting
6
7 aggregates.

9

10 11 12 **MATERIALS AND METHODS**

13
14
15
16 The Na⁺ salts of CLR01 and CLR03 were prepared and purified analogously to the Li
17
18 salts, as described previously (16).
19

20
21 *Cloning:* The coding sequence of the gene encoding human p53DBD was amplified
22
23 using the primers 5'-GGGAATTCGGATCCATGTCATCTTCTGTCCCTTCCCAG-
24
25 3' and 5'-TCTGACCTCGAGTCAGGTGTTGTTGGACAGTGCTCGC-3'. The
26
27 G245S-p53DBD mutant or R249S-p53DBD were generated by PCR site-directed
28
29 mutagenesis using the primer 5'-CTGCATGGGCaGCATGAACC-3' or 5'-
30
31 CATGAACCGGAGcCCCATC-3', respectively (lower-case letter indicates the
32
33 substitution made to produce the mutation). The PCR products were digested with
34
35 *Bam*HI and *Xho*I, purified, and cloned into a modified pET24a+ expression vector.
36
37 The resulting plasmids encoded fusion proteins comprising an N-terminal 6 \times His-tag,
38
39 the lipoyl domain of the dihydrolipoamide acetyltransferase from *Bacillus*
40
41 *stearothermophilus*, and a TEV-protease cleavage site followed by p53DBD.
42
43
44

45
46 *Protein expression and purification:* The appropriate vector was transformed into
47
48 competent *E. coli* BL21 tuner cells (Novagen) for overexpression. Expression cultures
49
50 were incubated at 37°C with shaking at 220 rpm until OD₆₀₀ reached 0.7-0.8. The
51
52 medium was supplemented with 0.1 mM ZnSO₄ and expression was induced with 0.5
53
54 mM Isopropyl β -D-1-thiogalactopyranoside at 18 °C. Cells were harvested 14 hours
55
56 later by centrifugation. The cell pellet from 3 liters of culture was suspended in 50
57
58
59
60

1
2
3 mM Tris-HCl, pH 7.2, 200 mM NaCl, 0.8% triton, 10% glycerol, 5 mM imidazole, 10
4
5 mM β -mercaptoethanol and X50 tablets of EDTA-free complete protease inhibitor
6
7 (Roche). Cells were sonicated on ice for a total time of 8 minutes, with 90 seconds in
8
9 between 30-second pulses. The soluble fraction was loaded onto an Amersham 26/20
10
11 column packed with Ni-Sepharose (GE-Healthcare). The His-tagged fusion protein
12
13 was eluted using a 0–500 mM imidazole gradient over ten column volumes. The
14
15 pooled fractions from the Ni-Sepharose column were digested with TEV protease
16
17 overnight and dialyzed against a low-salt buffer containing 50 mM Tris-HCl, pH 7.2,
18
19 50 mM NaCl, 10% glycerol and 10 mM β -mercaptoethanol. The dialyzed sample was
20
21 purified further on a HiPrep Heparin 16/10 FF ion-exchange column (GE-Healthcare).
22
23 Elution was done using a 0-500 mM NaCl gradient over 10 column volumes. The
24
25 pooled fractions were concentrated using an Amicon ultra-15 with a 30-kDa cutoff
26
27 (Millipore) and buffer-exchanged to 25 mM sodium phosphate, pH 7.2, 10% glycerol,
28
29 300 mM NaCl and 1 mM *tris* 2-carboxyethyl phosphine (TCEP). To obtain high-
30
31 purity proteins, a final gel-filtration step was carried out. Gel-filtration column
32
33 (Superdex 75 HiLoad 16/60, GE Healthcare) was equilibrated with 25 mM sodium
34
35 phosphate, pH 7.2, 10% glycerol, 300 mM NaCl and 1 mM TCEP. The loading
36
37 volume of concentrated proteins was 0.5 mL per run. Separation was carried out by
38
39 running 1.5 column volumes of the buffer and collecting 0.5 mL fractions. Protein
40
41 samples were flash-frozen and stored in liquid nitrogen for further use. The purified
42
43 p53 variants were verified by Western blot analysis under denaturing conditions using
44
45 an anti-p53 monoclonal antibody (PAb 240, Abcam).
46
47
48
49
50

51
52 *Differential scanning fluorimetry (DSF)*: Experiments were performed using SYPRO
53
54 Orange (Invitrogen) as the fluorescent probe, which binds quantitatively to the
55
56 hydrophobic protein patches exposed upon thermal denaturation. Real-time melting
57
58
59
60

1
2
3 analysis was performed using a Corbett Rotor-Gene 6000 real-time qPCR
4 thermocycler. The excitation (λ_{ex}) and emission (λ_{em}) wavelengths used were 460 nm
5 and 510 nm, respectively. Heating from 28 to 70°C was applied at a constant heating
6 rate of 250°C/h. 10 μ M of the protein were briefly mixed with SYPRO orange (10 \times)
7 in 25 mM sodium phosphate buffer, pH 7.2, 300 mM NaCl, 10% glycerol, 10%
8 DMSO and 1 mM TCEP. The apparent melting temperature (T_m) of the protein was
9 determined from the inflection point of the melting curve.
10
11

12
13
14
15
16
17
18 *Static light scattering (SLS)*: Protein aggregation was monitored by measuring static
19 light scattering at 500 nm as excitation and emission wavelengths (excitation slit
20 width 0.8 nm, emission slit width 2 nm) using a Horiba (Kyoto, Japan) FluoroMax-3
21 spectrophotometer. Experiments were performed using G245S-p53DBD or R249S-
22 p53DBD at concentration of 3 μ M in 25 mM sodium phosphate, pH 7.2, 300 mM
23 NaCl, 5% DMSO and 1 mM TCEP buffer that was pre-equilibrated for 30 min at 37
24 °C. The samples were stirred constantly. Data were analyzed using Kaleidagraph™
25 software (Synergy).
26
27
28
29
30
31
32
33
34
35

36
37 *Thioflavin-T (ThT) assay*: ThT fluorescence was measured at 482 nm upon excitation
38 at 450 nm for detecting β -sheet formation (excitation slit width 3 nm, emission slit
39 width 4 nm), using a Horiba FluoroMax-3 spectrofluorometer. Time-resolved
40 fluorescence was recorded immediately after adding 3 μ M of G245S-p53DBD or
41 R249S-p53DBD protein to pre-equilibrated buffer (25 mM sodium phosphate, pH 7.2,
42 300 mM NaCl, 5% DMSO, 1 mM TCEP and 10 μ M ThT.
43
44
45
46
47
48

49
50 *8-Anilino-1-naphthalene Sulfonic Acid (ANS) binding assay*: ANS fluorescence was
51 measured at 465 nm upon excitation at 350 nm for monitoring exposed hydrophobic
52 regions in proteins, using a Horiba Jobin Yvon FL3-11 spectrofluorometer. Time-
53 resolved fluorescence was recorded immediately after adding 5 μ M of G245S-
54
55

21
22
23
24
25
26

27 *Dot blot:* 50 μ l spots containing 5 μ M protein and different concentrations of the
28 tested compounds, after 20 min incubation at 37 °C, were applied, interspaced with
29 spots containing only buffer, to a nitrocellulose membrane using Minifold I Dot-Blot
30 96 Well Plate System (Whatman). The membrane was blocked for 1h in blocking
31 solution (5% nonfat milk powder in Tris-buffered saline (TBS)), and then incubated
32 in 1:1000 dilution of the OC antibody (a generous gift from Dr. Rakez Kayed,
33 University of Texas Medical Branch, Galveston, TX) in blocking solution. The
34 membrane was then washed three times for 15min each in TTBS (0.1% Tween-20 in
35 TBS), incubated for 40 min in the anti-rabbit secondary antibody and washed three
36 times for 10 min in TTBS. The membrane was developed using EZ-ECL (Biological
37 Industries, Israel), according to the manufacturer's instructions, and exposed to Fuji
38 Medical X-Ray Film for up to 5 min. Films were developed using Kodak X-OMAT
39 2000.

31
32

33
34 *Cell viability assay:* G245S-p53DBD or R249S-p53DBD aggregates (5 μ M) were
35 obtained by overnight incubation at 37 °C in the absence or presence of either CLR01
36 or CLR03 at different concentrations. The pre-formed aggregates were added to
37 human H1299 non-small cell lung carcinoma cells and incubated for 24 hours. Cell
38 viability was measured using the (2,3-bis-(2-methoxy-4-nitro-5-sulfophenyl)-2H-
39 tetrazolium-5-carboxanilide) (XTT) reduction assay according to the manufacturer's
40 recommendations (Biological Industries Ltd, Israel) with 3 wells per condition. As a
41 negative control, CLR01 or CLR03 at different concentrations without G245S-
42 p53DBD or R249S-p53DBD aggregates were added to cells. For a positive control,
43 0.1% Triton-X100 was used for induced cell lethality.

RESULTS

CLR01 does not affect the thermo-stability of the structural mutant G245S-p53DBD

Inactivation of p53 by denaturation involves the initial unfolding of the core domain, which occurs naturally but is reversible (Fig. 1). It was shown previously that CLR01 had no stabilizing effect on other amyloidogenic proteins such as transthyretin (TTR) (19). Similarly, MTs would not be expected to stabilize the native conformation of p53, however, they could do that serendipitously, complicating data interpretation. Therefore, to rule out this possibility, CLR01 and the negative control derivative, CLR03, (Fig. 2b), were tested *in vitro* for potential stabilizing effects towards the oncogenic p53DBD structural mutant G245S.

We used differential scanning fluorimetry to measure whether increased concentrations of CLR01 affected the thermodynamic stability of G245S-p53DBD. Concentrations below 100 μM of CLR01 did not affect the apparent T_m of G245S-p53DBD (Fig. 3). At higher concentrations, CLR01 destabilized the protein. Therefore, we set 100 μM as the maximum concentration for further analysis. CLR03, which served as a negative control, had no effect on the apparent T_m of the protein, as expected.

CLR01 induces rapid formation of intermediate, β -sheet-rich, mutant p53DBD aggregates.

Aggregation of p53DBD is accompanied by a conformational transition into amyloid-like structures characterized by a high β -sheet content that can be measured using ThT binding (6). Alterations of the pH may influence aggregation rates dramatically (6). Therefore, we measured the effect of increased concentrations of CLR01 or CLR03

1
2
3 on the pH of the solution and found that CLR01 or CLR03 caused little change in the
4
5 pH up to the highest concentration examined – 100 μ M (Fig. S1).
6

7 ThT binding is independent of the size of protein aggregates. Therefore, it is useful
8
9 for monitoring the early stages of p53DBD aggregation (5). Using this method, we
10
11 found that at a protein:CLR molar ratio of 1:5, respectively, CLR01 rapidly enhanced
12
13 ThT binding by G245S-p53DBD (Fig. 4), suggesting induction of formation of a β -
14
15 sheet-rich structure. This effect was similar to that reported previously by Sinha et al.
16
17 for insulin, β_2 -microglobulin, and TTR (14), though the experiments in that study had
18
19 substantially lower time resolution than measured here. Therefore they observed a
20
21 high ThT fluorescence signal already at the earliest time point measured, whereas we
22
23 monitored the development of the signal during the first ~30 seconds.
24
25
26

27 Next, we used circular dichroism (CD) spectroscopy to evaluate the secondary
28
29 structure of the G245S-p53DBD mutant in the presence of increased molar ratios of
30
31 CLR01. In the absence of CLR01, G245S-p53DBD displayed typical α -helix-rich CD
32
33 spectra characterized by minima at ~207 and 220 nm, in which the 207 nm minimum
34
35 was slightly lower than the one at 220 nm (Fig. 5) as previously reported (21). In the
36
37 presence of CLR01, a shift was evident towards a β -sheet-rich structure, characterized
38
39 by a single minimum at 216 nm (Fig. 5). In contrast, CLR03 had no effect on the
40
41 conformation of G245S-p53DBD, as expected. These CD results corroborated the
42
43 ThT data.
44
45
46

47 We also used dot blots with antibody OC, which specifically recognizes β -sheet-rich
48
49 amyloid fibrils (22), to examine the effect of CLR01 on aggregation of G245S-
50
51 p53DBD. We found that increased concentrations of CLR01 (up to 5-fold excess)
52
53 resulted in higher OC binding, suggesting enrichment of β -sheet-rich structures (Fig.
54
55
56
57
58
59
60
60 6). To examine whether this effect was specific for the G245S mutant, we studied

1
2
3 similarly an additional structural p53DBD mutant, R249S (23). In the presence of
4
5 CLR01, R249S-p53DBD also displayed enrichment of β -sheet-rich structures. This
6
7 result indicated that the effect of CLR01 was not unique to G245S-p53DBD.
8
9 Surprisingly, in the presence of CLR03, R249S-p53DBD, but not G245S-p53DBD
10
11 also showed a moderate increase in OC binding, demonstrating a different behavior of
12
13 the two p53DBD variants (Fig. 6).
14
15

16 We examined further the effect of CLR01 on aggregation of G245S-p53DBD using
17
18 static light scattering, which is most effective for monitoring intermediate-size
19
20 assemblies. The experiments showed dose-dependent acceleration of the aggregation
21
22 reaction, resulting both from shortening of the lag phase, and from an increase in
23
24 aggregate-growth rate (Fig. 7). At the highest molar ratio examined, 1:10
25
26 protein:CLR01, respectively, the reaction plateaued at ~500 seconds. Together, the
27
28 ThT fluorescence, CD spectra, OC binding and static light scattering data suggest that
29
30 upon binding of CLR01 to G245S-p53DBD, the protein rapidly forms β -sheet-rich,
31
32 intermediate-size aggregates. In contrast, binding of CLR03 to G245S-p53DBD had
33
34 no effect on the protein aggregation, as expected.
35
36
37

38 To further investigate the conformational changes of G245S-p53DBD or R249S-
39
40 p53DBD induced by CLR01, we measured the change in fluorescence upon binding
41
42 of ANS, a common probe for exposed hydrophobic regions in proteins (24). When
43
44 ANS is free in solution, its fluorescence emission is negligible, but once it binds to
45
46 hydrophobic patches, its fluorescence emission increases (25). Consequently, ANS
47
48 has been used widely for characterizing intermediate states of proteins such as the
49
50 molten globule state (26). We found that CLR01 binding to the p53DBD mutants
51
52 G245S or R249S dramatically reduced ANS emission by ~6- and ~4-fold,
53
54 respectively, compared to the untreated proteins. This low ANS emission was evident
55
56
57
58
59
60

1
2
3 both by the rate and by the amplitude of ANS binding. This suggests that CLR01
4 reduces exposure of hydrophobic residues in the protein already at the early stages of
5 the folding-unfolding equilibrium of the p53DBD mutants, and further when
6 aggregation is initiated. Interestingly, CLR03 had no effect on G245S-p53DBD, as
7 expected, but slightly reduced ANS emission of R249S-p53DBD (Fig. 8), in
8 agreement with the differences observed between the two p53DBD mutants in OC
9 binding.
10
11

12 Collectively, our results suggest that CLR01 induces formation of β -sheet-rich
13 structures in the p53DBD mutants studied and simultaneously inhibits the exposure of
14 hydrophobic pockets in these proteins, presumably by inducing sequestration of
15 hydrophobic patches through intermolecular association and formation of
16 intermediate-size aggregates.
17
18

19 ***CLR01 inhibits the late stages of mutant p53DBD aggregation***

20 To monitor the effect of molecular tweezers on the formation rate of the late stages of
21 G245S-p53DBD or R249S-p53DBD aggregation and on the morphology of the
22 resulting aggregates, proteins were incubated in the absence or presence of increasing
23 concentrations of MTs and the reaction was monitored using turbidity and
24 transmission electron microscopy (TEM). R249S-p53DBD exhibited faster and higher
25 degree of aggregation compared to G245S-p53DBD, correlating with the kinetics
26 observed in the ANS binding assay (Fig. 8 and reference (3)).
27
28

29 Consistent with the results obtained in the ThT, CD, OC-antibody binding and static
30 light scattering experiments described above, the initial turbidity of the solution in the
31 presence of 1:1 molar ratio of CLR01 was higher than the turbidity of G245S-
32 p53DBD or the same as R249S-p53DBD alone. However, whereas in the solution
33 containing G245S-p53DBD on its own, a lag phase of ~25 minutes was observed
34

57
58
59
60

1
2
3 before the turbidity increased, in the presence of CLR01 the turbidity decreased in the
4 first 15 minutes and then began to increase (Fig 9a). Interestingly, at a molar ratio of
5 1:1 protein:CLR01, respectively, the amplitude of the turbidity was higher than that of
6 G245S-p53DBD alone, whereas at a molar ratio of 1:2 protein:CLR01, respectively,
7 the turbidity amplitude was similar to that of G245S-p53DBD alone.
8

9
10
11
12
13
14 Increasing the concentration of CLR01 to a molar ratio of 1:5 protein:CLR01,
15 respectively, resulted in decreased turbidity and at a molar ratio of 1:8 protein:CLR01,
16 respectively, no change of turbidity was observed throughout the experiment,
17 suggesting that at this concentration, aggregation was inhibited completely (Fig. 9).
18

19
20
21
22
23 Similar results were observed with R249S-p53DBD, which is less folded than G245S
24 (9). CLR01 inhibited the aggregation of R249S-p53DBD in a dose-dependent manner
25 starting at a 1:1 ratio (Fig. 9), though in this case, CLR01 inhibited the growth-rate of
26 R249S-p53DBD, but not its nucleation rate. CLR03 did not affect the aggregation of
27 the p53DBD mutants measured by turbidity, as expected (Fig.9). These results
28 recapitulate the previously reported inhibitory effect of CLR01 on the aggregation of
29 other amyloidogenic proteins (14, 27).

55
56
57
58
59
60
TEM analysis indicated that in the presence of CLR01 the p53DBD mutant
aggregates were smaller and more dispersed (Fig. 10). Higher magnification images
revealed occasional small, curvilinear fibrils (Fig. 10C). Interestingly, at 1:10
protein:CLR01 molar ratio, the aggregates were less dispersed. CLR03 had no effect
on G245S-p53DBD aggregates but did reduce R249S-p53DBD aggregates. Both MTs
had little effect on the morphology of the aggregates (Fig. 10).

Taken together, the results described above indicate that CLR01 enhances self-
assembly of the p53DBD mutants examined into β -sheet-rich structures. Apparently,
however, these structures are “off pathway” for formation of typical later-stage

1
2
3 p53DBD mutant aggregates because the kinetics of formation of the later-stage
4 aggregates and the final amount of these aggregates are reduced in the presence of
5 CLR01 in a dose-dependent manner. The modulatory activity of CLR01 requires the
6 hydrophobic side arms of the molecular tweezer, because the negative control CLR03
7 shows little or no effect on the aggregation of the p53DBD mutants.
8
9

10
11
12
13
14 ***CLR01 reduces the toxicity of p53DBD aggregates.***
15

16 The next important question was whether the assemblies stabilized by CLR01 were
17 cytotoxic. Introduction of *in vitro* pre-formed aggregates of p53DBD mutants to cells
18 has been reported to reduce cell viability (6), similarly to other amyloidogenic
19 proteins (14, 28). We examined next whether the MTs affect this cytotoxicity in
20 H1299 lung carcinoma cells. CLR01 was reported to be non-toxic in differentiated
21 PC-12 cells up to 200 μM and to induce mild toxicity at 400 μM (14). However,
22 toxicity can vary depending on the cell line used. Therefore, we tested the effect of
23 CLR01 and CLR03 on H1299 cells. We found that in agreement with the results
24 reported in PC-12 cells and primary neurons (29), CLR01 at 10-100 μM , and CLR03
25 at 100 μM were not cytotoxic (Fig. S2).
26
27
28
29
30
31
32
33
34
35
36
37

38 To test the effect of the MTs on cytotoxicity induced by mutant p53DBD we
39 incubated pre-formed G245S-p53DBD or R249S-p53DBD aggregates with CLR01 at
40 molar ratios from 1:2-1:10 or CLR03 at 1:10, respectively, and applied the mixtures
41 to H1299 cells. CLR01 protected the cells significantly from the harmful effect of
42 G245S-p53DBD or R249S-p53DBD aggregates (Fig. 11). The protective effect
43 displayed hormetic behavior as at a 1:10 molar ratio, lower, non-significant protection
44 was observed. Thus, the maximal protection was observed at 1:5 and 1:2 molar ratio
45 for G245S-p53DBD and R249S-p53DBD, respectively. This was not due to toxicity
46 of CLR01 itself, as shown in Figure S2, and at this point the basis for this behavior is
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 not clear. Interestingly, CLR03 had a significant, dose-independent rescue effect on
4
5 the viability of R249S-p53DBD-treated cells. This may reflect its moderate effect on
6
7 R249S-p53DBD observed in the OC, ANS binding, and TEM.
8
9

10 11 12 **DISCUSSION**

13
14
15
16 Aggregation of p53 conformational mutants has gained recent interest because it
17
18 accounts for both their dominant-negative and gain of toxic function effects. Our
19
20 findings that aggregation of p53 mutants converts their native conformation into a β -
21
22 sheet rich, amyloid-like structure are in line with recent data reported by other groups
23
24 which used Congo-red staining and ThT fluorescence for monitoring β -sheet
25
26 structures, as well as recognition by antibody A11, which binds specifically to
27
28 oligomers of amyloidogenic proteins (5, 6). Thus, cancers resulting from misfolded
29
30 p53 may belong to the broad spectrum of diseases called amyloidoses, including
31
32 Alzheimer's disease, Parkinson's disease, prion diseases and amyotrophic lateral
33
34 sclerosis, which are caused by abnormal misfolding and aggregation of
35
36 amyloidogenic proteins (30-32). This novel view of p53 aggregation suggests that
37
38 therapeutics based on modulating aggregation of amyloidogenic proteins also may be
39
40 effective against p53 aggregation and the cytotoxicity of the resulting aggregates.
41
42
43

44
45 The proposed mechanism of action of CLR01 is binding selectively to exposed Lys
46
47 residues (and to a lower extent to Arg residues), thereby disrupting hydrophobic and
48
49 electrostatic interactions that mediate oligomerization and aggregation of
50
51 amyloidogenic proteins and preventing their toxicity (33). The selectivity of the
52
53 compound is based on the fact that the forces controlling the abnormal aggregation
54
55 process are relatively weak, hence the oligomers are unstable and are in a dynamic
56
57
58
59
60

1
2
3 quasi-equilibrium. The binding of CLR01 is highly labile (34) and of moderate
4
5 (micromolar) affinity, and therefore does not interfere with the structure or function of
6
7 normal proteins, whose three-dimensional structure has been optimized by millions of
8
9 years of evolution.

10
11 The recent suggestion that p53 aggregates into amyloid-like structures (5, 12, 30-32,
12
13 35) prompted us to examine if CLR01 could inhibit aggregation and toxicity of
14
15 “conformational” p53 mutants. In the 393-residue sequence of the native p53
16
17 monomer there are 20 Lys (5.1%) and 26 Arg (6.6%) residues, whereas in the 179-
18
19 residue DBD, the Arg content is higher, 8.9% and the Lys content is 2.2%. These
20
21 numbers are on par with amyloidogenic proteins studied previously (14) and
22
23 suggested that CLR01 might be able to inhibit the aggregation of mutant p53 and the
24
25 toxicity of the aggregates.
26
27

28
29 Of the amyloidogenic proteins for which CLR01’s inhibitory activity was studied
30
31 previously (14, 27, 36, 37), A β 40, A β 42, tau, α -synuclein and islet amyloid
32
33 polypeptide are intrinsically disordered, insulin, β ₂-microglobulin, and TTR are
34
35 natively structured, and calcitonin is a relatively short peptide that is partially
36
37 structured in aqueous solution. Analysis of the behavior of the mixture of each of
38
39 these proteins with CLR01 in ThT fluorescence or turbidity experiments (14) revealed
40
41 a pattern. For intrinsically disordered proteins, initial ThT binding was minimal and
42
43 the fluorescence in the beginning of the aggregation reaction was close to background
44
45 values. In contrast, for the natively structured proteins, the initial ThT
46
47 fluorescence/turbidity signal was substantially higher in the presence of CLR01 than
48
49 in its absence, suggesting that binding of CLR01 rapidly induced formation of
50
51 aggregates in which the β -sheet content was increased relative to the CLR01-unbound
52
53 state. In the case of calcitonin, the increase in the initial ThT fluorescence was small
54
55
56
57
58
59
60

1
2
3 relative to the structured proteins, as would be expected for a partially structured
4
5 peptide (14).

6
7 Because similarly to insulin, β_2 -microglobulin, and TTR, p53 has a well-defined
8
9 stable structure, we expected that upon interaction with G245S-p53DBD or R249S-
10
11 p53DBD, CLR01 would induce formation of β -sheet-rich aggregates. This was indeed
12
13 what we found. Turbidity measurements showed that at the initial time points, larger
14
15 aggregates were present in samples of G245S-p53DBD or R249S-p53DBD in the
16
17 presence of CLR01 than in its absence (Fig. 9). Therefore, we conducted ThT
18
19 fluorescence, CD spectra, OC binding, ANS fluorescence and static light scattering
20
21 experiments with higher time-resolution than the experiments conducted previously
22
23 with other proteins or the turbidity measurements performed here. Using the higher
24
25 time-resolution, we observed the rapid formation of β -sheet-rich, intermediate-size,
26
27 G245S-p53DBD:CLR01 complexes within ~ 1 min of mixing the protein and the
28
29 molecular tweezer (Figs. 4, 7). Examination by TEM, and static light scattering
30
31 experiments, showed that the size and morphology of the initial G245S-p53DBD and
32
33 R249S-p53DBD aggregates formed in the absence or presence of CLR01 were similar
34
35 (Fig. 10), suggesting that the differences between the two types of aggregates were
36
37 subtle and deciphering these differences would require higher spatial-resolution
38
39 methods.
40
41
42
43
44

45 Similarly to other amyloidogenic proteins, p53 aggregation is thought to occur via
46
47 nucleation-dependent polymerization (5), characterized by a slow nucleation step
48
49 followed by fast growth of aggregates (38). Our observations support this model. We
50
51 found that the initial stage of aggregation of the mutant p53 examined occurs at a
52
53 slow rate followed by a rapid phase of aggregation evidenced by a steep slope
54
55 (indicated as L and F, respectively in Fig. 9). The final stage is a decrease in the rate
56
57
58
59
60

1
2
3 of aggregation and ultimately a plateau, as the system reaches equilibrium (P in Fig.
4
5 9). During the final slow step, formation of larger aggregates by association of smaller
6
7 ones is thought to be a secondary mechanism, though it is difficult to distinguish
8
9 kinetically from the growth of individual aggregates by currently available
10
11 techniques. Our data suggest that binding of CLR01 greatly accelerated a nucleation-
12
13 like phase of G245S-p53DBD or R249S-p53DBD, but the protein:CLR01
14
15 assemblies/nuclei had a distinct, off-pathway structure from that of these proteins
16
17 alone. The hetero-assemblies of G245S-p53DBD or R249S-p53DBD with CLR01 did
18
19 not promote further growth or propagation of the β -sheet structure. Importantly, these
20
21 hetero-assemblies had reduced toxicity relative to those formed by G245S-p53DBD
22
23 or R249S-p53DBD alone.
24
25
26

27 Cellular effects of p53 aggregation in cancer are associated with cell survival and
28
29 proliferation rather than with cell death, in contrast to neurodegeneration. However,
30
31 our cell viability results support recent findings showing that *in vitro* pre-formed
32
33 aggregates of mutant p53 are cytotoxic (13) and suggest that CLR01 can protect cells
34
35 from this cytotoxicity, in agreement with its effect on other amyloidogenic proteins.
36
37

38 Interestingly, though CLR03 was used as a negative control and was not expected to
39
40 affect the aggregation or toxicity of the p53DBD mutants, we found that it moderately
41
42 increased OC binding and decreased ANS binding, selectively to R249S-p53DBD. In
43
44 correlation with these data, CLR03 also showed moderate, dose-independent
45
46 protection of H1299 cells against the toxicity of R249S-p53DBD, suggesting that it
47
48 might promote formation of non-toxic aggregates by a currently unknown
49
50 mechanism. In most of the studies reported to date CLR03 was found to behave as a
51
52 negative control, i.e., did not affect the proteins under study where CLR01 had a clear
53
54 impact. This was the case also in all the experiments we performed using G245S-
55
56
57
58
59
60

1
2
3 p53DBD. In a recent study, CLR03 was found to induce moderate enhancement of
4
5 oligomerization of A β 40 and A β 42 using ion-mobility spectroscopy–mass-
6
7 spectrometry (39), similar to its effect on G245S-p53DBD. The basis for this activity
8
9 currently is unknown.

10
11 Conformational p53 mutants co-aggregate with wild-type p53 in cells (12). If this
12
13 were also the case *in vivo*, this aggregation would result in even lower availability of
14
15 the wild-type protein, and a higher propensity for malignant cell proliferation. Ideally,
16
17 inhibition of the abnormal aggregation of mutant p53 would lead to degradation of the
18
19 misfolded, mutant protein, and release of the normal, wild-type protein, increasing its
20
21 availability for DNA transcription regulation. Our data suggest that the use of
22
23 aggregation modulators, such as CLR01, could lead to selective degradation of
24
25 misfolded p53, thereby increasing the availability of normal p53. Determining the
26
27 extent of the protective effect provided by inhibiting the aggregation of mutant p53
28
29 will require further investigation.

30 31 32 33 34 **Description of Supporting Information**

35
36 Supplementary figures show effect of increased concentrations of molecular tweezers
37
38 on the pH of the buffer (Fig. S1) and on cell viability (Fig. S2). This material is
39
40 available free of charge via the Internet at <http://pubs.acs.org>.

FIGURE LEGENDS

FIGURE 1. Illustration of the process of denaturation and subsequent aggregation of p53. Folded and unfolded p53 are in equilibrium, but unfolded p53 can irreversibly denature and form small, soluble aggregates, which cluster and precipitate over time. Adapted from (3).

FIGURE 2. Structure of the molecular tweezers. (A) CLR01; (B) CLR03. Reprinted with permission from Sinha *et al.*, J. Am. Chem. Soc. 2011;133:16958-69. Copyright (2011) American Chemical Society.

FIGURE 3. Effect of molecular tweezers on thermo-stability of p53DBD. The effect of increased molar ratio of either CLR01 or CLR03 on stability of the G245S-p53DBD mutant was measured using differential scanning fluorimetry.

FIGURE 4. Effect of molecular tweezers on the early stage of p53DBD aggregation. The effect of CLR01 or CLR03 on the early stage of aggregation of G245S-p53DBD was monitored at 37 °C using ThT fluorescence ($\lambda_{\text{ex}} = 450 \text{ nm}$, $\lambda_{\text{em}} = 482 \text{ nm}$).

FIGURE 5. Effect of molecular tweezers on secondary structure of p53DBD. Far UV CD spectra of G245S-p53DBD in the absence or presence of increasing molar ratio of CLR01 or CLR03. CD spectra measurements were conducted at 37 °C after 20 min incubation. The table presents percentage of secondary structure calculated using the CDNN software (20).

FIGURE 6. p53DBD aggregation monitored by dot blot with antibody OC. Dot blot was performed using the OC antibody with pre-formed aggregates of G245S-p53DBD or R249S-p53DBD in the absence or presence of increasing molar ratio of CLR01 or CLR03.
