Abstract

Covalent Targeting of Glutamate Cysteine Ligase to Inhibit Glutathione Synthesis

By

Lydia Hanping Zhang

Doctor of Philosophy in Metabolic Toxicology

University of California, Berkeley

Professor Daniel K. Nomura, Chair

Cancer is a complex disease with high incidence and mortality rates. Conventional therapies, such as radiation or chemotherapy, often come with harmful side effects and have limited effectiveness against aggressive forms of cancer. Newer approaches, including immunotherapy and targeted therapy, have shown promise in improving therapeutic outcomes and sparing normal healthy cells from damage. While advanced sequencing technologies and research have uncovered cancer-driving molecular targets, specifically modulating those targets have remained challenging. Many proteins lack robust biochemical characterization or obvious binding pockets that traditional drugs target, rendering them "undruggable". Chemoproteomics and fragment-based covalent ligand libraries have emerged as innovative tools for addressing these challenges, offering a more efficient and rational path to drug discovery. Furthermore, covalent drugs provide pharmacological advantages such as enhanced potency, selectivity, and prolonged duration of action.

Dysregulated oxidative stress plays a major role in cancer pathogenesis, offering a unique vulnerability for intervention. Targeting glutamate-cysteine ligase (GCL) to inhibit the synthesis of the major antioxidant glutathione (GSH) may be a promising therapeutic strategy for certain cancer types that are particularly sensitive to oxidative stress. In this dissertation, I use fragment library screening and chemoproteomic approaches for identifying new covalent inhibitors against GCL. We have discovered an acrylamide-containing cysteine-reactive ligand, EN25, that covalently targets cysteine C114 on GCLM, the modifier subunit of GCL. We show that EN25 allosterically reduces GCL activity, lowers cellular GSH levels, and impairs cell viability in ARID1A-deficient cancer cells that are particularly sensitive to glutathione depletion. We also performed a small-scale SAR study and identified additional covalent ligands with moderately enhanced binding affinity *in vitro*. Our studies reveal a new ligandable site within GCLM that can be targeted to inhibit the GSH synthesis in vulnerable cancer cell types.

Table of Contents

List of Figures

List of Appendices

Appendix A: Supplementary Synthetic Methods

Appendix B: Supplementary Datasets

List of Abbreviations

ABPP	Activity-Based Protein Profiling
ALDH7A1	Aldehyde dehydrogenase 7 family member A1
ARID1A	AT-rich interactive domain-containing protein 1A
ATP	Adenosine triphosphate
BCA	Bicinchoninic acid assay
BSA	Bovine Serum Albumin
BSO	Buthionine sulfoximine
C114	Cysteine at position 114
c9orf142	XRCC4-like small protein
CMV	Cytomegalovirus
CO2	Carbon dioxide
CuAAC	Copper(I) Azide-Alkyne Cycloaddition
DMEM	Dulbecco's modified eagle medium
DMSO	Dimethylsulfoxide
DNA	Deoxyribonucleic acid
DTT	Dithiothreitol
EDTA	Ethylenediaminetetraacetic acid
FBLD	Fragment-based ligand discovery
FBS	Fetal bovine serum
FLAG Tag	DYKDDDDK polypeptide protein tag
GAPDH	Glyceraldehyde-3-phosphate dehydrogenase
GC	Glutamylcysteine
GCL	Glutamate cysteine ligase
GCLC	Glutamate cysteine ligase-catalytic subunit
GCLM	Glutamate cysteine ligase-modifier subunit
GPKOW	G-Patch Domain And KOW Motifs
GPx	Glutathione peroxidases
GRx	Glutathione redoxin
GSH	Glutathione (reduced)
GSSG	Glutathione (oxidized)
GST	Glutathione-S-Transferases
HNRNPA3	Heterogeneous Nuclear Ribonucleoprotein A3
HTS	High throughput screening
IA	Iodoacetamide
IA-alkyne	Iodoacetamide-alkyne conjugate (N-5-Hexyn-1-yl-2-iodoacetamide)
IC50	50 % inhibitory concentration
isoTOP-ABPP	Isotopic tandem orthogonal proteolysis-enabled ABPP
KEAP1	Kelch-like ECH-associated protein 1

KO	Knockout
LC-MS	Liquid chromatography–mass spectrometry
MEM	Minimum Essential Medium
MQ	Methylene quinuclidinone
MS	Mass spectrometer
MS/MS	Tandem mass spectrometry
MS1	First MS for detection of initial ionization in MS/MS
MS2	Second MS for detection of fragment ionization in MS/MS
MTHFD1L	Methylenetetrahydrofolate dehydrogenase
MudPIT	Multidimensional protein identification technology
NDA	Naphthalene-2,3-dicaboxaldehyde
NRF2	Nuclear factor erythroid 2-related factor 2
NUP85	Nucleoporin 85
PAGE	Polyacrylamide gel electrophoresis
PBS	Phosphate-buffered saline
PNN	Pinin
QQQ	Triple-quadrupole mass spectrometer
RNA	Ribonucleic acid
RNS	Reactive nitrogen species
ROS	Reactive oxygen species
RPMI	Roswell Park Memorial Institute Medium
RT	Room temperature
SAR	Structure-activity relationship
SDS	Sodium dodecyl sulphate
SDS-PAGE	Sodium dodecyl sulphate–polyacrylamide gel electrophoresis
siRNA	Short interfering RNA
SIRT6	Sirtuin 6
SLC7A11	Solute carrier family 7 member 11
SRM	Single reaction monitoring
TCA	Trichloroacetic acid
TCEP	tris(2-carboxyethyl)phosphine
TES/SB	N-[Tris(hydroxymethyl)methyl]-2-aminoethanesulfonic acid sodium salt/sodium borate buffer
TEV	Tobacco etch virus
TrxR1	Thioredoxin reductase
U2URP	U2 snRNP-associated SURP
WT	Wild-type

Dedication

I dedicate this dissertation to my parents whose immense sacrifices and hard work have afforded me a comfortable life. I also dedicate this to Lucia Zhang, my younger sister and best friend who has always been there to encourage, support, and listen to me during all the highs and lows. Thank you, fam, for your unconditional love.

To Jiahao Liang: you are the sweetest and most caring partner. Thank you for your unwavering support this past year. I have learned to live more passionately and in the moment with you and it has been liberating. Your mindfulness, ability to make friends wherever you go, zest for life, and confidence inspire me every day. I also thank your family for feeding me the most delicious home-cooked Asian food and welcoming me with such warmth and open arms.

To my PhD advisor Dan Nomura: Your generosity, efficiency, passion, and ambition constantly motivate me to become a better scientist and worker. I am grateful to have been in your lab and I appreciate your support throughout grad school!

To my undergrads Michelle Tang, Xavier Tao, and Justin Hatcher: It was a pleasure to mentor you all and I couldn't have asked for a better team to work with. I thank you guys for your hard work and eagerness to learn. I'll forever treasure our lydzsquad slack channel, and your company during all the long lab days. Thanks for keeping lab entertaining for me.

To the scientists I met at UCSF: Michael Hornsby, Jie Zhou, Kevin Leung, Jeff Glasgow, and Melissa (Trieu) Sahu—I attribute my scientific growth spurt to you all. Thank you for being enthusiastic mentors and phenomenal scientists to learn from at the bench.

Most importantly, I could not have survived grad school without my friends. To my dearest childhood friend Irene Liou: Thank you for your encouragement, faith, and care throughout the last decade and a half. To my soul-sister Nix Tan: Our long-distance friendship is so special to me, and I value your wise insights, deal-finding, and silly conversations. To Randall Lin, you have been my intellectual role model and best friend for most of grad school. Thank you for encouraging me to find research in the first place nearly a decade ago and for all the care and wisdom you've imparted on the way. To the Caltech Dongsquad, thank you for inviting me to all the fun vacations, cooking nights, karaoke, clothes swaps, and other gatherings throughout the past few years. To all the members of the following group chats, Chamaly, CLAMZ, Chaqily, and ELMZ (&Thang Docong), I cherish all the food dates, spontaneous hang outs, nature getaways, shows, crafts, and board game nights we experienced. I genuinely appreciate every single one of you for providing me such a vibrant life outside of the lab.

To the Nomura lab, its alumni, and anyone else who have given me words of encouragement and thoughtful advice throughout the past five years, thank you!

Acknowledgments

Chapter 1: Covalent Ligand Approaches Towards Drug Discovery in Cancer

1.1   Introduction

Cancer is a disease that arises from uncontrolled and unregulated proliferation of cells and remains as the second leading cause of death globally with very high incidence and mortality rates[1]. While early diagnosis and advanced therapies have helped reduce cancer death rates, treating cancer is still a complicated process due to cancer's evolving nature, complexity, and loss of control. Conventional treatments such as radiation therapy, resection, and chemotherapy have been widely used for decades but have harmful side effects and low response rates once the cancer metastasizes[1,2]. Newer, more advanced therapies such as immunotherapy, stem cell therapy, endocrine therapy, and targeted therapy have emerged in the recent years to improve therapeutic outcomes. Current research efforts focus on unraveling the molecular underpinnings of cancer progression to inform development of these new therapeutic modalities. However, the biggest challenge in developing modern therapeutics is being able to not just discover but effectively and safely modulate the molecular targets involved in driving cancer phenotypes[3]. In this chapter, we will discuss the chemoproteomic targeted drug discovery platform that aims to couple novel drug and target discovery efforts.

1.2   Chemoproteomic platforms used in drug discovery

1.2.1   The undruggable genome

The development of DNA sequencing and genotyping technologies have facilitated the discovery of disease-associated DNA sequence variants and disease-causing mutations in the genome. However, translating disease-controlling protein targets into pharmacological targets remains difficult, primarily due to the fact that limited gene products encode proteins that can be directly targeted by small molecules[4]. Currently, just around 2% of predicted gene products have known small molecule modulators and it is estimated that only 10-15% of all human genes are considered "druggable"[3,5,6]. This category of druggable gene products only shares a 25% overlap with disease-modifying targets. Even so, certain established small molecules can either partially act on a protein or target multiple proteins in ways that cannot be predicted by considering genetic insights, structure, or function. The disconnect between our genetic understanding of disease and our ability to study and develop drugs against these targets presents significant challenges in the field of drug development.

At the core of this disconnect lies the "undruggable" proteome, which includes proteins lacking obvious binding pockets, those without functional assays amenable for high-throughput(HTS) screening, and proteins that are not well characterized biochemically. These factors hinder further investigation and assaying efforts[7]. Developing small-molecule modulators against the "undruggable" proteome for targets implicated in

disease has remained a daunting but vital task. Chemical proteomics, or chemoproteomics, has recently emerged as a powerful method to interrogate protein-small molecule interactions, providing a promising approach to bridge the gap between disease-driving targets and their functional modulation.

1.2.2   Activity-based protein profiling

Chemoproteomic technologies couple the discovery of new "ligandable" sites in proteins with developing small-molecule modulators for these sites. An example of this technology is activity-based protein profiling (ABPP) which utilizes reactivity-based chemical probes to directly map reactive, functional, and ligandable hotspots in proteomes. These probes consist of two features: 1) a warhead for binding to functional sites within proteins and 2) a chemical handle (e.g., fluorophores, biotin, or alkynes) for visualization, enrichment, or biorthogonal conjugation for further analysis of protein activities and quantification with mass spectrometry (MS)[8]. **(Fig. 1.1a).** To enable lead discovery, covalently-acting small-molecules can be competed against reactivity-based probes to assess level of binding. This approach can be applied to target-based HTS screens using gel-based or plate-based approaches for rapid identification of covalent ligands and ligandable sites in target proteins that can be assayed with ABPP methods. Lead inhibitors can also be used to make biorthogonal analog probes to further assess inhibitor selectivity[9]. Furthermore, ABPP can enable quantitative assessments of target engagement and proteome-wide selectivity *in vitro*, *in situ*, or *in vivo* using mass-spectrometry-based approaches through a platform termed isotopic tandem orthogonal proteolysis-enabled ABPP (isoTOP-ABPP)[10].

isoTOP-ABPP employs a broadly reactive electrophilic probe to globally map protein functionality in the proteome. These probes include a chemical alkyne handle for 'click chemistry' conjugation to an azide-functionalized peptide linker tag that incorporates a TEV protease recognition site, a biotin group for avidin enrichment, and an isotopically light or heavy valine for precise ratiometric MS-based analysis of labeled peptide. More specifically, the broadly reactive electrophilic probe can react with nucleophilic hotspots within proteomes, such as catalytic sites, solvent-accessible binding pockets, post-translational modification sites, metal binding sites, and other regulatory or functional domains[11–14]. The isotopically labelled tag that appends to the reactive probe allows for identification and quantitative comparison of the reactivity of probes against specific amino acid sites which can eventually be druggable. This ABPP strategy has found applications in examining targets in various proteomes. For example, isoTOP-ABPP can be used to identify dysregulated protein targets in cancer cells compared to normal cells, discover hyper reactive functional hotspots by comparing varying probe concentrations, profile the off-targets of known chemicals, or develop inhibitors against ligandable hotspots **(Fig. 1.1b-d)**[8,15–17].

1.2.3   Chemoproteomic profiling of cysteine reactivity for drug discovery

One parameter that defines functional reactive sites within the proteome is the reactivity of amino acid sidechains. These reactive sites are notably abundant in residues involved in catalysis, protein-protein interactions, or regulatory mechanisms and their reactivity can signal

as a functional "hotspot" accessible for modification[10]. One such amino acid, cysteine, stands out as an appealing target for covalent modifications due to a few unique characteristics. Despite being the least frequently modifiable amino acid residue, cysteine is amenable to a wide array of reagents, including iodoacetamides, acrylamides, maleimides, and chloroacetimides. Cysteine residues play vital roles in catalysis and redox sensing, and their oxidative status renders them susceptible to various post-translational modifications, such as S-nitrosylation, S-prenylation, and oxidation to sulfenic and sulfonic acids[12,13,18–20]. Beyond their catalytic roles, cysteines also serve essential non-catalytic roles such as stabilizing protein tertiary structure through the formation of disulfide cross-links and coordinating enzyme cofactors like metals[21–23]. The highly nucleophilic nature of the cysteine thiolate makes it a prime target for most covalent inhibition strategies explored to date. With an average abundance of 1.9%, cysteine's unique reactivity and multifaceted functional roles establish it an important residue in the realm of covalent protein targeting.

Among the reactivity-based probes used to broadly modify cysteines, the iodoacetamide-alkyne (IA-alkyne) probe stands out as a popular tool utilized in these ABPP applications[10,24]. IA-alkyne's covalent binding indicates the hyper reactive and functional hotspots within specific complex biological systems. When IA-alkyne is used in competition with specifically cysteine-reactive small-molecules, it helps pinpoint where these small molecules bind. Using isoTOP-ABPP, researchers can also assess the proteome-wide selectivity of such cysteine-reactive small molecules. This capability allows investigators to conduct medicinal chemistry efforts to optimize ligand selectivity or identify off-target effects of pharmaceuticals, a step towards streamlining the drug discovery process.

1.3   Covalent Fragment-Based Ligand Discovery

The benefits of covalent drugs in pharmacology include increased potency, improved selectivity, and extended duration of effectiveness. Hence, developing cysteine-reactive covalently-bound small molecule fragment libraries synergizes well with the chemoproteomic platforms mentioned above for rapid discovery and validation of small molecule modulators of disease relevant targets. **(Fig. 1.2)**

These fragment-based ligand discovery (FBLD) platforms have been increasingly used by pharmaceutical industries in lieu of traditional libraries as they offer more efficient, rational, and targeted approach to drug discovery[25]. Traditional library-based approaches used compounds that were randomly assembled or from previous drug-discovery programs[26]. Other combinatorial chemistry synthesis methods for generating libraries can be time-consuming and costly. In reality, the number of every small drug-like molecules that exist is estimated to be around 10^{63}, a number that is unrealistic to screen every target against[27]. In contrast, the FBLD approach uses smaller, low-molecular-weight fragment compounds, which are cheaper and more efficient to screen. The reduced size of fragments also minimizes the risk of off-target effects and toxicity, enhancing safety in later stages of drug development. Investigators can also design sets of fragments with desired structural moieties in a more rational and focused approach, especially when a protein's binding pocket or structure is known. These fragments expose fundamental chemical interactions which can be used to

explore unique chemical spaces. Once initial hits are identified, fragments can be systematically expanded into larger compounds, facilitating further drug development[28].

The combination of FBLD and chemoproteomic ABPP methods represent two powerful advancements to modern drug discovery. FBLD streamlines the drug discovery process, providing a more efficient and targeted approach, while also generating high-quality leads. When these leads are then applied to chemoproteomic ABPP techniques, binding selectivity, specificity, and off-target profiles can be read out—aspects usually defined later in the drug development stage. An illustrative example in Chapter 2 of our work involves the use of a fragment-based cysteine-reactive ligand library and ABPP methods to facilitate rapid and effective identification of a novel drug that targets glutathione synthesis in cancer cells, showcasing the potential of this integrated approach.

1.4   Figures
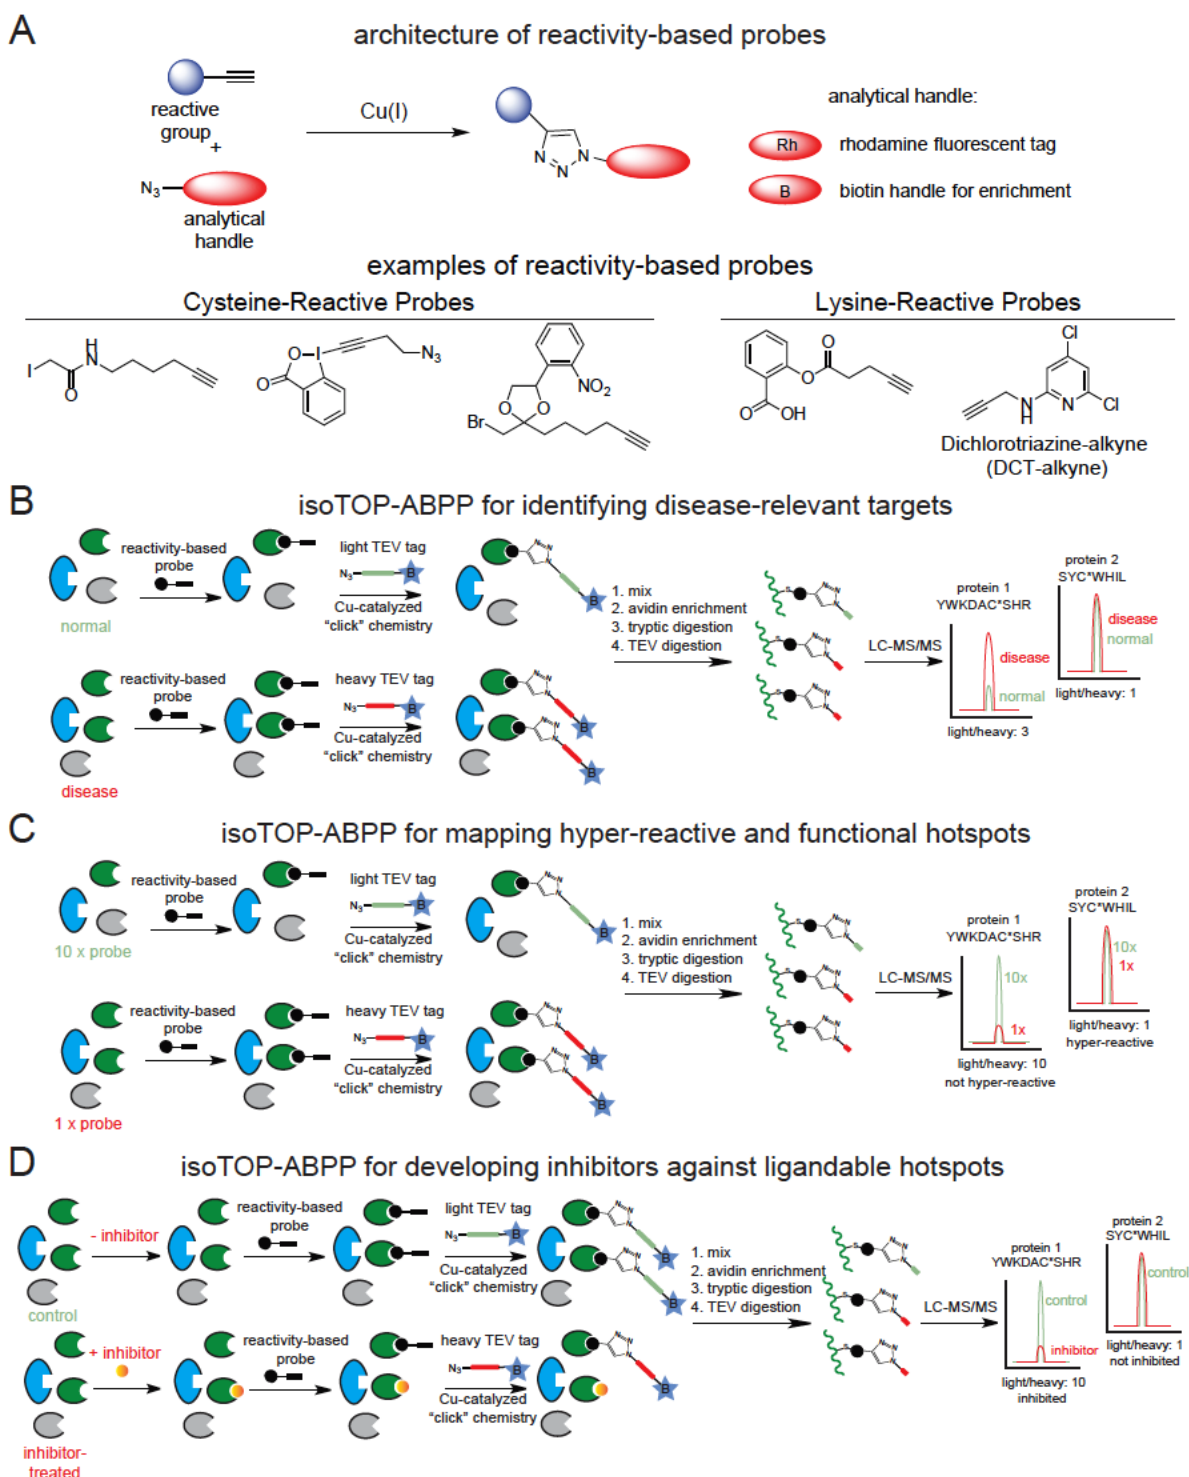

Figure 1.1. Schematic of isotopic tandem orthogonal proteolysis-enabled activity-based protein profiling. (A) Architecture of activity-based and reactivity-based biorthogonal probes and example structures. (B) Using isoTOP-ABPP platforms for identifying disease-relevant targets. Normal and diseased proteomes can be labeled

with activity or reactivity-based probes, followed by a click reaction to append isotopically light or heavy analytical biotin handles bearing a TEV protease cleavage sequence, followed by mixing of proteomes in a 1:1 ratio, avidin enrichment of probe-labeled proteins, TEV digestion to release probe-modified tryptic peptides, and quantitative proteomic analysis of probe-modified peptides. (C) Using isoTOP-ABPP for mapping hyper-reactive and functional hotspots in the proteome. The procedures would follow those described in (B), except that proteomes would be labeled with varying concentrations of probes (e.g. 10 x vs 1 x probe concentration) to quantitatively map highly reactive sites. (D) Using isoTOP-ABPP for pharmacological interrogation of ligandable sites. The procedures would mirror those described in (B), except that proteomes would be treated with vehicle or ligand to map not only the sites of probe labeling, but also sites where the ligand displaced probe labeling, facilitating both ligand discovery for targets of interest as well as an assessment of its proteome-wide selectivity.
Figure 1.2. Examples of fragment-based covalent ligand libraries for targeting cysteine residues. Acrylamide and chloroacetamide warheads on small molecules enable fragment screening efforts against solvent-accessible cysteine residues found in proteins.

Chapter 2: Covalent Targeting of *De Novo* Glutathione Synthesis for Cancer Therapy

This chapter is based on the paper "Covalent Targeting of Glutamate Cysteine Ligase to Inhibit Glutathione Synthesis"[29] DOI: https://doi.org/10.1002/cbic.202300371 and has been adapted with permission from all co-authors.

2.1 Summary

Many different types of cancers have dysregulated redox homeostasis which contributes to fueling cancer pathogenicity and acquiring drug resistance, but also presents a vulnerability that can be pharmacologically targeted for cancer therapy[30]. For example, MYC-driven liver tumors show suppression of glutathione synthesis, and instead use glutamine-derived carbons for use in other metabolic pathways to support tumor growth. However, this alteration in metabolism makes these MYC-driven tumors hyper-sensitive to oxidative stress[31]. Previous studies have revealed that ARID1A-deficient cancers, through their downregulation of the cystine transporter SLC7A11, are specifically vulnerable to inhibition of glutathione synthesis[32]. Thus, targeting the synthesis of glutathione in cancer cells is an attractive strategy towards impairing certain types of human cancers through heightening oxidative stress and inducing cell death in cancer cells[33].

The glutathione (GSH) synthesis pathway is a two-step ATP-dependent process. The first step is carried out by the glutamate-cysteine ligase (GCL) which consists of two subunits--glutamate-cysteine ligase modifier subunit (GCLM) and glutamate-cysteine ligase catalytic subunit (GCLC). These two proteins come together in the rate-limiting step of GSH synthesis[34]. While developing GCL inhibitors would potentially have chemotherapeutic implications, there are no drug-like GCL inhibitors. Buthionine sulfoximine (BSO), a substrate mimetic with poor drug-like properties, currently represents one of the best currently available GCL inhibitors[35]. We sought to use covalent ligand discovery and chemoproteomic approaches to identify unique ligandable sites within and functional inhibitors for GCL.

We have discovered a cysteine-reactive covalent ligand, EN25, that covalently targets an allosteric cysteine C114 on GCLM, the modifier subunit of GCL. Using an *in vitro* activity assay, we show that EN25 functions to allosterically reduce ligase activity in the catalytic subunit, GCLC. We also used ARID1A-deficient cancer cells, A2780, that are particularly vulnerable to glutathione depletion, to show that EN25 lowers cellular GSH levels, and impairs cell viability compared to ARID1A-positive cancer cells, RMG-1. To study how the EN25 structure affects activity, we performed a small-scale SAR study and identified additional covalent ligands with moderately enhanced binding affinity *in vitro*. Our studies reveal a novel potentially ligandable site within GCLM that can be targeted to inhibit the GSH synthesis in cancer cells and induce cell death in cancer cell types that are vulnerable to oxidative dysregulation.

2.2 Introduction

Metabolic rewiring is fundamental to enabling cancer cells to constitutively proliferate, survive, and grow. Cancer cells are known to have increased aerobic glycolysis and glucose uptake, which leads to increased metabolism and aberrant signaling[36–38]. To keep up with the demands of these processes, cancer cells end up producing and sustaining heightened levels of reactive oxygen species (ROS). ROS are involved in diverse signaling pathways and are essential for a variety of biological processes which in turn can fuel cancer initiation, promotion, progression, and maintenance of particular tumor cell phenotypes[39–41]. However, excess ROS that are not eliminated through the antioxidant defense mechanisms exert oxidative stress onto the cells in both normal and cancerous cells. Oxidative stress can lead to lipid peroxidation, which disrupts the cell membrane, allowing water to come in to cause cell swelling, lysis, and death[42,43]. Additionally, ROS can oxidatively inactivate Ca2+/ATPases to elevate calcium influx, which disrupts cell morphology and impairs cellular functions[44]. As such, precise regulation of redox homeostasis is critical for cell survival[45]. Cancer cells, therefore, must counteract their elevated ROS, putting a selective pressure on pre-neoplastic cells to develop robust antioxidant defense mechanisms.

2.2.1 The role of glutathione in redox homeostasis

Glutathione (GSH) is the most abundant antioxidant and regulates cellular redox states by scavenging for and reacting with ROS, reactive nitrogen species (RNS), free radicals or xenobiotics to neutralize them[46]. In a normal resting cell, the molar oxidized to reduced glutathione (GSH:GSSG) ratio exceeds 100:1, while in various models of oxidative stress, this ratio can fall to 10:1 and even 1:1[47–49]. GSH can directly react with radicals such as superoxide anion radical and regenerate enzymatic antioxidants such as α-tocopherol[50,51]. GSH can also indirectly contribute to the antioxidant response as it is a major cofactor and substrate for several enzymes that participate in redox and conjugation reactions. For example, glutathione peroxidases (GPx) convert hydrogen peroxides and lipids to water or alcohols, by reducing GSH to GSSG to protect cells from lipid oxidation and reduce radical formation from Fenton reactions[52–54]. Similarly, glutathione redoxin (GRx) uses GSH to regenerate oxidized cysteines in proteins and reduce disulfide bonds or glutathylated proteins to protect from protein damage[55,56]. In drug metabolism, Glutathione-S-Transferases (GST) bioconjugate GSH to xenobiotics and electrophiles for detoxification and subsequent excretion from the body[57,58].

2.2.2 Manipulating the redox homeostasis in cancer cells for therapy

One way to reduce a cancer cell's ability to resist ROS-induced cell death is to dismantle its antioxidant response[1,2]. With the increased levels of ROS, comes a precarious balance between ROS and its antioxidants. Targeting glutathione, a major antioxidant, in cancer cells presents an attractive strategy to push the threshold of ROS to trigger death mechanisms[59].

Cancers with decreased GSH synthesis have shown hyper-sensitivity to oxidative stress. For example, MYC-driven liver tumors attenuate glutamate cysteine ligase (GCL) expression through miR-18a and show decreased GSH levels and increased sensitivity to oxidative stress, even though they are able to use glutamine-derived carbons for other metabolic pathways that support tumor growth[31]. Another study revealed that ARID1A-deficient cancers, through their downregulation of the cystine transporter SLC7A11, are specifically vulnerable to inhibition of GSH synthesis[32]. ARID1A encodes a transcription factor protein involved in the SWItch-SNiF chromatin-remodeling complex. This complex is involved in widescale transcriptional regulation, and the mutation perturbs transcriptional homeostasis and processes in DNA repair which contributes to its pathogenicity. Ovarian clear cell carcinoma and ovarian endometrioid carcinomas cancers frequently (50% and 30%, respectively) show ARID1A deficiency[60]. Currently there are no effective therapies against these cancers, but studies show that inhibiting GSH in ARID1A-deficient cancer cells causes apoptosis by ROS in cells as well as tumor xenografts compared to non ARID1A-deficient cancer cells[32,61,62], a promising direction for therapeutic development.

On a pharmacological level, modulating GSH levels within cancer cells could enhance the efficacy of other anticancer therapies. Certain cancer therapeutics, such as carboplatin and cisplatin, act by cross-linking DNA to prevent replication and transcription, thereby initiating apoptosis [63,64]. Increased GSH levels, as reflected by increased glutathione synthesis enzyme activity and corresponding gene transcription, have been shown to be associated with drug resistance in cancer cells [65,66]. In these cancer populations, the excess GSH scavenges for these drugs in the cytosol before they can cross-link DNA and therefore reduces drug efficiency and increases drug-resistance[63,67–69].

2.2.3 Targeting *de novo* synthesis of glutathione

The majority of intracellular GSH comes from *de novo* GSH synthesis. GSH biosynthesis occurs via two ATP-dependent steps. First, GCL ligates glutamate and cysteine to form gamma-glutamylcysteine. This dipeptide is then converted into GSH by glutathione synthetase. The rate-limiting step is catalyzed by GCL, a holoenzyme composed of a catalytic (GCLC) and modulatory (GCLM) subunit . GCLM does not possess enzymatic activity alone, but when bound to GCLC, it increases GCLC productivity by nearly 5-fold[71]. In fact, oxidative stress enhances holoenzyme formation in addition to inducing expression of GCL subunits via the NRF2/KEAP1 signaling pathway to bolster the antioxidant response[72–74].

Currently, the only known inhibitor targeting *de novo* GSH synthesis is L-buthionine sulfoximine (BSO), which targets specifically GCLC as an ATP mimetic inhibitor. Unfortunately, BSO does not demonstrate substantial therapeutic benefits on its own in clinical trials[75]. BSO is not very specific towards normal and malignant cells and has poor bioavailability and *in vivo* PD/PK in mice and thus imposes limitations on its therapeutic potential[76,77]. Another compound known to decrease GSH levels is the

prodrug APR-246 which is converted to methylene quinuclidinone (MQ). MQ targets cysteines on the tumor suppressor p53 to encourage refolding, and is not directly involved in GSH synthesis, but rather, it inhibits thioredoxin reductase (TrxR1) and prevents conversion of GSSG into GSH to deplete GSH pools[78]. However, APR-246 has many other targets and is not specific to the glutathione synthesis pathway[79] and there is evidence that *de novo* GSH synthesis, and not recycling of GSSG plays an important role in modulating ROS homeostasis in T cells[80]. Thus, inhibiting *de novo* GSH biosynthesis reveals a mechanism of cancer vulnerability and an improved GCL inhibitor is highly desired for treating tumors that are sensitive to oxidative stress.

2.3 Results

2.3.1 Identification and characterization of a GCL inhibitor

In this study, we screened a library of 679 cysteine-reactive covalent fragment ligands against pure human GCLC and GCLM protein in an activity assay to look for ligands that inhibit GCL function. This assay reads out a derivatized form of the GCL product, gamma-glutamylcysteine via colorimetry. Compounds that showed >80% inhibition of activity were next examined for potency via dose-dependent activity assays. Through this screen, we identified the acrylamide EN25 to be a top hit that dose-responsively inhibited GCL activity with a 50% inhibitory concentration (IC50) of 16μM. **(Fig. 2.1a-c).**

We next sought to identify the site of EN25 modification on the GCL protein complex by performing LC-MS/MS analysis of tryptic digests from GCLC and GCLM labeled with EN25. We identified selective and covalent EN25 modification of C114 on GCLM. This modification had not been previously detected in our ligandability database and thus presented a new ligandable hotspot within GCL. Given that GCLM is the regulatory subunit of the GCL complex, we postulate that covalent targeting of C114 results in allosteric inhibition of GCLC catalytic enzyme activity. **(Fig. 2.1d).**

To further demonstrate covalent modification of this scaffold with GCLM, we synthesized an alkyne-functionalized analog of EN25, EN25-alkyne. We first treated GCL with EN25 and then EN-25 alkyne which was then subjected to copper-catalyzed click reaction for appending rhodamine. We saw that this probe showed covalent labeling of GCLM and dose-responsive competition by EN25. The EN25-alkyne also demonstrated an IC50 for GCL activity of 3.6 μM. All together, these experiments suggest that this alkyne probe can be used as a tool to enable competitive chemoproteomic studies. **(Fig. 2.1e-f).**

2.3.2 Chemoproteomic studies of EN25 in cellular models to look at EN25 selectivity

Previous studies have used A2780 and RMG-1 ovarian cancer cells as representative ARID1A-deficient and ARID1A-positive cells to demonstrate ARID1A-deficiency-mediated susceptibility to glutathione synthesis inhibition.[32] The A2780 model cell line expresses lower levels of SLC7A11 and has reduced cystine transport. Cystine, once reduced to cysteine, is used by a multitude of antioxidant molecules beyond just GSH[81].

Limiting these other antioxidants along with GSH will enhance the effects we see when targeting the GSH pathway.

To understand the proteome-wide selectivity of EN25 and identify potential off-targets, we next performed cysteine chemoproteomic profiling using isoTOP-ABPP [7,8,17,82]. The isoTOP-ABPP is a competitive assay between a covalently-acting molecule and a broader reactive probe, which enables read-out of potential EN25-targeting hotspots. As such, we treated A2780 ARID1A-negative cancer cells with either vehicle or EN25, and subsequently treated resulting cell lysates with the alkyne functionalized cysteine-reactive iodoacetamide probe, after which isotopically encoded cleavable biotin-azide enrichment handles were appended onto probe-labeled proteins by click-chemistry, and subjected to avidin-enrichment, tryptic digestion, elution of probe-modified tryptic peptides, and analysis by quantitative proteomic methods. We identified >10,000 peptides bearing light or heavy IA-alkyne-modified cysteines, with 9 targets showing >4 light:heavy ratios. While we were not able to identify a probe-modified tryptic peptide encompassing C114 of GCLM, these nine potential off-targets of EN25 out of >5000 cysteines within proteins quantified in cells **(Fig. S2; Table S2)** indicate a moderate off target profile. These nine targets included HNRNPA3 C85, MTHFD1L C779, C9Orf142 C180, SIRT6 C18, GPKOW C137, PNN C439, ALDH7A1 C478, NUP85 C515, and U2URP C62. None of these nine off-targets were likely to influence glutathione metabolism, nor act directly in antioxidant compensatory pathways in cancer cells, so we deemed this overall selectivity to be sufficient for follow-up studies.

2.3.3 Characterizing the anticancer activity of EN25 in a cellular model

Given that ARID1A-negative cancer cells have been previously shown to be more susceptible to inhibition of glutathione synthesis compared to ARID1A-positive cancer cells, we next sought to determine whether EN25 selectively impairs cell viability of ARID1A-negative A2780 ovarian cancer cells, compared to ARID1A-positive RMG-1 ovarian cancer cells. Consistent with this premise, RMG-1 cancer cells showed resistance to EN25-mediated cell viability impairments compared to the more sensitive A2780 cancer cell line **(Fig. 2.2a).** We still observe impairments in cell viability with EN25 in RMG-1 cells which may be through other cellular targets of EN25 beyond GCLM.

To quantitatively measure changes in GSH in the cell, we use single reaction monitoring (SRM)-based LC-MS/MS to profile GSH metabolites after EN25 treatment. We further demonstrated that EN25 significantly lowered GSH levels in A2780 cancer cells compared to no changes observed in RMG-1 cells **(Fig. 2.2b).** These differences were not due to variation in GCLM expression between A2780 and RMG-1 cells as evidenced by Western blotting of the cells **(Fig. S3).**

We next hypothesized that GCL inhibition and depletion of cellular GSH levels with EN25 treatment in ARID1A-negative cancer cells would lead to accumulation of oxidative stress and lipid peroxidation, two hallmarks of ferroptosis-mediated cell death. To test this, we pre-treated A2780 cancer cells with a ferroptosis inhibitor, ferrostatin, before treatment with EN25. Consistent with our hypothesis, we saw that ferrostatin

treatment attenuated the cell viability impairments conferred by EN25 treatment in A2780 cancer cells **(Fig. 2.2e**). These results indicate that EN25 impairs cancer cell proliferation, at least partially, through ferroptosis-mediated mechanisms.

To confirm that the effects we observed were through on-target activity, we sought to see if GCLM knockdown with siRNA affected cell viability. With a knockdown of ~83% of GCLM, A2780 cells showed hypersensitivity to EN25 treatment and impaired cell viability compared to non-targeting siControl A2780 cells **(Fig. 2c-2d).** GCLM knockdown with siRNA did not impair A2780 cell viability by itself, potentially because of partial knockdown of GCLM or insufficient duration of GCLM knockdown.

2.3.4 SAR studies to optimize potency and selectivity of EN25

We also explored structure-activity relationship of EN25 analogs that were commercially available to inform future medicinal chemistry efforts. Through testing of 12 EN25 analogs that were commercially obtained through Enamine, we found a few analogs with improved potency. EN25-7 and EN25-8 showed the best inhibitory potency against GCL with IC50s of 8.9 and 6.8 µM, respectively **(Fig. 2.3).** We also demonstrated that the structurally related analog EN25-12 can serve as a potential negative control compound for EN25. EN25-12 does not inhibit GCL activity with an IC50 >50 µM and does did not show impaired cell viability or reductions in GSH levels **(Fig. S4).** We further showed that EN25-7 and EN25-9 reduced GSH levels in A2780 at the 2 h timepoint **(Fig. S5)**.

As previously mentioned, we postulated EN25 to allosterically disrupt GCL activity. To investigate whether EN25 or similar analogs manifests this effect through disrupting GCL holoenzyme formation, we did a preliminary test to see if we can pull-down GCLC with overexpressed GCLM in HEK cells. Taking EN25, EN25-7 and EN25-9, we treated HEK cells overexpressing GCLM-FLAG to see if endogenous GCLC could be pulled down through a co-immunoprecipitation experiment. We did not see reduction of GCLC after the pulldown, suggesting that at the 1 hour timepoint, EN25 and its analogs do not seem to disrupt GCLM binding to GCLC **(Fig. S6).**

2.4 Conclusion

In this study, we aimed to target *de novo* glutathione synthesis in cancer cells sensitive to oxidative stress, by targeting the first enzyme involved in glutathione synthesis, GCL. To achieve this, we used a cysteine-reactive covalent ligand library to functionally screen for GCL inhibitors. We have discovered a novel GCL inhibitor, EN25 that uniquely inhibits GCL activity through allosteric and covalent targeting of C114 on the regulatory GCLM subunit. Using a variety of biochemical and cell-based assays, we demonstrate that EN25 inhibits GCL activity, lowers glutathione levels and impairs cancer cell proliferation, preferentially in ARID1A-negative cancer cells through in-part a ferroptosis-mediated mechanism. EN25 represents a novel ligand and C114 on GCLM represents a novel ligandable site for inhibiting GCL activity. Through a small-scale SAR study, we identified additional covalent ligands with moderately enhanced binding

affiliity *in vitro*. Additionally, the EN25-alkyne probe can be used as a tool for future chemoproteomic studies and EN25-12 as a promising negative control.

2.5 Figures
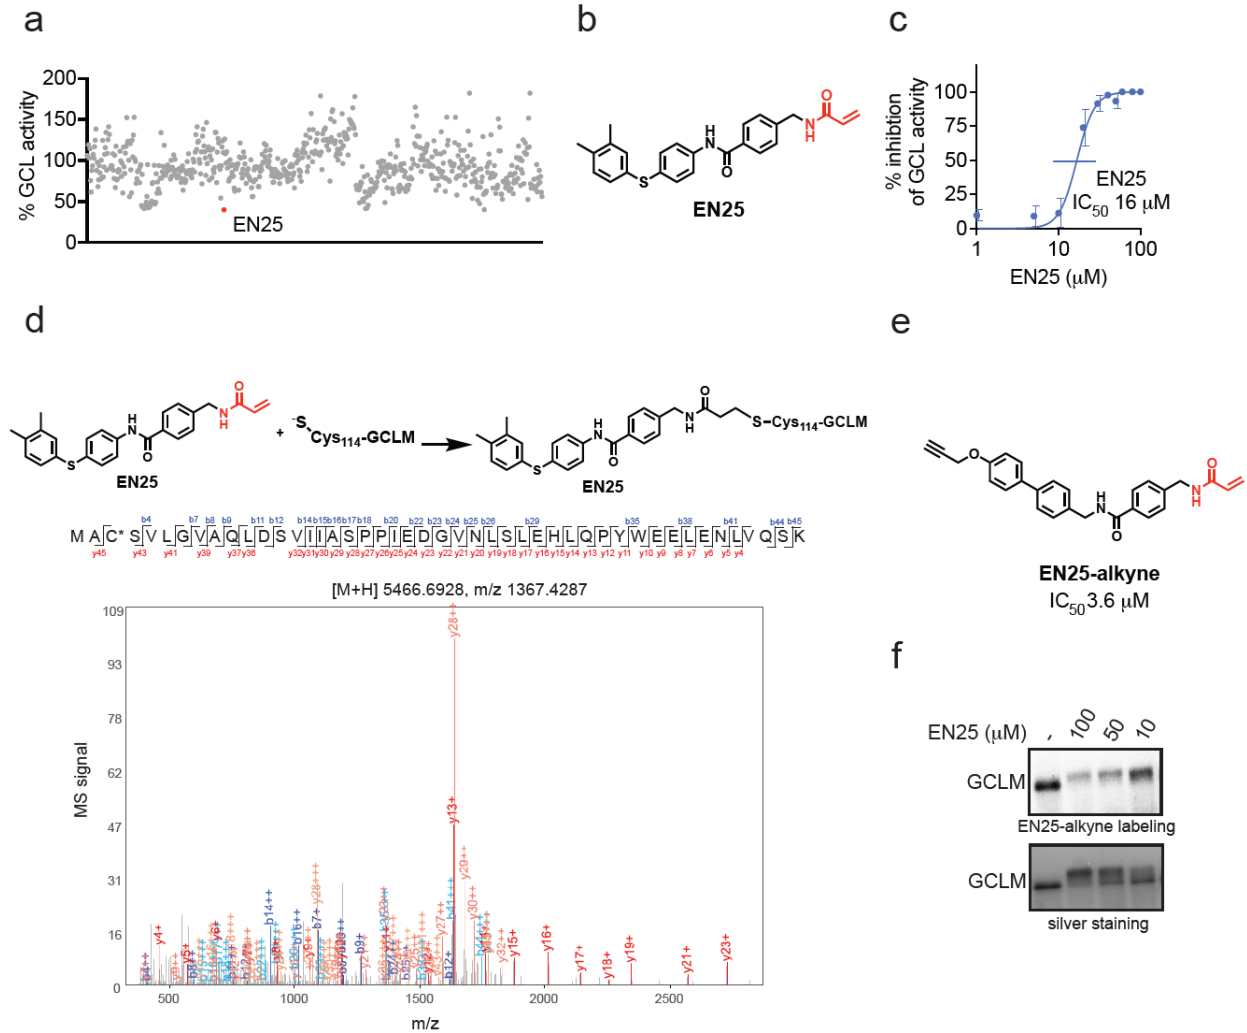

Figure 2.1. Identification of a covalent inhibitor of the GCL complex. (a) A functional screen of cysteine-reactive covalent ligands against GCL to look for inhibition of GCL activity. Pure GCL protein was incubated with its substrates, cofactors, and DMSO vehicle or covalent ligand. The product, gamma-glutamylcysteine (GluCys), was converted to a derivative of 2,3-napthalenedicarboxaldehyde (NDA), NDA-GluCys, to enable a colorimetric readout of product formation. The top hit, EN25, is shown in red. (b) Structure of EN25 with the cysteine-reactive acrylamide moiety highlighted in red. (c) EN25 showed an IC$_{50}$ of 16 µM on GCL activity. (d) MS/MS analysis of EN25 adduct on the GCL complex showed that EN25 modifies C114 on GCLM. Pure human GCLM and GCLC were incubated with EN25 (50µM) for 30 min at 37°C. The GCL complex was then subjected to tryptic digestion, and tryptic digests were analyzed by LC-MS/MS. (e) Structure of the alkyne-functionalized analog of EN25 (EN25-alkyne) that demonstrated an IC$_{50}$ of 3.6 µM on GCL activity. (f) Gel-based ABPP showing that EN25 displaces

EN25-alkyne labeling of pure human GCLM protein. GCLM was pre-incubated with DMSO vehicle or EN25 for 30 min at 37°C, prior to EN25-alkyne labeling (50 μM final) for 2 h at 37°C. Rhodamine-azide was appended to probe-modified protein by Copper-catalyzed azide-alkyne cycloaddition (CuAAC), subjected to SDS/PAGE, and analyzed by in-gel fluorescence. Shown below is a silver stain of the gel to show equal protein loading. Graph shown in (a) is representative of n=2 biologically independent replicates/group and percentage values for each compound and structures of compounds screened are listed in Table S1. Graph shown in (c) is representative of n=4 biologically independent replicates/group. Gel shown in (f) is representative of n=3 biologically independent replicates/group.
Figure 2.2. Characterizing the effect of EN25 on GCLM and glutathione (GSH) levels *in vitro*. (a) EN25 impairs A2780 cell viability over RMG-1 cell viability. Cells were treated with DMSO vehicle or EN25 and cell proliferation was assessed by Hoechst staining at 24 hr. (b) EN25 selectively reduces GSH levels in A2780 over

RMG-1 cell lines. Cells were treated with DMSO vehicle or EN25 and GSH levels were detected by SRM LC-MS/MS 4hr post treatment. (c-d) GCLM knockdown with siRNA in A2780 cells confers hypersensitivity to EN25-mediated cell viability impairments. A2780 cells were transfected with siControl or siGCLM for transient knockdown and used for experiments 48 hr after transfection. (c) Western blot for GCLM and loading control GAPDH in transfected A2780 cells. (d) Cell proliferation of siGCLM A2780 cell lines compared to siControl A2780 cell lines after 24 hr treatment with EN25. Proliferation was measured by Hoechst staining. (e) Ferrostatin-1 attenuates EN25-mediated cell viability impairments in A2780. A2780 cells were treated with DMSO vehicle or 2 µM of Ferrostatin-1 immediately prior to DMSO vehicle or EN25 treatment. Cell viability was measured at 48 hr with Hoechst staining. Data in (a, b, c, d, e) are shown as percentage compared with DMSO vehicle control and show average ± sem of n=6 for (a, c, d, e) and n=3 for (b) biologically independent replicates/group. Statistical significance is calculated as *$p < 0.05$ compared to DMSO vehicle and #$p < 0.05$ compared to cells treated with EN25 alone. Blot shown in (c) is representative of n=3 biologically independent replicates/group.

a
Figure 2.3. Structures of EN25 analogs and associated IC$_{50}$ values for GCL inhibition. (a) Structures of EN25 analogs with the cysteine reactive acrylamide moieties highlighted in red. The associated IC$_{50}$ values listed below were determined via the functional assay described in (Fig. 1a).

15
Figure S1. An additional MS/MS spectra of an EN25 adduct on the GCL complex showing that EN25 modifies C114 on GCLM. Pure human GCLM and GCLC were incubated with EN25 (50µM) for 30 min at 37°C. The GCL complex was then subjected to tryptic digestion, and tryptic digests were analyzed by LC-MS/MS.
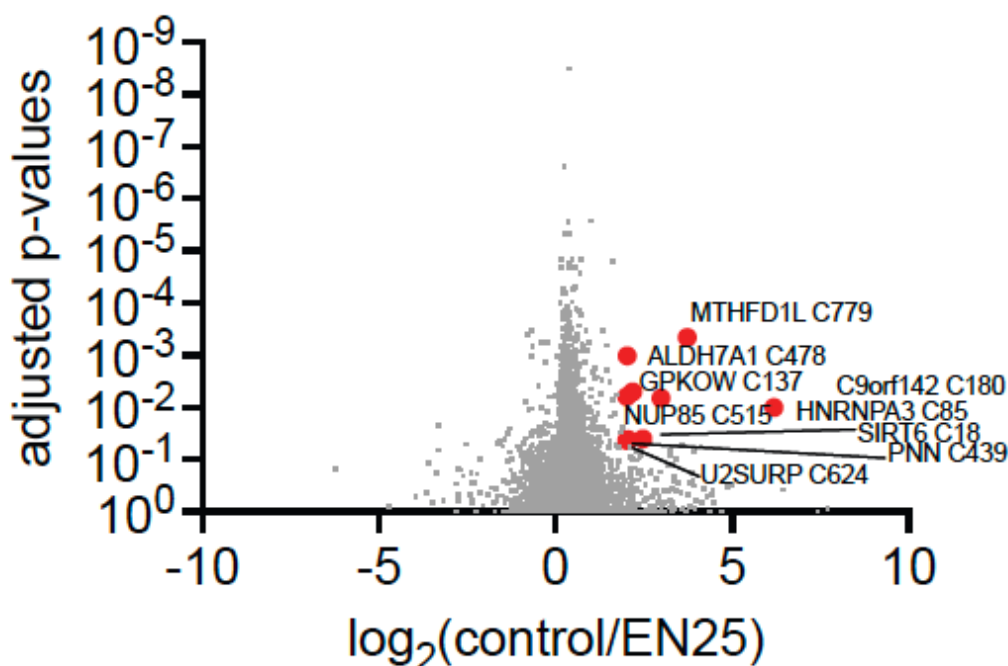

Figure S2. isoTOP-ABPP analysis of EN25 in A2780 ovarian cancer cells. A2780 cells were treated *in situ* with DMSO vehicle or EN25 (50 µM) for 90 min prior to labeling of the proteomes ex situ with IA-alkyne (100 µM) for 1 hr. Isotopically light (for DMSO-treated) or heavy (for compound-treated) TEV protease-cleavable biotin-azide tags were appended by CuAAC and probe-labeled proteomes were mixed in a 1:1 control/treated ratio, enriched with avidin, digested with trypsin, and eluted with TEV protease for isoTOP-ABPP analysis. Shown are control versus EN25 probe-modified peptide ratios and adjusted p-values for peptides identified in at least 2 out of the 4 biological replicates/group. Shown in red are the modified residues of targets that showed >2-fold control/EN25 ratio with adjusted $p < 0.05$. Raw proteomic data is in Table S2.
Figure S3. GCLM expression in RMG-1 and A2780 cells. GCLM and loading control GAPDH levels in RMG-1 and A2780 cells assessed by Western blotting. Shown is a representative blot from n=3 biological replicates/group.

17
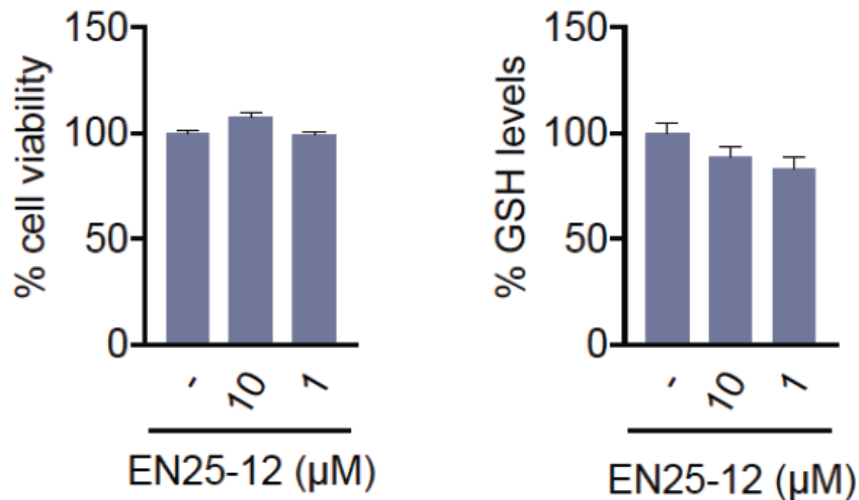

Figure S4. Cell viability and GSH levels with EN25-12 treatment in A2780 cells.
A2780 cells were treated with DMSO vehicle or EN25-12 for 4 h and cell viability and
GSH levels were assessed. Data shown are average ± sem of n=6 biologically
independent replicates/group.
Figure S5. GSH Levels with EN25-7 and EN25-9 treatment in A2780 cells. A2780
cells were treated with DMSO vehicle or EN25-7 and EN25-9 for 2 h and GSH levels
were assessed. Data shown are average ± sem of n=6 biologically independent
replicates/group.
Figure S6. Flag pulldown of GCLM in HEK lysates with EN25, EN25-7, and EN25-9 treatment. HEK cells overexpressed with a GCLM-Flag tag construct were treated with DMSO vehicle, EN25, EN25-7, or EN25-9 for 1 h. The HEK cell lysates were incubated with Flag-agarose slurry for 1.5hr and washed with PBS before elution with 3 x FLAG peptide. GCLM, GCLC, and loading control GAPDH levels before and after the pulldown were assessed by Western blotting. Shown is a representative blot from n=3 biological replicates/group.

2.6 Methods

Cysteine-reactive covalent ligand libraries purchased from Enamine or their synthesis were previously described [83–86]. Their structures are all shown in Table S1. EN25 was purchased from Enamine (catalog number EN300-6724985).

2.6.1 Cell Culture

A2780 cells (obtained from Sigma-Aldrich, 93112519-1VL) were cultured in RPMI-1640 Medium containing 10% (v/v) fetal bovine serum (FBS) and 10mM glutamine and maintained at 37°C with 5% CO2. RMG-1 cells (obtained from Fisher Scientific, NC0992912) were cultured in Ham's F12 Medium containing 10% (v/v) fetal bovine serum (FBS) and 10mM glutamine and maintained at 37°C with 5% CO2. HEK cells (obtained from American Type Culture Collection) were cultured in DMEM Medium containing 10% (v/v) fetal bovine serum (FBS) and 10mM glutamine and maintained at 37°C with 5% CO2.

2.6.2 GCL Functional Assay Screen

GCL activity was determined by the fluorescence assay described by Chen et al.[87] For the activity assay screen, pure human recombinant GCLC (0.05µM) and GCLM (0.1µM) protein (obtained from Ono Pharmaceuticals) were mixed in PBS and aliquoted into a

96-well v-bottom assay plate (Corning, P-96-450V-C) in a total volume of 20µl. Covalent ligands or DMSO vehicle were then added (0.5 µl) to the protein and incubated for 30 minutes at 37ºC. Next, 20 µl of GCL-reaction cocktail [400 mM Tris-HCl, 40 mM adenosine triphosphate (ATP), 40 mM L-glutamic acid, 2 mM EDTA, 20 mM sodium borate, 2 mM serine and 40 mM $MgCl_2$] was added to each well and incubated at 37°C for 5 min. The reaction was initiated with 20 µl of 30 mM cysteine solution (dissolved in TES/SB buffer) and the mixtures were incubated at 37°C for 15 min. The GCL reaction was stopped by precipitation of proteins with 200 mM 5-sulfosalicylic acid (Sigma Aldrich, 247006) and then put onto ice for 20 min. Afterwards, the mixtures were centrifuged at 2,500 rpm at 4°C for 10 min and 20 µl of the supernatant that contained the γ-glutamylcysteine (γ -GC) product was added to a half-area black 96-well plate (Corning, 3904). For fluorescence detection, 100 µl 2,3-naphthalenedicarboxyaldehyde (NDA) solution [50 mM Tris, pH 10, 0.5 N NaOH, and 10 mM NDA in Me2SO, v/v/v 1.4/0.2/0.2] was added into each well and incubated in the dark at room temperature for 30 min. The formation of NDA-γ-GC was measured (472 nm excitation/528 nm emission) using a fluorescent plate reader (Spark; Tecan Group Ltd.).

2.6.3   LC/MS-MS Analysis of EN25 Interactions with GCLC/GCLM

The GCL complex made in a 2:1 GCLM:GCLC molar ratio totaling 50 µg in 50 µL PBS was incubated for 30 min at 37°C with EN25 (50 µM). To precipitate the protein, 10 µL of 100% (w/v) TCA was added to the sample which was then cooled to -80 °C for 1 h. The sample was then spun at 20,000 x g for 10 min at 4°C and washed three times with ice cold 0.01 M HCl/90 % acetone solution. The pellet was resuspended in 4 M urea containing 0.1 % Protease Max (Promega Corp. V2071) and diluted in 40 mM ammonium bicarbonate buffer. Next, the sample was reduced with 10µl of 10 mM TCEP and incubated at 60 °C for 30 min. Afterwards, 10µl of 150mM iodoacetamide was added and incubated at room temperature for 30 minutes. The sample was then diluted 50% with PBS before addition of sequencing grade trypsin (1 µg per sample, Promega Corp, V5111) and incubated overnight at 37 °C. The next day, formic acid was added to the samples to a final concentration of 5 % and centrifuged at 13,200 rpm for 30 min at room temperature. The supernatant was transferred to a new tube and stored at -80°C until MS analysis and was analyzed as previously described, wherein a search was ran for the predicted mass adduct on cysteines [86,88].

2.6.4   Cell Viability Assessment

Cell viability assays were performed using Hoechst 33342 dye (Invitrogen, H3570) according to the manufacturer's protocol and as previously described [85]. Cells were seeded into 96-well plates (6,000 per well) in a total volume of 200 µL and left to adhere overnight. Cells were treated with 1 µL of compound working stock or DMSO vehicle. After the appropriate incubation period, media was aspirated from each well and 100 µL of staining solution containing 10% formalin and Hoechst 33342 dye was added to each well and incubated in the dark for 15 min at room temperature. Staining solution was removed, and wells were washed three times with PBS before fluorescent reading (Spark; Tecan Group Ltd.).

2.6.5 LC-MS/MS-Based Quantification of GSH Levels in Cells

Cells were seeded into 6 cm dishes at $2x10^6$ million cells per well in 2 mL and allowed to adhere overnight. Cells were treated the next day with DMSO or EN25 for 4 h before harvesting on ice with PBS. Cells were lysed by probe sonication and pelleted by centrifugation. Pellets were frozen at -80°C for one hour. For polar extraction, 180µl of 40:40:20 acetonitrile:methanol:water was added to each frozen cell pellet on dry ice. An internal standard of L-Serine-^{15}N,d_3 (1 nmole final, Cambridge Isotope Labs, DNLM-6863) was added to each sample. Precipitated proteins and lipids were pelleted by centrifugation at 16,000 x g for 10 min. The supernatant was then transferred into a polyspring insert inside an LC-MS/MS vial, briefly vortexed, and ran through a QQQ mass spec through a C18 reverse phase column (Phenomenex, 00B-4435-E0) at a 0.7ml/min flow rate. GSH levels were detected by single reaction monitoring (SRM) and normalized to internal standard and compared against GSH levels in DMSO-treated controls. Data was analyzed as previously reported [28][28].

2.6.6 Determining GSH Levels using the GSH-Glo Kit

To assess cellular glutathione levels, we used the GSH-Glo™ Glutathione Assay Kit (Promega, V6911) and the protocol was followed as described in the manufacture's instructions. Cells were seeded into flat white 96-well plates (Corning, 3917) at 6,000 cells per well in 200 µL and allowed to adhere overnight. Cells were then treated with DMSO vehicle or compound. After the appropriate treatment time, media was aspirated from each well before addition of 1X GSH-Glo™ Reagent (100 µl) and incubated at room temperature for 30 minutes on a plate shaker. Next, Luciferin Detection Reagent (100 µl) was added to the wells and the plate was incubated at room temperature for 15 minutes on a plate shaker before measurement of luminescence with a plate reader.

2.6.7 Gel-based ABPP

Gel-based ABPP methods were performed as previously described [86]. Recombinant pure human GCLM (0.1 µg), provided by from Ono Pharmaceuticals, was pre-incubated with DMSO vehicle or EN25 (10-100µM final concentration) for 30min at 37°C, prior to labeling by the covalently-acting EN25-alkyne probe (50µM) for 2 hr in a volume of 50µL of PBS. CuAAC was performed to append rhodamine-azide (1 mM final concentration) onto alkyne probe-labeled proteins. Samples were then diluted with 30 µL of 4 x reducing Laemmli SDS sample loading buffer (Alfa Aesar) and heated at 90 °C for 5 min. The samples were separated on precast 4-20% TGX gels (Bio-Rad Laboratories, Inc.) and scanned using a ChemiDoc MP (Bio-Rad Laboratories, Inc).

2.6.8 Silver staining

Silver staining of pure protein was performed according to the manufacturer's protocol to detect total protein on polyacrylamide gels (Pierce, PI24612). Briefly, gels were fixed in 30:10 ethanol:acetic acid solution for 2 x 15 minutes and washed with 10% ethanol for 2 x 5 minutes and then milliQ water for 2 x 5 minutes. Gels were sensitized with

Sensitizer solution for 1 minute before 2 x 1 wash with water. Gels were stained for 30 minutes with the Stain solution before development with Developer. Development was stopped with 5% acetic acid for 10 minutes before imaging.

2.6.9 IsoTOP-ABPP Chemoproteomic Profiling

IsoTOP-ABPP studies were done as previously reported[17,82,85,90]. Cells were seeded and grown to a confluency of approximately 90% and treated for 90 min with either DMSO vehicle or EN25 before harvest and lysis. Cells were lysed by probe sonication in PBS and protein concentrations were measured by a bicinchoninic acid (BCA) assay and normalized to 4 mg/ml. Proteomes were subsequently labeled with 100 µM of a cysteine-reactive alkyne functionalized iodoacetamide probe (IA-alkyne) for 1 hour at room temperature. CuAAC was performed by sequential addition of 1 mM TCEP (Sigma), 34mM tris((1-benzyl-1H-1,2,3-triazol-4-yl)methyl)amine, 1mM copper(II) sulfate, and a functionalized biotin-linker-azide with a TEV protease recognition sequence containing an isotopically light (for control) or heavy (for treatment) valine. Following CuAAC, proteomes were precipitated by centrifugation at 6500 x g, washed in ice-cold methanol, combined in a 1:1 control/treated ratio, washed again, then denatured and resolubilized by heating in 1.2 % SDS/PBS to 80°C for 5 minutes. Insoluble components were precipitated by centrifugation at 6500 x g and the soluble proteome was diluted in 5 ml 0.2% SDS/PBS. Avidin-agarose beads (Thermo Pierce, PI20349) were added to the labeled proteins and samples were rotated overnight at 4°C to encourage binding. Bead-linked proteins were enriched by washing three times each in PBS and water, then resuspended in 6 M urea/PBS (Sigma) and reduced in 1 mM TCEP, alkylated with 18 mM iodoacetamide (IA) (Sigma, 786-228), then washed and resuspended in 2 M urea and trypsinized overnight with 0.5 µg/µl sequencing grade trypsin (Promega, V5111). Tryptic peptides were eluted off with spin columns (BioRad, 7326204) under a vacuum manifold. Beads were then washed three times each in PBS and water, washed in TEV buffer solution (water, TEV buffer, 100 µM dithiothreitol), and resuspended in buffer with Ac-TEV protease and incubated overnight. Peptides were diluted in water and acidified with 1.2M formic acid (Thomas Scientific, A11750) in preparation for mass spectrometry analysis.

2.6.10 IsoTOP-ABPP Mass Spectrometry Analysis

Peptides from all chemoproteomic experiments were pressure-loaded onto a 250 µm inner diameter fused silica capillary tubing packed with 4 cm of Aqua C18 reverse-phase resin (Phenomenex, 04A-4299), which was previously equilibrated on an Agilent 600 series high-performance liquid chromatograph using the gradient from 100% buffer A to 100% buffer B over 10 min, followed by a 5 min wash with 100% buffer B and a 5 min wash with 100% buffer A. The samples were then attached using a MicroTee PEEK 360 µm fitting (Thermo Fisher Scientific p-888) to a 13 cm laser pulled column packed with 10 cm Aqua C18 reverse-phase resin and 3 cm of strong-cation exchange resin for isoTOP-ABPP studies. Samples were analyzed using an Q-Exactive Plus mass spectrometer (Thermo Fisher Scientific) using a five-step Multidimensional Protein Identification Technology (MudPIT) program, using 0, 25, 50, 80 and 100% salt bumps

of 500 mM aqueous ammonium acetate and using a gradient of 5–55% buffer B in buffer A (buffer A: 95:5 water:acetonitrile, 0.1% formic acid; buffer B 80:20 acetonitrile:water, 0.1% formic acid). Data were collected in data-dependent acquisition mode with dynamic exclusion enabled (60 s). One full mass spectrometry (MS1) scan (400–1,800 mass-to-charge ratio (m/z)) was followed by 15 MS2 scans of the nth most abundant ions. Heated capillary temperature was set to 200 °C and the nanospray voltage was set to 2.75 kV. Data were extracted in the form of MS1 and MS2 files using Raw Extractor v.1.9.9.2 (Scripps Research Institute) and searched against the Uniprot human database using ProLuCID search methodology in IP2 v.3v.5 (Integrated Proteomics Applications, Inc.) (Xu et al., 2015). Cysteine residues were searched with a static modification for carboxyaminomethylation (+57.02146) and up to two differential modifications for methionine oxidation and either the light or heavy TEV tags (+464.28596 or +470.29977, respectively). Peptides were required to be fully tryptic peptides and to contain the TEV modification. ProLUCID data was filtered through DTASelect to achieve a peptide false-positive rate below 5%. Only those probe-modified peptides that were evident across two out of three biological replicates were interpreted for their isotopic light to heavy ratios. For those probe-modified peptides that showed ratios greater than two, we only interpreted those targets that were present across all three biological replicates, were statistically significant and showed good quality MS1 peak shapes across all biological replicates. Light versus heavy isotopic probe-modified peptide ratios are then calculated by taking the mean of the ratios of each replicate paired light versus heavy precursor abundance for all peptide-spectral matches associated with a peptide. The paired abundances were used to calculate a paired sample t-test P value to estimate constancy in paired abundances and significance in change between treatment and control. P-values were corrected using the Benjamini–Hochberg method.

2.6.11 GCLM Knockdown Studies

RNAi was performed by using siRNA purchased from Dharmacon specific to GCLM. A2780 cells were seeded at a density of 3x10^5 cells per mL in a 6-well format and allowed to adhere overnight. The next day, cells were transfected with 25 nM of small interfering RNA (siRNA) to GCLM (Dharmacon L-011670-01-0005) or a non-targeting negative control (ON-TARGETplus Non-targeting Control Pool, Dharmacon #D-001810-10-05) using 50 nM of DharmaFECT4 (Horizon Discovery, T-2005-01) as a transfection reagent. Transfection reagent was added to OPTIMEM (ThermoFisher, 31985070) media and allowed to incubate for 5 min at room temperature. Meanwhile, siRNA was added to an equal amount of OPTIMEM. Solutions of transfection reagent and siRNA in OPTIMEM were then combined and allowed to incubate for 30 minutes at room temperature. These combined solutions were diluted with complete DMEM to provide 200µl per well, and the media was exchanged. After 48 h, cells were supplemented with DMSO or compound and cultured for an additional 24 to 48 h before undergoing cell viability testing as described above. Cells were then harvested, and lysates were obtained to analyze protein abundance via Western blotting.

2.6.12 Western Blots and Quantification

Proteins were resolved by SDS/PAGE and transferred to nitrocellulose membranes (BioRad, 1704159) using the Trans-Blot Turbo transfer system (Bio-Rad). Membranes were blocked with 5% BSA in Tris-buffered saline containing Tween 20 (TBST) solution for 1 hr at RT, washed in TBST, and probed with primary antibody diluted per recommended manufacturer procedures in 5% TBST and incubated while rotating overnight at 4℃. After 3 washes with TBST, the membranes were incubated in the dark with IR680- or IR800-conjugated secondary antibodies (LI-COR) at 1:10,000 dilution in 5% BSA in TBST at RT for 1 h. After 3 additional washes with TBST, blots were visualized using an Odyssey Li-Cor Clx fluorescent scanner. Antibodies used in this study were Rb to GCLM (Abcam, ab126704), Rb to GCLC (Abcam, ab190685), Ms to GAPDH (Proteintech Group Inc., 60004-1-Ig), IRDye 680RD Goat anti-Mouse (LI-COR 926-60870), and IRDye 800CW Goat anti-Rabbit (LICOR 926-32211). Band quantification was performed using ImageJ software.

2.6.13 Ferrostatin Rescue Experiments

Cells were seeded in a 96 well plate at 10,000/well in a 200 µl volume and allowed to adhere overnight. Ferrostatin-1 (Cayman chemicals, 17729) was added to the wells (2µM final) at 2µl and followed with addition of 2µl of EN25 (50µM final) or DMSO vehicle. Cells were incubated at 37°C for varying time points before proliferation was assayed by Hoechst staining.

2.6.14 Transfection of GCLM-FLAG for overexpression in HEK Cell Lines

Human GCLM with a C-terminal FLAG tag and a CMV promoter (Origene, RC207224) was transfected into a 15 cm plate of HEK 293 cells using Lipofectamine 3000 transfection reagent (ThemoFischer, 11668019). Briefly, 28 µg of plasmid and 56 µL of P3000 was mixed with 650 µL of Opti-MEM medium in one tube, and Lipofectamine 3000 reagent (43.4 µL) was diluted in 650 µL of Opti-MEM medium and incubated in a second tube for 5 minutes before addition to the first tube. The DNA-lipid complex was allowed to form for 30 min before addition of 6mL of DMEM to the tube and subsequent addition to the cells. Expression of GCLM-FLAG was evaluated by Western blot.

2.6.15 GCLM-FLAG Pulldown

HEK 293 cells expressing GCLM-FLAG were seeded into a 15 cm plate. Cells were treated at 80% confluency with either DMSO vehicle or compound (10µM) for 1 hr. Cells were harvested in PBS and lysed by sonication. Clarified lysates were incubated 1.5 hr at 4 °C with 30 µL of FLAG-agarose slurry. After incubation, samples were spun down and washed 4 times with 1 mL PBS. Proteins were eluted using 3 x 500µL washes of PBS supplemented with 800 ng/µL 3 × FLAG peptide (ApexBio A6001). Loading buffer was added to the samples and levels of protein after pulldown were evaluated via Western blot.

2.7 Author contributions

LZ, DKN conceived of the project idea, designed experiments, performed experiments, analyzed and interpreted the data, and wrote the paper. MT, XT, QS, VT, SS, MK, WI, TI designed and performed experiments and analyzed and interpreted the data. Most notably, QS, XT, VT synthesized compounds for the paper and SS, MK, WI, TI, designed, expressed, purified, and validated proteins for the paper.

2.8 Acknowledgements

Chapter 3: Final Remarks

Many forms of cancer still lack targeted therapies that are effective and have high response rates. Even with the completion of the Human Genome Project nearly two decades ago—a huge feat that aided scientists in mapping genes related to cancer—the development of drugs against these gene products has not been as proliferative. This is in part because many of these proteins are considered "undruggable," meaning they do not possess well-defined binding pockets, or lack functional assays amenable for HTS. However, chemoproteomics and fragment-based covalent ligand libraries have proven to overcome some of these challenges, providing more efficient pathways in drug discovery.

In this study, we used fragment cysteine-reactive-ligand screening and chemoproteomic approaches to identify new covalent inhibitors against GCL. Inhibiting GCL to reduce GSH levels has shown potential in inducing death specifically in cancer cells sensitive to oxidative stress. Here, we introduced EN25 as an acrylamide-containing cysteine-reactive ligand that covalently targets cysteine C114 on GCLM (the modifier subunit of GCL). We show that this interaction leads to the inhibition of GCL activity, resulting in reduced cellular GSH levels and a decrease in cell viability. These effects are specifically observed in ARID1A-deficient cancer cells, which are particularly sensitive to glutathione depletion, while ARID1A-positive cancer cells remain unaffected by EN25. We also conducted a small-scale structure-activity relationship (SAR) study, revealing additional covalent ligands with moderately improved binding affinity *in vitro*. Our research highlights a previously undiscovered binding site within GCLM that can be targeted to disrupt GSH synthesis in susceptible cancer cell types.

We show promise in the fragment screening approach to identify small molecules that can be built upon either for lead optimization or tool development. The fragment small molecule EN25 directed SAR studies with a more focused set of analog fragments to unveil higher potency inhibitors—an indication that larger analog libraries and medicinal chemistry efforts could further improve EN25's selectivity and affinity. The EN25-alkyne was developed as an activity-based probe, a tool for investigating GCLM in future chemoproteomic studies through biorthogonal labeling of the proteome. Meanwhile, using isoTOP-ABPP enabled the chemoproteomic profiling of EN25 off-targets, which will aid pharmacological development and mechanistic studies. In summary, this research not only opens the therapeutic door to the modification of GCL with tractable covalent ligands, but also underscores the remarkable potential of chemoproteomic and covalent fragment-ligand-based approaches in driving the future of drug discovery against cancer targets.

Appendices

A. Synthetic Methods and Characterization
EN-25 Alkyne probe

Procedure for the preparation of EN25 Alkyne probe:
Add the phenol compound (976 mg, 1 equiv.) and K_2CO_3 (1.5 g) to acetone (6 ml) and stirred briefly. Then add propargyl bromide (0.753 ml, 2 equiv.) dropwise and heated reaction to reflux at 70 degrees. After overnight, the reaction is cooled to room temperature and quenched with water, extracted with DCM, washed with brine, then dried over $MgSO_4$. After filter and concentration, the pale-yellow solid product was recrystallized from hot EtOH. The product was concentrated under vacuum.

LAH (3 ml of 2.0 M in THF) was added slowly to the nitrile compound (700 mg) in dry THF under N_2 at 0 °C, stirred for 6 h. Then quenched with water, filtered over celite, washed with water, extracted with EtOAc, washed with brine, then dried over $MgSO_4$. After filter and concentration, the product was purified by silica gel chromatography (0-10% MeOH in DCM). Yield of two steps is 50%.

(4'-(prop-2-yn-1-yloxy)-[1,1'-biphenyl]-4-yl)methanamine

^{1}H NMR (500 MHz, MeOD) δ 7.62 – 7.48 (m, 4H), 7.40 (d, J = 8.3 Hz, 2H), 7.07 (d, J = 8.7 Hz, 2H), 4.77 (d, J = 2.2 Hz, 2H), 3.84 (s, 2H). ^{13}C NMR (126 MHz, MeOD) δ 157.27, 140.43, 139.33, 134.02, 127.57, 127.45, 126.34, 114.94, 55.28, 44.89. MS (ESI-TOF) Calcd for $C_{16}H_{13}O^-$ [M-NH$_2$]$^-$: 221.10; found: 221.20.
Treat the amine compound (71.2 mg) with Boc protected benzoic acid (100.52 mg) with HATU (152 mg) and DIPEA (104 µl) in DMF (6 ml), the reaction mixture was stirred overnight at room temperature. The product mixture was concentrated under vacuum and purified through column (0-20% EtOAc in DCM).

t-butyl(4-(((4'-(prop-2-yn-1-yloxy)-[1,1'-biphenyl]-4-yl)methyl)carbamoyl)benzyl) carbamate

^{1}H NMR (600 MHz, CDCl$_3$) δ 7.75 (d, J = 7.9 Hz, 2H), 7.54 – 7.47 (m, 4H), 7.38 (d, J = 7.8 Hz, 2H), 7.32 (d, J = 7.9 Hz, 2H), 7.04 (d, J = 8.7 Hz, 2H), 5.00 (s, 1H), 4.72 (d, J = 2.4 Hz, 2H), 4.64 (d, J = 5.4 Hz, 2H), 4.33 (d, J = 5.9 Hz, 2H), 2.54 (s, 1H), 1.45 (s, 9H). ^{13}C NMR (151 MHz, CDCl$_3$) δ 167.29, 157.18, 155.99, 142.95, 139.99, 136.75, 134.11, 133.24, 128.32, 128.09, 127.41, 127.31, 127.08, 115.26, 79.78, 78.52, 75.67, 28.39, 18.51, 17.06, 12.61. HRMS (ESI-TOF) Calcd for $C_{24}H_{23}N_2O_2^+$ [M+H-Boc]$^+$: 371.18; found: 371.09.
TFA (0.25 ml) was added to a vigorously stirring solution of the Boc protected alkyne compound (52 mg) in DCM (1.5 ml). The reaction mixture was stirred for 2 hours at room temperature. The product mixture was concentrated under vacuum. Then acryloyl chloride (27 µl, 3 equiv.) and DIPEA (95.3 µl, 5 equiv.) was added to the compound in DCM at 0 °C, stirred for overnight. The product mixture was concentrated under vacuum and purified through column (0-20% EtOAc in DCM).

4-(acrylamidomethyl)-N-((4'-(prop-2-yn-1-yloxy)-[1,1'-biphenyl]-4-yl)methyl)benzamide (EN25 Alkyne probe)

^{1}H NMR (500 MHz, DMSO) δ 9.02 (t, J = 6.0 Hz, 1H), 8.65 (d, J = 6.0 Hz, 1H), 7.87 (d, J = 7.9 Hz, 2H), 7.58 (t, J = 8.3 Hz, 4H), 7.36 (t, J = 7.8 Hz, 4H), 7.06 (d, J = 8.4 Hz, 2H), 6.29 (dd, J = 17.1, 10.2 Hz, 1H), 6.14 (dd, J = 17.1, 2.2 Hz, 1H), 5.64 (dd, J = 10.1, 2.2 Hz, 1H), 4.83 (s, 2H), 4.50 (d, J = 5.9 Hz, 2H), 4.41 (d, J = 5.9 Hz, 2H), 3.58 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 166.44, 165.15, 157.21, 143.15, 138.80, 138.71, 133.57, 133.43, 132.03, 128.28, 128.08, 127.83, 127.62, 126.65, 126.06, 115.76, 79.75, 78.78, 55.93, 42.80, 42.36. HRMS (ESI-TOF) Calcd for $C_{27}H_{24}N_2NaO_3^+$ [M+Na]$^+$: 447.1679; found: 447.1683.
