The value quoted here is obtained under the assumption that there is no color reconnection between W bosons; the value is a weighted average taking into account correlations in the systematic uncertainties.

<sup>2</sup>ABREU,P 00F measure  $\langle N_{\text{charged}} \rangle = 39.12 \pm 0.33 \pm 0.36$  and  $38.11 \pm 0.57 \pm 0.44$  in the fully hadronic final states at 189 and 183 GeV respectively, and  $\langle N_{\text{charged}} \rangle = 19.49 \pm 0.31 \pm 0.27$  and  $19.78 \pm 0.49 \pm 0.43$  in the semileptonic final states. The value quoted is a weighted average without assuming any correlations.

<sup>3</sup>ABBIENDI 99N use the final states  $W^+W^- \rightarrow q\bar{q}\ell\bar{\nu}_\ell$  to derive this value.

<sup>4</sup>ABREU 98c combine results from both the fully hadronic as well semileptonic WW final states after demonstrating that the W decay charged multiplicity is independent of the topology within errors.

## TRIPLE GAUGE COUPLINGS (TGC'S)

Revised April 2017 by M.W. Grunewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for ZWW and  $\gamma WW$ , completely describe the VWW vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve C and P individually, three violate CP, and one violates C and P individually while conserving CP. Assumption of C and P conservation and electromagnetic gauge invariance reduces the number of independent VWW couplings to five: one common set [1,2] is  $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$ , where  $\kappa_\gamma = \kappa_Z = g_1^Z = 1$  and  $\lambda_\gamma = \lambda_Z = 0$  in the Standard Model at tree level. The parameters  $\kappa_Z$  and  $\lambda_Z$  are related to the other three due to constraints of gauge invariance as follows:  $\kappa_Z = g_1^Z - (\kappa_\gamma - 1) \tan^2 \theta_W$  and  $\lambda_Z = \lambda_\gamma$ , where  $\theta_W$  is the weak mixing angle. The W magnetic dipole moment,  $\mu_W$ , and the W electric quadrupole moment,  $q_W$ , are expressed as  $\mu_W = e(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$  and  $q_W = -e(\kappa_\gamma - \lambda_\gamma)/M_W^2$ .

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the VWW coupling arises in W-pair production via s-channel exchange, or in single W production via the radiation of a virtual photon off the incident  $e^+$  or  $e^-$ . At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced W or Z signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of W-pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor  $\Lambda$ , where the coupling parameters are scaled by  $1/(1 + s/\Lambda^2)^2$ . For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted. Recently, EFT-inspired sets of couplings [4,5], such as  $c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$  which are linearly related to the couplings discussed above, are also determined by the LHC experiments.

<sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu, jijj, j\bar{j}X, \ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

<sup>2</sup> SCHAE1 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. The result quoted here is derived from the  $WW$ -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>3</sup> ABBIENDI 04D combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $0.923 < g_1^Z < 1.054$ .

<sup>4</sup> ACHARD 04b study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the  $WW$ -pair production sample including data from 161 to 183 GeV, ACCIARRI 99q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>5</sup> SIRUNYAN 20BA study electroweak production of a  $W$  boson in association with two jets, using  $W$  decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of  $2.39 \pm 0.17$  ( $1.054 \pm 0.058$ ) million events. Analyzing the transverse momentum distribution of the charged leptons from  $W$  decay, the following 95% C.L. limit is obtained:  $0.971 < g_1^Z < 1.044$ . Combining this result with that from the closely-related electroweak  $Z$ -jet-jet production SIRUNYAN 18BZ, the limit becomes:  $0.979 < g_1^Z < 1.034$ .

<sup>6</sup> SIRUNYAN 19CL study  $WW$  and  $WZ$  production in lepton + jet events, with one  $W$  boson decaying leptonically (electron or muon), and another  $W$  or  $Z$  boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the  $W(W/Z)$  category, while in the muon channel 3,996 (3,572) events are selected in the  $W(W/Z)$  category. Analyzing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained:  $0.9939 < g_1^Z < 1.0074$ .

<sup>7</sup> SIRUNYAN 18BZ study  $pp \rightarrow Z$  jet jet events at 13 TeV where  $Z \rightarrow e^+e^-/\mu^+\mu^-$ . Isolated electrons and muons are selected with  $p_T$  of the leading/sub-leading lepton  $> 30/20$  GeV and  $|\eta| < 2.4$ , with the di-lepton invariant mass within 15 GeV of the  $Z$  mass. The two highest  $p_T$  jets are selected with  $p_T$  of the leading/sub-leading jet  $> 50/30$  GeV respectively and dijet invariant mass  $> 200$  GeV. Templates in the transverse momentum of the  $Z$  are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained:  $0.965 < g_1^Z < 1.042$ .

<sup>8</sup> AABOUD 17s analyze electroweak production of a  $W$  boson in association with two jets at high dijet invariant mass, with the  $W$  boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with  $39 \pm 4$  events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $0.87 < g_1^Z < 1.12$ .

<sup>9</sup> AABOUD 17u analyze production of  $WW$  or  $WZ$  boson pairs with one  $W$  boson decaying to electron or muon plus neutrino, and the other  $W$  or  $Z$  boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analyzing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $0.979 < g_1^Z < 1.024$ .

<sup>10</sup> KHACHATRYAN 17o analyze  $WZ$  production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the  $Z$  boson mass. The  $Z$  transverse momentum spectrum is analyzed to set a 95% C.L. limit of:  $0.982 < g_1^Z < 1.035$ .

<sup>11</sup> SIRUNYAN 17x study  $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$  production at 8 TeV where  $\ell$  is an electron or muon with  $p_T > 30$  or 25 GeV respectively. Suitable cuts are put on the  $p_T$  of the dijet system and the missing  $E_T$  of the event yielding a total of 285 and 204  $WW$  events observed in the electron and muon channels. The following 95% C.L. limit is obtained:  $0.9913 < g_1^Z < 1.024$ .

<sup>12</sup> AAD 16AR study  $WW$  production in  $pp$  collisions and select 6636  $WW$  candidates in decay modes with electrons or muons with an expected background of  $1546 \pm 157$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda$  to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.984 < g_1^Z < 1.027$ .

<sup>13</sup> AAD 16P study  $WZ$  production in  $pp$  collisions and select 2091  $WZ$  candidates in 4 decay modes with electrons and muons, with an expected background of  $1825 \pm 7$  events. Analyzing the  $WZ$  transverse momentum distribution, the resulting 95% C.L. limit is:  $0.981 < g_1^Z < 1.029$ .

<sup>14</sup> AAD 14y determine the electroweak  $Z$ -dijet cross section in 8 TeV  $pp$  collisions.  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  decays are selected with the di-lepton  $p_T > 20$  GeV and mass in the 81–101 GeV range. Minimum two jets are required with  $p_T > 55$  and 45 GeV and no additional jets with  $p_T > 25$  GeV in the rapidity interval between them. The normalized  $p_T$  balance between the  $Z$  and the two jets is required to be  $< 0.15$ . This leads to a selection of 900 events with dijet mass  $> 1$  TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit  $0.5 < g_1^Z < 1.26$  for a form factor value  $\Lambda = \infty$ .

<sup>15</sup> AAD 13AL study  $WW$  production in  $pp$  collisions and select 1325  $WW$  candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda = \infty$ , a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.961 < g_1^Z < 1.052$ . Supersedes AAD 12Ac.

<sup>16</sup> CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of  $247 \pm 34$ . The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $0.905 \leq g_1^Z \leq 1.095$ .

<sup>17</sup> AAD 12CD study  $WZ$  production in  $pp$  collisions and select 317  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $0.943 < g_1^Z < 1.093$ . Supersedes AAD 12v.

<sup>18</sup> AALTONEN 12AC study  $WZ$  production in  $p\bar{p}$  collisions and select 63  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on the cross section and shape of the  $Z$  transverse momentum spectrum, the following 95% C.L. range is reported:  $0.92 < g_1^Z < 1.20$  for a form factor of  $\Lambda = 2$  TeV.

<sup>19</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma$ ,  $WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $g_1^Z = 1.022^{+0.032}_{-0.030}$ .

<sup>20</sup> ABAZOV 11 study the  $p\bar{p} \rightarrow 3\ell\nu$  process arising in  $WZ$  production. They observe 34  $WZ$  candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the  $Z$  boson leads to a 95% C.L. limit of  $0.944 < g_1^Z < 1.154$ , for a form factor  $\Lambda = 2$  TeV.

<sup>21</sup> AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is 654 of which  $320 \pm 47$  are estimated to be background. The 95% C.L. interval is  $0.76 < g_1^Z < 1.34$  for  $\Lambda = 1.5$  TeV and  $0.78 < g_1^Z < 1.30$  for  $\Lambda = 2$  TeV.

<sup>22</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $0.88 < g_1^Z < 1.20$ .

<sup>23</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell 2\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $0.86 < g_1^Z < 1.3$ , for a form factor  $\Lambda = 2$  TeV.

## Gauge &amp; Higgs Boson Particle Listings

## W

- <sup>24</sup> ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.
- <sup>25</sup> ABAZOV 07z set limits on anomalous TGCs using the measured cross section and  $p_T(Z)$  distribution in  $WZ$  production with both the  $W$  and the  $Z$  decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $0.86 < g_1^Z < 1.35$ .
- <sup>26</sup> ABAZOV 05s study  $\bar{p}p \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with  $WZ$  decay characteristics are observed from which they derive limits on the anomalous  $WWZ$  couplings. The 95% CL limit for a form factor scale  $\Lambda = 1.5$  TeV is  $0.51 < g_1^Z < 1.66$ , fixing  $\lambda_Z$  and  $\kappa_Z$  to their Standard Model values.
- <sup>27</sup> ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$  and  $W\nu_e$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $0.84 < g_1^Z < 1.13$ .
- <sup>28</sup> ABBOTT 99i perform a simultaneous fit to the  $W\gamma$ ,  $WW \rightarrow$  dilepton,  $WW/WZ \rightarrow e\nu jj$ ,  $WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow$  trilepton data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $0.63 < g_1^Z < 1.57$ , fixing  $\lambda_Z$  and  $\kappa_Z$  to their Standard Model values, and assuming Standard Model values for the  $WW\gamma$  couplings.

$\kappa_\gamma$  OUR FIT below is taken from [SCHAEL 13A].

- <sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu$ ,  $jjjj$ ,  $jjX$ ,  $\ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.
- <sup>2</sup> SCHAEEL 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>3</sup> ABBIENDI 04D combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $0.73 < \kappa_\gamma < 1.07$ .
- <sup>4</sup> ACHARD 04D study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- <sup>5</sup> AABOUD 17u analyze production of  $WW$  or  $WZ$  boson pairs with one  $W$  boson decaying to electron or muon plus neutrino, and the other  $W$  or  $Z$  boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FP} \rightarrow \infty$ :  $0.939 < \kappa_\gamma < 1.064$ .
- <sup>6</sup> SIRUNYAN 17x study  $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$  production at 8 TeV where  $\ell$  is an electron or muon with  $p_T > 30$  or 25 GeV respectively. Suitable cuts are put on the  $p_T$  of the dijet system and the missing  $E_T$  of the event yielding a total of 285 and 204  $WW$  events observed in the electron and muon channels. The following 95% C.L. limit is obtained:  $0.956 < \kappa_\gamma < 1.063$ .

- <sup>7</sup> CHATRCHYAN 14AB measure  $W\gamma$  production cross section for  $p_T^\gamma > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. After background subtraction the number of  $e\nu\gamma$  and  $\mu\nu\gamma$  events is determined to be  $3200 \pm 325$  and  $4970 \pm 543$  respectively, compatible with expectations from the SM. This leads to a 95% CL limit of  $0.62 < \kappa_\gamma < 1.29$ , assuming other parameters have SM values.
- <sup>8</sup> AAD 13AN study  $W\gamma$  production in  $pp$  collisions. In events with no additional jet, 4449 (6578)  $W$  decays to electron (muon) are selected, with an expected background of  $1662 \pm 262$  (2538  $\pm$  362) events. Analysing the photon  $p_T$  spectrum above 100 GeV yields a 95% C.L. limit of  $0.59 < \kappa_\gamma < 1.46$ . Supersedes AAD 12Bx.
- <sup>9</sup> CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of  $247 \pm 34$ . The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $0.79 \leq \kappa_\gamma \leq 1.22$ .
- <sup>10</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma$ ,  $WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $1.048^{+0.106}_{-0.105}$ .
- <sup>11</sup> ABAZOV 11AC study  $W\gamma$  production in  $p\bar{p}$  collisions at 1.96 TeV, with the  $W$  decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon  $E_T$  spectrum above 15 GeV yields at 95% C.L. the result:  $0.6 < \kappa_\gamma < 1.4$  for a formfactor  $\Lambda = 2$  TeV.
- <sup>12</sup> CHATRCHYAN 11M study  $W\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using  $36 \text{ pb}^{-1}$   $pp$  data with the  $W$  decaying to electron and muon. The total cross section is measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$ . The number of candidate (background) events is  $452$  ( $228 \pm 21$ ) for the electron channel and  $520$  ( $277 \pm 25$ ) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of  $-0.11 < \kappa_\gamma < 2.04$ .
- <sup>13</sup> AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is  $654$  of which  $320 \pm 47$  are estimated to be background. The 95% C.L. interval is  $0.37 < \kappa_\gamma < 1.72$  for  $\Lambda = 1.5$  TeV and  $0.43 < \kappa_\gamma < 1.65$  for  $\Lambda = 2$  TeV.
- <sup>14</sup> AARON 09B study single- $W$  production in  $ep$  collisions at 0.3 TeV C.M. energy. They select 53  $W \rightarrow e/\mu$  events with a standard model expectation of  $54.1 \pm 7.4$  events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of  $-3.7 < \kappa_\gamma < -1.5$  or  $0.3 < \kappa_\gamma < 1.5$ , where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.
- <sup>15</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $0.56 < \kappa_\gamma < 1.55$ .
- <sup>16</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $0.46 < \kappa_\gamma < 1.83$ , for a form factor  $\Lambda = 2$  TeV.
- <sup>17</sup> ABAZOV 08R use  $0.7 \text{ fb}^{-1}$   $p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV to select 263  $W\gamma + X$  events, of which 187 constitute signal, with the  $W$  decaying into an electron or a muon, which is required to be well separated from a photon with  $E_T > 9$  GeV. A likelihood fit to the photon  $E_T$  spectrum yields a 95% CL limit  $0.49 < \kappa_\gamma < 1.51$  with other couplings fixed to their Standard Model values.
- <sup>18</sup> ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.
- <sup>19</sup> AALTONEN 07L set limits on anomalous TGCs using the  $p_T(W)$  distribution in  $WW$  and  $WZ$  production with the  $W$  decaying to an electron or muon and the  $Z$  to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are  $0.54 < \kappa_\gamma < 1.39$  for a form factor scale  $\Lambda = 1.5$  TeV.
- <sup>20</sup> ABAZOV 06H study  $\bar{p}p \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+\nu_e e^-\bar{\nu}_e$ ,  $WW \rightarrow e^\pm\nu_e\mu^\mp\nu_\mu$ , or  $WW \rightarrow \mu^+\nu_\mu\mu^-\bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 1$  TeV is  $-0.05 < \kappa_\gamma < 2.29$ , fixing  $\lambda_\gamma = 0$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $0.68 < \kappa < 1.45$ .
- <sup>21</sup> ABAZOV 05i perform a likelihood fit to the photon  $E_T$  spectrum of  $W\gamma + X$  events, where the  $W$  decays to an electron or muon which is required to be well separated from the photon. For  $\Lambda = 2.0$  TeV the 95% CL limits are  $0.12 < \kappa_\gamma < 1.96$ . In the fit  $\lambda_\gamma$  is kept fixed to its Standard Model value.
- <sup>22</sup> ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}\gamma$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $0.87 < \kappa_\gamma < 1.68$ .
- <sup>23</sup> BREITWEG 00 search for  $W$  production in events with large hadronic  $p_T$ . For  $p_T > 20$  GeV, the upper limit on the cross section gives the 95%CL limit  $-3.7 < \kappa_\gamma < 2.5$  (for  $\lambda_\gamma = 0$ ).
- <sup>24</sup> ABBOTT 99i perform a simultaneous fit to the  $W\gamma$ ,  $WW \rightarrow$  dilepton,  $WW/WZ \rightarrow e\nu jj$ ,  $WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow$  trilepton data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $0.75 < \kappa_\gamma < 1.39$ .

<sup>1</sup> ABDALLAH 10 use data on the final states  $e^+e^- \rightarrow jj\ell\nu, jjjj, jjX, \ell X$ , at center-of-mass energies between 189–209 GeV at LEP2, where  $j = \text{jet}$ ,  $\ell = \text{lepton}$ , and  $X$  represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

<sup>2</sup> SCHAE 05A study single-photon, single- $W$ , and  $WW$ -pair production from 183 to 209 GeV. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>3</sup> ABBIENI 04d combine results from  $W^+W^-$  in all decay channels. Only  $CP$ -conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is  $-0.13 < \lambda_\gamma < 0.01$ .

<sup>4</sup> ACHARD 04b study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99q. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>5</sup> CHATRCHYAN 14AB measure  $W\gamma$  production cross section for  $p_T^\gamma > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. After background subtraction the number of  $e\nu\gamma$  and  $\mu\nu\gamma$  events is determined to be  $3200 \pm 325$  and  $4970 \pm 543$  respectively, compatible with expectations from the SM. This leads to a 95% CL limit of  $-0.050 < \lambda_\gamma < 0.037$ , assuming all other parameters have SM values.

<sup>6</sup> AAD 13AN study  $W\gamma$  production in  $pp$  collisions. In events with no additional jet, 4449 (6578)  $W$  decays to electron (muon) are selected, with an expected background of  $1662 \pm 262$  ( $2538 \pm 362$ ) events. Analysing the photon  $p_T$  spectrum above 100 GeV yields a 95% C.L. limit of  $-0.065 < \lambda_\gamma < 0.061$ . Supersedes AAD 12Bx.

<sup>7</sup> ABAZOV 12AG combine new results with already published results on  $W\gamma$ ,  $WW$  and  $WZ$  production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of  $\Lambda = 2$  TeV is  $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$ .

<sup>8</sup> ABAZOV 11AC study  $W\gamma$  production in  $p\bar{p}$  collisions at 1.96 TeV, with the  $W$  decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon  $E_T$  spectrum above 15 GeV yields at 95% C.L. the result:  $-0.08 < \lambda_\gamma < 0.07$  for a formfactor  $\Lambda = 2$  TeV.

<sup>9</sup> CHATRCHYAN 11M study  $W\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using 36  $\text{pb}^{-1}$   $pp$  data with the  $W$  decaying to electron and muon. The total cross section is measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$ . The number of candidate (background) events is 452 ( $228 \pm 21$ ) for the electron channel and 520 ( $277 \pm 25$ ) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of  $-0.18 < \lambda_\gamma < 0.17$ .

<sup>10</sup> AARON 09B study single- $W$  production in  $ep$  collisions at 0.3 TeV C.M. energy. They select 53  $W \rightarrow e/\mu$  events with a standard model expectation of  $54.1 \pm 7.4$  events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of  $-2.5 < \lambda_\gamma < 2.5$ .

<sup>11</sup> ABAZOV 09AD study the  $p\bar{p} \rightarrow \ell\nu 2\text{jet}$  process arising in  $WW$  and  $WZ$  production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the  $p_T$  spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is  $-0.10 < \lambda_\gamma < 0.11$ .

<sup>12</sup> ABAZOV 09AJ study the  $p\bar{p} \rightarrow 2\ell 2\nu$  process arising in  $WW$  production. They select 100 events with an expected  $WW$  signal of 65 events. An analysis of the  $p_T$  spectrum of the two charged leptons leads to 95% C.L. limits of  $-0.14 < \lambda_\gamma < 0.18$ , for a form factor  $\Lambda = 2$  TeV.

<sup>13</sup> ABAZOV 08R use 0.7  $\text{fb}^{-1}$   $p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV to select 263  $W\gamma + X$  events, of which 187 constitute signal, with the  $W$  decaying into an electron or a muon, which is required to be well separated from a photon with  $E_T > 9$  GeV. A likelihood fit to the photon  $E_T$  spectrum yields a 95% C.L. limit  $-0.12 < \lambda_\gamma < 0.13$  with other couplings fixed to their Standard Model values.

<sup>14</sup> ABDALLAH 08c determine this triple gauge coupling from the measurement of the spin density matrix elements in  $e^+e^- \rightarrow W^+W^- \rightarrow (qq)(\ell\nu)$ , where  $\ell = e$  or  $\mu$ . Values of all other couplings are fixed to their standard model values.

<sup>15</sup> AALTONEN 07L set limits on anomalous TGCs using the  $p_T(W)$  distribution in  $WW$  and  $WZ$  production with the  $W$  decaying to an electron or muon and the  $Z$  to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are  $-0.18 < \lambda_\gamma < 0.17$  for a form factor scale  $\Lambda = 1.5$  TeV.

<sup>16</sup> ABAZOV 06H study  $p\bar{p} \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+\nu_e e^-\bar{\nu}_e$ ,  $WW \rightarrow e^+\nu_e \mu^+\nu_\mu$  or  $WW \rightarrow \mu^+\nu_\mu \mu^-\bar{\nu}_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 1$  TeV is  $-0.97 < \lambda_\gamma < 1.04$ , fixing  $\kappa_\gamma = 1$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $-0.29 < \lambda < 0.30$ .

<sup>17</sup> ABAZOV 05J perform a likelihood fit to the photon  $E_T$  spectrum of  $W\gamma + X$  events, where the  $W$  decays to an electron or muon which is required to be well separated from the photon. For  $\Lambda = 2.0$  TeV the 95% CL limits are  $-0.20 < \lambda_\gamma < 0.20$ . In the fit  $\kappa_\gamma$  is kept fixed to its Standard Model value.

<sup>18</sup> ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}$  final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is  $-0.11 < \lambda_\gamma < 0.23$ .

<sup>19</sup> BREITWEG 00 search for  $W$  production in events with large hadronic  $p_T$ . For  $p_T > 20$  GeV, the upper limit on the cross section gives the 95%CL limit  $-3.2 < \lambda_\gamma < 3.2$  for  $\kappa_\gamma$  fixed to its Standard Model value.

<sup>20</sup> ABBOTT 99I perform a simultaneous fit to the  $W\gamma$ ,  $WW \rightarrow$  dilepton,  $WW/WZ \rightarrow e\nu jj$ ,  $WW/WZ \rightarrow \mu\nu jj$ , and  $WZ \rightarrow$  trilepton data samples. For  $\Lambda = 2.0$  TeV, the 95%CL limits are  $-0.18 < \lambda_\gamma < 0.19$ .

### $\kappa_Z$

This coupling is  $CP$ -conserving ( $C$ - and  $P$ -separately conserving).

<sup>1</sup> ACHARD 04b study  $WW$ -pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the  $WW$ -pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.

<sup>2</sup> SIRUNYAN 20BA study electroweak production of a  $W$  boson in association with two jets, using  $W$  decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2,382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of  $2.39 \pm 0.17$  (1.054  $\pm$  0.058) million events. Analysing the transverse momentum distribution of the charged leptons from  $W$  decay, the following 95% C.L. limit is obtained:  $0.956 < \kappa_Z < 1.044$ . Combining this result with that from the closely-related electroweak  $Z$ -jet-jet production SIRUNYAN 18Bz, the limit becomes:  $0.957 < \kappa_Z < 1.042$ .

<sup>3</sup> SIRUNYAN 19CL study  $WW$  and  $WZ$  production in lepton + jet events, with one  $W$  boson decaying leptonically (electron or muon), and another  $W$  or  $Z$  boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the  $WW(WZ)$  category, while in the muon channel 3,996 (3,572) events are selected in the  $WW(WZ)$  category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained:  $0.9921 < \kappa_Z < 1.0082$ .

<sup>4</sup> AABOUD 17s analyze electroweak production of a  $W$  boson in association with two jets at high dijet invariant mass, with the  $W$  boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with  $39 \pm 4$  events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $0.85 < \kappa_Z < 1.16$ .

<sup>5</sup> KHACHATRYAN 17o analyse  $WZ$  production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the  $Z$  boson mass. The  $Z$  transverse momentum spectrum is analyzed to set a 95% C.L. limit of:  $0.79 < \kappa_Z < 1.25$ .

<sup>6</sup> AAD 16AR study  $WW$  production in  $pp$  collisions and select 6636  $WW$  candidates in decay modes with electrons or muons with an expected background of  $1546 \pm 157$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda$  to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.975 < \kappa_Z < 1.020$ .

<sup>7</sup> AAD 16p study  $WZ$  production in  $pp$  collisions and select 2091  $WZ$  candidates in 4 decay modes with electrons and muons, with an expected background of  $1825 \pm 7$  events. Analysing the  $WZ$  transverse momentum distribution, the resulting 95% C.L. limit is:  $0.81 < \kappa_Z < 1.30$ .

<sup>8</sup> AAD 13AL study  $WW$  production in  $pp$  collisions and select 1325  $WW$  candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda = \text{infinity}$ , a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $0.957 < \kappa_Z < 1.043$ . Supersedes AAD 12AC.

<sup>9</sup> AAD 12CD study  $WZ$  production in  $pp$  collisions and select 317  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $0.63 < \kappa_Z < 1.57$ . Supersedes AAD 12V.

<sup>10</sup> AALTONEN 12AC study  $WZ$  production in  $p\bar{p}$  collisions and select 63  $WZ$  candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on

## Gauge &amp; Higgs Boson Particle Listings

## W

the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported:  $0.61 < \kappa_Z < 1.90$  for a form factor of  $\Lambda = 2$  TeV.

- 11 ABAZOV 11 study the  $p\bar{p} \rightarrow 3\ell\nu$  process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the Z boson leads to a 95% C.L. limit of  $0.600 < \kappa_Z < 1.675$ , for a form factor  $\Lambda = 2$  TeV.
- 12 ABAZOV 06H study  $p\bar{p} \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+\nu_e e^-\bar{\nu}_e$ ,  $WW \rightarrow e^\pm\nu_e\mu^\mp\nu_\mu$  or  $WW \rightarrow \mu^\pm\nu_\mu\mu^\mp\nu_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $0.55 < \kappa_Z < 1.55$ , fixing  $\lambda_Z=0$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $0.68 < \kappa < 1.45$ .
- 13 ABAZOV 05s study  $p\bar{p} \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale  $\Lambda = 1$  TeV is  $-1.0 < \kappa_Z < 3.4$ , fixing  $\lambda_Z$  and  $g_1^Z$  to their Standard Model values.

 $\lambda_Z$ 

This coupling is CP-conserving (C- and P- separately conserving).

- 1 ACHARD 04D study  $W^+W^-$  pair production, single- $W$  production and single-photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the  $W^+W^-$  pair production sample. Each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values.
- 2 SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of  $2.39 \pm 0.17$  ( $1.054 \pm 0.058$ ) million events. Analysing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained:  $-0.0088 < \lambda_Z < 0.0095$ . Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes:  $-0.0071 < \lambda_Z < 0.0076$ .
- 3 SIRUNYAN 19CL study  $WW$  and  $WZ$  production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the  $WW(WZ)$  category, while in the muon channel 3,996 (3572) events are selected in the  $WW(WZ)$  category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained:  $-0.0065 < \lambda_Z < 0.0066$ .
- 4 SIRUNYAN 18BZ study  $pp \rightarrow Z$  jet jet events at 13 TeV where  $Z \rightarrow e^+e^-/\mu^+\mu^-$ . Isolated electrons and muons are selected with  $p_T$  of the leading/sub-leading lepton  $> 30/20$  GeV and  $|\eta| < 2.4$ , with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest  $p_T$  jets are selected with  $p_T$  of the leading/sub-leading jet  $> 50/30$  GeV respectively and dijet invariant mass  $> 200$  GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained:  $-0.010 < \lambda_Z < 0.010$ .
- 5 AABOUD 17s analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with  $39 \pm 4$  events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $-0.053 < \lambda_Z < 0.042$ .
- 6 AABOUD 17U analyze production of  $WW$  or  $WZ$  boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $-0.013 < \lambda_Z < 0.013$ .
- 7 KHACHATRYAN 17o analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of:  $-0.018 < \lambda_Z < 0.016$ .
- 8 SIRUNYAN 17X study  $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$  production at 8 TeV where  $\ell$  is an electron or muon with  $p_T > 30$  or 25 GeV respectively. Suitable cuts are put on the  $p_T$  of the dijet system and the missing  $E_T$  of the event yielding a total of 285 and 204 WW events observed in the electron and muon channels. The following 95% C.L. limit is obtained:  $-0.011 < \lambda_Z < 0.011$ .
- 9 AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of  $1546 \pm 157$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda$  to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $-0.019 < \lambda_Z < 0.019$ .
- 10 AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of  $1825 \pm 7$  events. Analysing the WZ transverse momentum distribution, the resulting 95% C.L. limit is:  $-0.016 < \lambda_Z < 0.016$ .
- 11 AAD 14Y determine the electroweak Z-dijet cross section in 8 TeV pp collisions.  $Z \rightarrow ee$  and  $Z \rightarrow \mu\mu$  decays are selected with the di-lepton  $p_T > 20$  GeV and mass in the 81-101 GeV range. Minimum two jets are required with  $p_T > 55$  and 45 GeV and no additional jets with  $p_T > 25$  GeV in the rapidity interval between them. The normalized  $p_T$  balance between the Z and the two jets is required to be  $< 0.15$ . This leads to a selection of 900 events with dijet mass  $> 1$  TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit  $-0.15 < \lambda_Z < 0.13$  for a form factor value  $\Lambda = \infty$ .
- 12 AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of  $369 \pm 61$  events. Assuming the LEP formulation and setting the form-factor  $\Lambda = \infty$ , a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of  $-0.062 < \lambda_Z < 0.059$ . Supersedes AAD 12AC.
- 13 CHATRCHYAN 13BF determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of  $247 \pm 34$ . The  $p_T$  distribution of the leading lepton is fitted to obtain 95% C.L. limits of  $-0.048 \leq \lambda_Z \leq 0.048$ .
- 14 AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three  $\ell\nu$  decay modes with an expected background of  $68.0 \pm 10.0$  events. The resulting 95% C.L. range is:  $-0.046 < \lambda_Z < 0.047$ . Supersedes AAD 12v.
- 15 AALTONEN 12AC study WZ production in  $p\bar{p}$  collisions and select 63 WZ candidates in three  $\ell\nu$  decay modes with an expected background of  $7.9 \pm 1.0$  events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported:  $-0.08 < \lambda_Z < 0.10$  for a form factor of  $\Lambda = 2$  TeV.
- 16 ABAZOV 11 study the  $p\bar{p} \rightarrow 3\ell\nu$  process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the  $p_T$  spectrum of the Z boson leads to a 95% C.L. limit of  $-0.077 < \lambda_Z < 0.093$ , for a form factor  $\Lambda = 2$  TeV.
- 17 AALTONEN 10K study  $p\bar{p} \rightarrow W^+W^-$  with  $W \rightarrow e/\mu\nu$ . The  $p_T$  of the leading (second) lepton is required to be  $> 20$  (10) GeV. The final number of events selected is 654 of which  $320 \pm 47$  are estimated to be background. The 95% C.L. interval is  $-0.16 < \lambda_Z < 0.16$  for  $\Lambda = 1.5$  TeV and  $-0.14 < \lambda_Z < 0.15$  for  $\Lambda = 2$  TeV.
- 18 ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and  $p_T(Z)$  distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $-0.17 < \lambda_Z < 0.21$ .
- 19 ABAZOV 06H study  $p\bar{p} \rightarrow WW$  production with a subsequent decay  $WW \rightarrow e^+\nu_e e^-\bar{\nu}_e$ ,  $WW \rightarrow e^\pm\nu_e\mu^\mp\nu_\mu$  or  $WW \rightarrow \mu^\pm\nu_\mu\mu^\mp\nu_\mu$ . The 95% C.L. limit for a form factor scale  $\Lambda = 2$  TeV is  $-0.39 < \lambda_Z < 0.39$ , fixing  $\kappa_Z=1$ . With the assumption that the  $WW\gamma$  and  $WWZ$  couplings are equal the 95% C.L. one-dimensional limit ( $\Lambda = 2$  TeV) is  $-0.29 < \lambda < 0.30$ .
- 20 ABAZOV 05s study  $p\bar{p} \rightarrow WZ$  production with a subsequent trilepton decay to  $\ell\nu\ell'\bar{\ell}'$  ( $\ell$  and  $\ell' = e$  or  $\mu$ ). Three events (estimated background  $0.71 \pm 0.08$  events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale  $\Lambda = 1.5$  TeV is  $-0.48 < \lambda_Z < 0.48$ , fixing  $g_1^Z$  and  $\kappa_Z$  to their Standard Model values.

 $g_2^Z$ 

This coupling is CP-conserving but C- and P-violating.

**W ANOMALOUS MAGNETIC MOMENT**

The full magnetic moment is given by  $\mu_W = e(1+\kappa+\lambda)/2m_W$ . In the Standard Model, at tree level,  $\kappa = 1$  and  $\lambda = 0$ . Some papers have defined  $\Delta\kappa = 1-\kappa$  and assume that  $\lambda = 0$ . Note that the electric quadrupole moment is given by  $-e(\kappa-\lambda)/m_W^2$ . A description of the parameterization of these moments and additional references can be found in HAGIWARA 87 and BAUR 88. The parameter  $\Lambda$  appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the  $W$  boson becomes manifest.

- 1 ABREU 01i combine results from  $e^+e^-$  interactions at 189 GeV leading to  $W^+W^-$ ,  $W\nu_e$ , and  $\nu\bar{\nu}\gamma$  final states with results from ABREU 99L at 183 GeV to determine  $\Delta g_Z^f$ ,  $\Delta\kappa_\gamma$ , and  $\lambda_\gamma$ .  $\Delta\kappa_\gamma$  and  $\lambda_\gamma$  are simultaneously floated in the fit to determine  $\mu_W$ .
- 2 ABE 95G report  $-1.3 < \kappa < 3.2$  for  $\lambda=0$  and  $-0.7 < \lambda < 0.7$  for  $\kappa=1$  in  $p\bar{p} \rightarrow e\nu_e\gamma X$  and  $\mu\nu_\mu\gamma X$  at  $\sqrt{s} = 1.8$  TeV.
- 3 ALITTI 92C measure  $\kappa = 1 \pm 2.6$  and  $\lambda = 0 \pm 1.7$  in  $p\bar{p} \rightarrow e\nu\gamma + X$  at  $\sqrt{s} = 630$  GeV. At 95%CL they report  $-3.5 < \kappa < 5.9$  and  $-3.6 < \lambda < 3.5$ .
- 4 SAMUEL 92 use preliminary CDF and UA2 data and find  $-2.4 < \kappa < 3.7$  at 96%CL and  $-3.1 < \lambda < 4.2$  at 95%CL respectively. They use data for  $W\gamma$  production and radiative  $W$  decay.
- 5 SAMUEL 91 use preliminary CDF data for  $p\bar{p} \rightarrow W\gamma X$  to obtain  $-11.3 \leq \Delta\kappa \leq 10.9$ . Note that their  $\kappa = 1 - \Delta\kappa$ .
- 6 GRIFOLS 88 uses deviation from  $\rho$  parameter to set limit  $\Delta\kappa \lesssim 65 (M_W^2/\Lambda^2)$ .
- 7 GROTC 87 finds the limit  $-37 < \Delta\kappa < 73.5$  (90% CL) from the experimental limits on  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$  assuming three neutrino generations and  $-19.5 < \Delta\kappa < 56$  for four generations. Note their  $\Delta\kappa$  has the opposite sign as our definition.
- 8 VANDERBIJ 87 uses existing limits to the photon structure to obtain  $|\Delta\kappa| < 33 (m_W/\Lambda)$ . In addition VANDERBIJ 87 discusses problems with using the  $\rho$  parameter of the Standard Model to determine  $\Delta\kappa$ .
- 9 GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole ( $\lambda$ ) moments  $1.05 > \Delta\kappa \ln(\Lambda/m_W) + \lambda/2 > -2.77$ . In the Standard Model  $\lambda = 0$ .
- 10 SUZUKI 85 uses partial-wave unitarity at high energies to obtain  $|\Delta\kappa| \lesssim 190 (m_W/\Lambda)^2$ . From the anomalous magnetic moment of the muon, SUZUKI 85 obtains  $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$ . Finally SUZUKI 85 uses deviations from the  $\rho$  parameter and obtains a very qualitative, order-of-magnitude limit  $|\Delta\kappa| \lesssim 150 (m_W/\Lambda)^4$  if  $|\Delta\kappa| \ll 1$ .
- 11 HERZOG 84 consider the contribution of  $W$ -boson to muon magnetic moment including anomalous coupling of  $WW\gamma$ . Obtain a limit  $-1 < \Delta\kappa < 3$  for  $\Lambda \gtrsim 1$  TeV.

**$c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$**

These couplings are used in EFT-based approaches to anomalous couplings. They are linearly related to the couplings discussed above.

## W

- <sup>4</sup> AAD 21w analyze  $W^+W^-$  production in association with at least one jet. Events with exactly one oppositely-charged electron-muon pair and at least one hadronic jet of transverse momentum larger than 30 GeV (120 GeV) are selected. In the data, 89,239 (5,825) events are found, with a total Standard-Model expectation of  $91600 \pm 2500$  ( $5980 \pm 150$ ). Analyzing the electron-muon invariant mass distribution, the following limit at 95% C.L. is obtained:  $-0.33 < c_W/\Lambda^2 < 0.33$  ( $-0.60 < c_W/\Lambda^2 < 0.58$ ), for a fixed choice of  $\Lambda = 1$  TeV.
- <sup>5</sup> SIRUNYAN 21G measure  $W$  production where the  $W$  decays into electrons or muons. In the data, 385,224 (395,818) events are selected in the electron (muon) channel, with a total Standard-Model expectation of  $396913 \pm 54686$  ( $396257 \pm 22837$ ) events. Analysing the photon transverse momentum distribution, the following 95% C.L. limits are derived in units of  $\text{TeV}^{-2}$ :  $-0.90 < c_{WW}/\Lambda^2 < 0.91$ ,  $-40 < c_B/\Lambda^2 < 41$ ,  $-0.45 < c_{\overline{W}W}/\Lambda^2 < 0.45$ ,  $-20 < c_{\overline{W}}/\Lambda^2 < 20$ .
- <sup>6</sup> SIRUNYAN 20BA study electroweak production of a  $W$  boson in association with two jets, using  $W$  decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of  $2.39 \pm 0.17$  ( $1.054 \pm 0.058$ ) million events. Analysing the transverse momentum distribution of the charged leptons from  $W$  decay, the following 95% C.L. limits are obtained in units of  $\text{TeV}^{-2}$ :  $-2.3 < c_{WW}/\Lambda^2 < 2.5$ ,  $-8.8 < c_W/\Lambda^2 < 16$ ,  $-45 < c_B/\Lambda^2 < 46$ . Combining these results with those from the closely-related electroweak  $Z$ -jet-jet production SIRUNYAN 18BZ, the limits become:  $-1.8 < c_{WW}/\Lambda^2 < 2.0$ ,  $-5.8 < c_W/\Lambda^2 < 10$ ,  $-43 < c_B/\Lambda^2 < 45$ .
- <sup>7</sup> SIRUNYAN 20BF study  $W^+W^-$  production with the  $W$  bosons decaying to electrons or muons. The leading (subleading) lepton is required to have a transverse momentum larger than 25 (20) GeV. Events with a same-flavor di-lepton invariant mass within 15 GeV of the  $Z$  mass are rejected, as are event with a third lepton of transverse momentum larger than 10 GeV. In the same- (different-) flavor category a total of 9,604 (20,270) events are selected while the number of expected events is  $9640 \pm 490$  ( $20280 \pm 430$ ). Analysing the different-flavor di-lepton invariant mass distribution, the following 95% C.L. limits are obtained in units of  $\text{TeV}^{-2}$ :  $-1.8 < c_{WW}/\Lambda^2 < 1.8$ ,  $-3.6 < c_W/\Lambda^2 < 2.8$ ,  $-9.4 < c_B/\Lambda^2 < 8.5$ .
- <sup>8</sup> AABOUD 19BA study  $WW$  production in decay modes with an electron and a muon. The charged leptons are each required to have a transverse momentum larger than 27 GeV and rapidity less than 2.5. The electron-muon system is required to have a mass larger than 55 GeV and a transverse momentum larger than 30 GeV. The missing transverse energy must be larger than 20 GeV. Events containing a jet with transverse momentum exceeding 35 GeV and rapidity smaller than 4.5 are rejected. A total of 12,659 events are selected in the data, with an expected background of  $4240 \pm 477$  events. Analysing the transverse momentum spectrum of the leading charged lepton, the following 95% C.L. limits are derived in units of  $\text{TeV}^{-2}$ :  $-3.4 < c_{WW}/\Lambda^2 < 3.3$ ,  $-7.4 < c_W/\Lambda^2 < 4.1$ ,  $-21 < c_B/\Lambda^2 < 18$ ,  $-1.6 < c_{\overline{W}W}/\Lambda^2 < 1.6$ ,  $-76 < c_{\overline{W}}/\Lambda^2 < 76$ .
- <sup>9</sup> SIRUNYAN 19AD study inclusive  $WZ$  production, with  $W$  and  $Z$  decaying to electrons or muons. The leading (subleading) charged lepton candidate from the  $Z$  boson decay is required to have a transverse momentum larger than 25 GeV (10 GeV). The charged lepton candidate from the  $W$  boson decay is required to have a transverse momentum larger than 25 GeV. The invariant mass of the two leptons from  $Z$  decay is required to be within 15 GeV of the  $Z$  mass, while the invariant mass of the tri-lepton system is required to exceed 100 GeV. A total of 3,831 tri-lepton events are observed, with a fitted SM  $WZ$  signal of  $3166 \pm 62$  events and a fitted background of  $666 \pm 45$  events. The approximated  $WZ$  invariant mass distribution is analyzed to set 95% C.L. limits as follows:  $-4.1 < c_W/\Lambda^2 < 1.1$ ,  $-2.0 < c_{WW}/\Lambda^2 < 2.1$ ,  $-100 < c_B/\Lambda^2 < 160$ , in units of  $\text{TeV}^{-2}$ .
- <sup>10</sup> SIRUNYAN 19CL study  $WW$  and  $WZ$  production in lepton + jet events, with one  $W$  boson decaying leptonically (electron or muon), and another  $W$  or  $Z$  boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the  $W(W)Z$  category, while in the muon channel 3,996 (3,572) events are selected in the  $W(W)Z$  category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limits are obtained in units of  $\text{TeV}^{-2}$ :  $-1.58 < c_{WW}/\Lambda^2 < 1.59$ ,  $-2.00 < c_W/\Lambda^2 < 2.65$ ,  $-8.78 < c_B/\Lambda^2 < 8.54$ .
- <sup>11</sup> AABOUD 18Q study  $pp \rightarrow ZZ$  events at  $\sqrt{s} = 13$  TeV with  $Z \rightarrow e^+e^-$  or  $Z \rightarrow \mu^+\mu^-$ . The number of events observed in the  $4e$ ,  $2e2\mu$ , and  $4\mu$  channels is 249, 465, and 303 respectively. Analysing the  $p_T$  spectrum of the leading  $Z$  boson, the following the following 95% C.L. limits are derived in units of  $\text{TeV}^{-4}$ :  $-5.9 < c_{\overline{B}W}/\Lambda^4 < 5.9$ ,  $-3.0 < c_{WW}/\Lambda^4 < 3.0$ ,  $-3.3 < c_{BW}/\Lambda^4 < 3.3$ ,  $-2.7 < c_{BB}/\Lambda^4 < 2.8$ .
- <sup>12</sup> SIRUNYAN 18BZ study  $pp \rightarrow Z$  jet jet events at 13 TeV where  $Z \rightarrow e^+e^-/\mu^+\mu^-$ . Isolated electrons and muons are selected with  $p_T$  of the leading/sub-leading lepton  $> 30/20$  GeV and  $|\eta| < 2.4$ , with the di-lepton invariant mass within 15 GeV of the  $Z$  mass. The two highest  $p_T$  jets are selected with  $p_T$  of the leading/sub-leading jet  $> 50/30$  GeV respectively and dijet invariant mass  $> 200$  GeV. Templates in the transverse momentum of the  $Z$  are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limits are obtained in units of  $\text{TeV}^{-2}$ :  $-2.6 < c_{WW}/\Lambda^2 < 2.6$  and  $-8.4 < c_W/\Lambda^2 < 10.1$ .
- <sup>13</sup> AABOUD 17s analyze electroweak production of a  $W$  boson in association with two jets at high dijet invariant mass, with the  $W$  boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with  $39 \pm 4$  events expected in the Standard Model, yielding the following limits at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $-33 < c_W/\Lambda^2 < 30$ ,  $-170 < c_B/\Lambda^2 < 160$ ,  $-13 < c_{WW}/\Lambda^2 < 9$ ,  $-580 < c_{\overline{W}}/\Lambda^2 < 580$ ,  $-11 < c_{\overline{W}W}/\Lambda^2 < 11$ , in units of  $\text{TeV}^{-2}$ .
- <sup>14</sup> AABOUD 17u analyze production of  $WW$  or  $WZ$  boson pairs with one  $W$  boson decaying to electron or muon plus neutrino, and the other  $W$  or  $Z$  boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limits at 95% CL for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $-3.1 < c_{WW}/\Lambda^2 < 3.1$ ,  $-19 < c_B/\Lambda^2 < 20$ ,  $-5.1 < c_W/\Lambda^2 < 5.8$ , in units of  $\text{TeV}^{-2}$ .
- <sup>15</sup> KHACHATRYAN 17o analyse  $WZ$  production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV,

with one of the lepton pairs having an invariant mass within 20 GeV of the  $Z$  boson mass. The  $Z$  transverse momentum spectrum is analyzed to set 95% C.L. limits of:  $-260 < c_B/\Lambda^2 < 210$ ,  $-4.2 < c_W/\Lambda^2 < 8.0$ ,  $-4.6 < c_{WW}/\Lambda^2 < 4.2$ , in units of  $\text{TeV}^{-2}$ .

- <sup>16</sup> SIRUNYAN 17X study  $pp \rightarrow WW/WZ \rightarrow \ell\nu q\bar{q}$  production at 8 TeV where  $\ell$  is an electron or muon with  $p_T > 30$  or 25 GeV respectively. Suitable cuts are put on the  $p_T$  of the dijet system and the missing  $E_T$  of the event yielding a total of 285 and 204  $WV$  events observed in the electron and muon channels. The following 95% C.L. limits in units of  $\text{TeV}^{-2}$  are obtained:  $-2.7 < c_{WW}/\Lambda^2 < 2.7$ ,  $-14 < c_B/\Lambda^2 < 17$ ,  $-2.0 < c_W/\Lambda^2 < 5.7$ .
- <sup>17</sup> AAD 16AR study  $WV$  production in  $pp$  collisions and select 6636  $WW$  candidates in decay modes with electrons or muons with an expected background of  $1546 \pm 157$  events. Assuming an EFT formulation, a fit to the transverse momentum distribution of the leading charged lepton, leads to 95% C.L. ranges of:  $-4.61 < c_{WW}/\Lambda^2 < 4.60$ ,  $-5.87 < c_W/\Lambda^2 < 10.54$  and  $-20.9 < c_B/\Lambda^2 < 26.3$ , in units of  $\text{TeV}^{-2}$ .
- <sup>18</sup> AAD 16P study  $WZ$  production in  $pp$  collisions and select 2091  $WZ$  candidates in 4 decay modes with electrons and muons, with an expected background of  $1825 \pm 7$  events. Analysing the  $WZ$  transverse momentum distribution, the resulting 95% C.L. limits are:  $-3.9 < c_{WW}/\Lambda^2 < 4.0$ ,  $-4.3 < c_W/\Lambda^2 < 6.8$ , and  $-320 < c_B/\Lambda^2 < 210$ , in units of  $\text{TeV}^{-2}$ .
- <sup>19</sup> KHACHATRYAN 16Bl determine the  $W^+W^-$  production cross section using unlike sign di-lepton ( $e$  or  $\mu$ ) events with high  $p_T$ . The leptons have  $p_T > 20$  GeV/ $c$  and are isolated. Events are required to have no jets above  $p_T$  of 30 GeV/ $c$ . 4847 (2233) events are selected with different (same) flavor leptons, with an expected total background of  $1179 \pm 123$  ( $643 \pm 73$ ) events. Analysing the di-lepton invariant mass spectrum, the following values are obtained:  $c_{WW}/\Lambda^2 = 0.1 \pm 3.2$ ,  $c_W/\Lambda^2 = -3.6^{+5.0}_{-4.5}$  and  $c_B/\Lambda^2 = -3.2^{+15.0}_{-14.5}$ , in units of  $\text{TeV}^{-2}$ . The limits at 95% C.L. are:  $-5.7 < c_{WW}/\Lambda^2 < 5.9$ ,  $-11.4 < c_W/\Lambda^2 < 5.4$  and  $-29.2 < c_B/\Lambda^2 < 23.9$ , in units of  $\text{TeV}^{-2}$ .

### ANOMALOUS W/Z QUARTIC COUPLINGS

Revised March 2024 by M.W. Grunewald (U. College Dublin) and A. Gurtu (CERN; TIFR Mumbai).

Quartic couplings,  $WWZZ$ ,  $WWZ\gamma$ ,  $WW\gamma\gamma$ , and  $ZZ\gamma\gamma$ , were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the  $SU(2) \times U(1)$  gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings,  $a_0, a_c, a_n$ , are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha$$

$$L_6^c = -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha$$

$$L_6^n = -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} F^{\mu\nu}$$

$$\tilde{L}_6^0 = -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha$$

$$\tilde{L}_6^n = -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu}$$

where  $F, W$  are photon and  $W$  fields,  $L_6^0$  and  $L_6^c$  conserve  $C, P$  separately ( $\tilde{L}_6^0$  conserves only  $C$ ) and generate anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings,  $L_6^n$  violates  $CP$  ( $\tilde{L}_6^n$  violates both  $C$  and  $P$ ) and generates an anomalous  $W^+W^-Z\gamma$  coupling, and  $\Lambda$  is an energy scale for new physics. For the  $ZZ\gamma\gamma$  coupling the  $CP$ -violating term represented by  $L_6^n$  does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the  $WW\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings separately, leading to two sets parametrized as  $a_0^V/\Lambda^2$  and  $a_c^V/\Lambda^2$ , where  $V = W$  or  $Z$ .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is

broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned} \mathcal{L}_{AQGC} = & -\frac{e^2 a_0^W}{8 \Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+\alpha} W_a^- \\ & -\frac{e^2 a_c^W}{16 \Lambda^2} F_{\mu\nu} F^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ & -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+\alpha} W_a^- \\ & -\frac{e^2 g^2 \kappa_c^W}{2 \Lambda^2} F_{\mu\nu} Z^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ & + \frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}] \end{aligned}$$

The energy scale of possible new physics is  $\Lambda$ , and  $g = e/\sin(\theta_W)$ ,  $e$  being the unit electric charge and  $\theta_W$  the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators  $a_0^W/\Lambda^2$  and  $a_c^W/\Lambda^2$  are associated with the  $WW\gamma\gamma$  vertex. Among dimension 8 operators,  $\kappa_0^W/\Lambda^2$  and  $\kappa_c^W/\Lambda^2$  are associated with the  $WWZ\gamma$  vertex, whereas the parameter  $f_{T,0}/\Lambda^4$  contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters  $f_{M,i}/\Lambda^4$  as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,3}}{\Lambda^4}$$

where  $g' = e/\cos(\theta_W)$  and  $M_W$  is the invariant mass of the  $W$  boson. This relation provides a translation between limits on dimension 6 operators  $a_{0,c}^W$  and  $f_{M,j}/\Lambda^4$ . It is further required [4] that  $f_{M,0} = 2f_{M,2}$  and  $f_{M,1} = 2f_{M,3}$  which suppresses contributions to the  $WWZ\gamma$  vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total –  $f_{S,i}$ ,  $i = 1, 2$ ,  $f_{M,i}$ ,  $i = 0, \dots, 8$  and  $f_{T,i}$ ,  $i = 0, \dots, 9$  – each scaled by  $1/\Lambda^4$ .

Another approach to couplings is the so called K-matrix framework [7], in which the anomalous couplings can be expressed in terms of two parameters  $\alpha_4$  and  $\alpha_5$ , which account for all BSM effects.

The LHC collaborations have published couplings results based on various theoretical frameworks. It is hoped that the collaborations will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison, and to allow for a possible LHC combination.

Anomalous  $W$  quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the ‘‘Anomalous  $W/Z$  quartic couplings (QGCS),’’ the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

Some publications from LHC experiments derive limits for various assumed values of the form-factor cutoff  $\Lambda_{FF}$ . The values quoted below are for  $\Lambda_{FF} \rightarrow \infty$ .

<sup>1</sup> AAD 24c study the production of four charged leptons (electrons or muons) in association with two jets. Analysing the 4-lepton invariant mass distribution and the di-jet invariant mass distribution leads to the following 95% C.L. limits:  $-0.98 < f_{T,0}/\Lambda^4 < 0.93$ ,  $-1.2 < f_{T,1}/\Lambda^4 < 1.2$ ,  $-2.5 < f_{T,2}/\Lambda^4 < 2.4$ ,  $-2.5 < f_{T,5}/\Lambda^4 < 2.4$ ,  $-3.9 < f_{T,6}/\Lambda^4 < 3.9$ ,  $-8.5 < f_{T,7}/\Lambda^4 < 8.1$ ,  $-2.1 < f_{T,8}/\Lambda^4 < 2.1$ ,  $-4.5 < f_{T,9}/\Lambda^4 < 4.5$ , in units of  $\text{TeV}^{-4}$ . The article also reports limits on these couplings by cutting the EFT expansion at various values of the cut-off scale.

- <sup>2</sup>AAD 23BH study  $pp \rightarrow Z\gamma\gamma$  events with the Z boson decaying to electron or muon pairs. The number of observed data events is 148 for the electron mode and 171 for the muon mode. The respective number of (data-background) events is  $105.5 \pm 12.2(\text{stat}) \pm 8.1(\text{syst})$  and  $120.4 \pm 13.1(\text{stat}) \pm 9.4(\text{syst})$ . The corresponding number of predicted signal events is  $91.5 \pm 0.9$  and  $119.5 \pm 1.0$  using SHERPA (NLO), and  $91.0 \pm 1.0$  and  $118.1 \pm 1.2$  using MADGRAPH 5 AMC (NLO), where the error is statistical only. Analysing the transverse momentum distribution of the dilepton system, the following 95% C.L. limits are derived:  $-9.87 < f_{T,0}/\Lambda^4 < 9.33$ ,  $-9.88 < f_{T,1}/\Lambda^4 < 9.34$ ,  $-20.31 < f_{T,2}/\Lambda^4 < 18.68$ ,  $-4.64 < f_{T,5}/\Lambda^4 < 4.54$ ,  $-7.04 < f_{T,6}/\Lambda^4 < 6.94$ ,  $-15.55 < f_{T,7}/\Lambda^4 < 15.04$ ,  $-1.64 < f_{T,8}/\Lambda^4 < 1.61$ ,  $-3.26 < f_{T,9}/\Lambda^4 < 3.26$ , in units of  $\text{TeV}^{-4}$ .
- <sup>3</sup>AAD 23K measure Z production in association with a photon and two jets in proton-proton collisions at 13 TeV CM energy, where the Z boson decays into neutrinos. Within a sensitive fiducial phase-space region, 356 signal events are selected, with an expectation of  $357 \pm 30$ . Analysing the photon transverse energy distribution, the following 95% C.L. limits are derived in units of  $\text{TeV}^{-4}$ :  $-0.094 < f_{T,0}/\Lambda^4 < 0.084$ ,  $-0.088 < f_{T,5}/\Lambda^4 < 0.099$ ,  $-0.059 < f_{T,8}/\Lambda^4 < 0.059$ ,  $-0.13 < f_{T,9}/\Lambda^4 < 0.13$ ,  $-4.6 < f_{M,0}/\Lambda^4 < 4.6$ ,  $-7.7 < f_{M,1}/\Lambda^4 < 7.7$ ,  $-1.9 < f_{M,2}/\Lambda^4 < 1.9$ .
- <sup>4</sup>TUMASYAN 23AK study electroweak  $W\gamma$  production in association with 2 jets. The events selected for the couplings analysis are required to have a dijet invariant mass in excess of 800 GeV, jet-jet separation of at least 2.5 in rapidity, invariant mass of the  $W\gamma$  system larger than 150 GeV and transverse photon momentum larger than 100 GeV. Analysing the  $W\gamma$  invariant mass distribution, varying one coupling at a time while fixing the others to their Standard Model value, leads to the following 95% C.L. limits:  $-5.6 < f_{M,0}/\Lambda^4 < 5.5$ ,  $-7.8 < f_{M,1}/\Lambda^4 < 8.1$ ,  $-1.9 < f_{M,2}/\Lambda^4 < 1.9$ ,  $-2.7 < f_{M,3}/\Lambda^4 < 2.7$ ,  $-3.7 < f_{M,4}/\Lambda^4 < 3.6$ ,  $-3.9 < f_{M,5}/\Lambda^4 < 3.9$ ,  $-14 < f_{M,7}/\Lambda^4 < 14$ ,  $-0.47 < f_{T,0}/\Lambda^4 < 0.51$ ,  $-0.31 < f_{T,1}/\Lambda^4 < 0.34$ ,  $-0.85 < f_{T,2}/\Lambda^4 < 1.0$ ,  $-0.31 < f_{T,5}/\Lambda^4 < 0.33$ ,  $-0.25 < f_{T,6}/\Lambda^4 < 0.27$ ,  $-0.67 < f_{T,7}/\Lambda^4 < 0.73$ , in units of  $\text{TeV}^{-4}$ .
- <sup>5</sup>TUMASYAN 23AM use the combined CMS-TOTEM detector system to study exclusive  $\gamma\gamma \rightarrow WW$  and  $\gamma\gamma \rightarrow ZZ$  production in  $pp$  collisions at 13 TeV. The W and Z are identified through their hadronic decays with the added requirements of the invariant mass of the di-boson pair to be larger than 1 TeV, and the relative beam proton momentum loss between 0.04 and 0.20. The following limits are obtained at 95% C.L.: (i) on the dimension-6 (LEP like) couplings, in units of  $\text{GeV}^{-2}$ :  $|a_0^W/\Lambda^2| < 4.3 \times 10^{-6}$ ,  $|a_C^W/\Lambda^2| < 1.6 \times 10^{-5}$ ,  $|a_0^Z/\Lambda^2| < 0.9 \times 10^{-5}$ ,  $|a_C^Z/\Lambda^2| < 4.0 \times 10^{-5}$ . (ii) on the dimension-8 operators, in units of  $\text{TeV}^{-4}$ :  $|f_{M,0}/\Lambda^4| < 66.0$ ,  $|f_{M,1}/\Lambda^4| < 245.5$ ,  $|f_{M,2}/\Lambda^4| < 9.8$ ,  $|f_{M,3}/\Lambda^4| < 73.0$ ,  $|f_{M,4}/\Lambda^4| < 36.0$ ,  $|f_{M,5}/\Lambda^4| < 67.0$ ,  $|f_{M,7}/\Lambda^4| < 490.9$ .
- <sup>6</sup>SIRUNYAN 21 study electroweak Z-pair production in association with two jets, with the Z bosons decaying to oppositely-charged electron or muon pairs. Leptons with high transverse momentum are selected, with the di-lepton invariant mass of the two Z boson candidates between 60 GeV and 120 GeV, and the four-lepton invariant mass larger than 180 GeV. A total of 365 events are selected in the data, while the number of expected events is  $370 \pm 48$ . Analysing the four-lepton invariant mass distribution, the following 95% C.L. limits are derived:  $-0.24 < f_{T,0}/\Lambda^4 < 0.22$ ,  $-0.31 < f_{T,1}/\Lambda^4 < 0.31$ ,  $-0.63 < f_{T,2}/\Lambda^4 < 0.59$ ,  $-0.43 < f_{T,8}/\Lambda^4 < 0.43$ ,  $-0.92 < f_{T,9}/\Lambda^4 < 0.92$ , in units of  $\text{TeV}^{-4}$ .
- <sup>7</sup>TUMASYAN 21A study electroweak  $Z\gamma$  production in association with two jets, where the Z boson decays to electron or muon pairs and the pair of two jets has high invariant mass, superseding SIRUNYAN 20AL. The number of observed (expected) electron events in the barrel and endcap regions are 375 ( $349 \pm 9$ ) and 174 ( $166 \pm 6$ ) events, respectively, while for muon events the respective numbers are 584 ( $612 \pm 13$ ) and 320 ( $303 \pm 8$ ). Analysing the  $Z\gamma$  invariant mass distribution, the following 95% C.L. limits are derived:  $-15.8 < f_{M,0}/\Lambda^4 < 16.0$ ,  $-35.0 < f_{M,1}/\Lambda^4 < 34.7$ ,  $-6.55 < f_{M,2}/\Lambda^4 < 6.49$ ,  $-13.0 < f_{M,3}/\Lambda^4 < 13.0$ ,  $-13.0 < f_{M,4}/\Lambda^4 < 12.7$ ,  $-22.2 < f_{M,5}/\Lambda^4 < 21.3$ ,  $-56.6 < f_{M,7}/\Lambda^4 < 55.9$ ,  $-0.64 < f_{T,0}/\Lambda^4 < 0.57$ ,  $-0.81 < f_{T,1}/\Lambda^4 < 0.90$ ,  $-1.68 < f_{T,2}/\Lambda^4 < 1.54$ ,  $-0.58 < f_{T,5}/\Lambda^4 < 0.64$ ,  $-1.30 < f_{T,6}/\Lambda^4 < 1.33$ ,  $-2.15 < f_{T,7}/\Lambda^4 < 2.43$ ,  $-0.47 < f_{T,8}/\Lambda^4 < 0.47$ ,  $-0.91 < f_{T,9}/\Lambda^4 < 0.91$ , in units of  $\text{TeV}^{-4}$ .
- <sup>8</sup>TUMASYAN 21B measure W or Z boson production in association with two photons, using the leptonic decays modes of W and Z with electrons or muons. The number of selected  $W \rightarrow e(\mu)\nu$  events is 1987 (2384) and the number of selected  $Z \rightarrow ee(\mu\mu)$  events is 110 (272) respectively. Analysing the transverse momentum of the di-photon system, the following 95% C.L. limits are derived in units of  $\text{TeV}^{-4}$ . In the W production channel, the observed limits are:  $-39.9 < f_{M,2}/\Lambda^4 < 39.5$ ,  $-63.8 < f_{M,3}/\Lambda^4 < 65.0$ ,  $-1.30 < f_{T,0}/\Lambda^4 < 1.30$ ,  $-1.70 < f_{T,1}/\Lambda^4 < 1.66$ ,  $-3.64 < f_{T,2}/\Lambda^4 < 3.64$ ,  $-0.52 < f_{T,5}/\Lambda^4 < 0.60$ ,  $-0.60 < f_{T,6}/\Lambda^4 < 0.68$ ,  $-1.16 < f_{T,7}/\Lambda^4 < 1.16$ . In the Z production channel, the observed limits are:  $-5.70 < f_{T,0}/\Lambda^4 < 5.46$ ,  $-5.70 < f_{T,1}/\Lambda^4 < 5.46$ ,  $-11.4 < f_{T,2}/\Lambda^4 < 10.9$ ,  $-2.92 < f_{T,5}/\Lambda^4 < 2.92$ ,  $-3.80 < f_{T,6}/\Lambda^4 < 3.88$ ,  $-7.88 < f_{T,7}/\Lambda^4 < 7.72$ ,  $-1.06 < f_{T,8}/\Lambda^4 < 1.10$ ,  $-1.82 < f_{T,9}/\Lambda^4 < 1.82$ , in units of  $\text{TeV}^{-4}$ .
- <sup>9</sup>SIRUNYAN 20 study  $WZ$  and same-sign  $WW$  production in association with two jets, using the leptonic decays modes of the W and Z bosons with electrons or muons. Overall, 524  $WZ$  events and 229  $WW$  events are selected, with a Standard Model expectation of  $535 \pm 52$  and  $216 \pm 21$  events, respectively. Analysing the transverse mass spectrum of the di-boson system and the di-jet invariant mass, the following 95% C.L. limits are derived, not using any unitarization procedure:  $-0.25 < f_{T,0}/\Lambda^4 < 0.28$ ,  $-0.12 < f_{T,1}/\Lambda^4 < 0.14$ ,  $-0.35 < f_{T,2}/\Lambda^4 < 0.48$ ,  $-2.7 < f_{M,0}/\Lambda^4 < 2.9$ ,  $-4.1 < f_{M,1}/\Lambda^4 < 4.2$ ,  $-5.4 < f_{M,6}/\Lambda^4 < 5.8$ ,  $-5.7 < f_{M,7}/\Lambda^4 < 6.0$ ,  $-5.7 < f_{S,0}/\Lambda^4 < 6.1$ ,  $-16 < f_{S,1}/\Lambda^4 < 17$ , in units of  $\text{TeV}^{-4}$ . The article also reports limits on these couplings by cutting the EFT expansion at the unitarity limit.
- <sup>10</sup>SIRUNYAN 20AL study electroweak production of a Z boson and a photon in association with two jets in the electron and muon decay modes of the Z. A signal with a significance of 3.9 standard deviations is observed, compared to a Standard Model expectation of 5.2 standard deviations. Combining with KHACHATRYAN 17AA data at 8 TeV the final observed and expected signal significance is 4.7 and 5.5 standard deviations. Analysing the Z-photon invariant mass distribution, the following 95% C.L. limits are derived:  $-19.5 < f_{M,0}/\Lambda^4 < 20.3$ ,  $-40.5 < f_{M,1}/\Lambda^4 < 39.5$ ,  $-8.22 < f_{M,2}/\Lambda^4 < 8.10$ ,  $-17.7 < f_{M,3}/\Lambda^4 < 17.9$ ,  $-15.3 < f_{M,4}/\Lambda^4 < 15.8$ ,  $-25.1 < f_{M,5}/\Lambda^4 < 24.5$ ,  $-38.9 < f_{M,6}/\Lambda^4 < 40.6$ ,  $-60.3 < f_{M,7}/\Lambda^4 < 62.5$ ,  $-0.74 < f_{T,0}/\Lambda^4 < 0.69$ ,  $-0.98 < f_{T,1}/\Lambda^4 < 0.96$ ,  $-1.97 < f_{T,2}/\Lambda^4 < 1.86$ ,  $-0.70 < f_{T,5}/\Lambda^4 < 0.75$ ,  $-1.64 < f_{T,6}/\Lambda^4 < 1.68$ ,  $-2.59 < f_{T,7}/\Lambda^4 < 2.82$ ,  $-0.47 < f_{T,8}/\Lambda^4 < 0.47$ ,  $-1.27 < f_{T,9}/\Lambda^4 < 1.27$ , in units of  $\text{TeV}^{-4}$ .
- <sup>11</sup>SIRUNYAN 20BD study electroweak  $W\gamma$  production in association with two jets, where the W boson decays to electron or muon and the two jets have high invariant mass. The number of observed (expected) electron events with the photon in the barrel and endcap regions are 393 ( $397.1 \pm 18.5$ ) and 159 ( $145.2 \pm 10.0$ ) respectively, while for muon events the respective numbers are 565 ( $537.9 \pm 21.4$ ) and 201 ( $188.2 \pm 10.5$ ). Analysing the  $W\gamma$  invariant mass distribution, the following 95% C.L. limits are derived:  $-8.1 < f_{M,0}/\Lambda^4 < 8.0$ ,  $-12 < f_{M,1}/\Lambda^4 < 12$ ,  $-2.8 < f_{M,2}/\Lambda^4 < 2.8$ ,  $-4.4 < f_{M,3}/\Lambda^4 < 4.4$ ,  $-5.0 < f_{M,4}/\Lambda^4 < 5.0$ ,  $-8.3 < f_{M,5}/\Lambda^4 < 8.3$ ,  $-16 < f_{M,6}/\Lambda^4 < 16$ ,  $-21 < f_{M,7}/\Lambda^4 < 20$ ,  $-0.6 < f_{T,0}/\Lambda^4 < 0.6$ ,  $-0.4 < f_{T,1}/\Lambda^4 < 0.4$ ,  $-0.4$ ,  $-1.0 < f_{T,2}/\Lambda^4 < 1.2$ ,  $-0.5 < f_{T,5}/\Lambda^4 < 0.5$ ,  $-0.4 < f_{T,6}/\Lambda^4 < 0.4$ ,  $-0.9 < f_{T,7}/\Lambda^4 < 0.9$ , in units of  $\text{TeV}^{-4}$ .
- <sup>12</sup>SIRUNYAN 19BM search for the final state  $W^+W^-W^\pm$  using W decays to electrons or muons. Two event samples are considered, events with three leptons, or events with two oppositely charged leptons accompanied by two jets. In a kinematic region selected to enhance the effect of anomalous couplings, no events are selected in the data, and 95% C.L. upper limits are obtained as follows:  $-1.2 < f_{T,0}/\Lambda^4 < 1.2$ ,  $-3.3 < f_{T,1}/\Lambda^4 < 3.3$ ,  $-2.7 < f_{T,2}/\Lambda^4 < 2.6$ , in units of  $\text{TeV}^{-4}$  and without application of a form factor.
- <sup>13</sup>SIRUNYAN 19BP study  $WZ$  plus 2 jets production, using W and Z decay channels with electrons or muons. In the data, 75 events are selected, with a fitted SM signal of  $15.1 \pm 1.6$  events and a fitted background of  $62.4 \pm 2.8$  events. The transverse mass distribution of the  $WZ$  system is analyzed to set the following limits at 95% C.L., in units of  $\text{TeV}^{-4}$ :  $-9.15 < f_{M,0}/\Lambda^4 < 9.15$ ,  $-9.15 < f_{M,1}/\Lambda^4 < 9.45$ ,  $-26.5 < f_{S,0}/\Lambda^4 < 27.5$ ,  $-41.2 < f_{S,1}/\Lambda^4 < 42.8$ ,  $-0.75 < f_{T,0}/\Lambda^4 < 0.81$ ,  $-0.49 < f_{T,1}/\Lambda^4 < 0.55$ ,  $-1.49 < f_{T,2}/\Lambda^4 < 1.85$ .
- <sup>14</sup>SIRUNYAN 19CQ search for anomalous electroweak production of vector boson pairs in association with two jets. Events are selected by requiring two jets with a large invariant mass and rapidity separation, one or two leptons (electrons or muons), and a W or Z boson decaying hadronically. In the  $WV$  ( $ZV$ ) channel, 347 (47) events are selected in the data, with a total expected background of  $352 \pm 19$  ( $50.3 \pm 5.8$ ) events. Analysing the mass distribution of the  $WV$  or  $ZV$  system, the following 95% C.L. limits are obtained:  $-2.7 < f_{S,0}/\Lambda^4 < 2.7$ ,  $-3.4 < f_{S,1}/\Lambda^4 < 3.4$ ,  $-0.69 < f_{M,0}/\Lambda^4 < 0.70$ ,  $-2.0 < f_{M,1}/\Lambda^4 < 2.1$ ,  $-1.3 < f_{M,6}/\Lambda^4 < 1.3$ ,  $-3.4 < f_{M,7}/\Lambda^4 < 3.4$ ,  $-0.12 < f_{T,0}/\Lambda^4 < 0.11$ ,  $-0.12 < f_{T,1}/\Lambda^4 < 0.13$ ,  $-0.28 < f_{T,2}/\Lambda^4 < 0.28$ , in units of  $\text{TeV}^{-4}$ .
- <sup>15</sup>SIRUNYAN 18CC study  $pp$  collisions at  $\sqrt{s} = 13$  TeV leading to a pair of same-sign W pairs decaying leptonically ( $e$  or  $\mu$ ) associated with a pair of jets. Isolated leptons with  $p_T > 25$  (20) GeV for the leading (trailing) lepton, with  $|\eta| < 2.5$  (2.4) for  $e$  ( $\mu$ ) and jets with  $p_T > 30$  GeV,  $|\eta| < 5.0$ ,  $|\Delta\eta_{jj}| > 2.5$  and  $m_{jj} > 500$  GeV is required. Further cuts are applied to minimize  $Z \rightarrow ee$  events, non-promt leptons and hadronically decaying taus. The number of selected events is 201, with an expected SM signal of  $66.9 \pm 2.4$  and background of  $138 \pm 13$  events. Analysing the dilepton invariant mass spectrum the following 95% C.L. limits are derived:  $-7.7 < f_{S,0}/\Lambda^4 < 7.7$ ,  $-21.6 < f_{S,1}/\Lambda^4 < 21.8$ ,  $-6.0 < f_{M,0}/\Lambda^4 < 5.9$ ,  $-8.7 < f_{M,1}/\Lambda^4 < 9.1$ ,  $-11.9 < f_{M,6}/\Lambda^4 < 11.8$ ,  $-13.3 < f_{M,7}/\Lambda^4 < 12.9$ ,  $-0.62 < f_{T,0}/\Lambda^4 < 0.65$ ,  $-0.28 < f_{T,1}/\Lambda^4 < 0.31$ ,  $-0.89 < f_{T,2}/\Lambda^4 < 1.02$ .
- <sup>16</sup>AABOUD 17AA analyze  $W^\pm W^\pm$  production in association with two jets and W decay modes with electrons or muons. In the kinematic region of VBS the effect of anomalous QGCs is enhanced by requiring the transverse mass of the  $WW$  system to be larger than 400 GeV. In the data, 8 events are selected with a total background expected from SM processes of  $3.8 \pm 0.6$  events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the QGCs:  $-0.14 < \alpha_4 < 0.15$  and  $-0.22 < \alpha_5 < 0.22$ . Supersedes AAD 14AM.
- <sup>17</sup>AABOUD 17AG determine the  $W\gamma\gamma$  and  $WZ\gamma$  cross sections in 8 TeV  $pp$  interactions by studying the final states  $e\nu\mu\nu\gamma$  and  $e\nu j\gamma$  or  $\mu\nu j\gamma$ . Upper limits on the production cross sections are derived in a fiducial region optimized for BSM physics. These are used to derive the following 95% C.L. upper limits for quartic couplings assuming the form scale factor,  $\Lambda_{FF} = \infty$  (all in units of  $10^3 \text{TeV}^{-4}$ ):  $-0.3 < f_{M,0}/\Lambda^4 < 0.3$ ,  $-0.5 < f_{M,1}/\Lambda^4 < 0.5$ ,  $-1.8 < f_{M,2}/\Lambda^4 < 1.8$ ,  $-1.1 < f_{M,4}/\Lambda^4 < 1.1$ ,  $-1.7 < f_{M,5}/\Lambda^4 < 1.7$ ,  $-0.6 < f_{M,6}/\Lambda^4 < 0.6$ ,  $-1.1 < f_{M,7}/\Lambda^4 < 1.1$ ,  $-0.1 < f_{T,0}/\Lambda^4 < 0.1$ ,  $-0.2 < f_{T,1}/\Lambda^4 < 0.2$ ,  $-0.4 < f_{T,4}/\Lambda^4 < 0.4$ ,  $-1.5 < f_{T,5}/\Lambda^4 < 1.6$ ,  $-1.9 < f_{T,6}/\Lambda^4 < 1.9$ ,  $-4.3 < f_{T,7}/\Lambda^4 < 4.3$ .
- <sup>18</sup>AABOUD 17D analyze electroweak diboson ( $WV$ ,  $V = W, Z$ ) production in association with a high-mass dijet system. In the data, 32 events are selected with an expected total background of  $32 \pm 12$  events. Analysing the transverse mass distribution of the  $WV$  system, the following limits are set at 95% C.L.:  $-0.024 < \alpha_4 < 0.030$  and  $-0.028 < \alpha_5 < 0.033$ .
- <sup>19</sup>AABOUD 17J analyze the  $Z\gamma$  production in association with a high-mass dijet system, with the Z boson decaying into a pair of electrons, muons, or neutrinos. In the charged lepton (neutrino) channel, events are selected with a dijet mass larger than 500 (600) GeV and a transverse photon energy larger than 250 (150) GeV, with 2 (4) events selected in the data and  $0.30 \pm 0.08$  ( $1.6 \pm 0.5$ ) expected background events. The observed event yield is used to determine 95% CL limits as follows:  $-4.1 \times 10^3 <$

- $f_{T,9}/\Lambda^4 < 4.2 \times 10^3$ ,  $-1.9 \times 10^3 < f_{T,8}/\Lambda^4 < 2.1 \times 10^3$ ,  $-1.9 \times 10^1 < f_{T,0}/\Lambda^4 < 1.6 \times 10^1$ ,  $-1.6 \times 10^2 < f_{M,0}/\Lambda^4 < 1.8 \times 10^2$ ,  $-3.5 \times 10^2 < f_{M,1}/\Lambda^4 < 3.4 \times 10^2$ ,  $-8.9 \times 10^2 < f_{M,2}/\Lambda^4 < 8.9 \times 10^2$ ,  $-1.7 \times 10^3 < f_{M,3}/\Lambda^4 < 1.7 \times 10^3$ , in units of  $\text{TeV}^{-4}$  and without application of a form factor.
- 20** AABOUD 17M analyze tri-boson  $W^\pm W^\pm W^\mp$  production in decay channels with three charged leptons or two like-sign charged leptons with two jets, where the lepton can be an electron or muon. In the data, 24 tri-lepton events and 21 di-lepton plus jets events are selected, compared to a total event yield expected in the SM of  $30.8 \pm 3.0$  and  $21.9 \pm 2.0$ , respectively. Analysing the tri-lepton transverse mass or the transverse momentum sum of the two leptons, two jets and the missing transverse energy, the following limits at 95% CL are derived for the form factor cut-off scale  $\Lambda_{FF} \rightarrow \infty$ :  $-0.13 < f_{S,0}/\Lambda^4 < 0.18$ ,  $-0.21 < f_{S,1}/\Lambda^4 < 0.27$ , in units of  $10^4 \text{ TeV}^{-4}$ , which are converted into the following limits:  $-0.49 < \alpha_4 < 0.75$  and  $-0.48 < \alpha_5 < 0.62$ .
- 21** KHACHATRYAN 17AA analyse electroweak production of  $Z\gamma$  in association with two hadronic jets, with the Z boson decaying to electron or muon pairs. Events with photon transverse momentum larger than 60 GeV and di-jet invariant mass larger than 400 GeV are selected. The  $Z\gamma$  invariant mass spectrum is analysed to set 95% C.L. limits as follows:  $-71 < f_{M,0}/\Lambda^4 < 75$ ,  $-190 < f_{M,1}/\Lambda^4 < 182$ ,  $-32 < f_{M,2}/\Lambda^4 < 31$ ,  $-58 < f_{M,3}/\Lambda^4 < 59$ ,  $-3.8 < f_{T,0}/\Lambda^4 < 3.4$ ,  $-4.4 < f_{T,1}/\Lambda^4 < 4.4$ ,  $-9.9 < f_{T,2}/\Lambda^4 < 9.0$ ,  $-1.8 < f_{T,8}/\Lambda^4 < 1.8$ ,  $-4.0 < f_{T,9}/\Lambda^4 < 4.0$ , in units of  $\text{TeV}^{-4}$  and without application of a form factor.
- 22** KHACHATRYAN 17M analyse electroweak production of  $W\gamma$  in association with two hadronic jets, with the W boson decaying to electrons or muons. Events with photon transverse momentum larger than 200 GeV and di-jet invariant mass larger than 200 GeV are selected. The W transverse momentum spectrum is analysed to set 95% C.L. limits as follows:  $-77 < f_{M,0}/\Lambda^4 < 74$ ,  $-125 < f_{M,1}/\Lambda^4 < 129$ ,  $-26 < f_{M,2}/\Lambda^4 < 26$ ,  $-43 < f_{M,3}/\Lambda^4 < 44$ ,  $-40 < f_{M,4}/\Lambda^4 < 40$ ,  $-65 < f_{M,5}/\Lambda^4 < 65$ ,  $-129 < f_{M,6}/\Lambda^4 < 129$ ,  $-164 < f_{M,7}/\Lambda^4 < 162$ ,  $-5.4 < f_{T,0}/\Lambda^4 < 5.6$ ,  $-3.8 < f_{T,1}/\Lambda^4 < 4.0$ ,  $-11 < f_{T,2}/\Lambda^4 < 12$ ,  $-3.8 < f_{T,5}/\Lambda^4 < 3.8$ ,  $-2.7 < f_{T,6}/\Lambda^4 < 3.0$ ,  $-7.3 < f_{T,7}/\Lambda^4 < 7.7$ , in units of  $\text{TeV}^{-4}$  and without application of a form factor.
- 23** SIRUNYAN 17AD study  $pp$  collisions at  $\sqrt{s} = 13$  TeV to determine the cross section of  $ZZjj$  with the Z decaying to  $ee$  or  $\mu\mu$ . The ZZ mass distribution is used to set upper limits on the anomalous quartic couplings. The 95% upper limits for the relevant quartic couplings in units of  $\text{TeV}^{-4}$  are:  $-0.46 < f_{T,0}/\Lambda^4 < 0.44$ ,  $-0.61 < f_{T,1}/\Lambda^4 < 0.61$ ,  $-1.2 < f_{T,2}/\Lambda^4 < 1.2$ ,  $-0.84 < f_{T,8}/\Lambda^4 < 0.84$ ,  $-1.8 < f_{T,9}/\Lambda^4 < 1.8$ .
- 24** SIRUNYAN 17AR study  $pp$  collisions at  $\sqrt{s} = 8$  TeV to determine the cross section of  $pp \rightarrow W\gamma\gamma$  and  $pp \rightarrow Z\gamma\gamma$  where  $W \rightarrow \ell\nu$  and  $Z \rightarrow \ell^+\ell^-$ ,  $\ell$  being an electron or a muon. The number of W events in the e and  $\mu$  channels is 63 and 108 respectively, and the number of Z events in the e and  $\mu$  channels is 117 and 141. To increase sensitivity, the transverse momentum of the leading photon is required to be larger than 70 GeV. The 95% C.L. upper limits in units of  $\text{TeV}^{-4}$  are  $-701 < f_{M,2}/\Lambda^4 < 683$ ,  $-1170 < f_{M,3}/\Lambda^4 < 1220$ ,  $-33.5 < f_{T,0}/\Lambda^4 < 34.0$ ,  $-44.3 < f_{T,1}/\Lambda^4 < 44.8$ ,  $-93.8 < f_{T,2}/\Lambda^4 < 93.2$ .
- 25** AABOUD 16E study  $WW$  production in two-photon mediated  $pp$  collisions at 8 TeV where the W boson decays into an electron or muon, probing the  $\gamma\gamma WW$  vertex for anomalous quartic gauge couplings. The lepton  $p_T$  is required to be larger than 30 GeV. Limits on anomalous couplings are determined from events with  $p_T$  larger than 120 GeV where the aQGC effect is enhanced and the SM background reduced; in the data corresponding to an integrated luminosity of  $20.2\text{fb}^{-1}$ , 1 event is selected with an expected SM background of  $0.37 \pm 0.13$  events. The 95% C.L. limits without a form-factor cutoff ( $\Lambda_{\text{cutoff}} \rightarrow \infty$ ) are as follows:  $-1.7 < a_0^W/\Lambda^2 < 1.7$  and  $-6.4 < a_C^W/\Lambda^2 < 6.3$  in units of  $10^{-6} \text{ GeV}^{-2}$ . In terms of another set of variables:  $-6.6 < f_{M,0}/\Lambda^4 < 6.6$  and  $-24 < f_{M,1}/\Lambda^4 < 25$  in units of  $10^{-11} \text{ GeV}^{-4}$ .
- 26** AAD 16Q study  $Z\gamma\gamma$  production in  $pp$  collisions. In events with no additional jets, 29 ( $22$ ) Z decays to electron (muon) pairs are selected, with an expected background of  $3.3 \pm 1.1$  ( $6.5 \pm 2.0$ ) events, as well as 19 Z decays to neutrino pairs with an expected background of  $8.3 \pm 4.4$  events. Analysing the photon transverse momentum distribution for  $m_{\gamma\gamma}$  above 200 GeV (300 GeV) for lepton (neutrino) events, yields the 95% C.L. limits:  $-1.6 \times 10^4 < f_{M,2}/\Lambda^4 < 1.6 \times 10^4$ ,  $-2.9 \times 10^4 < f_{M,3}/\Lambda^4 < 2.7 \times 10^4$ ,  $-0.86 \times 10^2 < f_{T,0}/\Lambda^4 < 1.03 \times 10^2$ ,  $-0.69 \times 10^3 < f_{T,5}/\Lambda^4 < 0.68 \times 10^3$ ,  $-0.74 \times 10^4 < f_{T,9}/\Lambda^4 < 0.74 \times 10^4$  in units of  $\text{TeV}^{-4}$  and without application of a form factor  $\Lambda_{FF}$ .
- 27** KHACHATRYAN 16AX searches for anomalous  $WW\gamma\gamma$  quartic gauge couplings in the two-photon-mediated process  $pp \rightarrow ppWW$ , assuming the  $WW\gamma\gamma$  triple gauge boson couplings to be at their Standard Model values. 13 events containing an  $e^\pm\mu^\mp$  pair with  $p_T(e, \mu) > 30$  GeV are selected in a total luminosity of  $19.7 \text{ fb}^{-1}$ , with an expected  $\gamma\gamma \rightarrow WW$  signal of  $5.3 \pm 0.1$  events and an expected background of  $3.9 \pm 0.5$  events. When combining with the data collected at 7 TeV (KHACHATRYAN 13AA), and not assuming a form factor, the following 1-parameter limits at 95% C.L. are obtained from the  $p_T(e, \mu)$  spectrum:  $|a_0^W/\Lambda^2| < 1.1 \times 10^{-6} \text{ GeV}^{-2}$  ( $a_C^W = 0$ ), and  $|a_C^W/\Lambda^2| < 4.1 \times 10^{-6} \text{ GeV}^{-2}$  ( $a_0^W = 0$ ). In terms of another set of variables:  $|f_{M,0}/\Lambda^4| < 4.2 \times 10^{-12} \text{ GeV}^{-4}$ ,  $|f_{M,1}/\Lambda^4| < 16 \times 10^{-12} \text{ GeV}^{-4}$ ,  $|f_{M,2}/\Lambda^4| < 2.1 \times 10^{-12} \text{ GeV}^{-4}$ ,  $|f_{M,3}/\Lambda^4| < 7.8 \times 10^{-12} \text{ GeV}^{-4}$ .
- 28** AAD 15N study  $W\gamma\gamma$  events in 8 TeV  $pp$  interactions, where the W decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the  $p_T$  of the lepton and the photons being  $> 20$  GeV. The number of candidate events observed in the electron channel for  $N(\text{jet}) \geq 0$  and  $N(\text{jet}) = 0$  is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are  $30.2 \pm 7.4$ ,  $8.7 \pm 3.0$ ,  $52.1 \pm 12.2$ , and  $24.4 \pm 8.3$  respectively. The 95% C.L. limits on the values of the parameters  $f_{T,0}/\Lambda^4$ ,  $f_{M,2}/\Lambda^4$  and  $f_{M,3}/\Lambda^4$  are  $-0.9$ – $0.9 \times 10^2$ ,  $-0.8$ – $0.8 \times 10^4$ , and  $-1.5$ – $1.4 \times 10^4$  respectively, without application of a form factor  $\Lambda_{FF}$ .
- 29** KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from  $W^\pm W^\pm$  production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum  $> 20$  GeV. The dijet mass is required to be  $> 500$  GeV, the dilepton mass  $> 50$  GeV, with additional requirement of differing from the Z mass by  $> 15$  GeV. In the two categories  $W^+ W^+$  and  $W^- W^-$ , 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of  $19.4 \text{ fb}^{-1}$ , with an expected background of  $3.1 \pm 0.6$  and  $2.6 \pm 0.5$  events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of  $\text{TeV}^{-4}$ :  $-38 < f_{S,0}/\Lambda^4 < 40$ ,  $-118 < f_{S,1}/\Lambda^4 < 120$ ,  $-33 < f_{M,0}/\Lambda^4 < 32$ ,  $-44 < f_{M,1}/\Lambda^4 < 47$ ,  $-65 < f_{M,6}/\Lambda^4 < 63$ ,  $-70 < f_{M,7}/\Lambda^4 < 66$ ,  $-4.2 < f_{T,0}/\Lambda^4 < 4.6$ ,  $-1.9 < f_{T,1}/\Lambda^4 < 2.2$ ,  $-5.2 < f_{T,2}/\Lambda^4 < 6.4$ .
- 30** AAD 14AM analyze electroweak production of  $WW$  jet jet same-charge diboson plus two jets production, with the W bosons decaying to electron or muon, to study the quartic  $WWWW$  coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while  $29.8 \pm 2.4$  events are expected with a background of  $15.9 \pm 1.9$  events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% C.L. limits on the quartic gauge couplings:  $-0.14 < \alpha_4 < 0.16$  and  $-0.23 < \alpha_5 < 0.24$ .
- 31** KHACHATRYAN 14Q study  $WV\gamma$  production in 8 TeV  $pp$  collisions, in the single lepton final state, with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \text{dijet}$  or  $W \rightarrow \ell\nu$ ,  $W \rightarrow \text{dijet}$ , the dijet mass resolution precluding differentiation between the W and Z.  $p_T$  and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 70–100 GeV and  $|\Delta\eta_{jj}| < 1.4$ . The selected number of muon (electron) events are 183 (139), with SM expectation being  $194.2 \pm 11.5$  ( $147.9 \pm 10.7$ ) including signal and background. The photon  $E_T$  distribution is used to set limits on the anomalous quartic couplings. The following 95% C.L. limits are deduced (all in units of  $\text{TeV}^{-2}$  or  $\text{TeV}^{-4}$ ):  $-21 < a_0^W/\Lambda^2 < 20$ ,  $-34 < a_C^W/\Lambda^2 < 32$ ,  $-12 < \kappa_0^W/\Lambda^2 < 10$  and  $-18 < \kappa_C^W/\Lambda^2 < 17$ ; and  $-25 < f_{T,0}/\Lambda^4 < 24 \text{ TeV}^{-4}$ .
- 32** ABAZOV 13D searches for anomalous  $WW\gamma\gamma$  quartic gauge couplings in the two-photon-mediated process  $pp \rightarrow ppWW$ , assuming the  $WW\gamma\gamma$  triple gauge boson couplings to be at their Standard Model values. 946 events containing an  $e^+e^-$  pair with missing energy are selected in a total luminosity of  $9.7 \text{ fb}^{-1}$ , with an expectation of 983  $\pm$  108 events from Standard-Model processes. The following 1-parameter limits at 95% CL are obtained:  $|a_0^W/\Lambda^2| < 4.3 \times 10^{-4} \text{ GeV}^{-2}$  ( $a_C^W = 0$ ),  $|a_C^W/\Lambda^2| < 1.5 \times 10^{-3} \text{ GeV}^{-2}$  ( $a_0^W = 0$ ).
- 33** KHACHATRYAN 13AA searches for anomalous  $WW\gamma\gamma$  quartic gauge couplings in the two-photon-mediated process  $pp \rightarrow ppWW$ , assuming the  $WW\gamma\gamma$  triple gauge boson couplings to be at their Standard Model values. 2 events containing an  $e^\pm\mu^\mp$  pair with  $p_T(e, \mu) > 30$  GeV are selected in a total luminosity of  $5.05 \text{ fb}^{-1}$ , with an expected  $ppWW$  signal of  $2.2 \pm 0.4$  events and an expected background of  $0.84 \pm 0.15$  events. The following 1-parameter limits at 95% CL are obtained from the  $p_T(e, \mu)$  spectrum:  $|a_0^W/\Lambda^2| < 4.0 \times 10^{-6} \text{ GeV}^{-2}$  ( $a_C^W = 0$ ),  $|a_C^W/\Lambda^2| < 1.5 \times 10^{-5} \text{ GeV}^{-2}$  ( $a_0^W = 0$ ).
- 34** ABBIENDI 04B select 187  $e^+e^- \rightarrow W^+W^-\gamma$  events in the C.M. energy range 180–209 GeV, where  $E_\gamma > 2.5$  GeV, the photon has a polar angle  $|\cos\theta_\gamma| < 0.975$  and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the W mass within  $3 \Gamma_W$ . The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits:  $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.053 \text{ GeV}^{-2} < a_C/\Lambda^2 < 0.037 \text{ GeV}^{-2}$  and  $-0.16 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.15 \text{ GeV}^{-2}$ .
- 35** ABBIENDI 04L select 20  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  acoplanar events in the energy range 180–209 GeV and 176  $e^+e^- \rightarrow q\bar{q}\gamma\gamma$  events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  quartic couplings. Further combining with the  $W^+W^-\gamma$  sample of ABBIENDI 04B the following one-parameter 95% CL limits are obtained:  $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$ ,  $-0.029 < a_C^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$ ,  $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.052 < a_C^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ .
- 36** In the CM energy range 183 to 209 GeV HEISTER 04A select 30  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be  $> 5^\circ$ ,  $E_\gamma/\sqrt{s} > 0.025$  (the more energetic photon having energy  $> 0.2\sqrt{s}$ ),  $p_{T,\gamma}/E_{\text{beam}} > 0.05$  and  $|\cos\theta_\gamma| < 0.94$ . A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits:  $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_C^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_C^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$ .
- 37** ABDALLAH 03i select 122  $e^+e^- \rightarrow W^+W^-\gamma$  events in the C.M. energy range 189–209 GeV, where  $E_\gamma > 5$  GeV, the photon has a polar angle  $|\cos\theta_\gamma| < 0.95$  and is well isolated from the nearest charged fermion. A fit to the photon energy spectra yields  $a_C/\Lambda^2 = 0.000^{+0.019}_{-0.040} \text{ GeV}^{-2}$ ,  $a_0/\Lambda^2 = -0.004^{+0.018}_{-0.010} \text{ GeV}^{-2}$ ,  $\bar{a}_0/\Lambda^2 = -0.007^{+0.019}_{-0.008} \text{ GeV}^{-2}$ ,  $a_n/\Lambda^2 = -0.09^{+0.16}_{-0.05} \text{ GeV}^{-2}$ , and  $\bar{a}_n/\Lambda^2 = +0.05^{+0.07}_{-0.15} \text{ GeV}^{-2}$ , keeping the other parameters fixed to their Standard Model values (0). The 95% CL limits are:  $-0.063 \text{ GeV}^{-2} < a_C/\Lambda^2 < +0.032 \text{ GeV}^{-2}$ ,  $-0.020 \text{ GeV}^{-2} < a_0/\Lambda^2 < +0.020 \text{ GeV}^{-2}$ ,  $-0.18 \text{ GeV}^{-2} < \bar{a}_n/\Lambda^2 < +0.14 \text{ GeV}^{-2}$ ,  $-0.16 \text{ GeV}^{-2} < \bar{a}_n/\Lambda^2 < +0.17 \text{ GeV}^{-2}$ .
- 38** ACHARD 02F select 86  $e^+e^- \rightarrow W^+W^-\gamma$  events at 192–207 GeV, where  $E_\gamma > 5$  GeV and the photon is well isolated. They also select 43 acoplanar  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events in this energy range, where the photon energies are  $> 5$  GeV and  $> 1$  GeV and the photon polar angles are between  $14^\circ$  and  $166^\circ$ . All these 43 events are in the recoil mass region corresponding to the Z ( $75$ – $110$  GeV). Using the shape and normalization of the photon spectra in the  $W^+W^-\gamma$  events, and combining with the 42 event sample from 189 GeV data (ACCIARRI 00T), they obtain:  $a_0/\Lambda^2 = 0.000 \pm 0.010 \text{ GeV}^{-2}$ ,  $a_C/\Lambda^2 = -0.013 \pm 0.023 \text{ GeV}^{-2}$ , and  $a_n/\Lambda^2 = -0.002 \pm 0.076 \text{ GeV}^{-2}$ . Further combining the analyses of  $W^+W^-\gamma$  events with the low recoil mass region of  $\nu\bar{\nu}\gamma\gamma$  events (including samples collected at 183 + 189 GeV), they obtain the following one-parameter 95% CL

## Gauge &amp; Higgs Boson Particle Listings

## W, Z

limits:  $-0.015 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.015 \text{ GeV}^{-2}$ ,  $-0.048 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.026 \text{ GeV}^{-2}$ , and  $-0.14 \text{ GeV}^{-2} < a_n/\Lambda^2 < 0.13 \text{ GeV}^{-2}$ .

standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00q and ABBIENDI 04g for a detailed investigation of both these issues.

93.1 ± 1.0 ± 3.0	24	15 ALBAJAR 89	UA1	$E_{cm}^{p\bar{p}} = 546,630$ GeV

- AALTONEN 22 analyse Z decays in the di-muon and di-electron channels using their full Run-II data set. They obtain Z mass values of  $91192.0 \pm 6.4$  (stat.)  $\pm 4.0$  (syst.) MeV and  $91194.3 \pm 13.8$  (stat.)  $\pm 7.6$  (syst.) MeV, respectively. Combining these results using the systematic uncertainty contributions and their correlations as given in AALTONEN 22, we obtain an average of  $91192.3 \pm 5.8$  (stat.)  $\pm 4.1$  (syst.) MeV.
- This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00C, BARATE 00C, taking correlated uncertainties into account.
- ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic  $e^+p$  and  $e^-p$  neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.
- ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit-Wigner fits.
- ACHARD 04C select  $e^+e^- \rightarrow Z\gamma$  events with hard initial-state radiation. Z decays to  $q\bar{q}$  and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
- ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- The error includes 1.6 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- The error includes 1.8 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the  $\gamma/Z$  interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of  $\pm 2.3$  MeV due to the uncertainty on the  $\gamma Z$  interference.
- BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty. This result is included in the LEP average LEP-SLC 06.
- MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
- Enters fit through  $W/Z$  mass ratio given in the W Particle Listings. The ALITTI 92B systematic error ( $\pm 0.93$ ) has two contributions: one ( $\pm 0.92$ ) cancels in  $m_W/m_Z$  and one ( $\pm 0.12$ ) is noncancelling. These were added in quadrature.
- First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
- ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
- ALBAJAR 89 result is from a total sample of 33 Z  $\rightarrow e^+e^-$  events.

Z WIDTH

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note “The Z boson” and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included.

VALUE (GeV)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>2.4955 ± 0.0023 OUR EVALUATION</b>

3.8 ± 0.8 ± 1.0	188	ABE 89C	CDF	$E_{cm}^{p\bar{p}} = 1.8$ TeV
2.42 + 0.45 - 0.35	480	10 ABRAMS 89B	MRK2	$E_{cm}^{ee} = 89-93$ GeV
2.7 + 1.2 - 1.0 ± 1.3	24	11 ALBAJAR 89	UA1	$E_{cm}^{p\bar{p}} = 546,630$ GeV
2.7 ± 2.0 ± 1.0	25	12 ANSARI 87	UA2	$E_{cm}^{p\bar{p}} = 546,630$ GeV

- JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.
- VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity bias.
- ABBIENDI 04G obtain this result using the S-matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit-Wigner fits.
- ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.
- The error includes 1.2 MeV due to LEP energy uncertainty.
- The error includes 1.3 MeV due to LEP energy uncertainty.
- ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the  $\gamma/Z$  interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.
- BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.
- ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process  $e^+e^- \rightarrow Z \rightarrow \mu^+\mu^-$ .
- ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.
- ALBAJAR 89 result is from a total sample of 33 Z  $\rightarrow e^+e^-$  events.
- Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either  $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$ , CL = 90% or  $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$ . Assuming Standard-Model value  $\Gamma(W) = 2.65$  GeV then gives  $\Gamma(Z) < 2.89 \pm 0.19$  or  $= 2.17^{+0.50}_{-0.37} \pm 0.16$ .

[a]  $\ell$  indicates each type of lepton ( $e$ ,  $\mu$ , and  $\tau$ ), not sum over them.

[b] Here  $\ell$  indicates  $e$  or  $\mu$ .

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] This value is updated using the product of (i) the  $Z \rightarrow b\bar{b}$  fraction from this listing and (ii) the  $b$ -hadron fraction in an unbiased sample of weakly decaying  $b$ -hadrons produced in  $Z$ -decays provided by the Heavy Flavor Averaging Group (HFLAV, [http://www.slac.stanford.edu/xorg/hflav/osc/PDG\\_2009/#FRACZ](http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ)).

[e] See the Particle Listings below for the  $\gamma$  energy range used in this measurement.

[f] For  $m_{\gamma\gamma} = (60 \pm 5)$  GeV.

## Z PARTIAL WIDTHS

$\Gamma(e^+e^-)$   $\Gamma_1$   
For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06.

$\Gamma(\ell^+\ell^-)$   $\Gamma_4$   
 $\ell$  indicates each type of lepton ( $e$ ,  $\mu$ , and  $\tau$ ), not sum over them.

In our fit  $\Gamma(\ell^+\ell^-)$  is defined as the partial Z width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

$\Gamma(\text{invisible})$   $\Gamma_7$

The Z boson also decays to final states invisible in any detector, for example, the decay to a neutrino pair as predicted in the Standard Model. Measurements of  $\Gamma(\text{invisible})$  fall into two categories: direct or indirect. Direct measurements look for final states with missing energy, missing momentum, or missing mass, corresponding to the invisible decay of a produced Z boson, including single-photon final states which arise from initial-state radiation. The indirect determination is based on Z lineshape analyses performed at the LEP collider, where the invisible decay width is calculated by subtracting all visible partial decay widths from the total decay width of the Z boson. Within the framework of the Standard Model these two determinations should be identical, but not in non-SM scenarios.

• • • We do not use the following data for averages, fits, limits, etc. • • •

1 TUMASYAN 23E analyses leptonic Z decay modes, with the invisible Z decay identified by missing momentum.

2 The LEP Collaborations perform a combined fit to their line-shape results and determine this quantity as a difference between the total width and the sum of all the visible widths, assuming lepton universality. This result combines ABBIENDI 01A, ABREU 00F, ACCIARRI 00c, BARATE 00c, taking correlated uncertainties into account.

3 This analysis selects single-photon events arising from initial state radiation.

4 This is an indirect determination of  $\Gamma(\text{invisible})$  from a fit to the visible Z decay modes. It is included in the determination of the LEP average LEP-SLC 06 reported above.

$\Gamma(\text{hadrons})$   $\Gamma_8$   
This parameter is not directly used in the 5-parameter fit assuming lepton universality, but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

4.6 <sup>+1.0</sup> <sub>-0.9</sub> ± 0.2	28	<sup>5</sup> CHATRCHYAN	12BN CMS	$E_{cm}^{pp} = 7$ TeV

<sup>1</sup> AAD 21AQ analyze differential cross-sections in four-lepton events. Based on the measured cross section in the  $Z \rightarrow 4\ell$  channel, a branching fraction of  $B(Z \rightarrow 4\ell) = (4.41 \pm 0.13 \pm 0.23 \pm 0.09 \pm 0.12) \times 10^{-6}$  is obtained, where the uncertainties are statistical, systematic, theory and luminosity, respectively.

<sup>2</sup> AABOUD 19N reports  $(4.70 \pm 0.32 \pm 0.21 \pm 0.14) \times 10^{-6}$ , where the uncertainties are statistical, systematic, and luminosity. We have combined the latter two in quadrature.

<sup>3</sup> SIRUNYAN 18BT report the  $Z \rightarrow 4\ell$  branching fraction =  $(4.83^{+0.23+0.32}_{-0.22-0.29} \pm 0.08 \pm 0.12) \times 10^{-6}$ , where the uncertainties are statistical, systematic, due to theory, and luminosity. The last three have been added in quadrature to obtain the total systematic error.

<sup>4</sup> KHACHATRYAN 16CC reports  $(4.9^{+0.8+0.3+0.2+0.1}_{-0.7-0.2-0.1-0.1}) \times 10^{-6}$  value, where the uncertainties are statistical, systematic, theory, and due to luminosity. We have combined uncertainties in quadrature.

<sup>5</sup> CHATRCHYAN 12BN reports  $(4.2^{+0.9}_{-0.8} \pm 0.2) \times 10^{-6}$  value. Their result (both central value and uncertainties) is scaled up by 10% to account for the different phase-space definition used here (see RAINBOLT 19).

• • • We do not use the following data for averages, fits, limits, etc. • • •			
0.1623 ± 0.0085 ± 0.0209	6 ABREU	95D DLPH	$E_{cm}^{ee} = 88-94$ GeV

<sup>1</sup> ABE 05F use hadronic Z decays collected during 1996-98 to obtain an enriched sample of  $c\bar{c}$  events using a double tag method. The single  $c$ -tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and  $R_c$  is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of  $\pm 0.0006$  due to the uncertainty on  $R_b$ .

<sup>2</sup> ABREU 00 obtain this result properly combining the measurement from the  $D^{*+}$  production rate ( $R_c = 0.1610 \pm 0.0104 \pm 0.0077 \pm 0.0043$  (BR)) with that from the overall charm counting ( $R_c = 0.1692 \pm 0.0047 \pm 0.0063 \pm 0.0074$  (BR)) in  $c\bar{c}$  events. The systematic error includes an uncertainty of  $\pm 0.0054$  due to the uncertainty on the charmed hadron branching fractions.

<sup>3</sup> BARATE 00B use exclusive decay modes to independently determine the quantities  $R_c \times f(c \rightarrow X)$ ,  $X = D^0, D^+, D_s^+$ , and  $A_c$ . Estimating  $R_c \times f(c \rightarrow \Xi_c / \Omega_c) = 0.0034$ , they simply sum over all the charm decays to obtain  $R_c = 0.1738 \pm 0.0047 \pm 0.0088 \pm 0.0075$  (BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G,  $R_c = 0.1681 \pm 0.0054 \pm 0.0062$ ) to obtain the quoted value.

<sup>4</sup> ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet  $D^{*+}$  mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive  $D^{*+}$ ) tag is used. The  $b$  content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed  $D^{*+}$  meson in the opposite jet. The systematic error includes an uncertainty of  $\pm 0.006$  due to the external branching ratios.

<sup>5</sup> ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from  $D^0, D^+, D_s^+$ , and  $A_c^+$ , and assuming that strange-charmed baryons account for the 15% of the  $A_c^+$  production. An uncertainty of  $\pm 0.005$  due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

<sup>6</sup> ABREU 95D perform a maximum likelihood fit to the combined  $p$  and  $p_T$  distributions of single and dilepton samples. The second error includes an uncertainty of  $\pm 0.0124$  due to models and branching ratios.

$R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$   $\Gamma_{12}/\Gamma_8$

OUR FIT is obtained by a simultaneous fit to several  $c$ - and  $b$ -quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

The Standard Model predicts  $R_b = 0.21581$  for  $m_t = 174.3$  GeV and  $M_H = 150$  GeV.

<sup>1</sup> ABE 05F use hadronic Z decays collected during 1996-98 to obtain an enriched sample of  $b\bar{b}$  events using a double tag method. The single  $b$ -tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the  $D$ -meson mass). ABE 05F obtain  $R_b = 0.21604 \pm 0.00098 \pm 0.00074$  where the systematic error includes an uncertainty of  $\pm 0.00012$  due to the uncertainty on  $R_c$ . The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of  $\pm 0.00012$  due to the uncertainty on  $R_c$ .

<sup>2</sup> ACCIARRI 00 obtain this result using a double-tagging technique, with a high  $p_T$  lepton tag and an impact parameter tag in opposite hemispheres.

<sup>3</sup> ABBIENDI 99B tag  $Z \rightarrow b\bar{b}$  decays using leptons and/or separated decay vertices. The  $b$ -tagging efficiency is measured directly from the data using a double-tagging technique.

<sup>4</sup> ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event

shape variables). For  $R_c$  different from its Standard Model value of 0.172,  $R_b$  varies as  $-0.024 \times (R_c - 0.172)$ .

<sup>5</sup> BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify  $Z \rightarrow b\bar{b}$  candidates. They further use  $c$ - and  $ud$ -selection tags to identify the background. For  $R_c$  different from its Standard Model value of 0.172,  $R_b$  varies as  $-0.019 \times (R_c - 0.172)$ .

<sup>6</sup> ABREU 95D perform a maximum likelihood fit to the combined  $p$  and  $p_T$  distributions of single and dilepton samples. The second error includes an uncertainty of  $\pm 0.0023$  due to models and branching ratios.

<sup>7</sup> BUSKULIC 94G perform a simultaneous fit to the  $p$  and  $p_T$  spectra of both single and dilepton events.

<sup>8</sup> JACOBSEN 91 tagged  $b\bar{b}$  events by requiring coincidence of  $\geq 3$  tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties ( $\pm 0.014$ ).

$\Gamma(b\bar{b}b\bar{b})/\Gamma(\text{hadrons})$   $\Gamma_{13}/\Gamma_8$

<sup>1</sup> SIRUNYAN 19AJ study  $Z \rightarrow J/\psi\gamma$  with  $J/\psi \rightarrow \mu^+ \mu^-$ . Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is required to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the  $\mu\mu$  ( $\mu\mu\gamma$ ) system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the Z branching fraction is obtained assuming the  $J/\psi$  to be unpolarized.

<sup>2</sup> AABOUD 18BL study  $Z \rightarrow J/\psi\gamma$  in 13 TeV  $pp$  interactions. Two triggers were used: isolated photon of  $p_T > 35(25)$  GeV and a muon with  $p_T > 18(24)$  GeV. The  $J/\psi$  is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the  $J/\psi$  in the plane transverse to the beam direction is  $> \pi/2$ . The number of observed/expected background events is 92/89  $\pm 6$  in the dimuon mass range 2.9–3.3 GeV leading to the quoted 95% C.L. limit.

<sup>3</sup> AAD 15I use events with the highest  $p_T$  muon in the pair required to have  $p_T > 20$  GeV, the dimuon mass required to be within 0.2 GeV of the  $J/\psi(1S)$  mass and it's transverse momentum required to be  $> 36$  GeV. The photon is also required to have it's  $p_T > 36$  GeV.

<b><math>0.67 \pm 0.18 \pm 0.05</math></b>		<sup>1</sup> SIRUNYAN	18Dz	CMS	$pp$ at 13 TeV	

<sup>1</sup> SIRUNYAN 18Dz observe the decay  $Z \rightarrow \Psi \ell^+ \ell^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV, where  $\Psi$  includes  $J/\psi$  as well as  $\psi(2S) \rightarrow J/\psi X$ , and  $\ell^+ \ell^-$  represents an electron or muon pair while the  $J/\psi$  is detected via its  $\mu^+ \mu^-$  decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of  $Z \rightarrow \mu^+ \mu^- \mu^+ \mu^-$  within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and  $J/\psi$  transverse momentum. The number of selected  $\Psi \mu^+ \mu^-$  ( $\Psi e^+ e^-$ ) candidate events is 29 (18). Analyzing the  $\mu^+ \mu^-$  and  $\mu^+ \mu^- \ell^+ \ell^-$  invariant mass distributions, a yield of  $13.0 \pm 3.9$  ( $11.2 \pm 3.4$ ) events for the  $\Psi \mu^+ \mu^-$  ( $\Psi e^+ e^-$ ) mode is obtained. The ratio of the branching fractions is determined as  $0.67 \pm 0.18 \pm 0.05$  within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of  $B(Z \rightarrow \mu^+ \mu^- \mu^+ \mu^-) = (1.20 \pm 0.08) \times 10^{-6}$ , they estimate  $B(Z \rightarrow J/\psi \ell^+ \ell^-) = 8 \times 10^{-7}$ .

<sup>1</sup> ACKERSTAFF 98o searched for the decay modes  $B_c \rightarrow J/\psi \pi^+$ ,  $J/\psi a_1^+$ , and  $J/\psi \ell^+ \nu_\ell$ , with  $J/\psi \rightarrow \ell^+ \ell^-$ ,  $\ell = e, \mu$ . The number of candidates (background) for

the three decay modes is  $2(0.63 \pm 0.2)$ ,  $0(1.10 \pm 0.22)$ , and  $1(0.82 \pm 0.19)$  respectively. Interpreting the  $2B_c \rightarrow J/\psi\pi^+$  candidates as signal, they report  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\pi^+)/\Gamma(\text{hadrons}) = (3.8_{-2.4}^{+5.0} \pm 0.5) \times 10^{-5}$ . Interpreted as background, the 90% CL bounds are  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\pi^+)/\Gamma(\text{hadrons}) < 1.06 \times 10^{-4}$ ,  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi a_1^+)/\Gamma(\text{hadrons}) < 5.29 \times 10^{-4}$ ,  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\ell^+\nu_\ell)/\Gamma(\text{hadrons}) < 6.96 \times 10^{-5}$ .

<sup>2</sup> ABREU 97E searched for the decay modes  $B_c \rightarrow J/\psi\pi^+$ ,  $J/\psi\ell^+\nu_\ell$ , and  $J/\psi(3\pi)^+$ , with  $J/\psi \rightarrow \ell^+\ell^-$ ,  $\ell = e, \mu$ . The number of candidates (background) for the three decay modes is 1(1.7), 0(0.3), and 1(2.3) respectively. They report the following 90% CL limits:  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\pi^+)/\Gamma(\text{hadrons}) < (1.05-0.84) \times 10^{-4}$ ,  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\ell^+\nu_\ell)/\Gamma(\text{hadrons}) < (5.8-5.0) \times 10^{-5}$ ,  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi(3\pi)^+)/\Gamma(\text{hadrons}) < 1.75 \times 10^{-4}$ , where the ranges are due to the predicted  $B_c$  lifetime (0.4-1.4) ps.

<sup>3</sup> BARATE 97H searched for the decay modes  $B_c \rightarrow J/\psi\pi^+$  and  $J/\psi\ell^+\nu_\ell$  with  $J/\psi \rightarrow \ell^+\ell^-$ ,  $\ell = e, \mu$ . The number of candidates (background) for the two decay modes is 0(0.44) and 2(0.81) respectively. They report the following 90% CL limits:  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\pi^+)/\Gamma(\text{hadrons}) < 3.6 \times 10^{-5}$  and  $\Gamma(B_c^+ X) \times B(B_c \rightarrow J/\psi\ell^+\nu_\ell)/\Gamma(\text{hadrons}) < 5.2 \times 10^{-5}$ .

### $\Gamma(\Lambda_c^+ X)/\Gamma(\text{hadrons})$ $\Gamma_{54}/\Gamma_8$

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.022 ± 0.005 OUR AVERAGE</b>			
0.024 ± 0.005 ± 0.006	<sup>1</sup> ALEXANDER 96R	OPAL	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV
0.021 ± 0.003 ± 0.005	<sup>2</sup> BUSKULIC 96V	ALEP	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV

<sup>1</sup> ALEXANDER 96R measure  $R_b \times f(b \rightarrow \Lambda_c^+ X) \times B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (0.122 \pm 0.023 \pm 0.010)\%$  in hadronic Z decays; the value quoted here is obtained using our best value  $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (5.0 \pm 1.3)\%$ . The first error is the total experiment's error and the second error is the systematic error due to the branching fraction uncertainty.

<sup>2</sup> BUSKULIC 96V obtain the production fraction of  $\Lambda_c^+$  baryons in hadronic Z decays  $f(b \rightarrow \Lambda_c^+ X) = 0.110 \pm 0.014 \pm 0.006$  using  $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (4.4 \pm 0.6)\%$ ; we have rescaled using our best value  $B(\Lambda_c^+ \rightarrow pK^-\pi^+) = (5.0 \pm 1.3)\%$  obtaining  $f(b \rightarrow \Lambda_c^+ X) = 0.097 \pm 0.013 \pm 0.025$  where the first error is their total experiment's error and the second error is the systematic error due to the branching fraction uncertainty. The value quoted here is obtained multiplying this production fraction by our value of  $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$ .

### $\Gamma(\Xi_c^0 X)/\Gamma(\text{hadrons})$ $\Gamma_{55}/\Gamma_8$

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
seen	<sup>1</sup> ABDALLAH 05c	DLPH	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV

<sup>1</sup> ABDALLAH 05c searched for the charmed strange baryon  $\Xi_c^0$  in the decay channel  $\Xi_c^0 \rightarrow \Xi^-\pi^+$  ( $\Xi^- \rightarrow \Lambda\pi^-$ ). The production rate is measured to be  $f_{\Xi_c^0} \times B(\Xi_c^0 \rightarrow \Xi^-\pi^+) = (4.7 \pm 1.4 \pm 1.1) \times 10^{-4}$  per hadronic Z decay.

### $\Gamma(\Xi_b X)/\Gamma(\text{hadrons})$ $\Gamma_{56}/\Gamma_8$

Here  $\Xi_b$  is used as a notation for the strange  $b$ -baryon states  $\Xi_b^-$  and  $\Xi_b^0$ .

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
seen	<sup>1</sup> ABDALLAH 05c	DLPH	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV
seen	<sup>2</sup> BUSKULIC 96T	ALEP	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV
seen	<sup>3</sup> ABREU 95v	DLPH	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV

<sup>1</sup> ABDALLAH 05c searched for the beauty strange baryon  $\Xi_b$  in the inclusive semileptonic decay channel  $\Xi_b \rightarrow \Xi^-\ell^+\nu_\ell X$ . Evidence for the  $\Xi_b$  production is seen from the observation of  $\Xi\bar{\Xi}$  production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs  $\Xi\bar{\Xi}\ell^+\ell^-$  compared to "wrong-sign" pairs  $\Xi\bar{\Xi}\ell^\pm\ell^\pm$  the production rate is measured to be  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^-\ell^+ X) = (3.0 \pm 1.0 \pm 0.3) \times 10^{-4}$  per lepton species, averaged over electrons and muons.

<sup>2</sup> BUSKULIC 96T investigate  $\Xi$ -lepton correlations and find a significant excess of "right-sign" pairs  $\Xi\bar{\Xi}\ell^+\ell^-$  compared to "wrong-sign" pairs  $\Xi\bar{\Xi}\ell^\pm\ell^\pm$ . This excess is interpreted as evidence for  $\Xi_b$  semileptonic decay. The measured product branching ratio is  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow X_c X \ell^+ \nu_\ell) \times B(X_c \rightarrow \Xi^- X') = (5.4 \pm 1.1 \pm 0.8) \times 10^{-4}$  per lepton species, averaged over electrons and muons, with  $X_c$  a charmed baryon.

<sup>3</sup> ABREU 95v observe an excess of "right-sign" pairs  $\Xi\bar{\Xi}\ell^+\ell^-$  compared to "wrong-sign" pairs  $\Xi\bar{\Xi}\ell^\pm\ell^\pm$  in jets; this excess is interpreted as evidence for the beauty strange baryon  $\Xi_b$  production, with  $\Xi_b \rightarrow \Xi^-\ell^+\nu_\ell X$ . They find that the probability for this signal to come from non  $b$ -baryon decays is less than  $5 \times 10^{-4}$  and that  $\Lambda_b$  decays can account for less than 10% of these events. The  $\Xi_b$  production rate is then measured to be  $B(b \rightarrow \Xi_b) \times B(\Xi_b \rightarrow \Xi^-\ell^+ X) = (5.9 \pm 2.1 \pm 1.0) \times 10^{-4}$  per lepton species, averaged over electrons and muons.

### $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons})$ $\Gamma_{57}/\Gamma_8$

"OUR EVALUATION" is obtained using our current values for  $f(b \rightarrow b\text{-baryon})$  and  $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$ . We calculate  $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons}) = R_b \times f(b \rightarrow b\text{-baryon})$ .

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.0197 ± 0.0032 OUR EVALUATION</b>	(Produced by HFLAV)		
<b>0.0221 ± 0.0015 ± 0.0058</b>	<sup>1</sup> BARATE 98v	ALEP	$E_{\text{cm}}^{\text{ee}} = 88-94$ GeV

<sup>1</sup> BARATE 98v use the overall number of identified protons in  $b$ -hadron decays to measure  $f(b \rightarrow b\text{-baryon}) = 0.102 \pm 0.007 \pm 0.027$ . They assume  $\text{BR}(b\text{-baryon} \rightarrow pX) = (58 \pm 6)\%$  and  $\text{BR}(B_s^0 \rightarrow pX) = (8.0 \pm 4.0)\%$ . The value quoted here is obtained multiplying this production fraction by our value of  $R_b = \Gamma(b\bar{b})/\Gamma(\text{hadrons})$ .

## Z HADRONIC POLE CROSS SECTION

OUR EVALUATION is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). Corrections as discussed in VOUTSINAS 20 and JANOT 20 are also included. This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

VALUE (nb)	EVTS	DOCUMENT ID	TECN	COMMENT
<b>41.4802 ± 0.0325 OUR EVALUATION</b>				
41.4802 ± 0.0325		<sup>1</sup> JANOT 20		
• • • We do not use the following data for averages, fits, limits, etc. • • •				
41.500 ± 0.037		<sup>2</sup> VOUTSINAS 20		
41.541 ± 0.037		LEP-SLC 06		$E_{cm}^{ee} = 88-94$ GeV
41.501 ± 0.055	4.10M	<sup>3</sup> ABBIENDI 01A	OPAL	$E_{cm}^{ee} = 88-94$ GeV
41.578 ± 0.069	3.70M	ABREU 00F	DLPH	$E_{cm}^{ee} = 88-94$ GeV
41.535 ± 0.055	3.54M	ACCIARRI 00C	L3	$E_{cm}^{ee} = 88-94$ GeV
41.559 ± 0.058	4.07M	<sup>4</sup> BARATE 00C	ALEP	$E_{cm}^{ee} = 88-94$ GeV
42 ± 4	450	ABRAMS 89B	MRK2	$E_{cm}^{ee} = 89.2-93.0$ GeV

<sup>1</sup> JANOT 20 applies a correction to LEP-SLC 06 using an updated Bhabha cross section calculation. This result also includes a correction to account for correlated luminosity bias as presented in VOUTSINAS 20.

<sup>2</sup> VOUTSINAS 20 applies a correction to LEP-SLC 06 to account for correlated luminosity bias.

<sup>3</sup> ABBIENDI 01A error includes approximately 0.031 due to statistics, 0.033 due to event selection systematics, 0.029 due to uncertainty in luminosity measurement, and 0.011 due to LEP energy uncertainty.

<sup>4</sup> BARATE 00C error includes approximately 0.030 due to statistics, 0.026 due to experimental systematics, and 0.025 due to uncertainty in luminosity measurement.

## Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters,  $A_e$ ,  $A_\mu$ , and  $A_\tau$ . By convention the sign of  $g_A^e$  is fixed to be negative (and opposite to that of  $g_V^e$  obtained using  $\nu_e$  scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and  $A_e$ ,  $A_\mu$ , and  $A_\tau$  measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where  $p\bar{p}$  and  $e\bar{p}$  data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

<sup>1</sup> ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic  $e^+p$  and  $e^-p$  neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

<sup>2</sup> ABAZOV 11D study  $p\bar{p} \rightarrow Z/\gamma^* e^+e^-$  events using 5  $\text{fb}^{-1}$  data at  $\sqrt{s} = 1.96$  TeV. The candidate events are selected by requiring two isolated electromagnetic showers with  $E_T > 25$  GeV, at least one electron in the central region and the di-electron mass in the range 50–1000 GeV. From the forward-backward asymmetry, determined as a function of

the di-electron mass, they derive the axial and vector couplings of the  $u$ - and  $d$ -quarks and the value of  $\sin^2\theta_{eff}^l = 0.2309 \pm 0.0008(\text{stat}) \pm 0.0006(\text{syst})$ .

<sup>3</sup> LEP-SLC 06 is a combination of the results from LEP and SLC experiments using light quark tagging.  $s$ - and  $d$ -quark couplings are assumed to be identical.

<sup>4</sup> ACOSTA 05M determine the forward-backward asymmetry of  $e^+e^-$  pairs produced via  $q\bar{q} \rightarrow Z/\gamma^* \rightarrow e^+e^-$  in 15  $M(e^+e^-)$  effective mass bins ranging from 40 GeV to 600 GeV. These results are used to obtain the vector and axial-vector couplings of the Z to the light quarks, assuming the electron couplings are as predicted by the Standard Model. Higher order radiative corrections have not been taken into account.

<sup>5</sup> ABRAMOWICZ 16A determine the  $Z^0$  couplings to  $u$ - and  $d$ -quarks using the ZEUS polarised data from Run II together with the unpolarised data from both ZEUS and H1 Collaborations for Run I and unpolarised H1 data from Run II.

<sup>6</sup> ABT 16 determine the  $Z^0$  couplings to  $u$ - and  $d$ -quarks using the same techniques and data as ABRAMOWICZ 16A but additionally use the published H1 polarised data.

<sup>7</sup> AKTAS 06 fit the neutral current ( $1.5 \leq Q^2 \leq 30,000$   $\text{GeV}^2$ ) and charged current ( $1.5 \leq Q^2 \leq 15,000$   $\text{GeV}^2$ ) differential cross sections. In the determination of the  $u$ -quark couplings the electron and  $d$ -quark couplings are fixed to their standard model values.

## Z AXIAL-VECTOR COUPLINGS

These quantities are the effective axial-vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters,  $A_e$ ,  $A_\mu$ , and  $A_\tau$ . By convention the sign of  $g_A^e$  is fixed to be negative (and opposite to that of  $g_V^e$  obtained using  $\nu_e$  scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and  $A_e$ ,  $A_\mu$ , and  $A_\tau$  measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where  $p\bar{p}$  and  $e p$  data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

## Z COUPLINGS TO NEUTRAL LEPTONS

Averaging over neutrino species, the invisible Z decay width determines the effective neutrino coupling  $g^{\nu e}$ . For  $g^{\nu e}$  and  $g^{\nu\mu}$ ,  $\nu_e e$  and  $\nu_\mu e$  scattering results are combined with  $g_A^e$  and  $g_V^e$  measurements at the Z mass to obtain  $g^{\nu e}$  and  $g^{\nu\mu}$  following NOVIKOV 93c.

	<b><math>0.502 \pm 0.017</math></b>	<sup>1</sup> VILAIN 94	CHM2	From $\nu_\mu e$ scattering

- <sup>1</sup> VILAIN 94 derive this value from their measurement of the couplings  $g_A^{e\nu\mu} = -0.503 \pm 0.017$  and  $g_V^{e\nu\mu} = -0.035 \pm 0.017$  obtained from  $\nu_\mu e$  scattering. We have re-evaluated this value using the current PDG values for  $g_A^e$  and  $g_V^e$ .

## Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where  $g_V^f$  and  $g_A^f$  are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

$A_e$

Using polarized beams, this quantity can also be measured as  $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$ , where  $\sigma_L$  and  $\sigma_R$  are the  $e^+e^-$  production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in  $\mu^+\mu^-$  decays of the Z boson obtained with a polarized electron beam.
- <sup>2</sup> AAD 15BT study  $pp \rightarrow Z \rightarrow \ell^+\ell^-$  events where  $\ell$  is an electron or a muon in the dilepton mass region 70–1000 GeV. The background in the Z peak region is estimated to be < 1% for the muon channel. The muon asymmetry parameter is derived from the measured forward-backward asymmetry assuming the value of the quark asymmetry parameter from the SM. For this reason it is not used in the average.

 $A_\tau$ 

The LEP Collaborations derive this quantity from the measurement of the  $\tau$  polarization in  $Z \rightarrow \tau^+\tau^-$ . The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in  $Z \rightarrow \tau^+\tau^-$  produced using a polarized  $e^-$  beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter  $A_e$ .

0.688 ± 0.041		<sup>3</sup> ABE	01c SLD	$E_{cm}^{ee} = 91.25$ GeV

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $c\bar{c}$  events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c-quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events)  $A_c = 0.6747 \pm 0.0290 \pm 0.0233$ . Taking into account all correlations with earlier results reported in ABE 02G and ABE 01c, they obtain the quoted overall SLD result.
- <sup>2</sup> ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously  $A_b$  and  $A_c$ .
- <sup>3</sup> ABE 01c tag  $Z \rightarrow c\bar{c}$  events using two techniques: exclusive reconstruction of  $D^{*+}, D^+$  and  $D^0$  mesons and the soft pion tag for  $D^{*+} \rightarrow D^0\pi^+$ . The large background from D mesons produced in  $b\bar{b}$  events is separated efficiently from the signal using precision vertex information. When combining the  $A_c$  values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

 $A_b$ 

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in  $b\bar{b}$  production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter  $A_e$ . OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of  $b\bar{b}$  events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b-quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events)  $A_b = 0.9173 \pm 0.0184 \pm 0.0173$ . Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.
- <sup>2</sup> ABE 03F obtain an enriched sample of  $b\bar{b}$  events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying b quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure  $A_b = 0.906 \pm 0.022 \pm 0.023$ . The value quoted here is obtained combining the above with the result of ABE 98I (1993–1995 data sample).
- <sup>3</sup> ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously  $A_b$  and  $A_c$ .
- <sup>4</sup> ABE 99L obtain an enriched sample of  $b\bar{b}$  events tagging with an inclusive vertex mass cut. For distinguishing b and  $\bar{b}$  quarks they use the charge of identified  $K^\pm$ .

TRANSVERSE SPIN CORRELATIONS IN  $Z \rightarrow \tau^+\tau^-$ 

The correlations between the transverse spin components of  $\tau^+\tau^-$  produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

$$C_{TN} = -2 \frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \sin(\phi_{g_V^\tau} - \phi_{g_A^\tau})$$

$C_{TT}$  refers to the transverse-transverse (within the collision plane) spin correlation and  $C_{TN}$  refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal  $\tau$  polarization  $P_\tau (= -A_\tau)$  is given by:

$$P_\tau = -2 \frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2} \cos(\phi_{g_V^\tau} - \phi_{g_A^\tau})$$

Here  $\phi$  is the phase and the phase difference  $\phi_{g_V^\tau} - \phi_{g_A^\tau}$  can be obtained using both the measurements of  $C_{TN}$  and  $P_\tau$ .

 $C_{TT}$

FORWARD-BACKWARD  $e^+e^- \rightarrow f\bar{f}$  CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in  $e^+e^-$  interactions. Details of heavy flavor ( $c$ - or  $b$ -quark) tagging at LEP are described in the note on "The Z boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters  $M_Z = 91.187$  GeV,  $M_{top} = 174.3$  GeV,  $M_{Higgs} = 150$  GeV,  $\alpha_s = 0.119$ ,  $\alpha^{(5)}(M_Z) = 1/128.877$  and the Fermi constant  $G_F = 1.16637 \times 10^{-5}$  GeV<sup>-2</sup> (see the note on "The Z boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

### ———— $A_{FB}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+e^- \rightarrow b\bar{b}$ ————

OUR FIT, which is obtained by a simultaneous fit to several  $c$ - and  $b$ -quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06, refers to the **Z pole** asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

<sup>1</sup> ABDALLAH 05 obtain an enriched samples of  $b\bar{b}$  events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

<sup>2</sup> ABDALLAH 04F tag  $b$ - and  $c$ -quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of  $c\bar{c}$  and  $b\bar{b}$  events are obtained using lifetime information.

<sup>3</sup> ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the  $b$  and  $c$  quark forward-backward asymmetries as well as the average  $B^0$ - $\bar{B}^0$  mixing.

<sup>4</sup> ABBIENDI 02I tag  $Z^0 \rightarrow b\bar{b}$  decays using a combination of secondary vertex and lepton tags. The sign of the  $b$ -quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

<sup>5</sup> HEISTER 02H measure simultaneously  $b$  and  $c$  quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

<sup>6</sup> HEISTER 01D tag  $Z \rightarrow b\bar{b}$  events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The  $b$ -quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of  $A_{FB}^{c,b}$  and  $R_b$  is given as  $+0.103(A_{FB}^{c,b} - 0.0651) - 0.440(R_b - 0.21585)$ .

<sup>7</sup> ABREU 99Y tag  $Z \rightarrow b\bar{b}$  and  $Z \rightarrow c\bar{c}$  events by an exclusive reconstruction of several  $D$  meson decay modes ( $D^{*+}$ ,  $D^0$ , and  $D^+$  with their charge-conjugate states).

<sup>8</sup> ACCIARRI 99D tag  $Z \rightarrow b\bar{b}$  events using high  $p$  and  $p_T$  leptons. The analysis determines simultaneously a mixing parameter  $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$  which is used to correct the observed asymmetry.

<sup>9</sup> ACCIARRI 98U tag  $Z \rightarrow b\bar{b}$  events using lifetime and measure the jet charge using the hemisphere charge.

<sup>10</sup> ALEXANDER 97C identify the  $b$  and  $c$  events using a  $D/D^*$  tag.

### CHARGE ASYMMETRY IN $e^+e^- \rightarrow q\bar{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on  $B^0$ - $\bar{B}^0$  mixing and on other electroweak parameters.

### ANOMALOUS ZZ $\gamma$ , Z $\gamma\gamma$ , AND ZZV COUPLINGS

Revised September 2013 by M.W. Gr unewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell  $Z\gamma$  production, deviations from the Standard Model for the  $Z\gamma\gamma^*$  and  $Z\gamma Z^*$  couplings may be described in terms of eight parameters,  $h_i^V$  ( $i = 1, 4$ ;  $V = \gamma, Z$ ) [1]. The parameters  $h_i^\gamma$  describe the  $Z\gamma\gamma^*$  couplings and the parameters  $h_i^Z$  the  $Z\gamma Z^*$  couplings. In this formalism  $h_1^V$  and  $h_2^V$  lead to  $CP$ -violating and  $h_3^V$  and  $h_4^V$  to  $CP$ -conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation,  $h_i^V(s) = h_{i0}^V/(1 + s/\Lambda^2)^n$ , where  $\Lambda$  is the energy scale for the manifestation of a new phenomenon and  $n$  is a sufficiently large power. By convention one uses  $n = 3$  for  $h_{1,3}^V$  and  $n = 4$  for  $h_{2,4}^V$ . Usually limits on  $h_i^V$ 's are put assuming some value of  $\Lambda$ , sometimes  $\infty$ .

In on-shell  $ZZ$  production, deviations from the Standard Model for the  $ZZ\gamma^*$  and  $ZZZ^*$  couplings may be described by means of four anomalous couplings  $f_i^V$  ( $i = 4, 5$ ;  $V = \gamma, Z$ ) [2]. As above, the parameters  $f_i^\gamma$  describe the  $ZZ\gamma^*$  couplings and the parameters  $f_i^Z$  the  $ZZZ^*$  couplings. The anomalous couplings  $f_5^V$  lead to violation of  $C$  and  $P$  symmetries while  $f_4^V$  introduces  $CP$  violation. Also here, formfactors depending on a scale  $\Lambda$  are used.

All these couplings  $h_i^V$  and  $f_i^V$  are zero at tree level in the Standard Model; they are measured in  $e^+e^-$ ,  $p\bar{p}$  and  $pp$  collisions at LEP, Tevatron and LHC.

### $h_\gamma^V$

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13a]:

$$\begin{aligned} -0.12 < h_1^Z < +0.11, & \quad -0.07 < h_2^Z < +0.07, \\ -0.19 < h_3^Z < +0.06, & \quad -0.04 < h_4^Z < +0.13, \\ -0.05 < h_1^\gamma < +0.05, & \quad -0.04 < h_2^\gamma < +0.02, \\ -0.05 < h_3^\gamma < +0.00, & \quad +0.01 < h_4^\gamma < +0.05. \end{aligned}$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

- AAD 16Q study  $Z\gamma$  production in  $pp$  collisions. In events with no additional jets, 10268 (12738)  $Z$  decays to electron (muon) pairs are selected, with an expected background of  $1291 \pm 340$  ( $1537 \pm 408$ ) events, as well as 1039  $Z$  decays to neutrino pairs with an expected background of  $450 \pm 96$  events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits:  $-7.8 \times 10^{-4} < h_3^Z < 8.6 \times 10^{-4}$ ,  $-3.0 \times 10^{-6} < h_4^Z < 2.9 \times 10^{-6}$ ,  $-9.5 \times 10^{-4} < h_3^\gamma < 9.9 \times 10^{-4}$ ,  $-3.2 \times 10^{-6} < h_4^\gamma < 3.2 \times 10^{-6}$ .
- KHACHATRYAN 16AE determine the  $Z\gamma \rightarrow \nu\bar{\nu}\gamma$  cross section by selecting events with a photon of  $E_T > 145$  GeV and  $\cancel{E}_T > 140$  GeV. 630 candidate events are observed with an expected SM background of  $269 \pm 26$ . The  $E_T$  spectrum of the photon is used to set 95% C.L. limits as follows:  $-1.5 \times 10^{-3} < h_3^Z < 1.6 \times 10^{-3}$ ,  $-3.9 \times 10^{-6} < h_4^Z < 4.5 \times 10^{-6}$ ,  $-1.1 \times 10^{-3} < h_3^\gamma < 0.9 \times 10^{-3}$ ,  $-3.8 \times 10^{-6} < h_4^\gamma < 4.3 \times 10^{-6}$ .
- KHACHATRYAN 15AC study  $Z\gamma$  events in 8 TeV  $pp$  interactions, where the  $Z$  decays into 2 same-flavor, opposite sign leptons ( $e$  or  $\mu$ ) and a photon with  $p_T > 15$  GeV. The  $p_T$  of a lepton is required to be  $> 20$  GeV/c, their effective mass  $> 50$  GeV, and the photon should have a separation  $\Delta R > 0.7$  with each lepton. The observed  $p_T$  distribution of the photons is used to extract the 95% C.L. limits:  $-3.8 \times 10^{-3} < h_3^Z < 3.7 \times 10^{-3}$ ,  $-3.1 \times 10^{-5} < h_4^Z < 3.0 \times 10^{-5}$ ,  $-4.6 \times 10^{-3} < h_3^\gamma < 4.6 \times 10^{-3}$ ,  $-3.6 \times 10^{-5} < h_4^\gamma < 3.5 \times 10^{-5}$ .
- CHATRCHYAN 14AB measure  $Z\gamma$  production cross section for  $p_T^\gamma > 15$  GeV and  $R(\ell\gamma) > 0.7$ , which is the separation between the  $\gamma$  and the final state charged lepton ( $e$  or  $\mu$ ) in the azimuthal angle-pseudorapidity ( $\phi - \eta$ ) plane. The di-lepton mass is required to be  $> 50$  GeV. After background subtraction the number of  $e\bar{e}\gamma$  and  $\mu\mu\gamma$  events is determined to be  $3160 \pm 120$  and  $5030 \pm 233$  respectively, compatible with expectations from the SM. This leads to a 95% CL limits of  $-1 \times 10^{-2} < h_3^\gamma < 1 \times 10^{-2}$ ,  $-9 \times 10^{-5} < h_4^\gamma < 9 \times 10^{-5}$ ,  $-9 \times 10^{-3} < h_3^Z < 9 \times 10^{-3}$ ,  $-8 \times 10^{-5} < h_4^Z < 8 \times 10^{-5}$ , assuming  $h_1^V$  and  $h_2^V$  have SM values,  $V = \gamma$  or  $Z$ .
- AAD 13AN study  $Z\gamma$  production in  $pp$  collisions. In events with no additional jet, 1417 (2031)  $Z$  decays to electron (muon) pairs are selected, with an expected background of  $156 \pm 54$  ( $244 \pm 64$ ) events, as well as 662  $Z$  decays to neutrino pairs with an expected background of  $302 \pm 42$  events. Analysing the photon  $p_T$  spectrum above 100 GeV yields the 95% C.L. limits:  $-0.013 < h_3^Z < 0.014$ ,  $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$ ,  $-0.015 < h_3^\gamma < 0.016$ ,  $-9.4 \times 10^{-5} < h_4^\gamma < 9.2 \times 10^{-5}$ . Supersedes AAD 12Bx.
- CHATRCHYAN 13BI determine the  $Z\gamma \rightarrow \nu\bar{\nu}\gamma$  cross section by selecting events with a photon of  $E_T > 145$  GeV and a  $\cancel{E}_T > 130$  GeV. 73 candidate events are observed with an expected SM background of  $30.2 \pm 6.5$ . The  $E_T$  spectrum of the photon is used to set 95% C.L. limits as follows:  $|h_3^Z| < 2.7 \times 10^{-3}$ ,  $|h_4^Z| < 1.3 \times 10^{-5}$ ,  $|h_3^\gamma| < 2.9 \times 10^{-3}$ ,  $|h_4^\gamma| < 1.5 \times 10^{-5}$ .
- ABAZOV 12S study  $Z\gamma$  production in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV using  $6.2 \text{ fb}^{-1}$  of data where the  $Z$  decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of  $255 \pm 16$  ( $285 \pm 24$ ) events. Based on the photon  $p_T$  spectrum, and including also earlier data and the  $Z \rightarrow \nu\bar{\nu}$  decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported:  $|h_{03}^Z| < 0.026$ ,  $|h_{04}^Z| < 0.0013$ ,  $|h_{03}^\gamma| < 0.027$ ,  $|h_{04}^\gamma| < 0.0014$  for a form factor scale of  $\Lambda = 1.5$  TeV.
- AALTONEN 11S study  $Z\gamma$  events in  $p\bar{p}$  interactions at  $\sqrt{s} = 1.96$  TeV with integrated luminosity  $5.1 \text{ fb}^{-1}$  for  $Z \rightarrow e^+e^-/\mu^+\mu^-$  and  $4.9 \text{ fb}^{-1}$  for  $Z \rightarrow \nu\bar{\nu}$ . For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one  $> 20$  GeV and the other  $> 10$  GeV. The isolated photon must have  $E_T > 50$  GeV. They observe 91 events with  $87.2 \pm 7.8$  events expected from standard model processes. For the  $\nu\bar{\nu}$  case they require solitary photons with  $E_T > 25$  GeV and missing  $E_T > 25$  GeV and observe 85 events with standard model expectation of  $85.9 \pm 5.6$  events. Taking the form factor  $\Lambda = 1.5$  TeV they derive 95% C.L. limits as  $|h_3^{Z,\gamma}| < 0.022$  and  $|h_4^{Z,\gamma}| < 0.0009$ .
- CHATRCHYAN 11M study  $Z\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using  $36 \text{ pb}^{-1}$   $pp$  data, where the  $Z$  decays to  $e^+e^-$  or  $\mu^+\mu^-$ . The total cross sections are measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell,\gamma) > 0.7$  with the dilepton invariant mass requirement of  $M_{\ell\ell} > 50$  GeV. The number of  $e^+e^-\gamma$  and  $\mu^+\mu^-\gamma$  candidates is 81 and 90 with estimated backgrounds of  $20.5 \pm 2.5$  and  $27.3 \pm 3.2$  events respectively. The 95% CL limits for  $ZZ\gamma$  couplings are  $-0.05 < h_3^Z < 0.06$  and  $-0.0005 < h_4^Z < 0.0005$ , and for  $Z\gamma\gamma$  couplings are  $-0.07 < h_3^\gamma < 0.07$  and  $-0.0005 < h_4^\gamma < 0.0006$ .
- ABAZOV 09L study  $Z\gamma$ ,  $Z \rightarrow \nu\bar{\nu}$  production in  $p\bar{p}$  collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy  $E_T^\gamma$  larger than 90 GeV, with an expected background of 17 events. Based on the photon  $E_T$  spectrum and including also  $Z$  decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported:  $|h_{30}^Z| < 0.033$ ,  $|h_{40}^Z| < 0.0017$ ,  $|h_{30}^\gamma| < 0.033$ ,  $|h_{40}^\gamma| < 0.0017$ .
- ABAZOV 07M use 968  $p\bar{p} \rightarrow e^+e^-/\mu^+\mu^-X$  candidates, at 1.96 TeV center of mass energy, to tag  $p\bar{p} \rightarrow Z\gamma$  events by requiring  $E_T(\gamma) > 7$  GeV, lepton-gamma separation  $\Delta R_{\ell\gamma} > 0.7$ , and di-lepton invariant mass  $> 30$  GeV. The cross section is in agreement with the SM prediction. Using these  $Z\gamma$  events they obtain 95% C.L. limits on each  $h_i^V$ , keeping all others fixed at their SM values. They report:  $-0.083 < h_{30}^Z <$

- 0.082,  $-0.0053 < h_{40}^Z < 0.0054$ ,  $-0.085 < h_{30}^\gamma < 0.084$ ,  $-0.0053 < h_{40}^\gamma < 0.0054$ , for the form factor scale  $\Lambda = 1.2$  TeV.
- 12 Using data collected at  $\sqrt{s} = 183\text{--}208$ , ABDALLAH 07c select 1,877  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$ , 171  $e^+e^- \rightarrow ZZ$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $h_i^\gamma$ . Each limit is derived with other parameters set to zero. They report:  $-0.23 < h_1^Z < 0.23$ ,  $-0.30 < h_3^Z < 0.16$ ,  $-0.14 < h_1^\gamma < 0.14$ ,  $-0.049 < h_3^\gamma < 0.044$ .
- 13 ACHARD 04H select 3515  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$  at  $\sqrt{s} = 189\text{--}209$  GeV to derive 95% CL limits on  $h_i^\gamma$ . For deriving each limit the other parameters are fixed at zero. They report:  $-0.153 < h_1^Z < 0.141$ ,  $-0.087 < h_2^Z < 0.079$ ,  $-0.220 < h_3^Z < 0.112$ ,  $-0.068 < h_4^Z < 0.148$ ,  $-0.057 < h_1^\gamma < 0.057$ ,  $-0.050 < h_2^\gamma < 0.023$ ,  $-0.059 < h_3^\gamma < 0.004$ ,  $-0.004 < h_4^\gamma < 0.042$ .
- 14 ABBIENDI, G 00c study  $e^+e^- \rightarrow Z\gamma$  events (with  $Z \rightarrow q\bar{q}$  and  $Z \rightarrow \nu\bar{\nu}$ ) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings:  $h_1^Z = 0.000 \pm 0.100$  ( $-0.190, 0.190$ ),  $h_2^Z = 0.000 \pm 0.068$  ( $-0.128, 0.128$ ),  $h_3^Z = -0.074_{-0.103}^{+0.102}$  ( $-0.269, 0.119$ ),  $h_4^Z = 0.046 \pm 0.068$  ( $-0.084, 0.175$ ),  $h_1^\gamma = 0.000 \pm 0.061$  ( $-0.115, 0.115$ ),  $h_2^\gamma = 0.000 \pm 0.041$  ( $-0.077, 0.077$ ),  $h_3^\gamma = -0.080_{-0.041}^{+0.039}$  ( $-0.164, -0.006$ ),  $h_4^\gamma = 0.064_{-0.030}^{+0.033}$  ( $+0.007, +0.134$ ). The results are derived assuming that only one coupling at a time is different from zero.
- 15 ABBOTT 98M study  $p\bar{p} \rightarrow Z\gamma + X$ , with  $Z \rightarrow e^+e^-, \mu^+\mu^-, \nu\bar{\nu}$  at 1.8 TeV, to obtain 95% CL limits at  $\Lambda = 750$  GeV:  $|h_{30}^Z| < 0.36$ ,  $|h_{40}^Z| < 0.05$  (keeping  $h_i^Z = 0$ ), and  $|h_{30}^\gamma| < 0.37$ ,  $|h_{40}^\gamma| < 0.05$  (keeping  $h_i^\gamma = 0$ ). Limits on the CP-violating couplings are  $|h_{10}^Z| < 0.36$ ,  $|h_{20}^Z| < 0.05$  (keeping  $h_i^Z = 0$ ), and  $|h_{10}^\gamma| < 0.37$ ,  $|h_{20}^\gamma| < 0.05$  (keeping  $h_i^\gamma = 0$ ).
- 16 ABREU 98k determine a 95% CL upper limit on  $\sigma(e^+e^- \rightarrow \gamma + \text{invisible particles}) < 2.5$  pb using 161 and 172 GeV data. This is used to set 95% CL limits on  $|h_{30}^\gamma| < 0.8$  and  $|h_{30}^Z| < 1.3$ , derived at a scale  $\Lambda = 1$  TeV and with  $n = 3$  in the form factor representation.

 $f_i^\gamma$ 

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEEL 13A]:

$$\begin{aligned} -0.28 < f_4^Z < +0.32, & \quad -0.34 < f_5^Z < +0.35, \\ -0.17 < f_4^\gamma < +0.19, & \quad -0.35 < f_5^\gamma < +0.32. \end{aligned}$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

- 1 AAD 23CH measure  $ZZ$  production with the  $Z$  bosons decaying to electrons or muons. Analysing the angular information of the final-state four-lepton system, the following limits are derived at 95% C.L.:  $-0.012 < f_4^Z < 0.012$ ,  $-0.015 < f_4^\gamma < 0.015$ .
- 2 SIRUNYAN 21q measure  $ZZ$  production where both  $Z$  bosons decay in the electron or muon channel. Analysing the four-lepton invariant mass distribution, the following limits are derived at 95% C.L. in units of  $10^{-4}$ :  $-6.6 < f_4^Z < 6.0$ ,  $-5.5 < f_5^Z < 7.5$ ,  $-7.8 < f_4^\gamma < 7.1$ ,  $-6.8 < f_5^\gamma < 7.5$ . This set of parameters is linearly related to a set of EFT parameters, resulting in the following limits at 95% C.L. in units of  $\text{TeV}^{-4}$ :  $-2.3 < c_{BW}^4 < 2.5$ ,  $-1.4 < c_{WW}^4 < 1.2$ ,  $-1.4 < c_{BW}^4 < 1.3$ ,  $-1.2 < c_{BB}^4 < 1.2$ .
- 3 AABOUD 19AY study  $ZZ$  production in the  $\ell\ell\nu\nu$  decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (di-muon) events are found, with a total expected background of  $128 \pm 8$  (143  $\pm 8$ ) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of  $10^{-3}$ :  $-1.2 < f_4^\gamma < 1.2$ ,  $-1.0 < f_4^Z < 1.0$ ,  $-1.2 < f_5^\gamma < 1.2$ ,  $-1.0 < f_5^Z < 1.0$ .
- 4 AABOUD 18q study  $pp \rightarrow ZZ$  events at  $\sqrt{s} = 13$  TeV with  $Z \rightarrow e^+e^-$  or  $Z \rightarrow \mu^+\mu^-$ . The number of events observed in the  $4e$ ,  $2e2\mu$ , and  $4\mu$  channels is 249, 465, and 303 respectively. Analysing the  $p_T$  spectrum of the leading  $Z$  boson, the following

the following 95% C.L. limits are derived in units of  $10^{-4}$ :  $-1.8 < f_4^\gamma < 1.8$ ,  $-1.5 < f_4^Z < 1.5$ ,  $-1.8 < f_5^\gamma < 1.8$ ,  $-1.5 < f_5^Z < 1.5$ .

- 5 SIRUNYAN 18BT study  $ppZZ$  events at  $\sqrt{s} = 13$  TeV with  $Z \rightarrow e^+e^-$  or  $Z \rightarrow \mu^+\mu^-$ . The number of events observed in the  $4e$ ,  $2e2\mu$ , and  $4\mu$  channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of  $10^{-3}$ :  $-1.2 < f_4^\gamma < 1.3$ ,  $-1.2 < f_4^Z < 1.0$ ,  $-1.2 < f_5^\gamma < 1.3$ ,  $-1.0 < f_5^Z < 1.3$ .
- 6 KHACHATRYAN 15B study  $ZZ$  production in 8 TeV  $pp$  collisions. In the decay modes  $ZZ \rightarrow 4e$ ,  $4\mu$ ,  $2e2\mu$ ,  $54, 75, 148$  events are observed, with an expected background of  $2.2 \pm 0.9$ ,  $1.2 \pm 0.6$ , and  $2.4 \pm 1.0$  events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained:  $|f_4^Z| < 0.004$ ,  $|f_5^Z| < 0.004$ ,  $|f_4^\gamma| < 0.005$ ,  $|f_5^\gamma| < 0.005$ .
- 7 KHACHATRYAN 15BC use the cross section measurement of the final state  $pp \rightarrow ZZ \rightarrow 2\ell 2\nu$  ( $\ell$  being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton  $p_T > 45$  GeV. The reduced missing  $E_T$  is required to be  $> 65$  GeV, which takes into account the fake missing  $E_T$  due to detector effects. The numbers of  $e^+e^-$  and  $\mu^+\mu^-$  events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set:  $-0.0028 < f_4^Z < 0.0032$ ,  $-0.0037 < f_4^\gamma < 0.0033$ ,  $-0.0029 < f_5^Z < 0.0031$ ,  $-0.0033 < f_5^\gamma < 0.0037$ . Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states  $pp \rightarrow ZZ \rightarrow 2\ell 2\ell'$  where  $\ell$  and  $\ell'$  are an electron or a muon, the best limits are  $-0.0022 < f_4^Z < 0.0026$ ,  $-0.0029 < f_4^\gamma < 0.0026$ ,  $-0.0023 < f_5^Z < 0.0023$ ,  $-0.0026 < f_5^\gamma < 0.0027$ .
- 8 AAD 13z study  $ZZ$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. In the  $ZZ \rightarrow \ell^+\ell^-\ell^+\ell^-$  final state they observe a total of 66 events with an expected background of  $0.9 \pm 1.3$ . In the  $ZZ \rightarrow \ell^+\ell^-\nu\nu$  final state they observe a total of 87 events with an expected background of  $46.9 \pm 5.2$ . The limits on anomalous TGCs are determined using the observed and expected numbers of these  $ZZ$  events binned in  $p_T^Z$ . The 95% C.L. are as follows: for form factor scale  $\Lambda = \infty$ ,  $-0.015 < f_4^\gamma < 0.015$ ,  $-0.013 < f_4^Z < 0.013$ ,  $-0.016 < f_5^\gamma < 0.015$ ,  $-0.013 < f_5^Z < 0.013$ ; for form factor scale  $\Lambda = 3$  TeV,  $-0.022 < f_4^\gamma < 0.023$ ,  $-0.019 < f_4^Z < 0.019$ ,  $-0.023 < f_5^\gamma < 0.023$ ,  $-0.020 < f_5^Z < 0.019$ .
- 9 CHATRCHYAN 13B study  $ZZ$  production in  $pp$  collisions and select 54  $ZZ$  candidates in the  $Z$  decay channel with electrons or muons with an expected background of  $1.4 \pm 0.5$  events. The resulting 95% C.L. ranges are:  $-0.013 < f_4^\gamma < 0.015$ ,  $-0.011 < f_4^Z < 0.012$ ,  $-0.014 < f_5^\gamma < 0.014$ ,  $-0.012 < f_5^Z < 0.012$ .
- 10 Using data collected in the center of mass energy range 192–209 GeV, SCHAEEL 09 select 318  $e^+e^- \rightarrow ZZ$  events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits:  $-0.321 < f_4^\gamma < 0.318$ ,  $-0.534 < f_4^Z < 0.534$ ,  $-0.724 < f_5^\gamma < 0.733$ ,  $-1.194 < f_5^Z < 1.190$ .
- 11 ABAZOV 08k search for  $ZZ$  and  $Z\gamma^*$  events with  $1 \text{ fb}^{-1} p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV in  $(e^+e^-)(e^+e^-)$ ,  $(\mu^+\mu^-)(\mu^+\mu^-)$ ,  $(e^+e^-)(\mu^+\mu^-)$  final states requiring the lepton pair masses to be  $> 30$  GeV. They observe 1 event, which is consistent with an expected signal of  $1.71 \pm 0.15$  events and a background of  $0.13 \pm 0.03$  events. From this they derive the following limits, for a form factor ( $\Lambda$ ) value of 1.2 TeV:  $-0.28 < f_4^Z < 0.28$ ,  $-0.31 < f_5^Z < 0.29$ ,  $-0.26 < f_4^\gamma < 0.26$ ,  $-0.30 < f_5^\gamma < 0.28$ .
- 12 Using data collected at  $\sqrt{s} = 183\text{--}208$  GeV, ABDALLAH 07c select 171  $e^+e^- \rightarrow ZZ$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $f_i^\gamma$ . Each limit is derived with other parameters set to zero. They report:  $-0.40 < f_4^Z < 0.42$ ,  $-0.38 < f_5^Z < 0.62$ ,  $-0.23 < f_4^\gamma < 0.25$ ,  $-0.52 < f_5^\gamma < 0.48$ .
- 13 ABBIENDI 04c study  $ZZ$  production in  $e^+e^-$  collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits:  $-0.45 < f_4^Z < 0.58$ ,  $-0.94 < f_5^Z < 0.25$ ,  $-0.32 < f_4^\gamma < 0.33$ , and  $-0.71 < f_5^\gamma < 0.59$ .
- 14 ACHARD 03D study  $Z$ -boson pair production in  $e^+e^-$  collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively), 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01I results (656 events, expected background of 512 events), they report the following 95% CL limits:  $-0.48 < f_4^Z < 0.46$ ,  $-0.36 < f_5^Z < 1.03$ ,  $-0.28 < f_4^\gamma < 0.28$ , and  $-0.40 < f_5^\gamma < 0.47$ .

### ANOMALOUS W/Z QUARTIC COUPLINGS

Revised March 2024 by M.W. Grünewald (U. College Dublin) and A. Gurtu (CERN; TIFR Mumbai).

Quartic couplings,  $WWZZ$ ,  $WWZ\gamma$ ,  $WW\gamma\gamma$ , and  $ZZ\gamma\gamma$ , were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the

## Gauge &amp; Higgs Boson Particle Listings

## Z

Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the  $SU(2) \times U(1)$  gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings,  $a_0, a_c, a_n$ , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_{\nu}^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where  $F, W$  are photon and  $W$  fields,  $L_6^0$  and  $L_6^c$  conserve  $C, P$  separately ( $\tilde{L}_6^0$  conserves only  $C$ ) and generate anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings,  $L_6^n$  violates  $CP$  ( $\tilde{L}_6^n$  violates both  $C$  and  $P$ ) and generates an anomalous  $W^+W^-Z\gamma$  coupling, and  $\Lambda$  is an energy scale for new physics. For the  $ZZ\gamma\gamma$  coupling the  $CP$ -violating term represented by  $L_6^n$  does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the  $WW\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings separately, leading to two sets parametrized as  $a_0^V/\Lambda^2$  and  $a_c^V/\Lambda^2$ , where  $V = W$  or  $Z$ .

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned} \mathcal{L}_{AQGC} &= -\frac{e^2 a_0^W}{8 \Lambda^2} F_{\mu\nu} F^{\mu\nu} W^{+\alpha} W_a^- \\ &\quad -\frac{e^2 a_c^W}{16 \Lambda^2} F_{\mu\nu} F^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad -e^2 g^2 \frac{\kappa_0^W}{\Lambda^2} F_{\mu\nu} Z^{\mu\nu} W^{+\alpha} W_a^- \\ &\quad -\frac{e^2 g^2 \kappa_c^W}{2 \Lambda^2} F_{\mu\nu} Z^{\mu\alpha} (W^{+\nu} W_a^- + W^{-\nu} W_a^+) \\ &\quad + \frac{f_{T,0}}{\Lambda^4} Tr[\widehat{W}_{\mu\nu} \widehat{W}^{\mu\nu}] \times Tr[\widehat{W}_{\alpha\beta} \widehat{W}^{\alpha\beta}] \end{aligned}$$

The energy scale of possible new physics is  $\Lambda$ , and  $g = e/\sin(\theta_W)$ ,  $e$  being the unit electric charge and  $\theta_W$  the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators  $a_0^W/\Lambda^2$  and  $a_c^W/\Lambda^2$  are associated with the  $WW\gamma\gamma$  vertex. Among dimension 8 operators,  $\kappa_0^W/\Lambda^2$  and  $\kappa_c^W/\Lambda^2$  are associated with the  $WWZ\gamma$  vertex, whereas the parameter  $f_{T,0}/\Lambda^4$  contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters  $f_{M,i}/\Lambda^4$  as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2} \frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2} \frac{f_{M,3}}{\Lambda^4}$$

where  $g' = e/\cos(\theta_W)$  and  $M_W$  is the invariant mass of the  $W$  boson. This relation provides a translation between limits on dimension 6 operators  $a_{0,c}^W$  and  $f_{M,j}/\Lambda^4$ . It is further required [4] that  $f_{M,0} = 2f_{M,2}$  and  $f_{M,1} = 2f_{M,3}$  which suppresses contributions to the  $WWZ\gamma$  vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total –  $f_{S,i}$ ,  $i = 1, 2$ ,  $f_{M,i}$ ,  $i = 0, \dots, 8$  and  $f_{T,i}$ ,  $i = 0, \dots, 9$  – each scaled by  $1/\Lambda^4$ .

Another approach to couplings is the so called K-matrix framework [7], in which the anomalous couplings can be expressed in terms of two parameters  $\alpha_4$  and  $\alpha_5$ , which account for all BSM effects.

The LHC collaborations have published couplings results based on various theoretical frameworks. It is hoped that the collaborations will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison, and to allow for a possible LHC combination.

 $a_0/\Lambda^2, a_c/\Lambda^2$ 

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the  $ZZ\gamma\gamma$  vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$\begin{aligned} -0.008 < a_0^Z/\Lambda^2 < +0.021 \\ -0.029 < a_c^Z/\Lambda^2 < +0.039 \end{aligned}$$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous  $W/Z$  quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the  $W$  or only to the  $Z$  or to both. Thus, results on all other AQGCs are reported together in the  $W$  listings.

••• We do not use the following data for averages, fits, limits, etc. •••

1	ABBIENDI	04L	OPAL
2	HEISTER	04A	ALEP
3	ACHARD	02G	L3

<sup>1</sup> ABBIENDI 04L select 20  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  acoplanar events in the energy range 180–209 GeV and 176  $e^+e^- \rightarrow q\bar{q}\gamma\gamma$  events in the energy range 130–209 GeV. These samples

are used to constrain possible anomalous  $W^+ W^- \gamma \gamma$  and  $ZZ\gamma\gamma$  quartic couplings. Further combining with the  $W^+ W^- \gamma$  sample of **ABBIENDI 04b** the following one-parameter 95% CL limits are obtained:  $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$ ,  $-0.029 < a_1^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$ ,  $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.052 < a_C^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ .

<sup>2</sup>In the CM energy range 183 to 209 GeV **HEISTER 04a** select 30  $e^+ e^- \rightarrow \nu \bar{\nu} \gamma \gamma$  events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be  $> 5^\circ$ ,  $E_{\gamma}/\sqrt{s} > 0.025$  (the more energetic photon having energy  $> 0.2 \sqrt{s}$ ),  $p_{T,\gamma}/E_{\text{beam}} > 0.05$  and  $|\cos \theta_\gamma| < 0.94$ . A likelihood fit to the photon energy and recoil missing mass yields the following one-parameter 95% CL limits:  $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_1^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_C^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$ .

<sup>3</sup>**ACHARD 02g** study  $e^+ e^- \rightarrow Z\gamma\gamma \rightarrow q\bar{q}\gamma\gamma$  events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy  $> 5 \text{ GeV}$  and  $|\cos\theta| < 0.97$ , and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ( $\beta < 0.73$ ) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the  $q\bar{q}\gamma\gamma$  state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of **ACCIARRI 01e**, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values  $a_0/\Lambda^2 = 0.00 \pm 0.02 \text{ GeV}^{-2}$  and  $a_C/\Lambda^2 = 0.03 \pm 0.01 \text{ GeV}^{-2}$ , where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits  $-0.02 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.03 \text{ GeV}^{-2}$  and  $-0.07 \text{ GeV}^{-2} < a_C/\Lambda^2 < 0.05 \text{ GeV}^{-2}$ .

WEIGHTED AVERAGE  
125.20±0.11 (Error scaled by 1.4)

### H

was  $H^0$

In the following  $H$  refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of  $H$  and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ( $H^\pm$  and  $H^{\pm\pm}$ )", respectively.

125.17±0.11±0.09	8 AAD	23BU ATLS	pp, 13 TeV, $\gamma\gamma$

- AAD 23BP combine 13 TeV results of  $H \rightarrow \gamma\gamma$  (AAD 23BU) and  $H \rightarrow ZZ^* \rightarrow 4\ell$  where  $\ell = e, \mu$  (AAD 23AU) using  $140 \text{ fb}^{-1}$  of  $pp$  collision data. The result is  $125.10 \pm 0.09(\text{stat}) \pm 0.07(\text{syst}) \text{ GeV}$ .
- SIRUNYAN 20L result of  $H \rightarrow \gamma\gamma$  is combined with that of  $H \rightarrow ZZ^* \rightarrow 4\ell$  where  $\ell = e, \mu$  (SIRUNYAN 17AV).
- Combined value from  $\gamma\gamma$  and  $ZZ^* \rightarrow 4\ell$  final states.
- ATLAS and CMS data are fitted simultaneously.
- AAD 23AU use  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow ZZ^* \rightarrow 4\ell$  where  $\ell = e, \mu$ .
- AAD 23AU combine 13 TeV results with 7 and 8 TeV results (AAD 14W).
- AAD 23BP combine 13 TeV results with 7 and 8 TeV results. The result is  $125.11 \pm 0.09(\text{stat}) \pm 0.06(\text{syst}) \text{ GeV}$ .
- AAD 23BU use  $140 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow \gamma\gamma$ .
- AAD 23BU combine 13 TeV results with 7 and 8 TeV results (AAD 15B).
- SIRUNYAN 20L use  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow \gamma\gamma$ .
- SIRUNYAN 20L combine 13 TeV results with 7 and 8 TeV results (KHACHATRYAN 15AM).
- AABOUD 18BM use  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow ZZ^* \rightarrow 4\ell$  where  $\ell = e, \mu$ .
- AABOUD 18BM use  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow \gamma\gamma$ .
- AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.
- SIRUNYAN 17AV use  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow ZZ^* \rightarrow 4\ell$  where  $\ell = e, \mu$ .
- KHACHATRYAN 15AM use up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ .
- AAD 14W use  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $8 \text{ TeV}$ .
- CHATRCHYAN 14AA use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ .
- CHATRCHYAN 14K use  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ .

- 20 KHACHATRYAN 14P use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 21 AAD 13AK use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. Superseded by AAD 14w.
- 22 CHATRCHYAN 13J use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 12.2 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV.
- 23 AAD 12AI obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.8–5.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.9  $\sigma$  is observed at  $m_H = 126$  GeV. See also AAD 12DA.
- 24 CHATRCHYAN 12N obtain results based on 4.9–5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.1–5.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. An excess of events over background with a local significance of 5.0  $\sigma$  is observed at about  $m_H = 125$  GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

## H SPIN AND CP PROPERTIES

The observation of the signal in the  $\gamma\gamma$  final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the CP properties is in general much more difficult since in principle the observed state could consist of any admixture of CP-even and CP-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure CP-even and pure CP-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different CP states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a CP-even and a CP-odd state, as the cross section ratios depend in addition also on the coupling strengths of the CP-even and CP-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of CP mixing.

- 1 AAD 23AK measure the CP structure of the  $\tau$  Yukawa coupling using 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV. The CP-mixing angle  $\alpha$  for  $\tau$  Yukawa coupling is measured to be  $9 \pm 16^\circ$ . The data disfavour the pure CP-odd ( $\alpha = 90^\circ$ ) at 3.4  $\sigma$ .
- 2 AAD 23AN test CP invariance in  $H$  production via VBF using  $H \rightarrow \gamma\gamma$  decay channel with 139 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. By using the Optimal Observable method, the data constrain parameters describing the strength of the CP-odd component in the coupling between Higgs and  $W/Z$  in effective field theory bases:  $\tilde{d}$  in the HISZ basis and  $C_{H\tilde{W}}$  in the Warsaw basis. The result is  $-0.010 \leq \tilde{d} \leq 0.040$  and  $-0.15 \leq C_{H\tilde{W}} \leq 0.67$  at 68% CL. See their Table I, which shows the result combined with  $H \rightarrow \tau\tau$  (AAD 20N):  $-0.012 \leq \tilde{d} \leq 0.030$  at 68% CL.
- 3 TUMASYAN 23AJ constrain anomalous couplings of the Higgs to vector bosons and fermions using  $pp \rightarrow H \rightarrow \tau\tau$  at  $E_{\text{cm}} = 13$  TeV with 138 fb<sup>-1</sup> data. The CP-violating parameter in gluon-fusion production  $f_{a3}^{ggH}$  and the effective mixing angle  $\alpha_{Hff}$  are given in their Table VII with  $H \rightarrow \tau\tau$  and  $f_{a3}^{ggH}$  in their Table X with  $H \rightarrow \tau\tau$  and  $H \rightarrow 4\ell$ . Using the VBF production analysis, the CP-violating parameter  $f_{a3}$  and CP-conserving parameters  $f_{a2}, f_{\Lambda 1}$  and  $f_{\Lambda 1}^{Z\gamma}$  are given in their Table VIII with  $H \rightarrow \tau\tau$  and Table IX with  $H \rightarrow \tau\tau$  and  $H \rightarrow 4\ell$ . The CP-violating parameter  $f_{CP}^{H\tilde{t}t}$  is constrained to be  $0.03^{+0.17}_{-0.03}$  using  $H \rightarrow \tau\tau, H \rightarrow 4\ell$  and  $H \rightarrow \gamma\gamma$ .

- 4 TUMASYAN 23P constrain  $\tilde{\kappa}_t$  from  $t\bar{t}H$  and  $tH$  decaying  $H \rightarrow WW^*$  and  $H \rightarrow \tau\tau$  (multiplepton decay mode) with 138 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The  $\tilde{\kappa}_t$  is constrained to be  $|\tilde{\kappa}_t| \leq 1.4$  at 95% CL by fixing  $\kappa_t = 1$  and other couplings ( $\kappa_V$  etc.) to the SM values, see their Table 6 (see their Fig. 9 for 2-dim contours). The fractional contribution of the CP-odd component  $|f_{CP}^{H\tilde{t}t}|$  is constrained to (0.24, 0.81) at 68% CL with a best fit value of 0.59. The combination with other  $t\bar{t}H$  decaying  $H \rightarrow \gamma\gamma$  (SIRUNYAN 20AS) and  $H \rightarrow 4\ell$  (SIRUNYAN 21AE) constraints to be  $|\tilde{\kappa}_t| \leq 1.07$  at 95% CL and  $|f_{CP}^{H\tilde{t}t}| < 0.55$  at 68% CL with a best fit value of 0.28.
- 5 AAD 22V measure the CP properties of the effective Higgs-gluon interaction using gluon fusion  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$  plus two jets with 36.1 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV. The measured tangent of the CP-mixing angle  $\alpha$  is  $0.0 \pm 0.4 \pm 0.3$  assuming the standard model  $HVV$  couplings. See their Fig. 6.
- 6 TUMASYAN 22Y measure the CP structure of the  $\tau$  Yukawa coupling using 137 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV. The CP-mixing angle  $\alpha$  for  $\tau$  Yukawa coupling is measured to be  $-1 \pm 19^\circ$ . The data disfavour the pure CP-odd ( $\alpha = 90^\circ$ ) at 3.0  $\sigma$ .
- 7 AAD 20N test CP invariance in  $H$  production via VBF using  $H \rightarrow \tau\tau$  decay channel with 36.1 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. By using the Optimal Observable method, the data constrain a parameter  $\tilde{d}$ , which is for the strength of CP violation in an effective field theory, to be  $-0.090 \leq \tilde{d} \leq 0.035$  at 68% CL (see their Fig. 6).
- 8 AAD 20Z exclude a CP-mixing angle  $\alpha, |\alpha| > 43^\circ$  at 95% CL, where  $\alpha = 0$  represents the Standard Model, in 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV. The pure CP-odd structure of the top Yukawa coupling ( $\alpha = 90^\circ$ ) is excluded at 3.9  $\sigma$ .
- 9 SIRUNYAN 20AS exclude the pure CP-odd structure of the top Yukawa coupling at 3.2  $\sigma$  using  $t\bar{t}H, H \rightarrow \gamma\gamma$  in 137 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV. The fractional contribution of the CP-odd component  $f_{CP}^{H\tilde{t}t}$  is measured to be  $0.00 \pm 0.33$ .
- 10 SIRUNYAN 19BL measure the anomalous  $HVV$  couplings from on-shell and off-shell production in the  $4\ell$  final state. Data of 80.2 fb<sup>-1</sup> at 13 TeV, 19.7 fb<sup>-1</sup> at 8 TeV, and 5.1 fb<sup>-1</sup> at 7 TeV are used. See their Tables VI and VII for anomalous  $HVV$  couplings of CP-violating and CP-conserving parameters with on- and off-shells.
- 11 SIRUNYAN 19BZ constrain anomalous  $HVV$  couplings of the Higgs boson with data of 35.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV using Higgs boson candidates with two jets produced in VBF, ggF, and VH that decay to  $\tau\tau$ . See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the  $H \rightarrow 4\ell$  (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A CP-violating parameter is set to be  $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27) \times 10^{-3}$  and CP-conserving parameters are  $f_{a2}\cos(\phi_{a2}) = (0.08^{+1.04}_{-0.21}) \times 10^{-3}$ ,  $f_{\Lambda 1}\cos(\phi_{\Lambda 1}) = (0.00^{+0.53}_{-0.09}) \times 10^{-3}$ , and  $f_{\Lambda 1}^{Z\gamma}\cos(\phi_{\Lambda 1}^{Z\gamma}) = (0.0^{+1.1}_{-1.3}) \times 10^{-3}$ .
- 12 AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb<sup>-1</sup> of  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. Constraints are set on the non-Standard-Model CP-even and CP-odd couplings to Z bosons and on the CP-odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.
- 13 SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV, 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV, and 38.6 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A CP violation parameter  $f_{a3}$  is set to be  $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$  at 95% CL ( $\phi_{a3} = 0$  or  $\pi$ ).
- 14 AAD 16 study  $H \rightarrow \gamma\gamma$  with an effective Lagrangian including CP even and odd terms in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.
- 15 AAD 16BL study VBF  $H \rightarrow \tau\tau$  with an effective Lagrangian including a CP odd term in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. The measurement is consistent with the expectation of the Standard Model. The CP-mixing parameter  $\tilde{d}$  (a dimensionless coupling  $\tilde{d} = -(m_W^2/\Lambda^2)f_{WW}^{CP}$ ) is constrained to the interval of  $(-0.11, 0.05)$  at 68% CL under the assumption of  $\tilde{d} = \tilde{d}_B$ .
- 16 KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to  $W$  and  $Z$  with 18.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.
- 17 AAD 15AX compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV, using the process  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$ .  $2^+$  hypotheses are excluded at 84.5–99.4%CL,  $0^-$  at 96.5%CL,  $0^+$  (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible CP mixture parameters.
- 18 AAD 15CI compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV, using the processes  $H \rightarrow ZZ^* \rightarrow 4\ell, H \rightarrow \gamma\gamma$  and combine with AAD 15AX data.  $0^+$  (field strength coupling),  $0^-$  and several  $2^+$  hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible CP mixture parameters.
- 19 AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a  $0^-$  and a  $2^+$  state. Assuming the SM event rate, the  $J^{CP} = 0^-$  ( $2^+$ ) hypothesis is excluded at the 5.0 $\sigma$  (4.9 $\sigma$ ) level.
- 20 AALTONEN 15B compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in 9.45 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV, using the processes  $ZH \rightarrow \ell\ell b\bar{b}, WH \rightarrow \ell\nu b\bar{b}$ , and  $ZH \rightarrow \nu\nu b\bar{b}$ . Bounds on the production rates of  $0^-$  and  $2^+$  (graviton-like) states are set, see their tables II and III.
- 21 KHACHATRYAN 15Y compare the  $J^{CP} = 0^+$  Standard Model assignment with other  $J^{CP}$  hypotheses in up to 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 7$  TeV and up to 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV, using the processes  $H \rightarrow 4\ell, H \rightarrow WW^*$ , and  $H \rightarrow \gamma\gamma$ .  $0^-$  is excluded at 99.98% CL, and several  $2^+$  hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in  $ZZ^*$  and  $WW^*$  modes. Limits on anomalous couplings and several cross section fractions, treating the case of CP-mixed states, are also given.
- 22 ABAZOV 14F compare the  $J^{CP} = 0^+$  Standard Model assignment with  $J^{CP} = 0^-$  and  $2^+$  (graviton-like coupling) hypotheses in up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states  $ZH \rightarrow \ell\ell b\bar{b}, WH \rightarrow \ell\nu b\bar{b}$ , and  $ZH \rightarrow$

## Gauge &amp; Higgs Boson Particle Listings

## H

- $\nu\nu\bar{\nu}$ . The  $0^-$  ( $2^+$ ) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a  $0^+$  state with another  $J^{CP}$  state, the cross section fractions  $f_X = \sigma_X / (\sigma_{0^+} + \sigma_X)$  are considered, where  $X = 0^-, 2^+$ . Values for  $f_{0^-}$  ( $f_{2^+}$ ) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.
- 23 CHATRCHYAN 14AA compare the  $J^{CP} = 0^+$  Standard Model assignment with various  $J^{CP}$  hypotheses in 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV.  $J^{CP} = 0^-$  and  $1^\pm$  hypotheses are excluded at 99% CL, and several  $J = 2$  hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a  $0^+$  state with another  $J^{CP}$  state, the cross section fraction  $f_{a3} = |a_3|^2 \sigma_3 / (|a_1|^2 \sigma_1 + |a_2|^2 \sigma_2 + |a_3|^2 \sigma_3)$  is considered, where the case  $a_3 = 1, a_1 = a_2 = 0$  corresponds to a pure  $CP$ -odd state. Assuming  $a_2 = 0$ , a value for  $f_{a3}$  above 0.51 is excluded at 95% CL.
- 24 CHATRCHYAN 14G compare the  $J^{CP} = 0^+$  Standard Model assignment with  $J^{CP} = 0^-$  and  $2^+$  (graviton-like coupling) hypotheses in 4.9 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.4 fb $^{-1}$  at  $E_{cm} = 8$  TeV. Varying the fraction of the production of the  $2^+$  state via  $gg$  and  $q\bar{q}$ ,  $2^+$  hypotheses are disfavored at CL between 83.7 and 99.8%. The  $0^-$  hypothesis is disfavored against  $0^+$  at the 65.3% CL.
- 25 KHACHATRYAN 14P compare the  $J^{CP} = 0^+$  Standard Model assignment with a  $2^+$  (graviton-like coupling) hypothesis in 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV. Varying the fraction of the production of the  $2^+$  state via  $gg$  and  $q\bar{q}$ ,  $2^+$  hypotheses are disfavored at CL between 71 and 94%.
- 26 AAD 13AJ compare the spin 0,  $CP$ -even hypothesis with specific alternative hypotheses of spin 0,  $CP$ -odd, spin 1,  $CP$ -even and  $CP$ -odd, and spin 2,  $CP$ -even models using the Higgs boson decays  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow ZZ^* \rightarrow 4\ell$  and  $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  and combinations thereof. The data are compatible with the spin 0,  $CP$ -even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.
- 27 CHATRCHYAN 13J study angular distributions of the lepton pairs in the  $ZZ^*$  channel where both  $Z$  bosons decay to  $e$  or  $\mu$  pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure  $CP$ -even hypothesis, while the pure  $CP$ -odd hypothesis is disfavored.

## H DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to  $ZZ^*$  and interference effects between signal and background in Higgs decays to  $\gamma\gamma$  can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to  $ZZ^*$  rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

1 AAD 23BR use 139 fb $^{-1}$  at  $E_{cm} = 13$  TeV. The off-shell Higgs boson production in the  $ZZ \rightarrow 4\ell$  and  $ZZ \rightarrow 2\ell 2\nu$  decay channels and the on-shell production in the  $ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ , AAD 20AQ) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be  $1.1^{+0.7}_{-0.6}$  assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The scenario of no off-shell contribution is excluded at  $3.3 \sigma$ . Combining with the on-shell signal strength measurement, the total width normalized to its SM expectation  $\Gamma_H/\Gamma_H^{SM}$  is measured to be  $1.1^{+0.7}_{-0.6}$  assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The observed upper limit on the total width is 10.5 MeV at 95% CL. See their Fig. 7.

- 2 TUMASYAN 22AM use up to 140 fb $^{-1}$  at  $E_{cm} = 13$  TeV. The off-shell Higgs boson production in the  $ZZ \rightarrow 4\ell$  and  $ZZ \rightarrow 2\ell 2\nu$  decay channels and the on-shell production in the  $ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be  $0.62^{+0.68}_{-0.45}$  without the constraint on the ratio of the off-shell signal strengths for gluon-fusion and gauge-boson modes. The scenario of no off-shell contribution is excluded at  $3.6 \sigma$ . The results are shown in their Table 1 with other constraint scenarios and the decay widths assuming the same coupling modifiers for on- and off-shell couplings ( $g_p$  and  $g_d$  in their notation). The measurement of anomalous  $HVV$  couplings is shown in their Extended Data Table 1 and Fig. 8.
- 3 SIRUNYAN 19BL measure the width and anomalous  $HVV$  couplings from on-shell and off-shell production in the  $4\ell$  final state. Data of 80.2 fb $^{-1}$  at 13 TeV, 19.7 fb $^{-1}$  at 8 TeV, and 5.1 fb $^{-1}$  at 7 TeV are used. The total width for the SM-like couplings is measured to be also [0.08, 9.16] MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous  $HVV$  interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.
- 4 AABOUD 18BP use 36.1 fb $^{-1}$  at  $E_{cm} = 13$  TeV. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the  $ZZ \rightarrow 4\ell$  and  $ZZ \rightarrow 2\ell 2\nu$  decay channels ( $\ell = e, \mu$ ). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.
- 5 SIRUNYAN 17AV obtain an upper limit on the width from the  $m_{4\ell}$  distribution in  $ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) decays. Data of 35.9 fb $^{-1}$   $pp$  collisions at  $E_{cm} = 13$  TeV is used. The expected limit is 1.60 GeV.
- 6 KHACHATRYAN 16BA derive constraints on the total width from comparing  $WW^*$  production via on-shell and off-shell  $H$  using 4.9 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.4 fb $^{-1}$  at 8 TeV.
- 7 KHACHATRYAN 16BA combine the  $WW^*$  result with  $ZZ^*(^*)$  results of KHACHATRYAN 15BA and KHACHATRYAN 14D.
- 8 AAD 15BE derive constraints on the total width from comparing  $ZZ^*(^*)$  and  $WW^*$  production via on-shell and off-shell  $H$  using 20.3 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 8$  TeV. The K factor for the background processes is assumed to be equal to that for the signal.
- 9 KHACHATRYAN 15AM combine  $\gamma\gamma$  and  $ZZ^* \rightarrow 4\ell$  results. The expected limit is 2.3 GeV.
- 10 KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance  $\tau < 1.9 \times 10^{-13}$  s. 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at 8 TeV are used.
- 11 KHACHATRYAN 15BA derive constraints on the total width from comparing  $ZZ^*(^*)$  production via on-shell and off-shell  $H$  with an unconstrained anomalous coupling.  $4\ell$  final states in 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV are used.
- 12 AAD 14W use 4.5 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb $^{-1}$  at 8 TeV. The expected limit is 6.2 GeV.
- 13 CHATRCHYAN 14AA use 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV. The expected limit is 2.8 GeV.
- 14 KHACHATRYAN 14D derive constraints on the total width from comparing  $ZZ^*(^*)$  production via on-shell and off-shell  $H$ .  $4\ell$  and  $\ell\nu\nu$  final states in 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV are used.
- 15 KHACHATRYAN 14P use 5.1 fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb $^{-1}$  at  $E_{cm} = 8$  TeV. The expected limit is 3.1 GeV.

<sup>1</sup>TUMASYAN 23c search for  $H \rightarrow \Upsilon(nS)\Upsilon(mS)$  with  $\Upsilon(nS)$ ,  $\Upsilon(mS) \rightarrow \mu^+\mu^-$  ( $n, m = 1, 2, 3$ ) with 138 fb<sup>-1</sup> of  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The quoted value is for the Higgs decays for longitudinally polarized mesons. See their Table 1 for other cases.

<sup>2</sup>SIRUNYAN 19BR search for  $H \rightarrow \Upsilon(nS)\Upsilon(mS)$  with  $\Upsilon(nS)$ ,  $\Upsilon(mS) \rightarrow \mu^+\mu^-$  ( $n, m = 1, 2, 3$ ) for 37.5 fb<sup>-1</sup> of  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV.  $\Upsilon$ s from the Higgs decay are assumed to be unpolarized. For fully longitudinal (transverse) polarized  $\Upsilon$ s, limits change by  $-22\%$  ( $+10\%$ ). The three  $\Upsilon$  states selected in a mass range of 8.5–11 GeV are not distinguished.

- <sup>1</sup> AAD 23A report the combined results of 7, 8 (AAD 15CX) and 13 TeV assuming the Standard Model cross section ( $m_H = 125$  GeV). See their Table 1 and Fig. 3.
- <sup>2</sup> AAD 23A report the combined results using 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, where  $H$  decaying to invisible final states in VBF (AAD 22P),  $ZH, Z \rightarrow ee, \mu\mu$  (AAD 22D),  $pp \rightarrow t\bar{t}H$  (AAD 23AF), VBF+ $\gamma$  (AAD 22S) and gluon-fusion production with an energetic jet (AAD 21F) assuming the Standard Model cross section ( $m_H = 125$  GeV). See their Table 1 and Fig. 3.
- <sup>3</sup> AAD 23AF search for  $pp \rightarrow t\bar{t}H$  with  $H$  decaying to invisible final states using 139 fb<sup>-1</sup> of data. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model cross section. See their Table 3 for different decay topologies.
- <sup>4</sup> TUMASYAN 23BA search for  $H$  decaying to invisible final states produced in association with a  $t\bar{t}$  or a  $V$ , which decay to a fully hadronic final state. 138 fb<sup>-1</sup> of data is used. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model cross section. See their Fig. 6 for the results of individual topologies.
- <sup>5</sup> TUMASYAN 23BA report the combined results of 7, 8, and 13 TeV assuming the Standard Model cross section ( $m_H = 125$  GeV). They combine results from TUMASYAN 22G, SIRUNYAN 21A, SIRUNYAN 21B, TUMASYAN 21D, SIRUNYAN 20AH, KHACHATRYAN 17F, CHATRCHYAN 14B as shown in their Table 8. See their Fig. 7 and Table 9 for the results of individual topologies.
- <sup>6</sup> AAD 22D search for  $H$  decaying to invisible final states associated with a  $Z$  decaying  $ee/\mu\mu$  using 139 fb<sup>-1</sup> at 13 TeV. The limit is obtained for  $m_H = 125$  GeV and assuming the SM  $ZH$  production cross section. The branching ratio is obtained to be  $(0.3 \pm 9.0)\%$ .
- <sup>7</sup> AAD 22P search for  $pp \rightarrow qqHX$  (VBF) with  $H$  decaying to invisible final states using 139 fb<sup>-1</sup> of data. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model cross section.
- <sup>8</sup> AAD 22S observe electroweak  $Z(\rightarrow \nu\nu)\gamma+2$ jets production process with 139 fb<sup>-1</sup> of data. This result is applicable to search for  $pp \rightarrow qqH\gamma X$  (VBF+ $\gamma$ ) with  $H$  decaying to invisible final states. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model cross section.
- <sup>9</sup> ATLAS 22 report the combined results using 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, where  $H$  decaying to invisible final states in VBF (AAD 22P), and  $ZH, Z \rightarrow ee, \mu\mu$  (AAD 22D), assuming  $\kappa_V \leq 1$  and  $B_{\text{undetected}} \geq 0$ .

- <sup>10</sup> CMS 22 report the combined results using (a part of) 138 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, where  $H$  decaying to invisible final states in VBF (SIRUNYAN 19Bo) and other 13 TeV (KHACHATRYAN 17F for 2015 and SIRUNYAN 19Bo for 2016) for  $H$  decaying to invisible jet or a  $V(\rightarrow q\bar{q})$  (TUMASYAN 21D), and  $ZH, Z \rightarrow ee, \mu\mu$  (SIRUNYAN 21A) and assuming  $\kappa_V \leq 1$  and  $B_{\text{undetected}} \geq 0$ .
- <sup>11</sup> TUMASYAN 22G combine 13 TeV 101 fb<sup>-1</sup> results with 8 TeV (KHACHATRYAN 17F) and other 13 TeV (KHACHATRYAN 17F for 2015 and SIRUNYAN 19Bo for 2016) for  $H$  decaying to invisible final states with VBF topology. The quoted limit on the branching ratio is given for  $m_H = 125.38$  GeV and assumes the Standard Model production rates. The branching ratio is obtained to be  $0.086_{-0.052}^{+0.054}$ . See their Figs. 11 and 12.
- <sup>12</sup> TUMASYAN 22G search for  $pp \rightarrow qqHX$  (VBF) with  $H$  decaying to invisible final states using 101 fb<sup>-1</sup> of data (2017 and 2018). The quoted limit on the branching ratio is given for  $m_H = 125.38$  GeV and assumes the Standard Model cross section. See their Figs. 11 and 12.
- <sup>13</sup> AAD 21F search for an invisibly decaying Higgs boson with an energetic jet ( $p_T > 150$  GeV) and missing transverse momentum ( $> 200$  GeV) in 139 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV.
- <sup>14</sup> SIRUNYAN 21A search for  $H$  decaying to invisible final states associated with a  $Z$  decaying  $ee/\mu\mu$  using 137 fb<sup>-1</sup> at 13 TeV. The limit is obtained for  $m_H = 125$  GeV and assuming the SM  $ZH$  production cross section.
- <sup>15</sup> TUMASYAN 21D search for  $H$  decaying to invisible final states associated with an energetic jet or a  $V, V \rightarrow q\bar{q}$  using 101 fb<sup>-1</sup> at 13 TeV and the result is combined with SIRUNYAN 18S.
- <sup>16</sup> AABOUD 19AI search for  $pp \rightarrow qqHX$  (VBF) with  $H$  decaying to invisible final states using 36.1 fb<sup>-1</sup> of data. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model rates for VBF and gluon-fusion production.
- <sup>17</sup> AABOUD 19AL combine results of  $H$  decaying to invisible final states with VBF(AABOUD 19AI),  $ZH$ , and  $WH$  productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb<sup>-1</sup> of data at 13 TeV. The quoted limit is given for  $m_H = 125$  GeV and assumes the Standard Model rates for gluon fusion, VBF,  $ZH$ , and  $WH$  productions.
- <sup>18</sup> AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for  $H$  decaying to invisible final states.
- <sup>19</sup> SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb<sup>-1</sup> of data at 13 TeV.
- <sup>20</sup> SIRUNYAN 19Bo search for  $pp \rightarrow qqHX$  (VBF) with  $H$  decaying to invisible final states using 35.9 fb<sup>-1</sup> of data. The quoted limit on the branching ratio is given for  $m_H = 125.09$  GeV and assumes the Standard Model production rates.
- <sup>21</sup> SIRUNYAN 19Bo combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18S. The quoted limit on the branching ratio is given for  $m_H = 125.09$  GeV and assumes the Standard Model production rates.
- <sup>22</sup> SIRUNYAN 19Bo combine 13 TeV 35.9 fb<sup>-1</sup> results with 7, 8, 13 TeV (KHACHATRYAN 17F) for  $H$  decaying to invisible final states. The quoted limit on the branching ratio is given for  $m_H = 125.09$  GeV and assumes the Standard Model production rates. The branching ratio is obtained to be  $0.05 \pm 0.03$  (stat)  $\pm 0.07$  (syst).
- <sup>23</sup> AABOUD 18 search for  $pp \rightarrow HZX, Z \rightarrow ee, \mu\mu$  with  $H$  decaying to invisible final states in 36.1 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model rate for  $HZ$  production.
- <sup>24</sup> AABOUD 18CA search for  $H$  decaying to invisible final states using  $WH, ZH$  productions, where  $W$  and  $Z$  hadronically decay. The data of 36.1 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from  $WH, ZH, ggF$  and VBF production modes.
- <sup>25</sup> SIRUNYAN 18BV search for  $H$  decaying to invisible final states associated with a  $Z, Z \rightarrow \ell\ell$  using 35.9 fb<sup>-1</sup> at 13 TeV. The limit is obtained for  $m_H = 125$  GeV and assuming the SM  $ZH$  production cross section.
- <sup>26</sup> SIRUNYAN 18S search for  $H$  decaying to invisible final states associated with an energetic jet or a  $V, V \rightarrow q\bar{q}$  using 35.9 fb<sup>-1</sup> at 13 TeV.
- <sup>27</sup> AABOUD 17BD search for  $H$  decaying to invisible final states with  $\geq 1$  jet and VBF events using 3.2 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. A cross-section ratio  $R^{\text{miss}}$  is used in the measurement. The quoted limit is given for  $m_H = 125$  GeV.
- <sup>28</sup> KHACHATRYAN 17F search for  $H$  decaying to invisible final states with gluon fusion, VBF,  $ZH$ , and  $WH$  productions using 2.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV, 19.7 fb<sup>-1</sup> at 8 TeV, and 5.1 fb<sup>-1</sup> at 7 TeV. The quoted limit is given for  $m_H = 125$  GeV and assumes the Standard Model rates for gluon fusion, VBF,  $ZH$ , and  $WH$  productions.
- <sup>29</sup> AAD 16AF search for  $pp \rightarrow qqHX$  (VBF) with  $H$  decaying to invisible final states in 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model rates for VBF and gluon-fusion production.
- <sup>30</sup> AAD 16AN perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for  $m_0 = 125.09$  GeV.
- <sup>31</sup> AAD 15BD search for  $pp \rightarrow HWX$  and  $pp \rightarrow HZX$  with  $W$  or  $Z$  decaying hadronically and  $H$  decaying to invisible final states using data at  $E_{\text{cm}} = 8$  TeV. The quoted limit is given for  $m_H = 125$  GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from  $HW, HZ$  and the gluon-fusion process.
- <sup>32</sup> AAD 15CX search for  $H$  decaying to invisible final states with VBF,  $ZH$ , and  $WH$  productions using 20.3 fb<sup>-1</sup> at 8 TeV, and 4.7 fb<sup>-1</sup> at 7 TeV. The quoted limit is given for  $m_H = 125.36$  GeV and assumes the Standard Model rates for gluon fusion, VBF,  $ZH$ , and  $WH$  productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.
- <sup>33</sup> AAD 14O search for  $pp \rightarrow HZX, Z \rightarrow \ell\ell$ , with  $H$  decaying to invisible final states in 4.5 fb<sup>-1</sup> at  $E_{\text{cm}} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125.5$  GeV and assumes the Standard Model rate for  $HZ$  production.
- <sup>34</sup> CHATRCHYAN 14B search for  $pp \rightarrow HZX, Z \rightarrow \ell\ell$  and  $Z \rightarrow b\bar{b}$ , and also  $pp \rightarrow qqHX$  with  $H$  decaying to invisible final states using data at  $E_{\text{cm}} = 7$  and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from  $HZ$  and  $qqH$ . It is given for  $m_H = 125$  GeV and assumes the Standard Model rates for the two production processes.
- <sup>35</sup> CHATRCHYAN 14B search for  $pp \rightarrow HZX$  with  $H$  decaying to invisible final states and  $Z \rightarrow \ell\ell$  in 4.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV, and also with  $Z \rightarrow b\bar{b}$  in 18.9 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model rate for  $HZ$  production.
- <sup>36</sup> CHATRCHYAN 14B search for  $pp \rightarrow qqHX$  (vector boson fusion) with  $H$  decaying to invisible final states in 19.5 fb<sup>-1</sup> at  $E_{\text{cm}} = 8$  TeV. The quoted limit on the branching ratio is given for  $m_H = 125$  GeV and assumes the Standard Model rate for  $qqH$  production.

## H SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The  $H$  signal strength in a particular final state  $xx$  is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value,  $\sigma \cdot \text{B}(H \rightarrow xx) / (\sigma \cdot \text{B}(H \rightarrow xx))_{\text{SM}}$ , for the specified mass value of  $H$ . For the SM predictions, see DITTMAYER 11, DITTMAYER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

- <sup>1</sup> ATLAS 22 report combined results (see their Extended Data Table 1) using up to  $139 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.09 \text{ GeV}$ . The Higgs production cross-sections, branching fractions and several ratios are found in their Figs. 2 and 3.
- <sup>2</sup> CMS 22 report combined results (see their Extended Data Table 2) using  $138 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.38 \text{ GeV}$ . Signal strengths for production modes and decay channels are found in their Fig. 2.
- <sup>3</sup> AAD 16AN perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ . The signal strengths for individual production processes are  $1.03 \pm 0.16$  for gluon fusion,  $1.18 \pm 0.25$  for vector boson fusion,  $0.89 \pm 0.40$  for  $WH$  production,  $0.79 \pm 0.38$  for  $ZH$  production, and  $2.3 \pm 0.6$  for  $t\bar{t}H$  production.
- <sup>4</sup> AAD 16AN: The uncertainties represent statistics, experimental systematics, and added in quadrature theory systematics on the background and on the signal. The quoted signal strengths are given for  $m_H = 125.09 \text{ GeV}$ . In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.
- <sup>5</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to  $10.0 \text{ fb}^{-1}$  and  $9.7 \text{ fb}^{-1}$ , respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .
- <sup>6</sup> AAD 20 combine results of up to  $79.8 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.09 \text{ GeV}$ :  $\gamma\gamma, ZZ^*, WW^*, \tau\tau, b\bar{b}, \mu\mu$ , invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are  $1.04 \pm 0.09$  for gluon fusion,  $1.21 \pm 0.24$  for vector boson fusion,  $1.30 \pm 0.40$  for  $WH$  production,  $1.05 \pm 0.31$  for  $ZH$  production, and  $1.21 \pm 0.26$  for  $t\bar{t}H + tH$  production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and  $\kappa$ -frameworks

are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the  $\kappa$ -framework.

- <sup>7</sup> SIRUNYAN 19AT combine results of  $35.9 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.09 \text{ GeV}$ . The signal strengths for individual production processes are  $1.22 \pm 0.14$  for gluon fusion,  $0.73 \pm 0.30$  for vector boson fusion,  $2.18 \pm 0.58$  for  $WH$  production,  $0.87 \pm 0.44$  for  $ZH$  production, and  $1.18 \pm 0.30$  for  $t\bar{t}H$  production. Several results with the simplified template cross section and  $\kappa$ -frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the  $\kappa$ -framework.
- <sup>8</sup> SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using  $35.9 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $H \rightarrow \gamma\gamma, H \rightarrow ZZ^*$ , and  $H \rightarrow b\bar{b}$ . The total cross section for Higgs boson production is measured to be  $61.1 \pm 6.0 \pm 3.7 \text{ pb}$  using  $H \rightarrow \gamma\gamma$  and  $H \rightarrow ZZ^*$  channels. Several coupling measurements in the  $\kappa$ -framework are performed.
- <sup>9</sup> AAD 16K use up to  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are  $1.23 \pm 0.14 \pm 0.09 \pm 0.16$  for gluon fusion,  $1.23 \pm 0.28 \pm 0.13 \pm 0.11$  for vector boson fusion,  $0.80 \pm 0.31 \pm 0.17 \pm 0.10$  for  $W/ZH$  production, and  $1.81 \pm 0.52 \pm 0.58 \pm 0.31$  for  $t\bar{t}H$  production. The quoted signal strengths are given for  $m_H = 125.36 \text{ GeV}$ .
- <sup>10</sup> AAD 15P measure total and differential cross sections of the process  $pp \rightarrow HX$  at  $E_{\text{cm}} = 8 \text{ TeV}$  with  $20.3 \text{ fb}^{-1}$ .  $\gamma\gamma$  and  $4\ell$  final states are used.  $\sigma(pp \rightarrow HX) = 33.0 \pm 5.3 \pm 1.6 \text{ pb}$  is given. See their Figs. 2 and 3 for data on differential cross sections.
- <sup>11</sup> KHACHATRYAN 15AM use up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of  $0.85 \pm 0.19$  for gluon fusion,  $1.16 \pm 0.37$  for vector boson fusion,  $0.92 \pm 0.38$  for  $WH, ZH$  production, and  $2.90 \pm 1.08$  for  $t\bar{t}H$  production.
- <sup>12</sup> AAD 13AK use  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The combined signal strength is based on the  $\gamma\gamma, ZZ^* \rightarrow 4\ell$ , and  $WW^* \rightarrow \ell\nu\ell\nu$  channels. The quoted signal strength is given for  $m_H = 125.5 \text{ GeV}$ . Reported statistical error value modified following private communication with the experiment.
- <sup>13</sup> AALTONEN 13L combine all CDF results with  $9.45\text{--}10.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .
- <sup>14</sup> ABAZOV 13L combine all D0 results with up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .
- <sup>15</sup> AAD 12AI obtain results based on  $4.6\text{--}4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.8\text{--}5.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . An excess of events over background with a local significance of  $5.9 \sigma$  is observed at  $m_H = 126 \text{ GeV}$ . The quoted signal strengths are given for  $m_H = 126 \text{ GeV}$ . See also AAD 12DA.
- <sup>16</sup> CHATRCHYAN 12N obtain results based on  $4.9\text{--}5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.1\text{--}5.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . An excess of events over background with a local significance of  $5.0 \sigma$  is observed at about  $m_H = 125 \text{ GeV}$ . The combined signal strength is based on the  $\gamma\gamma, ZZ^*, WW^*, \tau^+\tau^-,$  and  $b\bar{b}$  channels. The quoted signal strength is given for  $m_H = 125.5 \text{ GeV}$ . See also CHATRCHYAN 13X.

- 1 CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV. See their Fig. 2 right.
- 2 AAD 16AN perform fits to the ATLAS and CMS data at  $E_{cm} = 7$  and 8 TeV. The signal strengths for individual production processes are  $0.84 \pm 0.17$  for gluon fusion,  $1.2 \pm 0.4$  for vector boson fusion,  $1.6^{+1.2}_{-1.0}$  for  $WH$  production,  $5.9^{+2.6}_{-2.2}$  for  $ZH$  production, and  $5.0^{+1.8}_{-1.7}$  for  $t\bar{t}H$  production.
- 3 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09$  GeV.
- 4 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb<sup>-1</sup> and 9.7 fb<sup>-1</sup>, respectively, of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- 5 AAD 23AP measure cross-sections times the  $H \rightarrow WW^*$  branching fraction in the  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$  channel using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV:  $\sigma_{ggF} \times B(H \rightarrow WW^*) = 12.0 \pm 1.4$  pb,  $\sigma_{VBF} \times B(H \rightarrow WW^*) = 0.75^{+0.19}_{-0.16}$  pb, and  $\sigma_{ggF+VBF} \times B(H \rightarrow WW^*) = 12.3 \pm 1.3$  pb. The results are given for  $m_H = 125.09$  GeV. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 5) simplified template cross section framework are shown in their Table VII and Fig. 15.
- 6 AAD 23BV measure fiducial total and differential cross sections of VBF process at  $E_{cm} = 13$  TeV with 139 fb<sup>-1</sup> using  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$ . The measured total fiducial cross section is  $1.68 \pm 0.33(\text{stat}) \pm 0.23(\text{syst})$  fb in their fiducial region (Table II and Section V). See their Fig. 9 for the comparison with theory predictions. The fiducial differential cross sections are shown in their Figs. 11, 12, and 13. Wilson coefficients in the Warsaw basis at 95% confidence interval are measured; see their Table V and Fig. 16.
- 7 TUMASYAN 23W measure Higgs production rates with  $H \rightarrow WW^*$  at  $E_{cm} = 13$  TeV with 138 fb<sup>-1</sup> data. The quoted results are given for  $m_H = 125.38$  GeV.
- 8 The quoted global signal strength is obtained assuming the relative ratios of different Higgs production modes fixed to the SM values.
- 9 The 4 signal strengths for gluon-fusion (ggF), VBF,  $WH$  and  $ZH$  modes are fit assuming  $t\bar{t}H$  and  $b\bar{b}H$  fixed to the SM values.
- 10 The quoted result is for ggF production mode.
- 11 The quoted result is for VBF production mode.
- 12 The quoted result is for  $WH$  production mode.
- 13 The quoted result is for  $ZH$  production mode.
- 14 Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 17) simplified template cross section framework (6 ggF, 4 VBF, and 4  $VH$ ) are shown in their Table 18 and Fig. 26.
- 15 AAD 22V measure the signal strength for ggF+2jets with 36.1 fb<sup>-1</sup> data at 13 TeV.
- 16 AAD 22V probe the Higgs couplings to longitudinally and transversely polarized  $W$  and  $Z$  using VBF ( $H \rightarrow WW^* \rightarrow e\nu\mu\nu$  plus two jets) with 36.1 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV. The ratios of the polarization-dependent couplings  $g_{H V_L V_L}$  and  $g_{H V_T V_T}$  to the Higgs- $V$  coupling predicted by the SM,  $a_L = g_{H V_L V_L} / g_{H V V}^{\text{SM}}$  and  $a_T = g_{H V_T V_T} / g_{H V V}^{\text{SM}}$  are measured to be  $0.91^{+0.10+0.09}_{-0.18-0.17}$  and  $1.2 \pm 0.4^{+0.2}_{-0.3}$ , respectively, assuming the standard  $Hgg$  coupling. These measurements are translated into pseudo-observables of  $\kappa_{VV}$  and  $\epsilon_{VV}$ :  $\kappa_{VV} = 0.91^{+0.10+0.09}_{-0.18-0.17}$  and  $\epsilon_{VV} = 0.13^{+0.28+0.08}_{-0.20-0.10}$ , where  $\kappa_{VV} = 1$  and  $\epsilon_{VV} = 0$  for the SM. See their Tables 9 and 10.
- 17 AABOUD 19F measure cross-sections times the  $H \rightarrow WW^*$  branching fraction in the  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$  channel using 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV:  $\sigma_{ggF} \times B(H \rightarrow WW^*) = 11.4^{+1.2+1.8}_{-1.1-1.7}$  pb and  $\sigma_{VBF} \times B(H \rightarrow WW^*) = 0.50^{+0.24}_{-0.22} \pm 0.17$  pb.
- 18 AAD 19A use 36.1 fb<sup>-1</sup> data at 13 TeV. The cross section times branching fraction values are measured to be  $0.67^{+0.31+0.18}_{-0.27-0.14}$  pb for  $WH, H \rightarrow WW^*$  and  $0.54^{+0.31+0.15}_{-0.24-0.07}$  pb for  $ZH, H \rightarrow WW^*$ .
- 19 SIRUNYAN 19AT perform a combine fit to 35.9 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV.
- 20 SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and  $VH$  production processes with 35.9 fb<sup>-1</sup> of data. The quoted signal strength is given for  $m_H = 125.09$  GeV. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10.  $\kappa_F = 1.52^{+0.48}_{-0.41}$  and  $\kappa_V = 1.10 \pm 0.08$  are obtained (see their Fig. 11 (right)).
- 21 AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at  $E_{cm} = 8$  TeV with 20.3 fb<sup>-1</sup> using  $H \rightarrow WW^* \rightarrow e\nu\mu\nu$ . The measured fiducial total cross section is  $36.0 \pm 9.7$  fb in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for  $m_H = 125$  GeV.
- 22 AAD 16K use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.36$  GeV.
- 23 AAD 15AA use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The signal strength for the gluon fusion and vector boson fusion mode is

- $1.02 \pm 0.19^{+0.22}_{-0.18}$  and  $1.27^{+0.44+0.30}_{-0.40-0.21}$ , respectively. The quoted signal strengths are given for  $m_H = 125.36$  GeV.
- 24 AAD 15AQ use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.36$  GeV.
- 25 AAD 15AQ combine their result on  $W/ZH$  production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for  $m_H = 125.36$  GeV.
- 26 CHATRCHYAN 14G use 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.4 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for  $m_H = 125.6$  GeV.
- 27 AAD 13AK use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.7 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV. Superseded by AAD 15AA.
- 28 AALTONEN 13L combine all CDF results with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- 29 ABAZOV 13I combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- 30 AAD 12AI obtain results based on 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.8 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strengths are given for  $m_H = 126$  GeV. See also AAD 12DA.
- 31 CHATRCHYAN 12N obtain results based on 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.1 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV. See also CHATRCHYAN 13Y.

- 1 CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV. See their Fig. 2 right.
- 2 AAD 20AQ perform analyses using  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. Results are given for  $m_H = 125$  GeV.
- 3 AAD 20AQ measured the inclusive cross section times branching ratio for  $H \rightarrow ZZ^*$  decay ( $|\eta(H)| < 2.5$ ) to be  $1.34 \pm 0.12$  pb (with  $1.33 \pm 0.08$  pb expected in the SM).
- 4 AAD 16AN perform fits to the ATLAS and CMS data at  $E_{cm} = 7$  and 8 TeV. The signal strengths for individual production processes are  $1.13^{+0.34}_{-0.31}$  for gluon fusion and  $0.1^{+1.1}_{-0.6}$  for vector boson fusion.
- 5 AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09$  GeV.
- 6 HAYRAPETYAN 23 measure the cross sections for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. They give  $\sigma = 2.73 \pm 0.22(\text{stat}) \pm 0.15(\text{syst})$  fb in their fiducial region (see their Section 5 and Table 2), where  $2.86 \pm 0.15$  fb is expected in the Standard Model for  $m_H = 125.38$  GeV. 26 differential and 6 double-differential cross sections are given; see their Figs. 6–23 and 24–25.
- 7 SIRUNYAN 21AE obtains constraints on anomalous couplings to vector bosons ( $W, Z$ , and gluon) and top quark using  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) with data of 137 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. Their Table 5 and Figs 14–17 show (effective) couplings to gluon and top with combining gluon fusion,  $t\bar{t}H$  and  $tH$  production channels and the result of  $t\bar{t}H, H \rightarrow \gamma\gamma$  (SIRUNYAN 20AS). Their Tables 6–9 and Figs 18–22 show couplings to  $W$  and  $Z$  for different assumptions and bases (Higgs and Warsaw).

## H

- <sup>8</sup> SIRUNYAN 21s measure cross sections with the  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) channel using  $137 \text{ fb}^{-1}$  data at  $E_{\text{cm}} = 13 \text{ TeV}$ . Results are given for  $m_H = 125.38 \text{ GeV}$ . The signal strengths for individual production processes in their Table 4. Cross sections are given in their Table 6 and Fig. 14, which are based on the simplified template cross section framework (reduced stage-1.2).
- <sup>9</sup> AAD 20AQ present several results for the channel  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) with the simplified template cross section with  $\kappa$ -frameworks and the effective field theory (EFT) approach; see their Table 8 and Fig. 10 for simplified template cross sections.  $\kappa_V = 1.02 \pm 0.06$  and  $\kappa_F = 0.88 \pm 0.16$  are obtained, see their Fig. 12 for the  $\kappa$ -framework. See their Tables 9 and 10 and Figs. 16–18 for the EFT-framework.
- <sup>10</sup> AAD 20BA measure the cross section for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using  $139 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . They give  $\sigma \cdot B = 3.28 \pm 0.30 \pm 0.11 \text{ fb}$  in their fiducial region, where  $3.41 \pm 0.18 \text{ fb}$  is expected in the Standard Model for  $m_H = 125 \text{ GeV}$ . Various differential cross sections are also given; see their Figs. 19–39. Constraints on Yukawa couplings for bottom and charm quarks are given in their Table 9 and Fig. 41.
- <sup>11</sup> AABOUD 19N measure the spectrum of the four-lepton invariant mass  $m_{4\ell}$  ( $\ell = e$  or  $\mu$ ) using  $36.1 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength upper limit is obtained from  $180 \text{ GeV} < m_{4\ell} < 1200 \text{ GeV}$ .
- <sup>12</sup> SIRUNYAN 19AT perform a combine fit to  $35.9 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ .
- <sup>13</sup> AABOUD 18AJ perform analyses using  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . Results are given for  $m_H = 125.09 \text{ GeV}$ . The inclusive cross section times branching ratio for  $H \rightarrow ZZ^*$  decay ( $|\eta(H)| < 2.5$ ) is measured to be  $1.73^{+0.26}_{-0.24} \text{ pb}$  (with  $1.34^{+0.09}_{-0.09} \text{ pb}$  expected in the SM).
- <sup>14</sup> AABOUD 18BP measure an off-shell Higgs boson production using  $ZZ \rightarrow 4\ell$  and  $ZZ \rightarrow 2\ell 2\nu$  ( $\ell = e, \mu$ ) decay channels with  $36.1 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength upper limit is obtained from a combination of these two channels, where  $220 \text{ GeV} < m_{4\ell} < 2000 \text{ GeV}$  for  $ZZ \rightarrow 4\ell$  and  $250 \text{ GeV} < m_{\ell\ell}^{ZZ} < 2000 \text{ GeV}$  for  $ZZ \rightarrow 2\ell 2\nu$  ( $m_{\ell\ell}^{ZZ}$  is defined in their Section 5). See their Table 2 for each measurement.
- <sup>15</sup> SIRUNYAN 17AV use  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength, obtained from the analysis of  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) decays, is given for  $m_H = 125.09 \text{ GeV}$ . The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.
- <sup>16</sup> AAD 16K use up to  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.36 \text{ GeV}$ .
- <sup>17</sup> KHACHATRYAN 16AR use data of  $5.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $8 \text{ TeV}$ . The fiducial cross sections for the production of 4 leptons via  $H \rightarrow 4\ell$  decays are measured to be  $0.56^{+0.67+0.21}_{-0.44-0.06} \text{ fb}$  at  $7 \text{ TeV}$  and  $1.11^{+0.41+0.14}_{-0.35-0.10} \text{ fb}$  at  $8 \text{ TeV}$  in their fiducial region (Table 2). The differential cross sections at  $E_{\text{cm}} = 8 \text{ TeV}$  are also shown in Figs. 4 and 5. The results are given for  $m_H = 125 \text{ GeV}$ .
- <sup>18</sup> AAD 15F use  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.36 \text{ GeV}$ . The signal strength for the gluon fusion production mode is  $1.66^{+0.45+0.25}_{-0.41-0.15}$ , while the signal strength for the vector boson fusion production mode is  $0.26^{+1.60+0.36}_{-0.91-0.23}$ .
- <sup>19</sup> AAD 14AR measure the cross section for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . They give  $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08 \text{ fb}$  in their fiducial region, where  $1.30 \pm 0.13 \text{ fb}$  is expected in the Standard Model for  $m_H = 125.4 \text{ GeV}$ . Various differential cross sections are also given; see their Fig. 2.
- <sup>20</sup> CHATRCHYAN 14AA use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.6 \text{ GeV}$ . The signal strength for the gluon fusion and  $t\bar{t}H$  production mode is  $0.80^{+0.46}_{-0.36}$ , while the signal strength for the vector boson fusion and  $WH, ZH$  production mode is  $1.7^{+2.2}_{-2.1}$ .
- <sup>21</sup> AAD 13AK use  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.5 \text{ GeV}$ .
- <sup>22</sup> CHATRCHYAN 13J obtain results based on  $ZZ \rightarrow 4\ell$  final states in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $12.2 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.8 \text{ GeV}$ . Superseded by CHATRCHYAN 14AA.
- <sup>23</sup> AAD 12AI obtain results based on  $4.7\text{--}4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.8 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strengths are given for  $m_H = 126 \text{ GeV}$ . See also AAD 12DA.
- <sup>24</sup> CHATRCHYAN 12N obtain results based on  $4.9\text{--}5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $5.1\text{--}5.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . An excess of events over background with a local significance of  $5.0 \sigma$  is observed at about  $m_H = 125 \text{ GeV}$ . The quoted signal strengths are given for  $m_H = 125.5 \text{ GeV}$ . See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.
- <sup>4</sup> AAD 16AN CMS  $pp, 7, 8 \text{ TeV}$
- <sup>13</sup> KHACHATRYAN...16G CMS  $pp, 8 \text{ TeV}$ , diff. x-section

- <sup>21</sup> CHATRCHYAN12N CMS  $pp \rightarrow HX, 7, 8 \text{ TeV}$
- <sup>1</sup> AAD 23Y use  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted results are given for  $m_H = 125.09 \text{ GeV}$  and  $\Gamma_H = 4.07 \text{ MeV}$ . Measured  $\sigma \cdot B$  and ratios to the SM predictions for the different production modes are shown in their Table 9 and Fig. 9. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 11) simplified template cross section framework are shown in their Table 10 and Fig. 12. Wilson coefficients in the Warsaw basis (see their Table 11) at 95% CL are measured; see their Table 16 and Fig. 17.
- <sup>2</sup> CMS 22 report combined results (see their Extended Data Table 2) using up to  $138 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.38 \text{ GeV}$ . See their Fig. 2 right.
- <sup>3</sup> AAD 16AN perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ . The signal strengths for individual production processes are  $1.10^{+0.23}_{-0.22}$  for gluon fusion,  $1.3 \pm 0.5$  for vector boson fusion,  $0.5^{+1.3}_{-1.2}$  for  $WH$  production,  $0.5^{+3.0}_{-2.5}$  for  $ZH$  production, and  $2.2^{+1.6}_{-1.3}$  for  $t\bar{t}H$  production.
- <sup>4</sup> AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09 \text{ GeV}$ .
- <sup>5</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to  $10.0 \text{ fb}^{-1}$  and  $9.7 \text{ fb}^{-1}$ , respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .
- <sup>6</sup> TUMASYAN 23Q measure fiducial and differential cross sections at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $137 \text{ fb}^{-1}$  data. The quoted results are given for  $m_H = 125.38 \text{ GeV}$ . The inclusive fiducial  $\sigma \cdot B$  is  $73.4^{+5.4}_{-5.3}(\text{stat})^{+2.4}_{-2.2}(\text{syst}) \text{ fb}$  with their defined fiducial region (see their Section 7 and Table 2), where  $75.4 \pm 4.1 \text{ fb}$  is expected in the Standard Model. See their Fig. 8 including other fiducial  $\sigma \cdot B$  defined in their Table 3. Differential  $\sigma \cdot B$  are shown in their Figs. 10–15. Double-differential  $\sigma \cdot B$  are in their Figs. 16 and 17.
- <sup>7</sup> AAD 22n measure fiducial and differential cross sections of  $pp \rightarrow H \rightarrow \gamma\gamma$  at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $139 \text{ fb}^{-1}$  data. The quoted results are given for  $m_H = 125.09 \text{ GeV}$ . The inclusive fiducial  $\sigma \cdot B$  is  $67 \pm 5 \pm 4 \text{ fb}$  with their defined fiducial region. Other fiducial  $\sigma \cdot B$  are in their Table 3. Differential  $\sigma \cdot B$  are shown in their Figs. 8–13, 15, 25–32, 36. Double-differential  $\sigma \cdot B$  are in their Figs. 14, 33, 34. Modifications of the  $b$ - and  $c$ -quark Yukawa couplings to  $H, \kappa_b$  and  $\kappa_c$  at 95% CL are in their Table 6 and Fig. 18. Wilson coefficients at 95% CL are in their Table 7 and Fig. 21.
- <sup>8</sup> SIRUNYAN 21o measures cross sections and couplings with the  $H \rightarrow \gamma\gamma$  channel using  $137 \text{ fb}^{-1}$  data at  $E_{\text{cm}} = 13 \text{ TeV}$ . Results are given for  $m_H = 125.38 \text{ GeV}$ . The signal strengths for individual production processes are given in their Fig. 16. Cross sections are given in their Tables 12 and 13 and Figs. 18 and 20, which are based on the simplified template cross section framework (reduced stage-1.2). Results in the  $\kappa$ -framework are given in their Fig. 22.
- <sup>9</sup> SIRUNYAN 19AT perform a combine fit to  $35.9 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ .
- <sup>10</sup> SIRUNYAN 19L measure fiducial and differential cross sections of the process  $pp \rightarrow H \rightarrow \gamma\gamma$  at  $E_{\text{cm}} = 13 \text{ TeV}$  with  $35.9 \text{ fb}^{-1}$ . See their Figs. 4–11.
- <sup>11</sup> AABOUD 18BO use  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The signal strengths for the individual production modes are:  $0.81^{+0.19}_{-0.18}$  for gluon fusion,  $2.0^{+0.6}_{-0.5}$  for vector boson fusion,  $0.7^{+0.9}_{-0.8}$  for  $VH$  production ( $V = W, Z$ ), and  $0.5 \pm 0.6$  for  $t\bar{t}H$  and  $tH$  production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for  $m_H = 125.09 \text{ GeV}$ .
- <sup>12</sup> SIRUNYAN 18ps use  $35.9 \text{ fb}^{-1}$  of  $pp \rightarrow H$  collisions with  $H \rightarrow \gamma\gamma$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The Higgs mass is floated in the measurement of a signal strength. The result is  $1.18^{+0.12}_{-0.11}(\text{stat.})^{+0.09}_{-0.07}(\text{syst.})^{+0.07}_{-0.06}(\text{theory})$ , which is largely insensitive to the Higgs mass around  $125 \text{ GeV}$ .
- <sup>13</sup> KHACHATRYAN 16G measure fiducial and differential cross sections of the process  $pp \rightarrow HX, H \rightarrow \gamma\gamma$  at  $E_{\text{cm}} = 8 \text{ TeV}$  with  $19.7 \text{ fb}^{-1}$ . See their Figs. 4–6 and Table 1 for data.
- <sup>14</sup> AAD 14BC use  $4.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for  $m_H = 125.4 \text{ GeV}$ . The signal strengths for the individual production modes are:  $1.32 \pm 0.38$  for gluon fusion,  $0.8 \pm 0.7$  for vector boson fusion,  $1.0 \pm 1.6$  for  $WH$  production,  $0.1^{+3.7}_{-0.1}$  for  $ZH$  production, and  $1.6^{+2.7}_{-1.8}$  for  $t\bar{t}H$  production.
- <sup>15</sup> AAD 14BJ measure fiducial and differential cross sections of the process  $pp \rightarrow HX, H \rightarrow \gamma\gamma$  at  $E_{\text{cm}} = 8 \text{ TeV}$  with  $20.3 \text{ fb}^{-1}$ . See their Table 3 and Figs. 3–12 for data.
- <sup>16</sup> KHACHATRYAN 14P use  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for  $m_H = 124.7 \text{ GeV}$ . The signal strength for the gluon fusion and  $t\bar{t}H$  production mode is  $1.13^{+0.37}_{-0.31}$ , while the signal strength for the vector boson fusion and  $WH, ZH$  production mode is  $1.16^{+0.63}_{-0.58}$ .
- <sup>17</sup> AAD 13AK use  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125.5 \text{ GeV}$ .
- <sup>18</sup> AALTONEN 13L combine all CDF results with  $9.45\text{--}10.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .
- <sup>19</sup> ABAZOV 13L combine all D0 results with up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .

<sup>1</sup> TUMASYAN 23AH search for  $VH, H \rightarrow c\bar{c}$  ( $V = W, Z$ ) using 138  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on  $\sigma(pp \rightarrow VH) \cdot B(H \rightarrow c\bar{c})$  is 0.94 pb at 95% CL. See their Fig. 4. The quoted values are given for  $m_H = 125.38 \text{ GeV}$ .

<sup>2</sup> TUMASYAN 23AD search for Higgs produced with transverse momenta greater than 450 GeV and decaying to  $c\bar{c}$  using 138  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ .

<sup>3</sup> AAD 22W search for  $VH, H \rightarrow c\bar{c}$  ( $V = W, Z$ ) using 139  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The results are given for  $m_H = 125 \text{ GeV}$ .

<sup>4</sup> The analysis of  $VH, H \rightarrow c\bar{c}$  is combined with  $VH, H \rightarrow b\bar{b}$  (AAD 21AB). The ratio  $|\kappa_c/\kappa_b|$  is constrained to be less than 4.5 at 95% CL. See their Fig. 7.

<sup>5</sup> The constraint on the charm Yukawa coupling modifier  $\kappa_c$  is measured to be  $|\kappa_c| < 8.5$  at 95% CL. See their Fig. 4.

<sup>6</sup> SIRUNYAN 20AE use 35.9  $\text{fb}^{-1}$  at  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The measured best fit value of  $\sigma(pp \rightarrow VH) \cdot B(H \rightarrow c\bar{c})$  is  $2.40^{+1.12+0.65}_{-1.11-0.61}$  pb (equivalent to < 4.5 pb at 95% CL upper limit, i.e. 70 times the standard model), where  $V$  is  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell\ell$ , or  $Z \rightarrow \nu\nu$  ( $\ell = e, \mu$ ). The quoted values are given for  $m_H = 125 \text{ GeV}$ .

<sup>7</sup> AABOUD 18M use 36.1  $\text{fb}^{-1}$  at  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on  $\sigma(pp \rightarrow ZH) \cdot B(H \rightarrow c\bar{c})$  is 2.7 pb at 95% CL. This corresponds to 110 times the standard model. The quoted values are given for  $m_H = 125 \text{ GeV}$ .

<sup>1</sup> CMS 22 report combined results (see their Extended Data Table 2) using up to 138  $\text{fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.38 \text{ GeV}$ . See their Fig. 2 right.

<sup>2</sup> AAD 21AB search for  $VH, H \rightarrow b\bar{b}$  ( $V = W, Z$ ) using 139  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The results are given for  $m_H = 125 \text{ GeV}$ . Cross sections are given in their Table 13 and Fig. 7, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 9.

<sup>3</sup> AAD 21AJ present measurements of  $H \rightarrow b\bar{b}$  in the VBF production mode. The inclusive VBF cross sections with and without the branching ratio of  $H \rightarrow b\bar{b}$  are  $2.07 \pm 0.70^{+0.46}_{-0.37}$  fb and  $3.56 \pm 1.21^{+0.80}_{-0.64}$  fb, respectively. The latter is obtained assuming the SM value of  $B(H \rightarrow b\bar{b}) = 0.5809$  and  $m_H = 125 \text{ GeV}$ .

<sup>4</sup> AAD 16AN perform fits to the ATLAS and CMS data at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ . The signal strengths for individual production processes are  $1.0 \pm 0.5$  for  $WH$  production,  $0.4 \pm 0.4$  for  $ZH$  production, and  $1.1 \pm 1.0$  for  $t\bar{t}H$  production.

<sup>5</sup> AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09 \text{ GeV}$ .

<sup>6</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0  $\text{fb}^{-1}$  and 9.7  $\text{fb}^{-1}$ , respectively, of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .

<sup>7</sup> AAD 22X measure cross sections using a boosted  $H \rightarrow b\bar{b}$  with large-radius jets. The data is 136  $\text{fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . All the results are given for  $m_H = 125 \text{ GeV}$ . The inclusive signal strength is given using data with a  $H$  candidate jet  $p_{T(H)} > 250 \text{ GeV}$ . The fiducial  $H$  production cross section ( $p_{T(H)} > 450 \text{ GeV}$  and  $|\eta(H)| < 2$ ) is < 115 fb (95% CL) and the upper limits for other four different  $p_{T(H)}$  regions are shown in their Fig. 12. The measured fiducial  $H$  production cross section ( $p_{T(H)} > 1 \text{ TeV}$ ) is  $2.3 \pm 3.9(\text{stat}) \pm 1.3(\text{syst}) \pm 0.5(\text{theory})$  fb.

<sup>8</sup> AAD 21H present measurements of  $H \rightarrow b\bar{b}$  with a boosted vector boson ( $p_{T(H)} > 250 \text{ GeV}$ ) using 139  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . Cross sections are given in their Table 6 and Fig. 4, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 5.

<sup>9</sup> AAD 21M search for  $VBF+\gamma, H \rightarrow b\bar{b}$  using 132  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ .

<sup>10</sup> SIRUNYAN 20BL search for boosted  $H \rightarrow b\bar{b}$  (a  $H$  candidate jet  $p_{T(H)} > 450 \text{ GeV}$ ) using 137  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength corresponds to a significance of 2.5 standard deviations and is given for  $m_H = 125 \text{ GeV}$ . A differential fiducial cross section as a function of Higgs boson  $p_{T(H)}$  for ggF is shown in their Fig. 7, assuming the other production modes occur at the expected SM rates. The reported value is  $3.7 \pm 1.2^{+0.8+0.8}_{-0.7-0.5}$  where the last uncertainty comes from theoretical modeling. We have combined the systematic uncertainties in quadrature.

<sup>11</sup> AABOUD 19U measure cross sections of  $pp \rightarrow VH, H \rightarrow b\bar{b}$  production as a function of the gauge boson transverse momentum using data of 79.8  $\text{fb}^{-1}$ . The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.

<sup>12</sup> SIRUNYAN 19AT perform a combine fit to 35.9  $\text{fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ .

<sup>13</sup> AABOUD 18BN search for  $VH, H \rightarrow b\bar{b}$  ( $V = W, Z$ ) using 79.8  $\text{fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for  $m_H = 125 \text{ GeV}$ .

<sup>14</sup> AABOUD 18BN combine results of 79.8  $\text{fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$  with results of  $VH$  at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ .

<sup>15</sup> AABOUD 18BN combine results of  $VH$  at  $E_{\text{cm}} = 7, 8$  and  $13 \text{ TeV}$  with results of VBF (+gluon fusion) and  $t\bar{t}H$  at  $E_{\text{cm}} = 7, 8$ , and  $13 \text{ TeV}$  to perform a search for the  $H \rightarrow b\bar{b}$  decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.

<sup>16</sup> AABOUD 18BQ search for  $H \rightarrow b\bar{b}$  produced through vector-boson fusion (VBF) and  $VBF+\gamma$  with 30.6  $\text{fb}^{-1}$   $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted signal strength is given for  $m_H = 125 \text{ GeV}$ .

<sup>17</sup> The signal strength is measured including all production modes (VBF, ggF,  $VH, t\bar{t}H$ ).

<sup>18</sup> The signal strength is measured for VBF-only and others (ggF,  $VH, t\bar{t}H$ ) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.

<sup>19</sup> AALTONEN 18C use 5.4  $\text{fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The upper limit at 95% CL on  $p\bar{p} \rightarrow H \rightarrow b\bar{b}$  is 33 times the SM prediction, which corresponds to a cross section of 40.6 pb.

## Gauge &amp; Higgs Boson Particle Listings

## H

- <sup>20</sup> SIRUNYAN 18AE use 35.9 fb<sup>-1</sup> of  $pp$  collision data at  $E_{cm} = 13$  TeV. The quoted signal strength corresponds to 3.3 standard deviations and is given for  $m_H = 125.09$  GeV.
- <sup>21</sup> SIRUNYAN 18AE combine the result of 35.9 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV with the results obtained from data of up to 5.1 fb<sup>-1</sup> at  $E_{cm} = 7$  TeV and up to 18.9 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV (CHATRCHYAN 14AI and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for  $m_H = 125.09$  GeV.
- <sup>22</sup> SIRUNYAN 18DB search for  $VH, H \rightarrow b\bar{b}$  ( $V = W, Z$ ) using 77.2 fb<sup>-1</sup> of  $pp$  collision data at  $E_{cm} = 13$  TeV. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for  $m_H = 125.09$  GeV.
- <sup>23</sup> SIRUNYAN 18DB combine the result of 77.2 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV with the results obtained from data of up to 5.1 fb<sup>-1</sup> at  $E_{cm} = 7$  TeV and up to 18.9 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for  $m_H = 125.09$  GeV.
- <sup>24</sup> SIRUNYAN 18DB combine results of 77.2 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV with results of gluon fusion (ggF), VBF and  $t\bar{t}H$  at  $E_{cm} = 7$  TeV, 8 TeV and 13 TeV to perform a search for the  $H \rightarrow b\bar{b}$  decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for  $m_H = 125.09$  GeV.
- <sup>25</sup> SIRUNYAN 18E use 35.9 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV. They measure  $\sigma \cdot B$  for gluon fusion production of  $H \rightarrow b\bar{b}$  with  $p_T > 450$  GeV,  $|\eta| < 2.5$  to be  $74 \pm 48^{+17}_{-10}$  fb.
- <sup>26</sup> AABOUD 17BA use 36.1 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV. They give  $\sigma(WH) \cdot B(H \rightarrow b\bar{b}) = 1.08^{+0.54}_{-0.47}$  pb and  $\sigma(ZH) \cdot B(H \rightarrow b\bar{b}) = 0.57^{+0.26}_{-0.23}$  pb.
- <sup>27</sup> AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>28</sup> AABOUD 16X search for vector-boson fusion production of  $H$  decaying to  $b\bar{b}$  in 20.2 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>29</sup> AAD 16K use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.36$  GeV.
- <sup>30</sup> AAD 15G use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.36$  GeV.
- <sup>31</sup> KHACHATRYAN 15Z search for vector-boson fusion production of  $H$  decaying to  $b\bar{b}$  in up to 19.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>32</sup> KHACHATRYAN 15Z combined vector boson fusion,  $WH, ZH$  production, and  $t\bar{t}H$  production results. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>33</sup> CHATRCHYAN 14AI use up to 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and up to 18.9 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV. See also CHATRCHYAN 14AJ.
- <sup>34</sup> AALTONEN 13L combine all CDF results with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>35</sup> ABAZOV 13L combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>36</sup> AAD 12AI obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. The quoted signal strengths are given in their Fig. 10 for  $m_H = 126$  GeV. See also Fig. 13 of AAD 12DA.
- <sup>37</sup> AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region  $m_H = 120$ –135 GeV, with a local significance of up to 3.3  $\sigma$ . The local significance at  $m_H = 125$  GeV is 2.8  $\sigma$ , which corresponds to  $(\sigma(HW) + \sigma(HZ)) \cdot B(H \rightarrow b\bar{b}) = (0.23^{+0.09}_{-0.08})$  pb, compared to the Standard Model expectation at  $m_H = 125$  GeV of  $0.12 \pm 0.01$  pb. Superseded by AALTONEN 13M.
- <sup>38</sup> CHATRCHYAN 12W obtain results based on 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.1 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV. See also CHATRCHYAN 13Y.

- <sup>1</sup> CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV. See their Fig. 2 right.
- <sup>2</sup> AAD 21 search for  $H \rightarrow \mu^+ \mu^-$  using 139 fb<sup>-1</sup> of  $pp$  collision data at  $E_{cm} = 13$  TeV. The quoted signal strength corresponds to a significance of 2.0 standard deviations and is given for  $m_H = 125.09$  GeV. The upper limit on the cross section times branching fraction is 2.2 times the SM prediction at 95% CL, which corresponds to the branching fraction upper limit of  $4.7 \times 10^{-4}$  (assuming SM production cross sections).

- <sup>3</sup> SIRUNYAN 21 search for  $H \rightarrow \mu^+ \mu^-$  using 137 fb<sup>-1</sup> of  $pp$  collision data at  $E_{cm} = 13$  TeV. The quoted signal strength corresponds to a significance of 3.0 standard deviations and is given for  $m_H = 125.38$  GeV.
- <sup>4</sup> SIRUNYAN 19AT perform a combine fit to 35.9 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV.
- <sup>5</sup> SIRUNYAN 19E search for  $H \rightarrow \mu^+ \mu^-$  using 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV and combine with results of 7 TeV (5.0 fb<sup>-1</sup>) and 8 TeV (19.7 fb<sup>-1</sup>). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of  $6.4 \times 10^{-4}$ .
- <sup>6</sup> AABOUD 17Y use 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV, 20.3 fb<sup>-1</sup> at 8 TeV and 4.5 fb<sup>-1</sup> at 7 TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>7</sup> AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09$  GeV.
- <sup>8</sup> KHACHATRYAN 15H use 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb<sup>-1</sup> at 8 TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>9</sup> AAD 14AS search for  $H \rightarrow \mu^+ \mu^-$  in 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV.

- <sup>1</sup> CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV. See their Fig. 2 right.
- <sup>2</sup> AABOUD 19AQ use 36.1 fb<sup>-1</sup> of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for  $m_H = 125$  GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the  $H \rightarrow \tau\tau$  decay channel ( $m_H = 125$  GeV) are measured to  $3.77^{+0.60}_{-0.59}$  (stat)  $^{+0.87}_{-0.74}$  (syst) pb for the inclusive,  $0.28 \pm 0.09^{+0.11}_{-0.09}$  pb for VBF, and  $3.1 \pm 1.0^{+1.6}_{-1.3}$  pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.
- <sup>3</sup> AAD 16AN perform fits to the ATLAS and CMS data at  $E_{cm} = 7$  and 8 TeV. The signal strengths for individual production processes are  $1.0 \pm 0.6$  for gluon fusion,  $1.3 \pm 0.4$  for vector boson fusion,  $-1.4 \pm 1.4$  for  $WH$  production,  $2.2^{+2.2}_{-1.8}$  for  $ZH$  production, and  $-1.9^{+3.7}_{-3.3}$  for  $t\bar{t}H$  production.
- <sup>4</sup> AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for  $m_H = 125.09$  GeV.
- <sup>5</sup> AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb<sup>-1</sup> and 9.7 fb<sup>-1</sup>, respectively, of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>6</sup> TUMASYAN 23Y measure Higgs production with  $pp \rightarrow H \rightarrow \tau\tau$  at  $E_{cm} = 13$  TeV with 138 fb<sup>-1</sup> data. The quoted results are given for  $m_H = 125.38$  GeV.
- <sup>7</sup> The inclusive  $\sigma \cdot B$  is  $2800^{+356}_{-335}$  fb (see their Figs. 10 and 14). See their Fig. 15 for the 68 % and 95 % CL contours in the  $\kappa_V - \kappa_F$  plane.

- <sup>8</sup> The quoted result is for the stage-0 simplified template cross section (STXS) and the  $\sigma_{ggF} \cdot B$  is  $2030^{+598}_{-555}$  fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 1) are shown in their Table 9 and Figs. 12 and 14.
- <sup>9</sup> The quoted result is for the stage-0 STXS and the  $\sigma_{VBF} \cdot B$  is  $267^{+53.9}_{-52.6}$  fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 2) are shown in their Table 9 and Figs. 12, 14.
- <sup>10</sup> The quoted result is for the stage-0 STXS and the  $\sigma_{VH} \cdot B$  is  $79.0^{+20.5}_{-18.6}$  fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 3) are shown in their Table 9 and Figs. 12, 14.
- <sup>11</sup> AAD 22q measure cross sections of  $pp \rightarrow H \rightarrow \tau\tau$  at  $E_{cm} = 13$  TeV with 139 fb<sup>-1</sup> data. The quoted results are given for  $m_H = 125.09$  GeV and  $|y(H)| < 2.5$  is required. The inclusive fiducial  $\sigma \cdot B$  is  $2.94 \pm 0.21^{+0.37}_{-0.32}$  pb. The fiducial  $\sigma \cdot B$  for the four dominant production modes are  $2.65 \pm 0.41^{+0.91}_{-0.67}$  pb for ggF,  $0.197 \pm 0.028^{+0.032}_{-0.026}$  pb for VBF,  $0.115 \pm 0.058^{+0.042}_{-0.040}$  pb for  $VH$ ,  $0.033 \pm 0.031^{+0.022}_{-0.017}$  pb for  $t\bar{t}H$ . Their cross sections using simplified template cross section framework (STXS) are given in their Fig. 14(a) and Table 15. The STXS bins (a reduced stage 1.2) are defined in their Fig. 1.
- <sup>12</sup> TUMASYAN 22AJ measure cross sections with  $pp \rightarrow H \rightarrow \tau\tau$  at  $E_{cm} = 13$  TeV with 138 fb<sup>-1</sup> data. The fiducial inclusive  $\sigma \cdot B$  is  $426 \pm 102$  fb while  $408 \pm 27$  fb is expected in the Standard Mode for  $m_H = 125.38$  GeV. Three differential cross sections are given; see their Fig. 1.
- <sup>13</sup> SIRUNYAN 19AF use 35.9 fb<sup>-1</sup> of data. The quoted signal strength is given for  $m_H = 125$  GeV and corresponds to 2.3 standard deviations.
- <sup>14</sup> SIRUNYAN 19AF use 35.9 fb<sup>-1</sup> of data.  $HW/Z$  channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for  $m_H = 125$  GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are:  $1.12^{+0.53}_{-0.50}$  for gluon fusion,  $1.13^{+0.45}_{-0.42}$  for vector boson fusion,  $3.39^{+1.68}_{-1.54}$  for  $WH$  and  $1.23^{+1.62}_{-1.35}$  for  $ZH$ . See their Fig. 7 for other couplings ( $\kappa_V, \kappa_F$ ).
- <sup>15</sup> SIRUNYAN 19AT perform a combine fit to 35.9 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV. This combination is based on SIRUNYAN 18Y.
- <sup>16</sup> SIRUNYAN 18Y use 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. The quoted signal strength is given for  $m_H = 125.09$  GeV and corresponds to 4.9 standard deviations.
- <sup>17</sup> SIRUNYAN 18Y combine the result of 35.9 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV with the results obtained from data of 4.9 fb<sup>-1</sup> at  $E_{cm} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV (KHACHATRYAN 15AM). The quoted signal strength is given for  $m_H = 125.09$  GeV and corresponds to 5.9 standard deviations.
- <sup>18</sup> AAD 16AC measure the signal strength with  $pp \rightarrow HW/ZX$  processes using 20.3 fb<sup>-1</sup> of  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>19</sup> AAD 16K use up to 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and up to 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.36$  GeV.
- <sup>20</sup> AAD 15AH use 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is  $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$  and that for vector boson fusion and  $W/ZH$  production modes is  $1.24^{+0.49}_{-0.45} \pm 0.31 \pm 0.08$ . The quoted signal strength is given for  $m_H = 125.36$  GeV.
- <sup>21</sup> CHATRCHYAN 14K use 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.7 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV. See also CHATRCHYAN 14AJ.
- <sup>22</sup> AALTONEN 13L combine all CDF results with 9.45–10.0 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>23</sup> ABAZOV 13L combine all D0 results with up to 9.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted signal strength is given for  $m_H = 125$  GeV.
- <sup>24</sup> AAD 12AI obtain results based on 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. The quoted signal strengths are given in their Fig. 10 for  $m_H = 126$  GeV. See also Fig. 13 of AAD 12DA.
- <sup>25</sup> CHATRCHYAN 12N obtain results based on 4.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.1 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV. See also CHATRCHYAN 13Y.

- <sup>1</sup> AAD 24D report combined results of ATLAS (AAD 20AG) and CMS (TUMASYAN 23F). The reported signal strength corresponds to a significance of 3.4  $\sigma$ .
- <sup>2</sup> TUMASYAN 23F search for  $H \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$  in 138 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV.  $\sigma(pp \rightarrow H) \cdot B(H \rightarrow Z\gamma)$  is measured to be  $0.21 \pm 0.08$  pb. The ratio of branching fractions  $B(H \rightarrow Z\gamma)/B(H \rightarrow \gamma\gamma)$  is measured to be  $1.5^{+0.7}_{-0.6}$ .
- <sup>3</sup> CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV, assuming  $m_H = 125.38$  GeV. See their Fig. 2 right.
- <sup>4</sup> AAD 20AG search for  $H \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. The signal strength is  $2.0 \pm 0.9^{+0.4}_{-0.3}$  at  $m_H = 125.09$  GeV, which corresponds to a significance of 2.2  $\sigma$ . The upper limit of  $\sigma(pp \rightarrow H) \cdot B(H \rightarrow Z\gamma)$  is 305 fb at 95% CL.
- <sup>5</sup> SIRUNYAN 18DQ search for  $H \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. The quoted signal strength (see their Figs. 6 and 7) is given for  $m_H = 125$  GeV.

- <sup>6</sup> AABOUD 17AW search for  $H \rightarrow Z\gamma, Z \rightarrow ee, \mu\mu$  in 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. The quoted signal strength is given for  $m_H = 125.09$  GeV. The upper limit on the branching ratio of  $H \rightarrow Z\gamma$  is 1.0% at 95% CL assuming the SM Higgs boson production.
- <sup>7</sup> AAD 14J search for  $H \rightarrow Z\gamma \rightarrow \ell\ell\gamma$  in 4.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 20.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The quoted signal strength is given for  $m_H = 125.5$  GeV.
- <sup>8</sup> CHATRCHYAN 13BK search for  $H \rightarrow Z\gamma \rightarrow \ell\ell\gamma$  in 5.0 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 19.6 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range  $m_H = 120$ –160 GeV at 95% CL. The quoted limit is given for  $m_H = 125$  GeV, where 10 is expected for no signal.

- AAD 23c measure the production of four top quarks with same-sign and multilepton final states with 140 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The results constraint the ratio of the top quark Yukawa coupling  $y_t$  to its Standard Model value, yielding  $|y_t/y_t^{\text{SM}}| < 1.8$  at 95% CL. See their Fig. 8 as a function of  $\kappa_t$  and  $CP$ -mixing angle.
- AAD 23y constrain  $\kappa_t$  from Higgs production rates with  $H \rightarrow \gamma\gamma$  with 139 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The quoted result is obtained assuming the SM loop structure in  $gg \rightarrow H$  and  $H \rightarrow \gamma\gamma$ . See their Fig. 14.
- AAD 23y constrain  $\kappa_t$  from Higgs production rates with  $H \rightarrow \gamma\gamma$  with 139 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The quoted result is obtained assuming effective couplings  $\kappa_{\text{gluon}}$  and  $\kappa_\gamma$  for  $gg \rightarrow H$  and  $H \rightarrow \gamma\gamma$ , respectively. See their Fig. 14.
- TUMASYAN 23P constrain  $\kappa_t$  from  $t\bar{t}H$  and  $tH$  decaying  $H \rightarrow WW^*$  and  $H \rightarrow \tau\tau$  (multilepton decay mode) with 138 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The  $\kappa_t$  is obtained by fixing  $\tilde{\kappa}_t = 0$  and other couplings ( $\kappa_V$  etc.) to the SM values. See their Fig. 9 for 2-dim contours and Table 6.
- The quoted result is obtained by combining with other  $t\bar{t}H$  decaying  $H \rightarrow \gamma\gamma$  (SIRUNYAN 20As) and  $H \rightarrow 4\ell$  (SIRUNYAN 21AE) and  $\tilde{\kappa}_t = 0$ . See their Fig. 12 for 2-dim contours and Table 7.
- ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, assuming  $m_H = 125.09$  GeV.
- All modifiers( $\kappa$ ) > 0, and  $\kappa_c = \kappa_t$  ( $B_{\text{inv}} = B_{\text{undetected}} = 0$ ) are assumed. Only SM particles assume to contribute to the loop-induced processes. See their Fig. 5, which shows both  $\kappa_c = \kappa_t$  and  $\kappa_c$  floating.
- $B_{\text{inv}} = B_{\text{undetected}} = 0$  is assumed. Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 6.
- $B_{\text{inv}}$  floating,  $B_{\text{undetected}} \geq 0$ , and  $\kappa_V \leq 1$  are assumed. Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 6.
- CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, assuming  $m_H = 125.38$  GeV.

- Only SM particles assume to contribute to the loop-induced processes. See their Fig. 3 right.
- Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 4 left.
- SIRUNYAN 21R constrain the ratio of the top quark Yukawa coupling  $y_t$  to its Standard Model value from  $t\bar{t}H$  and  $tH$  production rates using 137 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. Assuming a SM Higgs couplings to  $\tau$ 's, the joint interval  $-0.9 < \kappa_t (=y_t/y_t^{\text{SM}}) < -0.7$  and  $0.7 < \kappa_t < 1.1$  is obtained at 95% CL (see their Fig. 17).
- SIRUNYAN 20c search for the production of four top quarks with same-sign and multilepton final states with 137 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The results constraint the ratio of the top quark Yukawa coupling  $y_t$  to its Standard Model value by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding  $|y_t/y_t^{\text{SM}}| < 1.7$  at 95% CL. See their Fig. 5.
- SIRUNYAN 19bY measure the top quark Yukawa coupling from  $t\bar{t}$  kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between  $t$  and  $\bar{t}$ , in the  $\ell$ +jets final state with 35.8 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The results constraint the ratio of the top quark Yukawa coupling to its the Standard Model to be  $1.07^{+0.34}_{-0.43}$  with an upper limit of 1.67 at 95% CL (see their Table III).
- SIRUNYAN 18bU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb<sup>-1</sup>  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. The results constraint the ratio of the top quark Yukawa coupling  $y_t$  to its the Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding  $|y_t/y_t^{\text{SM}}| < 2.1$  at 95% CL.

- AAD 23c combine results of  $H \rightarrow \gamma\gamma$  and  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using 139 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. The Higgs boson transverse momentum ( $p_T^H$ ) distribution constrains  $\kappa_b$  and  $\kappa_c$ , assuming other couplings fixed to the SM values. The  $\kappa_b$  is obtained using the  $p_T^H$  shape and normalisation. Other cases are given in their Tables 6 and 7.
- AAD 23cd search for  $H \rightarrow T(nS)\gamma$ ,  $T(nS) \rightarrow \mu^+\mu^-$  ( $n=1,2,3$ ) with 138 fb<sup>-1</sup> of  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. They interpret the  $H \rightarrow T(nS)\gamma$  search to constraint the bottom Yukawa coupling by comparing to  $H \rightarrow \gamma\gamma$ . An observed 95% CL interval of  $(-37, 40)$  is obtained for  $\kappa_b/\kappa_\gamma$ .
- HAYRAPETYAN 23 measure the cross sections for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using 138 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. The  $\kappa_b$  is obtained from the  $p_T$  differential cross section of the ggF production employing the dependence of the branching fraction on  $\kappa_b$  and  $\kappa_c$ .
- ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, assuming  $m_H = 125.09$  GeV.
- All modifiers ( $\kappa$ ) > 0, and  $\kappa_c = \kappa_t$  ( $B_{\text{inv}} = B_{\text{undetected}} = 0$ ) are assumed. Only SM particles assume to contribute to the loop-induced processes. See their Fig. 5, which shows both  $\kappa_c = \kappa_t$  and  $\kappa_c$  floating.
- $B_{\text{inv}} = B_{\text{undetected}} = 0$  is assumed. Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 6.
- $B_{\text{inv}}$  floating,  $B_{\text{undetected}} \geq 0$ , and  $\kappa_V \leq 1$  are assumed. Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 6.
- CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb<sup>-1</sup> of data at  $E_{\text{cm}} = 13$  TeV, assuming  $m_H = 125.38$  GeV.
- Only SM particles assume to contribute to the loop-induced processes. See their Fig. 3 right.
- Coupling strength modifiers including effective photon,  $Z\gamma$  and gluon are measured. See their Fig. 4 left.

charm Yukawa coupling ( $\kappa_c$ )

- AAD 23c combine results of  $H \rightarrow \gamma\gamma$  and  $H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using 139 fb<sup>-1</sup> at  $E_{\text{cm}} = 13$  TeV. The Higgs boson transverse momentum ( $p_T^H$ ) distribution constrains  $\kappa_b$  and  $\kappa_c$ , assuming other couplings fixed to the SM values. The  $\kappa_c$  is obtained using the  $p_T^H$  shape and normalisation. Other cases are given in their Tables 6 and 7. See their Table 8 for results combined with  $VH$ ,  $H \rightarrow b\bar{b}$  and  $c\bar{c}$ .
- AAD 23cd search for  $H \rightarrow J/\psi\gamma$ ,  $J/\psi \rightarrow \mu^+\mu^-$  with 138 fb<sup>-1</sup> of  $pp$  collision data at  $E_{\text{cm}} = 13$  TeV. They interpret the  $H \rightarrow J/\psi\gamma$  search to constraint the charm Yukawa coupling by comparing to  $H \rightarrow \gamma\gamma$ . An observed 95% CL interval of  $(-133, 175)$  is obtained for  $\kappa_c/\kappa_\gamma$ .

<sup>3</sup> HAYRAPETYAN 23 measure the cross sections for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The  $\kappa_c$  is obtained from the  $p_T$  differential cross section of the ggF production employing the dependence of the branching fraction of  $\kappa_b$  and  $\kappa_c$ .

<sup>4</sup> TUMASYAN 23AH search for  $VH, H \rightarrow c\bar{c}$  ( $V = W, Z$ ) using  $138 \text{ fb}^{-1}$  of  $pp$  collision data at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted values are obtained from the measured signal strength in the  $\kappa$ -framework, where only the Higgs decay width for  $H \rightarrow c\bar{c}$  is changed while assuming all the other decay widths and the production cross section to be SM ones. The quoted values are given for  $m_H = 125.38 \text{ GeV}$ .

<sup>5</sup> ATLAS 22 report combined results (see their Extended Data Table 1) using up to  $139 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ , assuming  $m_H = 125.09 \text{ GeV}$ , and all modifiers ( $\kappa$ )  $> 0$  ( $B_{\text{inv}} = B_{\text{undetected}} = 0$ ). Only SM particles assume to contribute to the loop-induced processes. See their Fig. 5, which shows both  $\kappa_c = \kappa_t$  and  $\kappa_c$  floating.

- 1 AAD 23AT combine results from 126–139 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV for  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  (AAD 23BK),  $b\bar{b}\tau\tau$  (AAD 23Z), and  $b\bar{b}\gamma\gamma$  (AAD 22Y).
- 2 AAD 23AD search for non-resonant  $HH$  production in association with a vector boson using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The vector boson decays leptonically ( $W \rightarrow \ell\nu, Z \rightarrow \ell\ell, \nu\nu, \ell = e, \mu$ ).
- 3 AAD 23BK search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 126 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.
- 4 AAD 23Z search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 140 fb, which corresponds to 4.7 times the SM prediction (see their Table 6).
- 5 TUMASYAN 23AE search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$ , where both  $b\bar{b}$  pairs are highly boosted, with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.
- 6 TUMASYAN 23D search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.
- 7 The upper limit on the  $pp \rightarrow HH$  production cross section (gluon fusion and VBF) at 95% CL is measured to be 102 fb, which corresponds to 3.3 times the SM prediction (see their Table 2).
- 8 The upper limit on the VBF  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 212 fb, which corresponds to 124 times the SM prediction (see their Table 3).
- 9 TUMASYAN 23I search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}ZZ^*$  ( $ZZ^* \rightarrow 4\ell, \ell = e, \mu$ ) with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.
- 10 TUMASYAN 23O search for non-resonant  $HH$  production using  $HH \rightarrow WW^*WW^*, WW^*\tau\tau$ , and  $\tau\tau\tau\tau$  (multilepton) with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. See their Fig. 9 for different final states and these combination.
- 11 AAD 22Y search for non-resonant  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 130 fb, which corresponds to 4.2 times the SM prediction.
- 12 CMS 22 report combined results (see their Extended Data Table 2) using 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV. See their Fig. 5 (left) for different final states and these combination.
- 13 TUMASYAN 22AN search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 120 fb, which corresponds to 3.9 times the SM prediction.
- 14 SIRUNYAN 21K search for non-resonant  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of 137 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH \rightarrow \gamma\gamma b\bar{b}$  production cross section at 95% CL is measured to be 0.67 fb, which corresponds to about 7.7 times the SM prediction.
- 15 AAD 20C combine results of up to 36.1 fb<sup>-1</sup> data at  $E_{cm} = 13$  TeV for  $pp \rightarrow HH \rightarrow b\bar{b}\gamma\gamma, b\bar{b}\tau\tau, b\bar{b}b\bar{b}, b\bar{b}WW^*, WW^*\gamma\gamma, WW^*WW^*$  (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).
- 16 AAD 20E search non-resonant for  $HH$  production using  $HH \rightarrow b\bar{b}\ell\nu\ell\nu$ , where one of the Higgs bosons decays to  $b\bar{b}$  and the other decays to either  $WW^*, ZZ^*,$  or  $\tau\tau$ , with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.
- 17 AAD 20X search for  $HH \rightarrow b\bar{b}b\bar{b}$  process via VBF with data of 126 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the SM non-resonant  $HH$  production cross section is 1460 fb at 95% CL, which corresponds to 840 times the SM prediction.

## HH Production Cross Section in pp Collisions

The  $HH$  production cross section relative to the SM prediction.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
< 2.4	95	1 AAD	23AT ATLS	13 TeV, $b\bar{b}b\bar{b}, b\bar{b}\tau\tau, b\bar{b}\gamma\gamma$

- 18 AABOUD 19A search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  production cross section at 95% CL is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.
- 19 AABOUD 19o search for  $HH$  production using  $HH \rightarrow b\bar{b}WW^*$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}WW^*$  production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.
- 20 AABOUD 19T search for  $HH$  production using  $HH \rightarrow WW^*WW^*$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.
- 21 SIRUNYAN 19 search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow \gamma\gamma b\bar{b}$  production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction.
- 22 SIRUNYAN 19AB search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$ , where 4 heavy flavor jets from two Higgs bosons are resolved, with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  production cross section at 95% CL is measured to be 847 fb, which corresponds to about 75 times the SM prediction.
- 23 SIRUNYAN 19BE combine results of 13 TeV  $35.9 \text{ fb}^{-1}$  data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.
- 24 SIRUNYAN 19H search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$ , where one of  $b\bar{b}$  pairs is highly boosted and the other one is resolved, with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  production cross section at 95% CL is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.
- 25 AABOUD 18BU search for  $HH$  production using  $\gamma\gamma WW^*$  with the final state of  $\gamma\gamma\ell\nu jj$  using data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 7.7 pb, which corresponds to about 230 times the SM prediction. The upper limit on the  $pp \rightarrow HH \rightarrow \gamma\gamma WW^*$  at 95% CL is measured to be 7.5 fb (see their Table 6).
- 26 AABOUD 18CQ search for  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}\tau\tau$  production cross section at 95% CL is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.
- 27 AABOUD 18CW search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction.
- 28 SIRUNYAN 18A search for  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $gg \rightarrow HH \rightarrow b\bar{b}\tau\tau$  production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction.
- 29 SIRUNYAN 18F search non-resonant for  $HH$  production using  $HH \rightarrow b\bar{b}\ell\nu\ell\nu$ , where  $\ell\nu\ell\nu$  is either  $WW \rightarrow \ell\nu\ell\nu$  or  $ZZ \rightarrow \ell\nu\ell\nu$  ( $\ell = e, \mu$  or a leptonically decaying  $\tau$ ), with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $HH \rightarrow b\bar{b}\ell\nu\ell\nu$  production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.
- 30 SIRUNYAN 17CN search for  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of  $18.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . Results are then combined with the published results of the  $HH \rightarrow \gamma\gamma b\bar{b}$  and  $HH \rightarrow b\bar{b}b\bar{b}$ , which use data of up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The upper limit on the  $gg \rightarrow HH$  production cross section is measured to be 0.59 pb from  $b\bar{b}\tau\tau$ , which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for  $m_H = 125 \text{ GeV}$ .
- 31 AABOUD 16I search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of  $3.2 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is  $11.3^{+0.9}_{-1.0} \text{ fb}$  (NNLO+NNLL) including top quark mass effects. The quoted values are given for  $m_H = 125 \text{ GeV}$ .
- 32 KHACHATRYAN 16BQ search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The upper limit on the  $gg \rightarrow HH \rightarrow \gamma\gamma b\bar{b}$  production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for  $gg \rightarrow HH$  production cross section.
- 33 AAD 15CE search for  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  and  $HH \rightarrow \gamma\gamma WW$  with data of  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . These results are then combined with the published results of the  $HH \rightarrow \gamma\gamma b\bar{b}$  and  $HH \rightarrow b\bar{b}b\bar{b}$ , which use data of up to  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . The upper limits on the  $gg \rightarrow HH$  production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from  $b\bar{b}\tau\tau, \gamma\gamma WW, \gamma\gamma b\bar{b}$  and  $b\bar{b}b\bar{b}$ , respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for  $m_H = 125.4 \text{ GeV}$ . See their Table 4.

18 SIRUNYAN 18A CMS 13 TeV,  $b\bar{b}\tau\tau$   
– 17 to 22.5 95 19 KHACHATRYAN...16BQ CMS 8 TeV,  $\gamma\gamma b\bar{b}$
- 1 AAD 23AD search for non-resonant  $HH$  production in association with a vector boson using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of  $139 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The vector boson decays leptonically ( $W \rightarrow \ell\nu, Z \rightarrow \ell\ell, \nu\nu, \ell = e, \mu$ ). The quoted  $\kappa_\lambda$  is measured assuming all other Higgs boson couplings are at their SM value.
- 2 AAD 23AT combine results from 126–139  $\text{fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$  for  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  (AAD 23BK),  $b\bar{b}\tau\tau$  (AAD 23Z), and  $b\bar{b}\gamma\gamma$  (AAD 22Y). The quoted values are obtained from the profile likelihood scan as a function of  $\kappa_\lambda$  as shown in their Fig. 5(a). All other coupling modifiers are assumed to have their SM values.
- 3 AAD 23AT combine results from 126–139  $\text{fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$  for  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  (AAD 23BK),  $b\bar{b}\tau\tau$  (AAD 23Z), and  $b\bar{b}\gamma\gamma$  (AAD 22Y) with single-Higgs boson analyses ( $\gamma\gamma, ZZ^*, WW^*, \tau\tau, b\bar{b}$ , see their Table 1). The quoted values are obtained from the profile likelihood scan as a function of  $\kappa_\lambda$  as shown in their Fig. 5(a), assuming that all other Higgs boson couplings are at their SM values. Results with other assumptions are shown in their Table 2.
- 4 AAD 23BK search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of  $126 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted values are obtained from the one-dimensional profile likelihood scan as a function of  $\kappa_\lambda$ . See their Fig. 12 (a). The  $\mu_{\text{GF}+VBF}$  measurement for different values of  $\kappa_\lambda$  constrains  $-3.9 < \kappa_\lambda < 11.1$  at 95% CL as shown in their Fig. 10 (a).  $\kappa_{2V} = \kappa_V = 1$  is assumed in both cases.
- 5 HAYRAPETIAN 23 measure the cross sections for  $pp \rightarrow H \rightarrow ZZ^* \rightarrow 4\ell$  ( $\ell = e, \mu$ ) using  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ .
- 6 TUMASYAN 23AE search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$ , where both  $b\bar{b}$  pairs are highly boosted, with data of  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted  $\kappa_\lambda$  is measured assuming all other Higgs boson couplings are at their SM values.
- 7 TUMASYAN 23D search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted values are obtained from the upper limit on the  $HH$  production cross section times the  $b\bar{b}\tau\tau$  branching fraction for different values of  $\kappa_\lambda$ . See their Fig. 8 (left). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the  $\kappa_\lambda$  and  $\kappa_t$  couplings, with  $\kappa_{2V} = \kappa_V = 1$ , are shown in their Fig. 9 (left). The one-dimensional likelihood scan as a function of  $\kappa_\lambda$  is given in their Fig. 10 (left), from which a 95% confidence interval of  $-1.77 < \kappa_\lambda < 8.73$  is extracted.
- 8 TUMASYAN 23AI search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}ZZ^*$  ( $ZZ^* \rightarrow 4\ell, \ell = e, \mu$ ) with data of  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4.
- 9 TUMASYAN 23O search for non-resonant  $HH$  production using  $HH \rightarrow WW^*WW^*, WW^*\tau\tau$ , and  $\tau\tau\tau\tau$  (multilepton) with data of  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for different final states and these combination. Limits are set on a variety of new-physics models using an effective field theory approach. See their Figs. 11, 12, and 13.
- 10 AAD 22Y search for non-resonant  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $139 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted  $\kappa_\lambda$  is obtained from their Fig. 12 where the theory uncertainties are not included while a negative log-likelihood scan vs.  $\kappa_\lambda$  is shown in their Fig. 13 with the theory uncertainties, which provides  $\kappa_\lambda = 2.8^{+2.0}_{-2.2}$  for the  $1\sigma$  confidence interval.
- 11 CMS 22 report combined results (see their Extended Data Table 2) using  $138 \text{ fb}^{-1}$  of data at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 (left).
- 12 TUMASYAN 22AN search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of  $138 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is shown as a function of  $\kappa_\lambda$  in their Fig. 2 (top).
- 13 SIRUNYAN 21K search for non-resonant  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $137 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ .
- 14 AAD 20C combine results of up to  $36.1 \text{ fb}^{-1}$  data at  $E_{\text{cm}} = 13 \text{ TeV}$  for  $pp \rightarrow HH \rightarrow b\bar{b}\gamma\gamma, b\bar{b}\tau\tau, b\bar{b}b\bar{b}, b\bar{b}WW^*, WW^*\gamma\gamma, WW^*WW^*$  (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19o, AABOUD 18BU, and AABOUD 19T).
- 15 SIRUNYAN 19 search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted  $\kappa_\lambda$  is measured assuming all other Higgs boson couplings are at their SM value.
- 16 SIRUNYAN 19BE combine results of 13 TeV  $35.9 \text{ fb}^{-1}$  data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.
- 17 AABOUD 18CW search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $36.1 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The quoted  $\kappa_\lambda$  is measured assuming all other Higgs boson couplings are at their SM value.
- 18 SIRUNYAN 18A search for  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . The upper limit on production cross section times branching fraction at 95% CL is shown as a function of  $\kappa_\lambda/\kappa_t$  in their Fig. 6 (top) where  $\kappa_t = y_t / y_t^{\text{SM}}$  (top Yukawa coupling  $y_t$ ).
- 19 KHACHATRYAN 16BQ search for  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ .

### Higgs trilinear self coupling modifier $\kappa_\lambda$

Signal strength relative to the SM prediction,  $\kappa_\lambda = \lambda_{HHH} / \lambda_{HHH}^{\text{SM}}$ .

-0.43 to 2.56	95	9	AAD	20X ATLS	13 TeV, VBF, $b\bar{b}b\bar{b}$

- 1 AAD 23AD search for non-resonant  $HH$  production in association with a vector boson using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 139 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The vector boson decays leptonically ( $W \rightarrow \ell\nu, Z \rightarrow \ell\ell, \nu\nu, \ell = e, \mu$ ). The constraints on  $\kappa_{2W}$  and  $\kappa_{2Z}$  are separately measured to be  $-12.3 < \kappa_{2W} < 13.5$  and  $-9.9 < \kappa_{2Z} < 11.3$  (95% CL). The quoted  $\kappa_{2V}$  ( $V = W, Z$ ) is measured assuming all other Higgs boson couplings are at their SM value.
- 2 AAD 23AT combine results from 126-139 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV for  $pp \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  (AAD 23BK),  $b\bar{b}\tau\tau$  (AAD 23Z), and  $b\bar{b}\gamma\gamma$  (AAD 22Y). The quoted values are obtained from the 95% CL VBF  $HH$  cross-section upper limit as a function of  $\kappa_{2V}$  as shown in their Fig. 4(b). All other coupling modifiers are assumed to have their SM values.
- 3 AAD 23BK search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 126 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The quoted values are obtained from the one-dimensional profile likelihood scan as a function of  $\kappa_{2V}$ . See their Fig. 12 (b). The  $\mu\nu BF$  measurement for different values of  $\kappa_{2V}$  constrains  $-0.03 < \kappa_{2V} < 2.11$  at 95% CL as shown in their Fig. 10 (b).  $\kappa_\lambda = \kappa_V = 1$  is assumed in both cases.
- 4 TUMASYAN 23AE search for  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$ , where both  $b\bar{b}$  pairs are highly boosted, with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The  $\kappa_{2V} = 0$  is excluded at 6.3  $\sigma$  assuming all other Higgs boson couplings are at their SM values.
- 5 TUMASYAN 23D search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}\tau\tau$  with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The quoted values are obtained from the upper limits on the  $HH$  production cross section times the  $b\bar{b}\tau\tau$  branching fraction for different values of  $\kappa_{2V}$ . See their Fig. 8 (right). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the  $\kappa_{2V}$  and  $\kappa_V$  couplings, with  $\kappa_\lambda = \kappa_t = 1$ , are shown in their Fig. 9 (right). The one-dimensional likelihood scan as a function of  $\kappa_{2V}$  is given in their Fig. 10 (right), from which a 95% confidence interval of  $-0.34 < \kappa_{2V} < 2.49$  is extracted.
- 6 CMS 22 report combined results (see their Extended Data Table 2) using 138 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV. See their Fig. 6 (right).
- 7 TUMASYAN 22AN search for non-resonant  $HH$  production using  $HH \rightarrow b\bar{b}b\bar{b}$  with data of 138 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. The upper limit on the  $pp \rightarrow HH$  production cross section at 95% CL is shown as a function of  $\kappa_{2V}$  in their Fig. 2 (bottom).
- 8 SIRUNYAN 21K search for non-resonant  $HH$  production using  $HH \rightarrow \gamma\gamma b\bar{b}$  with data of 137 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.
- 9 AAD 20X search for  $HH \rightarrow b\bar{b}b\bar{b}$  process via VBF with data of 126 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV.

### tH Production

VALUE	DOCUMENT ID	TECN	COMMENT
<b>5.7 ± 2.7 ± 3.0</b>	1 SIRUNYAN	21R CMS	$pp, 13$ TeV

- ● ● We do not use the following data for averages, fits, limits, etc. ● ● ●
- 2 AAD 20Z ATLS  $pp, 13$  TeV
- 3 SIRUNYAN 19BK CMS  $pp, 13$  TeV
- 4 KHACHATRYAN 16AU CMS  $pp, 8$  TeV

- 1 SIRUNYAN 21R search for  $tH$  in final states with electrons, muons and hadronically decaying  $\tau$  leptons ( $H \rightarrow WW^*, ZZ^*, \tau\tau$ ) with 137 fb<sup>-1</sup> of  $pp$  collision data at  $E_{cm} = 13$  TeV. The quoted signal strength corresponds to a significance of 1.4 standard deviations and is given for  $m_H = 125$  GeV.
- 2 AAD 20Z search for the  $tH$  associated production using  $H \rightarrow \gamma\gamma$  in 139 fb<sup>-1</sup> of data at  $E_{cm} = 13$  TeV. An upper limit on its rate is set to be 12 times the Standard Model at 95% CL ( $m_H = 125.09$  GeV).
- 3 SIRUNYAN 19BK search for the  $tH$  associated production using multilepton signatures ( $H \rightarrow WW^*, H \rightarrow \tau\tau, H \rightarrow ZZ^*$ ) and signatures with a single lepton and a  $b\bar{b}$  pair ( $H \rightarrow b\bar{b}$ ) using 35.9 fb<sup>-1</sup> at  $E_{cm} = 13$  TeV. Results are combined with  $H \rightarrow \gamma\gamma$  (SIRUNYAN 18Ds). The observed 95% CL upper limit on the  $tH$  production cross section times  $H \rightarrow WW^* + \tau\tau + ZZ^* + b\bar{b} + \gamma\gamma$  branching fraction is 1.94 pb (assuming SM  $tH$  production cross section). See their Table X and Fig. 14. The values outside the ranges of  $[-0.9, -0.5]$  and  $[1.0, 2.1]$  times the standard model top quark Yukawa coupling are excluded at 95% CL.
- 4 KHACHATRYAN 16AU search for the  $tH$  associated production in 19.7 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. The 95% CL upper limits on the  $tH$  associated production cross section is measured to be 600-1000 fb depending on the assumed  $\gamma\gamma$  branching ratios of the Higgs boson. The  $\gamma\gamma$  branching ratio is varied to be by a factor of 0.5-3.0 of the Standard Model Higgs boson ( $m_H = 125$  GeV). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for  $m_H = 125$  GeV.

Gauge & Higgs Boson Particle Listings
H, Neutral Higgs Bosons, Searches for

Table listing Higgs boson searches for H, Neutral Higgs Bosons, Searches for. Columns include experiment name, publication reference, author name, and collaboration name. The table is organized into two columns of entries.

Neutral Higgs Bosons, Searches for

CONTENTS:

- Mass Limits for Neutral Higgs Bosons in Supersymmetric Models
- Mass Limits for heavy neutral Higgs bosons (H2, A0) in the MSSM
- Mass Limits for H1 (Higgs Boson) in Supersymmetric Models
Mass Limits for Neutral Higgs Bosons in Extended Higgs Models
- Mass Limits in General two-Higgs-doublet Models
- Mass Limits for H0 with Vanishing Yukawa Couplings
- Mass Limits for H0 Decaying to Invisible Final States
- Mass Limits for Light A0
- Other Mass Limits
Electroweak Constraints on the Standard Model Higgs Boson Mass

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H1, H2], where we define mH1 < mH2, a pseudoscalar (A0), and a charged Higgs pair (H±). H0 and H0 are also called h and H in the literature. There are two free parameters in the Higgs sector which can be chosen to be mA0 and tanβ = v2/v1, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be mH0 ≤ mZ, mH2 ≥ mZ, mA0 ≥ mH0, and mH± ≥ mW. However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "H", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar H0 with the Higgs discovered at 125 GeV at the LHC (AAD 12A1, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in e+e- collisions search for the processes e+e- -> H0 Z0 in the channels used for the Standard Model Higgs searches and e+e- -> H0 A0 in the final states b b b b and b b tau+ tau-. Unless otherwise stated, the following results assume no invisible H0 or A0 decays. Unless otherwise noted, the results are given in the mHmax scenario, CARENA 13.

In p p and p p collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on A0 mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between mA0 and mH0. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations

# Gauge & Higgs Boson Particle Listings

## Neutral Higgs Bosons, Searches for

depend, via potentially large radiative corrections, on the mass of the  $t$  quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger  $t$  and  $\bar{t}$  masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections and beyond (SLAVICH 21), and the results are given for the  $M_h^{125}$  benchmark scenario, see BAGNASCHI 19.

### Mass Limits for heavy neutral Higgs bosons ( $H_2^0, A^0$ ) in the MSSM

The limits rely on  $pp \rightarrow H_2^0/A^0 \rightarrow \tau^+\tau^-$  and assume that  $H_2^0$  and  $A^0$  are (sufficiently) mass degenerate. The limits depend on  $\tan\beta$ .

		1 TUMASYAN	23s	search for production of $H_2^0/A^0 \rightarrow \tau^+\tau^-$ by gluon fusion and $b$ -associated production using $138 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 13 for excluded regions in the $m_{A^0}$ - $\tan\beta$ plane in $M_h^{125}$ and $M_{hEFT}^{125}$ MSSM scenarios. In both scenarios $m_{A^0} < 350$ GeV is excluded at 95% CL.
		2 AAD	20AA	search for $H_2^0/A^0 \rightarrow \tau^+\tau^-$ produced by gluon fusion or $b$ -associated production using $139 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 2(c) for excluded region in the $M_h^{125}$ scenario of MSSM. Values of $\tan\beta > 8$ (21) are excluded for $m_{A^0} = 1.0$ (1.5) TeV at 95% CL.
		3 AAD	20	combine measurements on $H^0$ production and decay using data taken in years 2015–2017 (up to $79.8 \text{ fb}^{-1}$ ) of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.
		4 AAD	20c	combine searches for a scalar resonance decaying to $H^0 H^0$ in $36.1 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19o, AABOUD 18cQ, AABOUD 19T, AABOUD 18cW, and AABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.
		5 AAD	20L	search for $b$ -associated production of $H_2^0$ decaying to $b\bar{b}$ in $27.8 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in hMSSM, $m_h^{\text{mod}+}$ and $m_h^{\text{mod}-}$ scenarios of MSSM.
		6 SIRUNYAN	20AC	search for gluon-fusion and $b$ -associated production of $A^0$ decaying to $Z H^0$ in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for excluded regions in the $M_h^{125}$ and hMSSM scenarios of the MSSM.
		7 SIRUNYAN	20AF	search for $H_2^0/A^0 \rightarrow t\bar{t}$ with one or two charged leptons in the final state using kinematic variables in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded region in the hMSSM scenario of MSSM. Values of $\tan\beta$ below 1.0–1.5 are excluded for $m_{A^0} = 0.4$ –0.75 TeV at 95% CL.
		8 SIRUNYAN	20V	search for gluon-fusion and vector-boson-fusion production of $H_2^0$ decaying to $W^+ W^-$ in the final states $\ell\nu\ell\nu$ and $\ell\nu q\bar{q}$ in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Figs. 8 and 9 for excluded regions in various MSSM scenarios.
		9 SIRUNYAN	19CR	search for production of $H_2^0/A^0$ in gluon fusion and in association with a $b\bar{b}$ pair, decaying to $\mu^+\mu^-$ in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ and hMSSM scenarios.
		10 AABOUD	18G	search for production of $H_2^0/A^0 \rightarrow \tau^+\tau^-$ by gluon fusion and $b$ -associated production in $36.1 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the $m_{A^0}$ - $\tan\beta$ plane in several MSSM scenarios.
		11 SIRUNYAN	18A	search for production of a scalar resonance decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (lower) for excluded regions in the $m_{A^0}$ - $\tan\beta$ plane in the hMSSM scenario.
		12 SIRUNYAN	18BP	search for production of $H_2^0/A^0 \rightarrow b\bar{b}$ by $b$ -associated production in $35.7 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}, m_{A^0} = 0.3$ –1.3 TeV, and Fig. 7 for excluded regions in the $m_{A^0}$ - $\tan(\beta)$ plane in several MSSM scenarios.
		13 SIRUNYAN	18CX	search for production of $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ by gluon fusion and $b$ -associated production in $35.9 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the $m_{A^0}$ - $\tan(\beta)$ plane in several MSSM scenarios.
		14 AABOUD	16AA	search for production of a Higgs boson in gluon fusion and in association with a $b\bar{b}$ pair followed by the decay $A^0 \rightarrow \tau^+\tau^-$ in $3.2 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for $m_{A^0} = 200$ –1200 GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ and hMSSM scenarios.
		15 KHACHATRYAN	16A	search for production of a Higgs boson in gluon fusion and in association with a $b\bar{b}$ pair followed by the decay $H_{1,2}^0/A^0 \rightarrow \mu^+\mu^-$ in $5.1 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 7$ TeV and $19.3 \text{ fb}^{-1}$ at $E_{cm} = 8$ TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the $m_h^{\text{mod}+}$ benchmark scenario and Fig. 9 for limits on cross section times branching ratio.
		16 KHACHATRYAN	16P	search for gluon fusion production of an $H_2^0$ decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ and an $A^0$ decaying to $Z H^0 \rightarrow \ell^+\ell^-\tau^+\tau^-$ in $19.7 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 12 for excluded region in the $\tan\beta$ - $\cos(\beta-\alpha)$ plane for $m_{H_2^0}^0 = m_{A^0}$ .
		17 KHACHATRYAN	15AY	search for production of a Higgs boson in association with a $b$ quark in the decay $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ in $19.7 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for $m_{A^0} = 100$ –900 GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.
		18 AAD	14AW	search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ in $19.5$ – $20.3 \text{ fb}^{-1}$ of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 5.4$ is excluded at 95% CL in the $m_h^{\text{max}}$ scenario.

## Neutral Higgs Bosons, Searches for

- 19 KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a  $b$  quark followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 140 \text{ GeV}$ , the region  $\tan\beta > 3.8$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario.
- 20 AAD 13o search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  and  $\mu^+\mu^-$  with  $4.7\text{--}4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For  $m_{A^0} = 110\text{--}170 \text{ GeV}$ ,  $\tan\beta \gtrsim 10$  is excluded, and for  $\tan\beta = 50$ ,  $m_{A^0}$  below  $470 \text{ GeV}$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario.
- 21 AAIJ 13T search for production of a Higgs boson in the forward region in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $1.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.
- 22 CHATRCHYAN 13AG search for production of a Higgs boson in association with a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$  in  $2.7\text{--}4.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For  $m_{A^0} = 90\text{--}350 \text{ GeV}$ , upper bounds on  $\tan\beta$  of  $18\text{--}42$  at 95% CL are obtained in the  $m_h^{\text{max}}$  scenario with  $\mu = +200 \text{ GeV}$ .
- 23 AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.
- 24 AALTONEN 12X search for associated production of a Higgs boson and a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , with  $2.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.
- 25 ABAZOV 12G search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $7.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 90\text{--}180 \text{ GeV}$ ,  $\tan\beta \gtrsim 30$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario.
- 26 CHATRCHYAN 12K search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 160 \text{ GeV}$ , the region  $\tan\beta > 7.1$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario. Supersedes by KHACHATRYAN 14M.
- 27 ABAZOV 11K search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , in  $5.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 5/ Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for  $\mu = -200 \text{ GeV}$ .
- 28 ABAZOV 11W search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau\tau$ , in  $7.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- 29 AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in  $1.8 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 2 for the limit on  $\sigma \cdot \text{BR}(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- 30 ABDALLAH 08B give limits in eight  $CP$ -conserving benchmark scenarios and some  $CP$ -violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.
- 31 SCHAEEL 06B make a combined analysis of the LEP data. The quoted limit is for the  $m_h^{\text{max}}$  scenario with  $m_t = 174.3 \text{ GeV}$ . In the  $CP$ -violating CPX scenario no lower bound on  $m_{H_1^0}$  can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2-6 and Tabs. 14-21 for limits on  $\sigma(ZH^0) \cdot \text{BR}(H^0 \rightarrow b\bar{b}, \tau^+\tau^-)$  and  $\sigma(H_1^0 H_2^0) \cdot \text{BR}(H_1^0 H_2^0 \rightarrow b\bar{b}, \tau^+\tau^-)$ .
- 32 ACOSTA 05q search for  $H_{1,2}^0/A^0$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$  with  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ . At  $m_{A^0} = 100 \text{ GeV}$ , the obtained cross section upper limit is above theoretical expectation.
- 33 Search for  $e^+e^- \rightarrow H_1^0 A^0$  in the final states  $b\bar{b}b\bar{b}$  and  $b\bar{b}\tau^+\tau^-$ , and  $e^+e^- \rightarrow H_1^0 Z$ . Universal scalar mass of  $1 \text{ TeV}$ ,  $SU(2)$  gaugino mass of  $200 \text{ GeV}$ , and  $\mu = -200 \text{ GeV}$  are assumed, and two-loop radiative corrections incorporated. The limits hold for  $m_t = 175 \text{ GeV}$ , and for the  $m_h^{\text{max}}$  scenario.
- 34 ABBIENDI 04M exclude  $0.7 < \tan\beta < 1.9$ , assuming  $m_t = 174.3 \text{ GeV}$ . Limits for other MSSM benchmark scenarios, as well as for  $CP$  violating cases, are also given.
- 35 ABBIENDI 03G search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0$ ,  $A^0 \rightarrow c\bar{c}, gg$ , or  $\tau^+\tau^-$ . In the no-mixing scenario, the region  $m_{H_1^0} = 45\text{--}85 \text{ GeV}$  and  $m_{A^0} = 2\text{--}9.5 \text{ GeV}$  is excluded at 95% CL.
- 36 ACHARD 02H also search for the final state  $H_1^0 Z \rightarrow 2A^0 q\bar{q}, A^0 \rightarrow q\bar{q}$ . In addition, the MSSM parameter set in the "large- $\mu$ " and "no-mixing" scenarios are examined.
- 37 AKEROYD 02 examine the possibility of a light  $A^0$  with  $\tan\beta < 1$ . Electroweak measurements are found to be inconsistent with such a scenario.
- 38 HEISTER 02 excludes the range  $0.7 < \tan\beta < 2.3$ . A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

- 7 AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

### MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for  $H^0$  and  $A^0$  listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about  $125 \text{ GeV}$ , see section "H", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

1 AAD 23AD search for associated production of  $W/ZH_2^0$  and gluon fusion production of  $A^0$  decaying to  $ZH_2^0$ , with the decay chain  $H_2^0 \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ , using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 12 and 13 for excluded regions in Type-I and lepton-specific 2HDMs.

2 AAD 23BG search for production of  $H_2^0/A^0$  in association with a  $t\bar{t}$  pair, decaying to  $t\bar{t}$ , using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 8 for excluded regions in the parameter space of the type II 2HDM.

3 AAD 23O search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH$  in the final states  $\nu\bar{\nu}b\bar{b}$  and  $\ell^+\ell^-b\bar{b}$  using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 12 and 13 for excluded regions in the parameter space in various 2HDMs.

4 AAD 21AF search for production of a heavy  $H_2^0$  state decaying to  $ZZ$  in the final states  $\ell^+\ell^-\ell^+\ell^-$  and  $\ell^+\ell^-\nu\bar{\nu}$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 6 and 7 for excluded parameter regions of the 2HDM Type I and II.

5 AAD 21AI search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH_2^0 \rightarrow \ell^+\ell^-b\bar{b}$  or  $\ell^+\ell^-W^+W^-$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 10 and 14 for excluded regions in the parameter space of various 2HDMs.

6 AAD 20 combine measurements on  $H^0$  production and decay using data taken in years 2015-2017 (up to 79.8 fb<sup>-1</sup>) of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 18 for excluded regions in various 2HDMs.

7 AAD 20L search for  $b$ -associated production of  $H_2^0$  decaying to  $b\bar{b}$  in 27.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 10 and 11 for excluded regions in the flipped two Higgs doublet model.

8 SIRUNYAN 20AA search for  $H_2^0 \rightarrow ZA^0, A^0 \rightarrow b\bar{b}$  or  $A^0 \rightarrow ZH_2^0, H_2^0 \rightarrow b\bar{b}$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 8 and 9 for excluded regions in the parameter space of Type-II two Higgs doublet model.

9 SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of  $H_2^0$  decaying to  $W^+W^-$  in the final states  $\ell\nu\ell\nu$  and  $\ell\nu q\bar{q}$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 7 for excluded regions in Type I and II two Higgs doublet models.

10 SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a  $b\bar{b}$  pair, decaying to  $\tau^+\tau^-$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 4 for cross section limits for  $m_{A^0} = 25-70$  GeV and comparison with some representative 2HDMs.

11 SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or  $b$  associated production, decaying to  $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}$  ( $\ell = e, \mu$ ) or  $\nu\bar{\nu}b\bar{b}$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

12 AABOUD 18AH search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH_2^0 \rightarrow \ell^+\ell^-b\bar{b}$  in 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

13 AABOUD 18AI search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH^0$  in the final states  $\nu\bar{\nu}b\bar{b}$  and  $\ell^+\ell^-b\bar{b}$  in 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

14 AABOUD 18BF search for production of a heavy  $H_2^0$  state decaying to  $ZZ$  in the final states  $\ell^+\ell^-\ell^+\ell^-$  and  $\ell^+\ell^-\nu\bar{\nu}$  in 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

15 AABOUD 18CE search for the process  $pp \rightarrow H_2^0/A^0 t\bar{t}$  followed by the decay  $H_2^0/A^0 \rightarrow t\bar{t}$  in 36.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on  $\tan\beta$  for  $m_{H_2^0}, m_{A^0} = 0.4-1.0$  TeV in the 2HDM type II.

16 HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for allowed parameter regions from fits to LHC  $H^0$  measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

17 SIRUNYAN 18BP search for production of  $H_2^0/A^0 \rightarrow b\bar{b}$  by  $b$ -associated production in 35.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 6 for the limits on cross section times branching ratio for  $m_{H_2^0}, m_{A^0} = 0.3-1.3$  TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

18 SIRUNYAN 18ED search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH^0$  in the final states  $\nu\bar{\nu}b\bar{b}$  or  $\ell^+\ell^-b\bar{b}$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

19 AABOUD 17AN search for production of a heavy  $H_2^0$  and/or  $A^0$  decaying to  $t\bar{t}$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

20 SIRUNYAN 17AX search for  $A^0 b\bar{b}$  production followed by the decay  $A^0 \rightarrow \mu^+\mu^-$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. Limits are set in the range  $m_{A^0} = 25-60$  GeV. See their Fig. 5 for upper limits on  $\sigma(A^0 b\bar{b}) \cdot \mathcal{B}(A^0 \rightarrow \mu^+\mu^-)$ .

21 AAD 16AX search for production of a heavy  $H^0$  state decaying to  $ZZ$  in the final states  $\ell^+\ell^-\ell^+\ell^-, \ell^+\ell^-\nu\bar{\nu}, \ell^+\ell^-q\bar{q}$ , and  $\nu\bar{\nu}q\bar{q}$  in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

22	KHACHATRYAN 16P search for gluon fusion production of an $H_2^0$ decaying to $H^0 H^0 \rightarrow b\bar{b}\tau^+\tau^-$ and an $A^0$ decaying to $ZH^0 \rightarrow \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for limits on $\tan\beta$ for $m_{A^0} = 230-350$ GeV.
23	KHACHATRYAN 16W search for $A^0 b\bar{b}$ production followed by the decay $A^0 \rightarrow \tau^+\tau^-$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for upper limits on $\sigma(A^0 b\bar{b}) \cdot \mathcal{B}(A^0 \rightarrow \tau^+\tau^-)$ .
24	KHACHATRYAN 16Z search for $H_2^0 \rightarrow ZA^0$ followed by $A^0 \rightarrow b\bar{b}$ or $\tau^+\tau^-$ , and $A^0 \rightarrow ZH_2^0$ followed by $H_2^0 \rightarrow b\bar{b}$ or $\tau^+\tau^-$ , in 19.8 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.
25	AAD 15BK search for production of a heavy $H_2^0$ decaying to $H^0 H^0$ in the final state $b\bar{b}b\bar{b}$ in 19.5 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 15-18 for excluded regions in the parameter space.
26	AAD 15S search for production of $A^0$ decaying to $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}, \nu\bar{\nu}b\bar{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.
27	KHACHATRYAN 15BB search for $H_2^0, A^0 \rightarrow \gamma\gamma$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.
28	KHACHATRYAN 15N search for production of $A^0$ decaying to $ZH^0 \rightarrow \ell^+\ell^-b\bar{b}$ in 19.7 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta - \alpha)$ plane for $m_{A^0} = 300$ GeV.
29	AAD 14M search for the decay cascade $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$ decaying to $b\bar{b}$ in 20.3 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0} = 325-1025$ GeV and $m_{H^\pm} = 225-825$ GeV.
30	KHACHATRYAN 14Q search for $H_2^0 \rightarrow H^0 H^0$ and $A^0 \rightarrow ZH^0$ in 19.5 fb <sup>-1</sup> of $pp$ collisions at $E_{cm} = 8$ TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for $m_{H_2^0, A^0} = 260-360$ GeV and their Figs. 7-9 for limits in two-Higgs-doublet models.
31	AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb <sup>-1</sup> of $p\bar{p}$ collisions at $E_{cm} = 1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot \mathcal{B}(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
32	ABBIENDI 05A search for $e^+e^- \rightarrow H_1^0/A^0$ in general Type-II two-doublet models, with decays $H_1^0/A^0 \rightarrow q\bar{q}, gg, \tau^+\tau^-,$ and $H_1^0/A^0 \rightarrow A^0 A^0$ .
33	ABDALLAH 05D search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$ with $H^0, A^0$ decaying to two jets of any flavor including $gg$ . The limit is for SM $H^0 Z$ production cross section with $\mathcal{B}(H^0 \rightarrow jj) = 1$ .
34	ABDALLAH 04O search for $Z \rightarrow b\bar{b}H^0, b\bar{b}A^0, \tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states $4b, b\bar{b}\tau^+\tau^-$ , and $4\tau$ . See paper for limits on Yukawa couplings.
35	ABDALLAH 04o search for $e^+e^- \rightarrow H^0 Z$ and $H^0 A^0$ , with $H^0, A^0$ decaying to $b\bar{b}, \tau^+\tau^-$ , or $H^0 \rightarrow A^0 A^0$ at $E_{cm} = 189-208$ GeV. See paper for limits on couplings.
36	ABBIENDI 02D search for $Z \rightarrow b\bar{b}H_1^0$ and $b\bar{b}A^0$ with $H_1^0/A^0 \rightarrow \tau^+\tau^-$ , in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.
37	ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays $H_1^0, A^0 \rightarrow q\bar{q}, gg$ are searched for. See their Figs. 15,16 for excluded regions.
38	ABBIENDI 99E search for $e^+e^- \rightarrow H^0 A^0$ and $H^0 Z$ at $E_{cm} = 183$ GeV. The limit is with $m_H = m_A$ in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the $m_H - m_A$ plane. Updates the results of ACKERSTAFF 98s.
39	See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$ , the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.
40	PICH 92 analyse $H^0$ with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm, \eta$ rare decays are shown in Figs. 3.4. The considered mass region is not totally excluded.

### Mass Limits for $H^0$ with Vanishing Yukawa Couplings

These limits assume that  $H^0$  couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

- AALTONEN 13K search for  $H^0 \rightarrow WW^{(*)}$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to (1.3–6.6) times the expected cross section is given in the range  $m_{H^0} = 110\text{--}200 \text{ GeV}$  at 95% CL.
- AALTONEN 13L combine all CDF searches with  $9.45\text{--}10.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- ABAZOV 13G search for  $H^0 \rightarrow WW^{(*)}$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for  $m_{H^0} = 100\text{--}200 \text{ GeV}$  at 95% CL.
- ABAZOV 13H search for  $H^0 \rightarrow \gamma\gamma$  in  $9.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- ABAZOV 13I search for  $H^0$  production in the final state with one lepton and two or more jets plus missing  $E_T$  in  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The search is sensitive to  $WH^0, ZH^0$  and vector-boson fusion Higgs production with  $H^0 \rightarrow WW^{(*)}$ . A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range  $m_{H^0} = 100\text{--}200 \text{ GeV}$  at 95% CL.
- ABAZOV 13J search for  $H^0$  production in the final states  $e\mu, e\mu\mu, \mu\tau\tau$ , and  $e^\pm\mu^\pm$  in  $8.6\text{--}9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The search is sensitive to  $WH^0, ZH^0$  production with  $H^0 \rightarrow WW^{(*)}, ZZ^{(*)}$ , decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range  $m_{H^0} = 100\text{--}200 \text{ GeV}$  at 95% CL.
- ABAZOV 13L combine all D0 results with up to  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- CHATRCHYAN 13AL search for  $H^0 \rightarrow \gamma\gamma$  in  $5.1 \text{ fb}^{-1}$  and  $5.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ .
- AAD 12N search for  $H^0 \rightarrow \gamma\gamma$  with  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  in the mass range  $m_{H^0} = 110\text{--}150 \text{ GeV}$ .
- AALTONEN 12AN search for  $H^0 \rightarrow \gamma\gamma$  with  $10 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the mass range  $m_{H^0} = 100\text{--}150 \text{ GeV}$ .
- CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12B, and CHATRCHYAN 12C.
- AALTONEN 09AB search for  $H^0 \rightarrow \gamma\gamma$  in  $3.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the mass range  $m_{H^0} = 70\text{--}150 \text{ GeV}$ . Associated  $H^0 W, H^0 Z$  production and  $WW, ZZ$  fusion are considered.
- ABAZOV 08U search for  $H^0 \rightarrow \gamma\gamma$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the mass range  $m_{H^0} = 70\text{--}150 \text{ GeV}$ . Associated  $H^0 W, H^0 Z$  production and  $WW, ZZ$  fusion are considered. See their Tab. 1 for the limit on  $\sigma \cdot B(H^0 \rightarrow \gamma\gamma)$ , and see their Fig. 3 for the excluded region in the  $m_{H^0} - B(H^0 \rightarrow \gamma\gamma)$  plane.
- SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to  $WW^*$ . The limit is from this search and HEISTER 02L for a  $H^0$  with SM production cross section.
- Search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-,$  or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209 \text{ GeV}$ . The limit is for a  $H^0$  with SM production cross section.
- Updates ABREU 01F.
- ACHARD 03c search for  $e^+e^- \rightarrow ZH^0$  followed by  $H^0 \rightarrow WW^*$  or  $ZZ^*$  at  $E_{\text{cm}} = 200\text{--}209 \text{ GeV}$  and combine with the ACHARD 02c result. The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow WW^*) + B(H^0 \rightarrow ZZ^*) = 1, m_{H^0} > 108.1 \text{ GeV}$  is obtained. See Fig. 6 for the limits under different BR assumptions.
- For  $B(H^0 \rightarrow \gamma\gamma) = 1, m_{H^0} > 117 \text{ GeV}$  is obtained.
- ACHARD 02c search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-,$  or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209 \text{ GeV}$ . The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1, m_{H^0} > 114 \text{ GeV}$  is obtained.
- AFFOLDER 01H search for associated production of a  $\gamma\gamma$  resonance and a  $W$  or  $Z$  (tagged by two jets, an isolated lepton, or missing  $E_T$ ). The limit assumes Standard Model values for the production cross section and for the couplings of the  $H^0$  to  $W$  and  $Z$  bosons. See their Fig. 11 for limits with  $B(H^0 \rightarrow \gamma\gamma) < 1$ .
- ACCIARRI 00s search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at  $E_{\text{cm}} = 189 \text{ GeV}$ . The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1, m_{H^0} > 98 \text{ GeV}$  is obtained. See their Fig. 5 for limits on  $B(H \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow Hf\bar{f}) / \sigma(e^+e^- \rightarrow Hf\bar{f})$  (SM).
- BARATE 00L search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at  $E_{\text{cm}} = 88\text{--}202 \text{ GeV}$ . The limit is for a  $H^0$  with SM production cross section. For  $B(H^0 \rightarrow \gamma\gamma) = 1, m_{H^0} > 109 \text{ GeV}$  is obtained. See their Fig. 3 for limits on  $B(H \rightarrow \gamma\gamma) \cdot \sigma(e^+e^- \rightarrow Hf\bar{f}) / \sigma(e^+e^- \rightarrow Hf\bar{f})$  (SM).
- ABBIENDI 99o search for associated production of a  $\gamma\gamma$  resonance with a  $q\bar{q}, \nu\bar{\nu}$ , or  $\ell^+\ell^-$  pair in  $e^+e^-$  collisions at  $189 \text{ GeV}$ . The limit is for a  $H^0$  with SM production cross section. See their Fig. 4 for limits on  $\sigma(e^+e^- \rightarrow H^0 Z^0) \times B(H^0 \rightarrow \gamma\gamma) \times B(X^0 \rightarrow f\bar{f})$  for various masses. Updates the results of ACKERSTAFF 98y.
- ABBOTT 99B search for associated production of a  $\gamma\gamma$  resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the  $H^0$  to  $W$  and  $Z$  bosons. Limits in the range of  $\sigma(H^0 + Z/W) \cdot B(H^0 \rightarrow \gamma\gamma) = 0.80\text{--}0.34 \text{ pb}$  are obtained in the mass range  $m_{H^0} = 65\text{--}150 \text{ GeV}$ .
- ABREU 99P search for  $e^+e^- \rightarrow H^0 \gamma$  with  $H^0 \rightarrow b\bar{b}$  or  $\gamma\gamma$ , and  $e^+e^- \rightarrow H^0 q\bar{q}$  with  $H^0 \rightarrow \gamma\gamma$ . See their Fig. 4 for limits on  $\sigma \times B$ . Explicit limits within an effective interaction framework are also given.

### Mass Limits for $H^0$ Decaying to Invisible Final States

These limits are for a neutral scalar  $H^0$  which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of  $H^0$  to ordinary particles unless otherwise stated.

- AABOUD 19AI search for  $H^0_{1,2}$  production by vector boson fusion and decay to invisible final states in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6(b) for limits on cross section times branching ratios for  $m_{H^0_{1,2}} = 0.1\text{--}3 \text{ TeV}$ .
- AAD 15BD search for  $p\bar{p} \rightarrow H^0 WX$  and  $p\bar{p} \rightarrow H^0 ZX$  with  $W$  or  $Z$  decaying hadronically and  $H^0$  decaying to invisible final states in  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for a limit on the cross section times branching ratio for  $m_{H^0} = 115\text{--}300 \text{ GeV}$ .
- AAD 15BH search for events with a jet and missing  $E_T$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . Limits on  $\sigma(H^0) B(H^0 \rightarrow \text{invisible}) < (44\text{--}10) \text{ pb}$  (95%CL) is given for  $m_{H^0} = 115\text{--}300 \text{ GeV}$ .
- AAD 14BA search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays to collimated pairs of  $e^+e^-, \mu^+\mu^-,$  or  $\pi^+\pi^-$  plus invisible particles, in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 15 and 16 for limits on cross section times branching ratio.
- AAD 14O search for  $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$ , with  $H^0$  decaying to invisible final states in  $4.5 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $20.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 3 for a limit on the cross section times branching ratio for  $m_{H^0} = 110\text{--}400 \text{ GeV}$ .
- CHATRCHYAN 14B search for  $p\bar{p} \rightarrow H^0 ZX, Z \rightarrow \ell\ell$  and  $Z \rightarrow b\bar{b}$ , and also  $p\bar{p} \rightarrow qqH^0 X$  with  $H^0$  decaying to invisible final states using data at  $E_{\text{cm}} = 7$  and  $8 \text{ TeV}$ . See their Figs. 10, 11 for limits on the cross section times branching ratio for  $m_{H^0} = 100\text{--}400 \text{ GeV}$ .
- AAD 13AG search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays to  $\mu^+\mu^- X^0$ , in  $1.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio.
- AAD 13AT search for  $H^0$  production in the decay  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  eventually decays to collimated  $e^+e^-$  pairs, in  $2.04 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio.
- CHATRCHYAN 13BJ search for  $H^0$  production in the decay chain  $H^0 \rightarrow X^0 X^0, X^0 \rightarrow \mu^+\mu^- X^0$  in  $5.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio.
- AAD 12AQ search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle which decays mainly to  $b\bar{b}$  in the muon detector, in  $1.94 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio for  $m_{H^0} = 120, 140 \text{ GeV}, m_{X^0} = 20, 40 \text{ GeV}$  in the  $\tau$  range of  $0.5\text{--}35 \text{ ns}$ .
- AALTONEN 12AB search for  $H^0$  production in the decay  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  eventually decays to clusters of collimated  $\ell^+\ell^-$  pairs, in  $5.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.
- AALTONEN 12U search for  $H^0$  production in the decay mode  $H^0 \rightarrow X^0 X^0$ , where  $X^0$  is a long-lived particle with  $\tau \approx 1 \text{ cm}$  which decays mainly to  $b\bar{b}$ , in  $3.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Figs. 9 and 10 for limits on cross section times branching ratio for  $m_{H^0} = (130\text{--}170) \text{ GeV}, m_{X^0} = 20, 40 \text{ GeV}$ .
- ABBIENDI 10 search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying invisibly. The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ .
- ABBIENDI 07 search for  $e^+e^- \rightarrow H^0 Z$  with  $Z \rightarrow q\bar{q}$  and  $H^0$  decaying to invisible final states. The  $H^0$  width is varied between  $1 \text{ GeV}$  and  $3 \text{ TeV}$ . A limit  $\sigma \cdot B(H^0 \rightarrow \text{invisible}) < (0.07\text{--}0.57) \text{ pb}$  (95%CL) is obtained at  $E_{\text{cm}} = 206 \text{ GeV}$  for  $m_{H^0} = 60\text{--}114 \text{ GeV}$ .
- Search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying invisibly. The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ .
- ACCIARRI 00M search for  $e^+e^- \rightarrow ZH^0$  with  $H^0$  decaying invisibly at  $E_{\text{cm}} = 183\text{--}189 \text{ GeV}$ . The limit assumes SM production cross section and  $B(H^0 \rightarrow \text{invisible}) = 1$ . See their Fig. 6 for limits for smaller branching ratios.

### Mass Limits for Light $A^0$

These limits are for a pseudoscalar  $A^0$  in the mass range below  $O(10) \text{ GeV}$ .

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT

- 1 ADACHI 23A search for flavor-changing  $\tau$  decays  $\tau \rightarrow e A^0$  and  $\tau \rightarrow \mu A^0$ , with  $A^0$  invisible, using  $62.8 \text{ fb}^{-1}$  of  $e^+ e^-$  collisions at  $E_{\text{cm}} = 10.58 \text{ GeV}$ . Limits on  $\text{B}(\tau \rightarrow e A^0)/\text{B}(\tau \rightarrow e \nu \nu)$  in the range  $1.1 \times 10^{-3} - 9.7 \times 10^{-3}$  (95% CL) and  $\text{B}(\tau \rightarrow \mu A^0)/\text{B}(\tau \rightarrow \mu \nu \nu)$  in the range  $0.7 \times 10^{-3} - 12.2 \times 10^{-3}$  (95% CL) are given for  $m_{A^0} = 0 - 1.6 \text{ GeV}$ . See their Fig. 2.
- 2 TUMASYAN 23AR search for the decay  $H \rightarrow A^0 A^0$  with  $A^0 \rightarrow \gamma \gamma$  (detected as a merged photonlike object) using  $136 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Limits on  $\text{B}(H \rightarrow A^0 A^0) \cdot \text{B}^2(A^0 \rightarrow \gamma \gamma)$  in the range  $0.9 \times 10^{-3} - 3.3 \times 10^{-3}$  (95% CL) are given for  $m_{A^0} = 0.1 - 1.2 \text{ GeV}$ . See their Fig. 2.
- 3 ABLIKIM 22H search for the process  $J/\psi \rightarrow A^0 \gamma$  with  $A^0$  decaying to  $\mu^+ \mu^-$  in  $9 \times 10^9 J/\psi$  events and give limits on  $\text{B}(J/\psi \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $1.2 \times 10^{-9} - 7.78 \times 10^{-7}$  (90% CL) for  $0.212 \text{ GeV} \leq m_{A^0} \leq 3.0 \text{ GeV}$ . See their Fig. 4.
- 4 JIA 22 search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $\tau^+ \tau^-$  or  $\mu^+ \mu^-$  in  $158 \times 10^6 \Upsilon(2S)$  events and give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \tau^+ \tau^-)$  in the range  $3.8 \times 10^{-6} - 1.5 \times 10^{-4}$  (90% CL) for  $m_{A^0} = 3.6 - 9.2 \text{ GeV}$ , and  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $3.1 \times 10^{-7} - 1.6 \times 10^{-5}$  (90% CL) for  $m_{A^0} = 0.21 - 9.2 \text{ GeV}$ . See their Fig. 4.
- 5 AAD 20AE search for the decay  $H^0 \rightarrow ZA^0, Z \rightarrow \ell^+ \ell^-, A^0$  decaying hadronically ( $A^0 \rightarrow g\bar{g}$  or  $s\bar{s}$ ), in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Limit on the product of production cross section and the  $H^0 \rightarrow ZA^0$  branching ratio in the range  $17 - 340 \text{ pb}$  (95% CL) is given for  $m_{A^0} = 0.5 - 4.0 \text{ GeV}$ , see their Table 1.
- 6 AABOUD 18AP search for the decay  $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10(b) for limits on  $\text{B}(H^0 \rightarrow A^0 A^0)$  in the range  $m_{A^0} = 1 - 2.5, 4.5 - 8 \text{ GeV}$ , assuming a type-II two-doublet plus singlet model with  $\tan(\beta) = 5$ .
- 7 KHACHATRYAN 17AZ search for the decay  $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-, \mu^+ \mu^- b\bar{b}$ , and  $\mu^+ \mu^- \tau^+ \tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 4, 5, and 6 for cross section limits in the range  $m_{A^0} = 5 - 62.5 \text{ GeV}$ . See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 8 ABLIKIM 16E search for the process  $J/\psi \rightarrow A^0 \gamma$  with  $A^0$  decaying to  $\mu^+ \mu^-$  and give limits on  $\text{B}(J/\psi \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $2.8 \times 10^{-8} - 5.0 \times 10^{-6}$  (90% CL) for  $0.212 \leq m_{A^0} \leq 3.0 \text{ GeV}$ . See their Fig. 5.
- 9 KHACHATRYAN 16F search for the decay  $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 8 for cross section limits for  $m_{A^0} = 4 - 8 \text{ GeV}$ .
- 10 LEES 15H search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $c\bar{c}$  and give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow c\bar{c})$  in the range  $7.4 \times 10^{-5} - 2.4 \times 10^{-3}$  (90% CL) for  $4.00 \leq m_{A^0} \leq 8.95$  and  $9.10 \leq m_{A^0} \leq 9.25 \text{ GeV}$ . See their Fig. 6.
- 11 LEES 13C search for the process  $\Upsilon(2S, 3S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $\mu^+ \mu^-$  and give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3 - 9.7) \times 10^{-6}$  (90% CL) for  $0.212 \leq m_{A^0} \leq 9.20 \text{ GeV}$ . See their Fig. 5(e) for limits on the  $b - A^0$  Yukawa coupling derived by combining this result with AUBERT 09Z.
- 12 LEES 13L search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $g\bar{g}$  or  $s\bar{s}$  and give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow g\bar{g})$  between  $1 \times 10^{-6}$  and  $2 \times 10^{-2}$  (90% CL) for  $0.5 \leq m_{A^0} \leq 9.0 \text{ GeV}$ , and  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow s\bar{s})$  between  $4 \times 10^{-6}$  and  $1 \times 10^{-3}$  (90% CL) for  $1.5 \leq m_{A^0} \leq 9.0 \text{ GeV}$ . See their Fig. 4.
- 13 LEES 13R search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to  $\tau^+ \tau^-$  and give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \tau^+ \tau^-)$  in the range  $0.9 - 13 \times 10^{-5}$  (90% CL) for  $3.6 \leq m_{A^0} \leq 9.2 \text{ GeV}$ . See their Fig. 4 for limits on the  $b - A^0$  Yukawa coupling derived by combining this result with AUBERT 09P.

- 14 ABLIKIM 12 searches for the process  $\psi(3686) \rightarrow \pi \pi J/\psi, J/\psi \rightarrow A^0 \gamma$  with  $A^0$  decaying to  $\mu^+ \mu^-$ . It gives mass dependent limits on  $\text{B}(J/\psi \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $4 \times 10^{-7} - 2.1 \times 10^{-5}$  (90% C.L.) for  $0.212 \leq m_{A^0} \leq 3.0 \text{ GeV}$ . See their Fig. 2.
- 15 CHATRCHYAN 12V search for  $A^0$  production in the decay  $A^0 \rightarrow \mu^+ \mu^-$  with  $1.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on  $\sigma(A^0) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(1.5 - 7.5) \text{ pb}$  is given for  $m_{A^0} = (5.5 - 8.7)$  and  $(11.5 - 14) \text{ GeV}$  at 95% CL.
- 16 AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+ \tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $\text{B}(t \rightarrow bH^+) \cdot \text{B}(H^+ \rightarrow W^+ A^0) \cdot \text{B}(A^0 \rightarrow \tau^+ \tau^-)$  for  $90 < m_{H^+} < 160 \text{ GeV}$ .
- 17 ABOUZAI 11A search for the decay chain  $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit  $\text{B}(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-) < 1.0 \times 10^{-10}$  at 90% CL for  $m_{A^0} = 214.3 \text{ MeV}$ .
- 18 The search was motivated by PARK 05.
- 19 DEL-AMO-SANCHEZ 11J search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S) \pi^+ \pi^- \rightarrow A^0 \gamma \pi^+ \pi^-$  with  $A^0$  decaying to invisible final states. They give limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \text{invisible})$  in the range  $(1.9 - 4.5) \times 10^{-6}$  (90% CL) for  $0 \leq m_{A^0} \leq 8.0 \text{ GeV}$ , and  $(2.7 - 37) \times 10^{-6}$  for  $8.0 \leq m_{A^0} \leq 9.2 \text{ GeV}$ .
- 20 LEES 11H search for the process  $\Upsilon(2S, 3S) \rightarrow A^0 \gamma$  with  $A^0$  decaying hadronically and give limits on  $\text{B}(\Upsilon(2S, 3S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \text{hadrons})$  in the range  $1 \times 10^{-6} - 8 \times 10^{-5}$  (90% CL) for  $0.3 < m_{A^0} < 7 \text{ GeV}$ . The decay rates for  $\Upsilon(2S)$  and  $\Upsilon(3S)$  are assumed to be equal up to the phase space factor. See their Fig. 5.
- 21 ANDREAS 10 analyze constraints from rare decays and other processes on a light  $A^0$  with  $m_{A^0} < 2m_\mu$ , and give limits on its coupling to fermions at the level of  $10^{-4}$  times the Standard Model value.
- 22 HYUN 10 search for the decay chain  $B^0 \rightarrow K^* A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit on  $\text{B}(B^0 \rightarrow K^* A^0) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(2.26 - 5.53) \times 10^{-8}$  at 90% CL for  $m_{A^0} = 212 - 300 \text{ MeV}$ . The limit for  $m_{A^0} = 214.3 \text{ MeV}$  is  $2.26 \times 10^{-8}$ .
- 23 HYUN 10 search for the decay chain  $B^0 \rightarrow \rho^0 A^0, A^0 \rightarrow \mu^+ \mu^-$  and give a limit on  $\text{B}(B^0 \rightarrow \rho^0 A^0) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(1.73 - 4.51) \times 10^{-8}$  at 90% CL for  $m_{A^0} = 212 - 300 \text{ MeV}$ . The limit for  $m_{A^0} = 214.3 \text{ MeV}$  is  $1.73 \times 10^{-8}$ .
- 24 AUBERT 09P search for the process  $\Upsilon(3S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \tau^+ \tau^-$  for  $4.03 < m_{A^0} < 9.52$  and  $9.61 < m_{A^0} < 10.10 \text{ GeV}$ , and give limits on  $\text{B}(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \tau^+ \tau^-)$  in the range  $(1.5 - 16) \times 10^{-5}$  (90% CL).
- 25 AUBERT 09Z search for the process  $\Upsilon(2S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  for  $0.212 < m_{A^0} < 9.3 \text{ GeV}$  and give limits on  $\text{B}(\Upsilon(2S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3 - 8) \times 10^{-6}$  (90% CL).
- 26 AUBERT 09Z search for the process  $\Upsilon(3S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  for  $0.212 < m_{A^0} < 9.3 \text{ GeV}$  and give limits on  $\text{B}(\Upsilon(3S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-)$  in the range  $(0.3 - 5) \times 10^{-6}$  (90% CL).
- 27 TUNG 09 search for the decay chain  $K_L \rightarrow \pi^0 \pi^0 A^0, A^0 \rightarrow \gamma \gamma$  and give a limit on  $\text{B}(K_L \rightarrow \pi^0 \pi^0 A^0) \cdot \text{B}(A^0 \rightarrow \gamma \gamma)$  in the range  $(2.4 - 10.7) \times 10^{-7}$  at 90% CL for  $m_{A^0} = 194.3 - 219.3 \text{ MeV}$ . The limit for  $m_{A^0} = 214.3 \text{ MeV}$  is  $2.4 \times 10^{-7}$ .
- 28 LOVE 08 search for the process  $\Upsilon(1S) \rightarrow A^0 \gamma$  with  $A^0 \rightarrow \mu^+ \mu^-$  (for  $m_{A^0} < 2m_\tau$ ) and  $A^0 \rightarrow \tau^+ \tau^-$ . Limits on  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) \cdot \text{B}(A^0 \rightarrow \ell^+ \ell^-)$  in the range  $10^{-6} - 10^{-4}$  (90% CL) are given.
- 29 BESSION 07 give a limit  $\text{B}(\Upsilon(1S) \rightarrow \eta_b \gamma) \cdot \text{B}(\eta_b \rightarrow \tau^+ \tau^-) < 0.27\%$  (95% CL), which constrains a possible  $A^0$  exchange contribution to the  $\eta_b$  decay.
- 30 PARK 05 found three candidate events for  $\Sigma^+ \rightarrow p \mu^+ \mu^-$  in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with  $m_{A^0} = 214.3 \pm 0.5 \text{ MeV}$  and the branching fraction  $\text{B}(\Sigma^+ \rightarrow p A^0) \cdot \text{B}(A^0 \rightarrow \mu^+ \mu^-) = (3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$ .
- 31 BALEST 95 give limits  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) ; 1.5 \times 10^{-5}$  at 90% CL for  $m_{A^0} < 5 \text{ GeV}$ . The limit becomes  $< 10^{-4}$  for  $m_{A^0} < 7.7 \text{ GeV}$ .
- 32 ANTREASIAN 90C give limits  $\text{B}(\Upsilon(1S) \rightarrow A^0 \gamma) ; 5.6 \times 10^{-5}$  at 90% CL for  $m_{A^0} < 7.2 \text{ GeV}$ .  $A^0$  is assumed not to decay in the detector.

### Other Mass Limits

We use a symbol  $H_1^0$  if mass < 125 GeV or  $H_2^0$  if mass > 125 GeV. The notation  $H$  is reserved for the 125 GeV particle.

<sup>1</sup>AAD 24A search for the decay  $H_2^0 \rightarrow Z\gamma$  with  $Z$  decaying to  $e^+ e^-$  or  $\mu^+ \mu^-$  using  $140 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 4 for limits on production cross section times branching ratios for  $m_{H_2^0} = 0.22\text{--}3.4$  TeV.

<sup>2</sup>AAD 23AD search for associated production of  $W/ZH_2^0$  with the decay chain  $H_2^0 \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 9 for limits on cross section times branching ratios for  $m_{H_2^0} = 260\text{--}1000$  GeV.

# Gauge & Higgs Boson Particle Listings

## Neutral Higgs Bosons, Searches for

- 3 AAD 23AD search for gluon fusion production of  $A^0$  with the decay chain  $A^0 \rightarrow ZH_2^0$ ,  $H_2^0 \rightarrow HH \rightarrow b\bar{b}b\bar{b}$  using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for limits on cross section times branching ratios for  $m_{A^0} = 350\text{--}800 \text{ GeV}$  and  $m_{H_2^0} = 260\text{--}400 \text{ GeV}$ .
- 4 AAD 23AJ search for production of  $H^\pm$  in association with a top quark, followed by  $H^\pm \rightarrow W^\pm A^0$ ,  $A^0 \rightarrow$  invisible, using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for excluded parameter regions of 2HDM + CP-odd singlet model.
- 5 AAD 23BD search for a top quark decaying to  $qH_{1,2}^0$  ( $q = u, c$ ),  $H_{1,2}^0 \rightarrow b\bar{b}$ , using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9 for limits on production cross section times branching ratios for  $m_{H_{1,2}^0} = 20\text{--}160 \text{ GeV}$ .
- 6 AAD 23BE search for associated production of  $H_2^0 W$  and decay  $H_2^0 \rightarrow W^+ W^-$  assuming the presence of higher dimensional  $H_2^0 W^\pm W^\pm$  interactions, using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for excluded parameter region of higher dimensional operators, and Fig. 7 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.3\text{--}1.5 \text{ TeV}$ .
- 7 AAD 23BG search for production of  $H_2^0/A^0$  in association with a  $t\bar{t}$  pair, decaying to  $t\bar{t}$ , using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratios for  $m_{H_2^0} = m_{A^0} = 0.4\text{--}1.0 \text{ TeV}$ .
- 8 AAD 23BW search for  $A^0$  production in association with a  $t\bar{t}$  pair, decaying to  $\mu^+ \mu^-$ , using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5(a) for limits on production cross section times branching ratio for  $m_{A^0} = 15\text{--}72 \text{ GeV}$ .
- 9 AAD 23BX search for production of  $H \rightarrow \tau^+ \tau^-$  with missing transverse momentum using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for interpretation of the data in terms of 2HDM + a model.
- 10 AAD 23CA search for production of  $H_3^0$  decaying to  $H_2^0 H$ ,  $H_2^0 \rightarrow W^+ W^-$  or  $ZZ$ , and  $H \rightarrow \tau^+ \tau^-$  using  $140 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 4, 5 for limits on production cross section times branching ratios in the ranges  $m_{H_3^0} = 0.5\text{--}1.5 \text{ TeV}$  and  $m_{H_2^0} = 0.2\text{--}0.5 \text{ TeV}$ .
- 11 AAD 23CR search for  $H_2^0$  having flavor-violating couplings to  $tc$  or  $tu$ , produced in association with top quark(s), using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 14 for limits on production cross section times branching ratios for  $m_{H_2^0} = 0.2\text{--}1.5 \text{ TeV}$  with various assumptions on the flavor-changing couplings.
- 12 AAD 23o search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH$  in the final states  $\nu\bar{\nu}b\bar{b}$  and  $\ell^+ \ell^- b\bar{b}$  using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9 for limits on cross section times branching ratio for  $m_{A^0} = 0.22\text{--}2.0 \text{ TeV}$ , and Fig. 11 for limits with both production components.
- 13 AAD 23R search for the decay  $A^0 \rightarrow \gamma\gamma$  in  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_{A^0} = 10\text{--}70 \text{ GeV}$ .
- 14 AAD 23u search for the decay  $H_2^0 \rightarrow Z\gamma$  with  $Z$  decaying hadronically in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8(a) for limits on production cross section times branching ratios for  $m_{H_2^0} = 1.0\text{--}6.8 \text{ TeV}$ .
- 15 AAD 23z search for the decay chain  $H_2^0 \rightarrow HH \rightarrow b\bar{b}\tau^+\tau^-$  using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for limits on the product of production cross section times branching ratios for  $m_{H_2^0} = 0.251\text{--}1.6 \text{ TeV}$ .
- 16 HAYRAPETYAN 23c search for  $H_{1,2}^0 \rightarrow e\mu$  using  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on production cross section times branching ratio for  $m_{H_{1,2}^0} = 110\text{--}160 \text{ GeV}$ .
- 17 HAYRAPETYAN 23g search for dimuon resonance in the mass range  $1.1\text{--}2.6$  or  $4.2\text{--}7.9 \text{ GeV}$  in  $96.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , in inclusive and high  $p_T$  selections. See their Fig. 5 for cross section times branching ratio limits and Fig. 7 for mixing angle limits in two Higgs doublet plus singlet model (at 90% CL).
- 18 TUMASYAN 23 search for production of  $H_3^0$  decaying to  $H_{1,2}^0 H \rightarrow b\bar{b}b\bar{b}$  using  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for limits on production cross section times branching ratios for  $m_{H_3^0} = 0.9\text{--}4.0 \text{ TeV}$  and  $m_{H_{1,2}^0} = 60\text{--}600 \text{ GeV}$ , and their interpretation in the NMSSM and the Two Real Singlet Model (TRSM).
- 19 TUMASYAN 23M search for the decay chain  $H \rightarrow A^0 A^0 \rightarrow \gamma\gamma\gamma\gamma$  in  $132 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for limits on cross section times branching ratio in the range  $m_{A^0} = 15\text{--}62 \text{ GeV}$ .
- 20 TUMASYAN 23o search for  $H_2^0 \rightarrow HH$ , each  $H$  decaying to either  $WW^*$  or  $\tau^+ \tau^-$  using  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 14 (upper) for limit on the product of production cross section times branching ratios for  $m_{H_2^0} = 0.25\text{--}1.0 \text{ TeV}$ .
- 21 TUMASYAN 23s search for gluon fusion and  $b$ -associated production of  $H_{1,2}^0$  decaying to  $\tau^+ \tau^-$  using  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for limits on production cross section times branching ratios for  $m_{H_{1,2}^0} = 0.06\text{--}3.5 \text{ TeV}$ .
- 22 AAD 22A search for the decay chain  $H \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- b\bar{b}$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9 for limits on the overall branching fraction in the range  $m_{A^0} = 16\text{--}62 \text{ GeV}$ . See also Fig. 11 for limits without assuming  $A^0$  is pseudoscalar.
- 23 AAD 22d search for  $Z A^0$  associate production with  $Z \rightarrow \ell^+ \ell^-$ ,  $A^0$  decaying invisibly, in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for excluded regions in the mass parameter space of two Higgs doublet plus singlet (2HDM+ $A^0$ ) model with a certain choice of the model parameters.
- 24 AAD 22f search for gluon fusion production of  $H_2^0$  decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  using  $126\text{--}139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ .  $B(H \rightarrow b\bar{b}) = 0.582$  is assumed. See their Fig. 14 for limit on the product of production cross section times branching ratios for  $m_{H_2^0} = 0.251\text{--}5.0 \text{ TeV}$ .
- 25 AAD 22i search for  $ZH$  associate production with the decay chain  $H \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_1^0, \tilde{\chi}_2^0 \rightarrow A^0 \tilde{\chi}_1^0, A^0 \rightarrow b\bar{b}$ , and  $Z \rightarrow \ell^+ \ell^-$ , in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 3 and 4 for limits on the product of cross section times the branching ratios for  $m_{A^0} = 20\text{--}65 \text{ GeV}$  with various choices of NMSSM model parameters.
- 26 AAD 22j search for the decay  $H \rightarrow Z A^0$  with  $A^0 \rightarrow \mu^+ \mu^-$  and  $Z \rightarrow e^+ e^-$ ,  $\mu^+ \mu^-$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  assuming SM gluon-gluon fusion production of the  $H$ . See their Fig. 17(b) for limits on the product of cross section times the branching ratios for  $m_{A^0} = 15\text{--}30 \text{ GeV}$ .
- 27 AAD 22j search for the decay  $H \rightarrow A^0 A^0$  with  $A^0 \rightarrow \mu^+ \mu^-$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  assuming SM gluon-gluon fusion production of the  $H$  in the range of  $m_{A^0} = 1\text{--}60 \text{ GeV}$ . See their Fig. 14(b) for limits on the product of cross section times the branching ratios for  $m_{A^0} = 1.5\text{--}60 \text{ GeV}$  (excluding  $\psi$  and  $\Upsilon$  regions). The limit also applies to the decay  $H \rightarrow H_1^0 H_1^0$ .
- 28 AAD 22p search for invisibly decaying  $H_1^0, H_2^0$  produced by vector boson fusion in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Limit on the product of cross section times branching ratio in the range  $0.1\text{--}1 \text{ pb}$  (95% CL) is given for the mass range  $0.05\text{--}2 \text{ TeV}$ . See their Fig. 14.
- 29 AAD 22y search for gluon fusion production of  $H_2^0$  decaying to  $HH \rightarrow b\bar{b}\gamma\gamma$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 15 for limit on the product of production cross section times branching ratios to  $HH$  for  $m_{H_2^0} = 0.251\text{--}1.0 \text{ TeV}$ .
- 30 ABRATENKO 22A search for a singlet scalar boson  $H_1^0$  having a small mixing with the SM Higgs boson in the decay chain  $K^+ \rightarrow H_1^0 \pi^+, H_1^0 \rightarrow \mu^+ \mu^-$  from data corresponding to  $7.01 \times 10^{20}$  protons on NuMI target. See their Fig. 13 (right) and Table V for limits on the SM Higgs component of  $H_1^0$  for  $m_{H_1^0} = 212\text{--}279 \text{ MeV}$ .
- 31 TUMASYAN 22AK search for gluon-fusion production of  $H_3^0$  decaying to  $H_1^0 H_1^0 \rightarrow b\bar{b}b\bar{b}$  in  $138 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on cross section times branching ratio for  $m_{H_3^0} = 1\text{--}3 \text{ TeV}$ ,  $m_{H_1^0} = 25\text{--}100 \text{ GeV}$ .
- 32 TUMASYAN 22D search for production of an  $H_2^0$  (denoted radion in the paper) in gluon fusion and vector boson fusion, decaying to  $W^+ W^-$  in the final states  $\ell\nu$  + hadrons, using  $137 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_{H_2^0} = 1.0\text{--}4.5 \text{ TeV}$ .
- 33 AAD 21AF search for production of a heavy  $H_2^0$  state decaying to  $ZZ$  in the final states  $\ell^+ \ell^- \ell^+ \ell^-$  and  $\ell^+ \ell^- \nu\bar{\nu}$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for upper limits on cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}2.0 \text{ TeV}$  assuming ggF or VBF with narrow width approximation, and Fig. 5 for upper limits on cross section times branching ratio for  $m_{H_2^0} = 0.4\text{--}2.0 \text{ TeV}$  assuming ggF, and with several assumptions on its width.
- 34 AAD 21AI search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH_2^0 \rightarrow \ell^+ \ell^- b\bar{b}$  or  $\ell^+ \ell^- W^+ W^-$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 9 and 13 for cross section limits for  $m_{A^0} = 230\text{--}800 \text{ GeV}$  and  $m_{H_2^0} = 130\text{--}700 \text{ GeV}$ .
- 35 AAD 21AY search for production of a scalar resonance decaying to  $\gamma\gamma$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5(a) for limits on fiducial cross section times branching ratio for  $m_{H_2^0} = 0.16\text{--}3 \text{ TeV}$  with narrow width approximation, and Table 2 with several assumptions on the width.
- 36 AAD 21AZ search for production of  $A_2^0$  decaying to  $HA_1^0$  followed by  $H \rightarrow \gamma\gamma, A_1^0 \rightarrow$  invisible in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 10–12 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar and a fermionic Dark Matter particle.
- 37 AAD 21BB search for production of  $A_2^0$  by gluon fusion or associated  $A_2^0 b\bar{b}$  production, decaying to  $HA_1^0$  followed by  $H \rightarrow b\bar{b}, A_1^0 \rightarrow$  invisible in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.
- 38 AAD 21BE search for production of  $A_1^0$  associated with a single top quark and either a light quark or a  $W$  boson, decaying to invisible final states, in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 13–15 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar, which is assumed to decay to a pair of Dark Matter particles.
- 39 ABRATENKO 21 search for a singlet scalar boson  $H_1^0$  having a small mixing with the SM Higgs boson in the decay chain  $K^+ \rightarrow H_1^0 \pi^+, H_1^0 \rightarrow e^+ e^-$  from data corresponding to  $1.93 \times 10^{20}$  protons on NuMI target. See their Fig. 2 for limits on the SM Higgs component of  $H_1^0$  for  $m_{H_1^0} = 3\text{--}210 \text{ MeV}$ .
- 40 SIRUNYAN 21A search for  $H_2^0 \rightarrow Z A^0$  with  $Z \rightarrow \ell^+ \ell^-$ ,  $A^0$  decaying invisibly, in  $137 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for excluded regions in the mass parameter space of two Higgs doublet plus singlet model with a certain choice of the model parameters.
- 41 TUMASYAN 21F search for gluon fusion production of  $H_3^0$  decaying to  $HH_{1,2}^0 \rightarrow \tau^+ \tau^- b\bar{b}$  in  $137 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 5 and 6 for limits on cross section times branching ratios for  $m_{H_{1,2}^0} = 0.06\text{--}2.8 \text{ TeV}$  and  $m_{H_3^0} = 0.24\text{--}3.0 \text{ TeV}$ .
- 42 AAD 20AA search for  $H_2^0/A^0 \rightarrow \tau^+ \tau^-$  produced by gluon fusion or  $b$ -associated production using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 2(a), 2(b) for limits on the product of cross section and branching ratio for  $m_{H_2^0}, m_{A^0} = 0.2\text{--}2.5 \text{ TeV}$ .
- 43 AAD 20AI search for  $ZH$  production followed by the decay  $H \rightarrow A^0 A^0 \rightarrow b\bar{b}b\bar{b}$  in  $36 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The search looks for collimated  $A^0 \rightarrow b\bar{b}$  decays and is complementary to AABOUD 18bx. See their Fig. 10 for limits on the product of production cross section and branching ratios in the range  $m_{A^0} = 15\text{--}30 \text{ GeV}$ .

See key on page 1171

## Gauge & Higgs Boson Particle Listings

### Neutral Higgs Bosons, Searches for

- 44 AAD 20A0 search for gluon fusion production of  $H_2^0$  decaying to  $HH \rightarrow \tau^+ \tau^- b \bar{b}$  (with hadronically decaying  $\tau^+ \tau^-$ ) using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Limit on the product of production cross section times branching ratios in the range 28–817 fb (95% CL) is given for  $m_{A^0} = 1.0\text{--}3.0 \text{ TeV}$ , see their Fig. 13.
- 45 AAD 20c combine searches for a scalar resonance decaying to  $HH$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for  $m_{H_2^0} = 0.26\text{--}3 \text{ TeV}$ .
- 46 AAD 20L search for  $b$ -associated production of  $H_2^0$  decaying to  $b\bar{b}$  in  $27.8 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for limits on the product of cross section and branching ratio for  $m_{H_2^0} = 0.45\text{--}1.4 \text{ TeV}$ .
- 47 AAD 20x search for vector-boson-fusion production of  $H_2^0$  decaying to  $HH$  using  $126 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on the product of cross section and branching ratio for the assumptions of a narrow- and broad-width resonance.
- 48 AIJ 20AL search for dimuon resonance in the mass range  $0.2\text{--}60 \text{ GeV}$  in  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , in inclusive and  $b$  quark associated production. Displaced decays are searched for for masses below  $3 \text{ GeV}$ . See their Figs. 7–9 for cross section limits and Fig. 10 for limits for mixing angle in two Higgs doublet plus singlet model (at 90% CL).
- 49 SIRUNYAN 20 search for the decay  $H \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$  or  $\tau^+ \tau^- \mu^+ \mu^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range  $m_{A^0} = 4\text{--}15 \text{ GeV}$ .
- 50 SIRUNYAN 20AA search for  $H_2^0 \rightarrow Z A^0$ ,  $A^0 \rightarrow b\bar{b}$  or  $A^0 \rightarrow Z H_2^0$ ,  $H_2^0 \rightarrow b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on the product of cross section and branching ratio for  $m_{H_2^0} = 0.12\text{--}1 \text{ TeV}$  and  $m_{A^0} = 0.03\text{--}1 \text{ TeV}$ .
- 51 SIRUNYAN 20AC search for gluon-fusion production of  $A^0$  decaying to  $ZH$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on the product of cross section and branching ratios for  $m_{A^0} = 220\text{--}400 \text{ GeV}$ .
- 52 SIRUNYAN 20AD search for lepton-flavor violating decays  $H_2^0 \rightarrow \mu\tau$ ,  $e\tau$  of gluon-fusion-produced  $H_2^0$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 (9) and Table 5 (6) for limits on production cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}0.9 \text{ TeV}$  for the  $\mu\tau$  ( $e\tau$ ) final state.
- 53 SIRUNYAN 20AF search for  $H_2^0/A^0 \rightarrow t\bar{t}$  with one or two charged leptons in the final state using kinematic variables in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 5 and 6 for limits on top Yukawa coupling of  $H_2^0$  and  $A^0$  for  $m_{H_2^0}$ ,  $m_{A^0} = 0.4\text{--}0.75 \text{ TeV}$  for various width assumptions.
- 54 SIRUNYAN 20AP search for the decay  $H$  or  $H_2^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \tau^+ \tau^-$  (for  $m_{H_2^0} = 300 \text{ GeV}$ ) with boosted final-state topology in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range  $m_{A^0} = 3.6\text{--}21 \text{ GeV}$ , and Figs. 8 and 9 for its interpretation in terms of models with two Higgs doublets plus a singlet.
- 55 SIRUNYAN 20V search for gluon-fusion and vector-boson-fusion production of  $H_2^0$  decaying to  $W^+ W^-$  in the final states  $\ell\nu\ell\nu$  and  $\ell\nu q\bar{q}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for limits on the product of cross section and branching ratio for  $m_{H_2^0} = 0.2\text{--}3 \text{ TeV}$ .
- 56 SIRUNYAN 20Z search for  $H_{1,2}^0$  or  $A^0$  production in association with a  $t\bar{t}$  pair, decaying to  $e^+ e^-$  or  $\mu^+ \mu^-$ , in  $137 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 12 for limits on production cross section times branching ratio for  $m_{H_{1,2}^0}$ ,  $m_{A^0} = 15\text{--}75 \text{ GeV}$  and  $108\text{--}340 \text{ GeV}$ .
- 57 AABOUD 19A search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $27.5\text{--}36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9(a) for limits on cross section times branching ratios for  $m_{H_2^0} = 0.26\text{--}3 \text{ TeV}$ .
- 58 AABOUD 19AG search for the decay  $H \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- b\bar{b}$  in  $36.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range  $m_{A^0} = 20\text{--}60 \text{ GeV}$ .
- 59 AABOUD 19O search for a scalar resonance decaying to  $HH \rightarrow b\bar{b}W W^*$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 12 (left) for limits on cross section times branching ratio for  $m_{H_2^0} = 0.5\text{--}3 \text{ TeV}$ .
- 60 AABOUD 19T search for a scalar resonance decaying to  $HH \rightarrow W W^* W W^*$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio for  $m_{H_2^0} = 260\text{--}500 \text{ GeV}$ , assuming SM decay rates for the  $H$ .
- 61 AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with  $A_1^0$  decaying to invisible final states. See their Fig. 19 for excluded parameter regions.
- 62 AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or  $b$  associated production, decaying to  $\mu^+ \mu^-$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 4 and 5(a) for cross section limits for  $m_{H_2^0} = 0.2\text{--}1.0 \text{ TeV}$ .
- 63 AALTONEN 19 search for  $b$  associated production of a scalar particle decaying to  $b\bar{b}$  in  $5.4 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio for  $m_{H_{1,2}^0} = 100\text{--}300 \text{ GeV}$ .
- 64 SIRUNYAN 19 search for a narrow scalar resonance decaying to  $HH \rightarrow \gamma\gamma b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9 (left) for limits on cross section times branching ratios for  $m_{H_2^0} = 260\text{--}900 \text{ GeV}$ .
- 65 SIRUNYAN 19AE search for a scalar resonance produced in association with a  $b\bar{b}$  pair, decaying to  $\tau^+ \tau^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for cross section limits for  $m_{A^0} = 25\text{--}70 \text{ GeV}$ .
- 66 SIRUNYAN 19AN search for production of  $A_2^0$  decaying to  $HA_1^0$  followed by  $H \rightarrow b\bar{b}$ ,  $A_1^0 \rightarrow$  invisible in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , in the mass range  $m_{A_2^0} = 0.2\text{--}1.6 \text{ TeV}$ ,  $m_{A_1^0} = 0.15\text{--}0.5 \text{ TeV}$ . See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.
- 67 SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or  $b$ -associated production, decaying to  $ZH \rightarrow \ell^+ \ell^- b\bar{b}$  ( $\ell = e, \mu$ ) or  $\nu\bar{\nu}b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for cross section limits for  $m_{A^0} = 0.22\text{--}1.0 \text{ TeV}$ .
- 68 SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to  $b\bar{b}$ , in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of  $50\text{--}350 \text{ GeV}$ .
- 69 SIRUNYAN 19BB search for the decay  $H_1^0 \rightarrow \gamma\gamma$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $35.9 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 4–6 for limits on cross section times branching ratio for  $m_{H_1^0} = 80\text{--}110 \text{ GeV}$  (some results in Fig. 5 for  $m_{H_1^0} = 70\text{--}110 \text{ GeV}$ ).
- 70 SIRUNYAN 19BD search for the decay  $H \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on the product of cross section times branching ratios in the range  $m_{A^0} = 20\text{--}62.5 \text{ GeV}$ . See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 71 SIRUNYAN 19BE combine searches for  $H_2^0 \rightarrow HH$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$  in various  $H$  decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for  $m_{H_2^0} = 0.25\text{--}3 \text{ TeV}$ .
- 72 SIRUNYAN 19BQ search for production of  $H_{1,2}^0$  decaying to  $A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio for  $m_{H_{1,2}^0} = 90\text{--}150 \text{ GeV}$ ,  $m_{A^0} = 0.25\text{--}3.55 \text{ GeV}$ .
- 73 SIRUNYAN 19CR search for production of  $H_2^0/A^0$  in gluon fusion and in association with a  $b\bar{b}$  pair, decaying to  $\mu^+ \mu^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for limits on cross section times branching ratio.
- 74 SIRUNYAN 19H search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , where one  $b\bar{b}$  pair is resolved and the other not. Limits on cross section times branching ratios for  $m_{H_2^0} = 0.75\text{--}1.6 \text{ TeV}$  are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).
- 75 AABOUD 18AA search for production of a scalar resonance decaying to  $Z\gamma$ , with  $Z$  decaying hadronically, in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8(a) for limits on cross section times branching ratio for  $m_{H_2^0} = 1.0\text{--}6.8 \text{ TeV}$ .
- 76 AABOUD 18AG search for the decay  $H \rightarrow A^0 A^0 \rightarrow \gamma\gamma g g$  in  $36.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 2 and Table 6 for cross section limits in the range  $m_{A^0} = 20\text{--}60 \text{ GeV}$ .
- 77 AABOUD 18AH search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH_2^0 \rightarrow \ell^+ \ell^- b\bar{b}$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for cross section limits for  $m_{A^0} = 230\text{--}800 \text{ GeV}$  and  $m_{H_2^0} = 130\text{--}700 \text{ GeV}$ .
- 78 AABOUD 18AI search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH$  in the final states  $\nu\bar{\nu}b\bar{b}$  and  $\ell^+ \ell^- b\bar{b}$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for cross section limits for  $m_{A^0} = 0.2\text{--}2 \text{ TeV}$ . See also AABOUD 18CC.
- 79 AABOUD 18BF search for production of a heavy  $H_2^0$  state decaying to  $ZZ$  in the final states  $\ell^+ \ell^- \ell^+ \ell^-$  and  $\ell^+ \ell^- \nu\bar{\nu}$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 6 for upper limits on cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}1.2 \text{ TeV}$  assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for  $m_{H_2^0} = 0.4\text{--}1.0 \text{ TeV}$  assuming ggF, and with several assumptions on its width.
- 80 AABOUD 18BU search for a narrow scalar resonance decaying to  $HH \rightarrow \gamma\gamma W W^*$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratios for  $m_{H_2^0} = 260\text{--}500 \text{ GeV}$ .
- 81 AABOUD 18BX search for associated production of  $WH$  or  $ZH$  followed by the decay  $H \rightarrow A^0 A^0 \rightarrow b\bar{b}b\bar{b}$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 9 for limits on cross section times branching ratios for  $m_{A^0} = 20\text{--}60 \text{ GeV}$ . See also their Fig. 10 for the dependence of the limit on  $A^0$  lifetime.
- 82 AABOUD 18CQ search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}\tau^+ \tau^-$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 2 (above) for limits on cross section times branching ratios for  $m_{H_2^0} = 260\text{--}1000 \text{ GeV}$ .
- 83 AABOUD 18F search for production of a narrow scalar resonance decaying to  $W^+ W^-$  and  $ZZ$ , followed by hadronic decays of  $W$  and  $Z$ , in  $36.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5(c) for limits on cross section times branching ratio for  $m_{H_2^0} = 1.2\text{--}3.0 \text{ TeV}$ .
- 84 AIJ 18AM search for gluon-fusion production of  $H_{1,2}^0$  decaying to  $\mu\tau$  in  $2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio for  $m_{H_{1,2}^0} = 45\text{--}195 \text{ GeV}$ .
- 85 AIJ 18AQ search for gluon-fusion production of a scalar particle  $A^0$  decaying to  $\mu^+ \mu^-$  in  $1.99 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $0.98 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio for  $m_{A^0} = 5.5\text{--}15 \text{ GeV}$  (using the  $E_{\text{cm}} = 8 \text{ TeV}$  data set).
- 86 AIJ 18AQ search for the decay  $H \rightarrow A^0 A^0$ , with one of the  $A^0$  decaying to  $\mu^+ \mu^-$ , in  $1.99 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $0.98 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 5 (right) for limits on the product of branching ratios for  $m_{A^0} = 5.5\text{--}15 \text{ GeV}$  (using the  $E_{\text{cm}} = 8 \text{ TeV}$  data set).
- 87 SIRUNYAN 18AF search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , where both  $b\bar{b}$  pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for  $m_{H_2^0} = 0.75\text{--}3 \text{ TeV}$ .

## Neutral Higgs Bosons, Searches for

- 88 SIRUNYAN 18BA search for production of a heavy  $H_2^0$  state decaying to  $ZZ$  in the final states  $\ell^+\ell^-\ell^+\ell^-$ ,  $\ell^+\ell^-q\bar{q}$ , and  $\ell^+\ell^-\nu\bar{\nu}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 10 and 11 for upper limits on cross section times branching ratio for  $m_{H_2^0} = 0.13\text{--}3 \text{ TeV}$  with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.
- 89 SIRUNYAN 18CW search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ , where both  $b\bar{b}$  pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for  $m_{H_2^0} = 260\text{--}1200 \text{ GeV}$ .
- 90 SIRUNYAN 18DK search for production of a scalar resonance decaying to  $Z\gamma$ , with  $Z$  decaying to  $\ell^+\ell^-$  or hadronically, in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.35\text{--}4 \text{ TeV}$  for different assumptions on the width of the resonance.
- 91 SIRUNYAN 18DT search for the decay  $H \rightarrow A^0 A^0 \rightarrow \tau^+\tau^- b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on the product of branching ratios in the range  $m_{A^0} = 15\text{--}60 \text{ GeV}$ . See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 92 SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to  $\gamma\gamma$  in  $35.9 \text{ fb}^{-1}$  (taken in 2016) of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 3 (right) for limits on cross section times branching ratio for  $m_{H_2^0} = 0.5\text{--}5 \text{ TeV}$  for several values of its width-to-mass ratio.
- 93 SIRUNYAN 18ED search for production of an  $A^0$  in gluon-gluon fusion and in association with a  $b\bar{b}$ , decaying to  $ZH$  in the final states  $\nu\tau b\bar{b}$  or  $\ell^+\ell^- b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for cross section limits for  $m_{A^0} = 0.8\text{--}2 \text{ TeV}$ .
- 94 SIRUNYAN 18EE search for the decay  $H \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\tau^+\tau^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for limits on the product of branching ratios in the range  $m_{A^0} = 15\text{--}62.5 \text{ GeV}$ , normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 95 SIRUNYAN 18F search for a narrow scalar resonance decaying to  $HH \rightarrow WWb\bar{b}$  or  $ZZb\bar{b}$  in the final state  $\ell\ell\nu\nu b\bar{b}$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratios for  $m_{H_2^0} = 250\text{--}900 \text{ GeV}$ .
- 96 ABOUD 17 search for production of a scalar resonance decaying to  $Z\gamma$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for the limits on cross section times branching ratio for  $m_{H_2^0} = 0.25\text{--}3.0 \text{ TeV}$ .
- 97 ABOUD 17AP search for production of a scalar resonance decaying to  $\gamma\gamma$  in  $36.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4(a) for limits on fiducial cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}2.7 \text{ TeV}$  with narrow width approximation.
- 98 ABOUD 17AW search for production of a scalar resonance decaying to  $Z\gamma$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.25\text{--}2.4 \text{ TeV}$ .
- 99 KHACHATRYAN 17AZ search for the decay  $H \rightarrow A^0 A^0 \rightarrow \tau^+\tau^-\tau^+\tau^-$ ,  $\mu^+\mu^- b\bar{b}$ , and  $\mu^+\mu^-\tau^+\tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 4, 5, and 6 for cross section limits in the range  $m_{A^0} = 5\text{--}62.5 \text{ GeV}$ . See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.
- 100 KHACHATRYAN 17D search for production of a scalar resonance decaying to  $Z\gamma$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $2.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 3 and 4 for the limits on cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}2.0 \text{ TeV}$ .
- 101 KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to  $\gamma\gamma$  in  $12.9 \text{ fb}^{-1}$  (taken in 2016) of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.5\text{--}4.5 \text{ TeV}$  for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.
- 102 SIRUNYAN 17CN search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}\tau^+\tau^-$  in  $18.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for  $m_{H_2^0} = 0.3\text{--}1 \text{ TeV}$ , and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.
- 103 SIRUNYAN 17Y search for production of a scalar resonance decaying to  $Z\gamma$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $2.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.7\text{--}3.0 \text{ TeV}$ , and Fig. 5 for the corresponding limits for  $m_{H_2^0} = 0.2\text{--}3.0 \text{ TeV}$  from combination with KHACHATRYAN 17D data.
- 104 ABOUD 16AB search for associated production of  $WH$  with the decay  $H \rightarrow A^0 A^0 \rightarrow b\bar{b}b\bar{b}$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for limits on cross section times branching ratios for  $m_{A^0} = 20\text{--}60 \text{ GeV}$ .
- 105 ABOUD 16AE search for production of a narrow scalar resonance decaying to  $W^+W^-$  and  $ZZ$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.5\text{--}3 \text{ TeV}$ .
- 106 ABOUD 16H search for production of a scalar resonance decaying to  $\gamma\gamma$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 12 for limits on cross section times branching ratio for  $m_{H_2^0} = 0.2\text{--}2 \text{ TeV}$  with different assumptions on the width.
- 107 ABOUD 16I search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 10(c) for limits on cross section times branching ratios for  $m_{H_2^0} = 0.5\text{--}3 \text{ TeV}$ .
- 108 AAD 16AX search for production of a heavy  $H$  state decaying to  $ZZ$  in the final states  $\ell^+\ell^-\ell^+\ell^-$ ,  $\ell^+\ell^-\nu\bar{\nu}$ ,  $\ell^+\ell^-q\bar{q}$ , and  $\nu\tau b\bar{b}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 12 for upper limits on  $\sigma(H) \text{B}(H \rightarrow ZZ)$  for  $m_H$  ranging from  $140 \text{ GeV}$  to  $1000 \text{ GeV}$ .
- 109 AAD 16C search for production of a heavy  $H$  state decaying to  $W^+W^-$  in the final states  $\ell\nu\ell\nu$  and  $\ell\nu q\bar{q}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 12, 13, and 16 for upper limits on  $\sigma(H) \text{B}(H \rightarrow W^+W^-)$  for  $m_H$  ranging from  $300 \text{ GeV}$  to  $1000$  or  $1500 \text{ GeV}$  with various assumptions on the total width of  $H$ .
- 110 AAD 16L search for the decay  $H \rightarrow A^0 A^0 \rightarrow \gamma\gamma\gamma\gamma$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM  $H$  cross section) for  $m_{A^0} = 10\text{--}60 \text{ GeV}$ .
- 111 AAD 16L search for the decay  $H_2^0 \rightarrow A^0 A^0 \rightarrow \gamma\gamma\gamma\gamma$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 4 (lower right) for limits on cross section times branching ratios for  $m_{H_2^0} = 600 \text{ GeV}$  and  $m_{A^0} = 10\text{--}245 \text{ GeV}$ , and Table 5 for limits for  $m_{H_2^0} = 300$  and  $900 \text{ GeV}$ .
- 112 AALTONEN 16C search for electroweak associated production of  $H_1^0 H^\pm$  followed by the decays  $H^\pm \rightarrow H_1^0 W^*$ ,  $H_1^0 \rightarrow \gamma\gamma$  for  $m_{H_1^0} = 10\text{--}105 \text{ GeV}$  and  $m_{H^\pm} = 30\text{--}300 \text{ GeV}$ . See their Fig. 3 for excluded parameter region in a two-doublet model in which  $H_1^0$  has no direct decay to fermions.
- 113 KHACHATRYAN 16BG search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for limits on the cross section times branching ratios for  $m_{H_2^0} = 1.15\text{--}3 \text{ TeV}$ .
- 114 KHACHATRYAN 16BQ search for a resonance decaying to  $HH \rightarrow \gamma\gamma b\bar{b}$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 9 for limits on the cross section times branching ratios for  $m_{H_2^0} = 0.26\text{--}1.1 \text{ TeV}$ .
- 115 KHACHATRYAN 16F search for the decay  $H \rightarrow H_1^0 H_1^0 \rightarrow \tau^+\tau^-\tau^+\tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 8 for cross section limits for  $m_{H_1^0} = 4\text{--}8 \text{ GeV}$ .
- 116 KHACHATRYAN 16M search for production of a narrow resonance decaying to  $\gamma\gamma$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and  $3.3 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 3 (top) for limits on cross section times branching ratio for  $m_{H_2^0} = 0.5\text{--}4 \text{ TeV}$ .
- 117 KHACHATRYAN 16P search for gluon fusion production of an  $H_2^0$  decaying to  $HH \rightarrow b\bar{b}\tau^+\tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 8 (lower right) for cross section limits for  $m_{H_2^0} = 260\text{--}350 \text{ GeV}$ .
- 118 KHACHATRYAN 16P search for gluon fusion production of an  $A^0$  decaying to  $ZH \rightarrow \ell^+\ell^-\tau^+\tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 10 for cross section limits for  $m_{H_2^0} = 220\text{--}350 \text{ GeV}$ .
- 119 AAD 15BK search for production of a heavy  $H_2^0$  decaying to  $HH$  in the final state  $b\bar{b}b\bar{b}$  in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 14(c) for  $\sigma(H_2^0) \text{B}(H_2^0 \rightarrow HH)$  for  $m_{H_2^0} = 500\text{--}1500 \text{ GeV}$  with  $\Gamma_{H_2^0} = 1 \text{ GeV}$ .
- 120 AAD 15BZ search for the decay  $H \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\tau^+\tau^-$  ( $m_H = 125 \text{ GeV}$ ) in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for limits on cross section times branching ratio for  $m_{A^0} = 3.7\text{--}50 \text{ GeV}$ .
- 121 AAD 15BZ search for a state  $H_2^0$  via the decay  $H_2^0 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\tau^+\tau^-$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for limits on cross section times branching ratio for  $m_{H_2^0} = 100\text{--}500 \text{ GeV}$  and  $m_{A^0} = 5 \text{ GeV}$ .
- 122 AAD 15CE search for production of a heavy  $H_2^0$  decaying to  $HH$  in the final states  $b\bar{b}\tau^+\tau^-$  and  $\gamma\gamma WW^*$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$  and combine with data from AAD 15H and AAD 15BK. A limit  $\sigma(H_2^0) \text{B}(H_2^0 \rightarrow HH) < 2.1\text{--}0.011 \text{ pb}$  (95% CL) is given for  $m_{H_2^0} = 260\text{--}1000 \text{ GeV}$ . See their Fig. 6.
- 123 AAD 15H search for production of a heavy  $H_2^0$  decaying to  $HH$  in the final state  $\gamma\gamma b\bar{b}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . A limit of  $\sigma(H_2^0) \text{B}(H_2^0 \rightarrow HH) < 3.5\text{--}0.7 \text{ pb}$  is given for  $m_{H_2^0} = 260\text{--}500 \text{ GeV}$  at 95% CL. See their Fig. 3.
- 124 AAD 15S search for production of  $A^0$  decaying to  $ZH \rightarrow \ell^+\ell^- b\bar{b}$ ,  $\nu\tau b\bar{b}$  and  $\ell^+\ell^-\tau^+\tau^-$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 3 for cross section limits for  $m_{A^0} = 200\text{--}1000 \text{ GeV}$ .
- 125 KHACHATRYAN 15AW search for production of a heavy state  $H_2^0$  of an electroweak singlet extension of the Standard Model via the decays of  $H_2^0$  to  $W^+W^-$  and  $ZZ$  in up to  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and up to  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$  in the range  $m_{H_2^0} = 145\text{--}1000 \text{ GeV}$ . See their Figs. 8 and 9 for limits in the parameter space of the model.
- 126 KHACHATRYAN 15BB search for production of a resonance  $H$  decaying to  $\gamma\gamma$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_H = 150\text{--}850 \text{ GeV}$ .
- 127 KHACHATRYAN 15N search for production of  $A^0$  decaying to  $ZH \rightarrow \ell^+\ell^- b\bar{b}$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratios for  $m_{A^0} = 225\text{--}600 \text{ GeV}$ .
- 128 KHACHATRYAN 15O search for production of a high-mass narrow resonance  $A^0$  decaying to  $ZH \rightarrow q\bar{q}\tau^+\tau^-$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for limits on cross section times branching ratios for  $m_{A^0} = 800\text{--}2500 \text{ GeV}$ .
- 129 KHACHATRYAN 15R search for a narrow scalar resonance decaying to  $HH \rightarrow b\bar{b}b\bar{b}$  in  $17.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 5 (top) for limits on cross section times branching ratios for  $m_{H_2^0} = 0.27\text{--}1.1 \text{ TeV}$ .
- 130 AAD 14AP search for a second  $H$  state decaying to  $\gamma\gamma$  in addition to the state at about  $125 \text{ GeV}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio for  $m_H = 65\text{--}600 \text{ GeV}$ .
- 131 AAD 14M search for the decay cascade  $H_2^0 \rightarrow H^\pm W^\mp \rightarrow HW^\pm W^\mp$ ,  $H$  decaying to  $b\bar{b}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Table III for limits on cross section times branching ratio for  $m_{H_2^0} = 325\text{--}1025 \text{ GeV}$  and  $m_{H^\pm} = 225\text{--}925 \text{ GeV}$ .
- 132 CHATRCHYAN 14G search for a second  $H$  state decaying to  $WW^*$  in addition to the observed signal at about  $125 \text{ GeV}$  using  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.4 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 21 (right) for cross section limits in the mass range  $110\text{--}600 \text{ GeV}$ .

## Neutral Higgs Bosons, Searches for

133 KHACHATRYAN 14P search for a second  $H$  state decaying to  $\gamma\gamma$  in addition to the observed signal at about 125 GeV using  $5.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  and  $19.7 \text{ fb}^{-1}$  at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.

134 AALTONEN 13P search for production of a heavy Higgs boson  $H^{0'}$  that decays into a charged Higgs boson  $H^{\pm}$  and a lighter Higgs boson  $H$  via the decay chain  $H^{0'} \rightarrow H^{\pm} W^{\mp}, H^{\pm} \rightarrow W^{\pm} H, H \rightarrow b\bar{b}$  in the final state  $\ell\nu$  plus 4 jets in  $8.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio in the  $m_{H^{\pm}} - m_{H^{0'}}$  plane for  $m_H = 126 \text{ GeV}$ .

135 CHATRCHYAN 13BJ search for  $H$  production in the decay chain  $H \rightarrow A^0 A^0, A^0 \rightarrow \mu^+ \mu^-$  in  $5.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio.

136 AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+ \tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160 \text{ GeV}$ .

137 ABBIENDI 10 search for  $e^+ e^- \rightarrow ZH$  with the decay chain  $H \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (\gamma \text{ or } Z^*)$ , when  $\tilde{\chi}_1^0$  and  $\tilde{\chi}_2^0$  are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on  $m_H$  of 108.4 (107.0) GeV (95% CL) is obtained for SM  $ZH$  cross section and  $B(H \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0) = 1$ .

138 SCHAEFEL 10 search for the process  $e^+ e^- \rightarrow HZ$  followed by the decay chain  $H \rightarrow A^0 A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$  with  $Z \rightarrow \ell^+ \ell^-, \nu\bar{\nu}$  at  $E_{\text{cm}} = 183\text{--}209 \text{ GeV}$ . For a  $HZZ$  coupling equal to the SM value,  $B(H \rightarrow A^0 A^0) = B(A^0 \rightarrow \tau^+ \tau^-) = 1$ , and  $m_{A^0} = 4\text{--}10 \text{ GeV}$ ,  $m_H$  up to 107 GeV is excluded at 95% CL.

139 ABAZOV 09V search for  $H$  production followed by the decay chain  $H \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$  or  $\mu^+ \mu^- \tau^+ \tau^-$  in  $4.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . See their Fig. 3 for limits on  $\sigma(H) \cdot B(H \rightarrow A^0 A^0)$  for  $m_{A^0} = 3.6\text{--}19 \text{ GeV}$ .

140 ABBIENDI 05A search for  $e^+ e^- \rightarrow H_1^0 A^0$  in general Type-II two-doublet models, with decays  $H_1^0, A^0 \rightarrow q\bar{q}, gg, \tau^+ \tau^-$ , and  $H_1^0 \rightarrow A^0 A^0$ .

141 ABBIENDI 04K search for  $e^+ e^- \rightarrow HZ$  with  $H$  decaying to two jets of any flavor including  $g\bar{g}$ . The limit is for SM production cross section with  $B(H \rightarrow jj) = 1$ .

142 ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to  $W$  or  $Z$  bosons, assuming SM decays of the Higgs. Results in Fig. 26.

143 ACHARD 04B search for  $e^+ e^- \rightarrow HZ$  with  $H$  decaying to  $b\bar{b}, c\bar{c}$ , or  $g\bar{g}$ . The limit is for SM production cross section with  $B(H \rightarrow jj) = 1$ .

144 ACHARD 04F search for  $H$  with anomalous coupling to gauge boson pairs in the processes  $e^+ e^- \rightarrow H\gamma, e^+ e^- H, HZ$  with decays  $H \rightarrow f\bar{f}, \gamma\gamma, Z\gamma$ , and  $W^* W$  at  $E_{\text{cm}} = 189\text{--}209 \text{ GeV}$ . See paper for limits.

145 ABBIENDI 03F search for  $H \rightarrow$  anything in  $e^+ e^- \rightarrow HZ$ , using the recoil mass spectrum of  $Z \rightarrow e^+ e^-$  or  $\mu^+ \mu^-$ . In addition, it searched for  $Z \rightarrow \nu\bar{\nu}$  and  $H \rightarrow e^+ e^-$  or photons. Scenarios with large width or continuum  $H$  mass distribution are considered. See their Figs. 11–14 for the results.

146 ABBIENDI 03G search for  $e^+ e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, g\bar{g}$ , or  $\tau^+ \tau^-$  in the region  $m_{H_1^0} = 45\text{--}86 \text{ GeV}$  and  $m_{A^0} = 2\text{--}11 \text{ GeV}$ . See their Fig. 7 for the limits.

147 Search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+ \ell^-$ , or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209 \text{ GeV}$ . The limit is for a  $H$  with SM production cross section and  $B(H \rightarrow f\bar{f})=0$  for all fermions  $f$ .

148 For  $B(H \rightarrow \gamma\gamma)=1, m_H > 113.1 \text{ GeV}$  is obtained.

149 HEISTER 02M search for  $e^+ e^- \rightarrow HZ$ , assuming that  $H$  decays to  $q\bar{q}, g\bar{g}$ , or  $\tau^+ \tau^-$  only. The limit assumes SM production cross section.

150 ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at  $E_{\text{cm}} \leq 189 \text{ GeV}$ . In addition to usual final states, the decays  $H_1^0, A^0 \rightarrow q\bar{q}, g\bar{g}$  are searched for. See their Figs. 15,16 for excluded regions.

151 ACCIARRI 00R search for  $e^+ e^- \rightarrow H\gamma$  with  $H \rightarrow b\bar{b}, Z\gamma$ , or  $\gamma\gamma$ . See their Fig. 3 for limits on  $\sigma \cdot B$ . Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.

152 ACCIARRI 00R search for the two-photon type processes  $e^+ e^- \rightarrow e^+ e^- H$  with  $H \rightarrow b\bar{b}$  or  $\gamma\gamma$ . See their Fig. 4 for limits on  $\Gamma(H \rightarrow \gamma\gamma) \cdot B(H \rightarrow \gamma\gamma \text{ or } b\bar{b})$  for  $m_H = 70\text{--}170 \text{ GeV}$ .

153 GONZALEZ-GARCIA 98b use  $D\bar{0}$  limit for  $\gamma\gamma$  events with missing  $E_T$  in  $p\bar{p}$  collisions (ABBOTT 98) to constrain possible  $ZH$  or  $WH$  production followed by unconventional  $H \rightarrow \gamma\gamma$  decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

154 KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no  $H_1^0 Z$  coupling and obtain  $m_{H_1^0} \gtrsim 5 \text{ GeV}$  or  $m_{A^0} \gtrsim 5 \text{ GeV}$  for  $\tan\beta > 50$ . Other Higgs bosons are assumed to be much heavier.

155 ALEXANDER 96H give  $B(Z \rightarrow H\gamma) \times B(H \rightarrow q\bar{q}) < 1\text{--}4 \times 10^{-5}$  (95%CL) and  $B(Z \rightarrow H\gamma) \times B(H \rightarrow b\bar{b}) < 0.7\text{--}2 \times 10^{-5}$  (95%CL) in the range  $20 < m_H < 80 \text{ GeV}$ .

91<sup>+31</sup><sub>-24</sub> 4 ERLER 10A RVUE

129<sup>+74</sup><sub>-49</sub> 5 LEP-SLC 06 RVUE

1 HALLER 18 make Standard Model fits to  $Z$  and neutral current parameters,  $m_t, m_W$ , and  $\Gamma_W$  measurements available in 2018. The direct mass measurement at the LHC is not used in the fit.

2 BAAK 12 make Standard Model fits to  $Z$  and neutral current parameters,  $m_t, m_W$ , and  $\Gamma_W$  measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is  $120^{+12}_{-5} \text{ GeV}$ .

3 BAAK 12A make Standard Model fits to  $Z$  and neutral current parameters,  $m_t, m_W$ , and  $\Gamma_W$  measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.

4 ERLER 10A makes Standard Model fits to  $Z$  and neutral current parameters,  $m_t, m_W$  measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.

5 LEP-SLC 06 make Standard Model fits to  $Z$  parameters from LEP/SLC and  $m_t, m_W$ , and  $\Gamma_W$  measurements available in 2005 with  $\Delta\alpha_{\text{had}}^{(5)}(m_Z) = 0.02758 \pm 0.00035$ . The 95% CL limit is 285 GeV.

### Electroweak Constraints on the Standard Model Higgs Boson Mass

Here we list constraints on the mass of the Higgs boson derived from fits to precision electroweak observables, assuming the minimal Standard Model with a doublet Higgs field and three generations of fermions.

## Gauge & Higgs Boson Particle Listings

### Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

Searches in  $e^+e^-$  collisions at and above the  $Z$  pole have conclusively ruled out the existence of a charged Higgs in the region  $m_{H^\pm} \lesssim 45$  GeV, and are meanwhile superseded by the searches in higher energy  $e^+e^-$  collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the  $e^+e^- \rightarrow H^\pm H^\mp$  process. Limits from  $b \rightarrow s\gamma$  decays are usually stronger in generic 2HDM models than in Supersymmetric models.

- AAD 15AF search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  in 19.5 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. Upper limits on  $B(t \rightarrow bH^+)B(H^+ \rightarrow \tau\nu)$  between  $2.3 \times 10^{-3}$  and  $1.3 \times 10^{-2}$  (95% CL) are given for  $m_{H^\pm} = 80\text{--}160$  GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region  $m_{H^\pm} < 140$  GeV is excluded for  $\tan\beta > 1$  in the considered scenarios.
- KHACHATRYAN 15AX search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  in 19.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 8$  TeV. Upper limits on  $B(t \rightarrow bH^+)B(H^+ \rightarrow \tau\nu)$  between  $1.2 \times 10^{-2}$  and  $1.5 \times 10^{-3}$  (95% CL) are given for  $m_{H^\pm} = 80\text{--}160$  GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region  $m_{H^\pm} < 155$  GeV is excluded for  $\tan\beta > 1$  in the considered scenarios.
- LEP 13 give a limit that refers to the Type II scenario. The limit for  $B(H^+ \rightarrow \tau\nu) = 1$  is 94 GeV (95% CL), and for  $B(H^+ \rightarrow c\bar{s}) = 1$  the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode  $H^+ \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ , which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if  $m_{A^0} > 12$  GeV.
- ABBIENDI 12 also search for the decay mode  $H^+ \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ .
- AAD 23AH search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow \ell^\pm\nu\ell^+\ell^-$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 9 for limits on cross section times branching ratio in the Georgi-Machacek model for  $m_{H^\pm} = 0.2\text{--}1.0$  TeV, and also for limits on the triplet vacuum expectation value fraction.
- AAD 23BB search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow c\bar{b}$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 8 for limits on the product of branching ratios for  $m_{H^\pm} = 60\text{--}160$  GeV.
- Charge conjugated states are also implied.
- AAD 23BW search for  $t \rightarrow bH^+$  from pair produced top quarks, with the decay chain  $H^+ \rightarrow W^+A^0, A^0 \rightarrow \mu^+\mu^-$  using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 5(b)–(d) for limits on the product of branching ratios for  $m_{H^\pm} = 120, 140, 160$  GeV, and  $m_{A^0} = 15\text{--}72$  GeV.
- TUMASYAN 23AV search for production of  $H^\pm$  in association with a top quark, decaying to  $H_2^0 W^\pm, H_2^0 \rightarrow \tau^+\tau^-$ , using 138 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 9 for limits on production cross section times branching ratios for  $m_{H^\pm} = 0.3\text{--}0.7$  TeV and  $m_{H_2^0} = 0.2$  TeV.
- TUMASYAN 22B search for production of scalar resonance decaying to  $W^\pm\gamma \rightarrow qq\gamma$  in 137 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 5 for limits on cross section times branching ratio for the mass range 0.7–6.0 TeV, assuming narrow width or  $\Gamma/M = 0.05$ .
- AAD 21V search for  $\bar{t}bH^+$  associated production followed by  $H^+ \rightarrow t\bar{b}$  in 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 6 for upper limits on cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}2$  TeV. See also their Fig. 7 for the excluded region in the parameter space of the hMSSM and the following MSSM benchmark scenarios:  $M_h^{125}, M_h^{125}(\tilde{\chi}), M_h^{125}(\tilde{\tau}), M_h^{125}(\text{alignment}), M_h^{125}(\text{CPV})$ .
- SIRUNYAN 21W search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow \ell^+\nu\ell^+\ell^-$  in 137 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 8 for limits on cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}3.0$  TeV, and also for limits on the fraction of the triplet vev contribution to the  $W$  mass in the Georgi-Machacek model.
- AAD 20W search for dijet resonances in events with isolated leptons using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. As a byproduct,  $H^+ \rightarrow t\bar{b}$  produced in association with  $\bar{t}b$  is searched for. Limits on the product of cross section times branching ratio for  $m_{H^\pm} = 0.6\text{--}2$  TeV are given in their Fig. 5(c).
- SIRUNYAN 20AO search for  $H^+ \rightarrow t\bar{b}$  produced in association with  $t(b)$  in all jet final states in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 6 for limits on the product of cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}3$  TeV. Limits for  $s$ -channel production are also given for  $m_{H^\pm} = 0.8\text{--}3$  TeV. See also Fig. 7 for the corresponding limits in scenarios in the minimal supersymmetric standard model. Cross section limits from combined results with SIRUNYAN 20AV are given in Fig. 8.
- SIRUNYAN 20AV search for  $H^+ \rightarrow t\bar{b}$  produced in association with  $t(b)$  in final states with one or two leptons, in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 5 for limits on the product of cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}3$  TeV, and their Fig. 6 for the corresponding limits in scenarios in the minimal supersymmetric standard model.
- SIRUNYAN 20BE search for  $t \rightarrow bH^+$  followed by the decay  $H^+ \rightarrow c\bar{s}$  in pair produced top quark events using 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. Limits on the branching ratio in the range 1.68–0.25% (95%CL) are given for  $m_{H^\pm} = 80\text{--}160$  GeV, see their Fig. 4.
- SIRUNYAN 19AH search for  $H^+$  in the decay of a pair-produced  $t$  quark, or in associated  $tH^+$  or nonresonant  $b\bar{b}H^+ W^-$  production, followed by  $H^+ \rightarrow \tau^+\nu$ , in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for  $m_{H^\pm} = 80\text{--}3000$  GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the  $m_h^{\text{mod-}}$  scenario of the MSSM.
- SIRUNYAN 19BP search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow \ell^+\nu\ell^+\ell^-$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 7 for limits on cross section times branching ratio for  $m_{H^\pm} = 0.3\text{--}2.0$  TeV, and also for limits on the fraction of the triplet vev contribution to the  $W$  mass in the Georgi-Machacek model.
- SIRUNYAN 19CC search for  $t \rightarrow bH^+$  from pair produced top quarks, with the decay chain  $H^+ \rightarrow W^+A^0, A^0 \rightarrow \mu^+\mu^-$  in 35.9 fb<sup>-1</sup> of  $pp$  collisions at  $E_{\text{cm}} = 13$  TeV. See their Fig. 2 for limits on the product of branching ratios for  $m_{A^0} = 15\text{--}75$  GeV.

# Gauge & Higgs Boson Particle Listings

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

- 20 SIRUNYAN 19CQ search for vector boson fusion production of  $H^+$  decaying to  $H^+ \rightarrow W^+ Z \rightarrow \ell^+ \nu q \bar{q}$  or  $q \bar{q} \ell^+ \ell^-$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on cross section times branching ratio for  $m_{H^+} = 0.6\text{--}2.0 \text{ TeV}$ , and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 21 AABOUD 18BW search for  $\bar{t}bH^+$  associated production or the decay  $t \rightarrow bH^+$ , followed by  $H^+ \rightarrow \tau^+ \nu$ , in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8(a) for upper limits on cross section times branching ratio for  $m_{H^+} = 90\text{--}2000 \text{ GeV}$ , and Fig. 8(b) for limits on  $B(t \rightarrow bH^+) B(H^+ \rightarrow \tau^+ \nu)$  for  $m_{H^+} = 90\text{--}160 \text{ GeV}$ . See also their Fig. 9 for the excluded region in the hMSSM parameter space.
- 22 AABOUD 18CD search for  $\bar{t}bH^+$  associated production followed by  $H^+ \rightarrow t\bar{b}$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for upper limits on cross section times branching ratio for  $m_{H^+} = 0.2\text{--}2 \text{ TeV}$ . See also their Fig. 9 for the excluded region in the parameter space of the  $m_h^{\text{mod-}}$  and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded  $m_{H^+}$  range are shown without their respective uncertainty band.
- 23 AABOUD 18CH search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow \ell^\pm \nu \ell^+ \ell^-$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 7 for limits on cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}0.9 \text{ TeV}$ , and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 24 HALLER 18 give 95% CL lower limits on  $m_{H^\pm}$  of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for  $B(b \rightarrow s\gamma)$ .
- 25 SIRUNYAN 18DO search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow c\bar{b}$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 3 for upper limits on  $B(t \rightarrow bH^+) B(H^+ \rightarrow c\bar{b})$  for  $m_{H^+} = 90\text{--}150 \text{ GeV}$  assuming that  $B(H^+ \rightarrow c\bar{b}) = 1$  and  $B(t \rightarrow bH^+) + B(t \rightarrow bW^+) = 1$ .
- 26 MISIAK 17 give 95% CL lower limits on  $m_{H^\pm}$  between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for  $B(b \rightarrow s(d)\gamma)$ .
- 27 SIRUNYAN 17AE search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow \ell^\pm \nu \ell^+ \ell^-$  in  $15.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio for  $m_{H^\pm} = 0.2\text{--}2.0 \text{ TeV}$ , and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 28 AABOUD 16A search for  $t(b) H^\pm$  associated production followed by  $H^\pm \rightarrow \tau^\pm \nu$  in  $3.2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Upper limits on  $\sigma(t(b) H^\pm) B(H^\pm \rightarrow \tau^\pm \nu)$  between 1.9 pb and 15 fb (95% CL) are given for  $m_{H^\pm} = 200\text{--}2000 \text{ GeV}$ , see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.
- 29 AAD 16AJ search for  $t(b) H^\pm$  associated production followed by  $H^\pm \rightarrow tb$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 6 for upper limits on  $\sigma(t(b) H^\pm) B(H^\pm \rightarrow tb)$  for  $m_{H^\pm} = 200\text{--}600 \text{ GeV}$ .
- 30 AAD 16AJ search for  $H^\pm$  production from quark-antiquark annihilation, followed by  $H^\pm \rightarrow tb$ , in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 10 for upper limits on  $\sigma(H^\pm) B(H^\pm \rightarrow tb)$  for  $m_{H^\pm} = 400\text{--}3000 \text{ GeV}$ .
- 31 AAD 15AF search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow \tau^\pm \nu$  in  $19.5 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow \tau^\pm \nu)$  between 760 and 4.5 fb (95% CL) are given for  $m_{H^\pm} = 180\text{--}1000 \text{ GeV}$ . See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.
- 32 AAD 15M search for vector boson fusion production of  $H^\pm$  decaying to  $H^\pm \rightarrow W^\pm Z \rightarrow q\bar{q}\ell^+\ell^-$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 2 for limits on cross section times branching ratio for  $m_{H^\pm} = 200\text{--}1000 \text{ GeV}$ , and Fig. 3 for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.
- 33 KHACHATRYAN 15AX search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow tb$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow t\bar{b})$  between 2.0 and 0.13 pb (95% CL) are given for  $m_{H^\pm} = 180\text{--}600 \text{ GeV}$ . See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.
- 34 KHACHATRYAN 15AX search for  $tH^\pm$  associated production followed by  $H^\pm \rightarrow \tau^\pm \nu$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . Upper limits on  $\sigma(tH^\pm) B(H^\pm \rightarrow \tau^\pm \nu)$  between 380 and 25 fb (95% CL) are given for  $m_{H^\pm} = 180\text{--}600 \text{ GeV}$ . See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.
- 35 KHACHATRYAN 15BF search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow c\bar{s}$  in  $19.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+) B(H^+ \rightarrow c\bar{s})$  between  $1.2 \times 10^{-2}$  and  $6.5 \times 10^{-2}$  (95% CL) are given for  $m_{H^+} = 90\text{--}160 \text{ GeV}$ .
- 36 AAD 14M search for the decay cascade  $H_2^0 \rightarrow H^\pm W^\mp \rightarrow H^0 W^\pm W^\mp, H^0$  decaying to  $b\bar{b}$  in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Table III for limits on cross section times branching ratio for  $m_{H_2^0} = 325\text{--}1025 \text{ GeV}$  and  $m_{H^\pm} = 225\text{--}925 \text{ GeV}$ .
- 37 AALTONEN 14A measure  $B(t \rightarrow b\tau\nu) = 0.096 \pm 0.028$  using  $9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . For  $m_{H^\pm} = 80\text{--}140 \text{ GeV}$ , this measured value is translated to a limit  $B(t \rightarrow bH^+) < 0.059$  at 95% CL assuming  $B(H^+ \rightarrow \tau^+ \nu) = 1$ .
- 38 AAD 13AC search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow c\bar{s}$  (flavor unidentified) in  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.05 and 0.01 (95%CL) are given for  $m_{H^+} = 90\text{--}150 \text{ GeV}$  and  $B(H^+ \rightarrow c\bar{s}) = 1$ .
- 39 AAD 13V search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$  through violation of lepton universality with  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.032 and 0.044 (95% CL) are given for  $m_{H^+} = 90\text{--}140 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+ \nu) = 1$ . By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for  $m_{H^+} = 90\text{--}160 \text{ GeV}$ . See their Fig. 7 for the excluded region in the  $m_h^{\text{max}}$  scenario of the MSSM.
- 40 AAD 12BH search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$  with  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.01 and 0.05 (95% CL) are given for  $m_{H^+} = 90\text{--}160 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+ \nu) = 1$ . See their Fig. 8 for the excluded region in the  $m_h^{\text{max}}$  scenario of the MSSM.
- 41 CHATRCHYAN 12AA search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$  with  $2 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.019 and 0.041 (95% CL) are given for  $m_{H^+} = 80\text{--}160 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+ \nu) = 1$ .
- 42 AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+ A^0, A^0 \rightarrow \tau^+ \tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160 \text{ GeV}$ .
- 43 DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays,  $b \rightarrow s\gamma, B, B_s$  mixings, and  $Z \rightarrow b\bar{b}$ . The limit holds irrespective of  $\tan\beta$ .
- 44 AALTONEN 09AJ search for  $t \rightarrow bH^+, H^+ \rightarrow c\bar{s}$  in  $t\bar{t}$  events in  $2.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.08 and 0.32 (95% CL) are given for  $m_{H^+} = 60\text{--}150 \text{ GeV}$  and  $B(H^+ \rightarrow c\bar{s}) = 1$ .
- 45 ABAZOV 09AC search for  $t \rightarrow bH^+, H^+ \rightarrow \tau^+ \nu$  in  $t\bar{t}$  events in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.19 and 0.25 (95% CL) are given for  $m_{H^+} = 80\text{--}155 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+ \nu) = 1$ . See their Fig. 4 for an excluded region in a MSSM scenario.
- 46 ABAZOV 09AG measure  $t\bar{t}$  cross sections in final states with  $\ell + \text{jets}$  ( $\ell = e, \mu$ ),  $\ell\ell$ , and  $\tau\ell$  in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ , which constrains possible  $t \rightarrow bH^+$  branching fractions. Upper limits (95% CL) on  $B(t \rightarrow bH^+)$  between 0.15 and 0.40 (0.48 and 0.57) are given for  $B(H^+ \rightarrow \tau^+ \nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ .
- 47 ABAZOV 09AI search for  $t \rightarrow bH^+$  in  $t\bar{t}$  events in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Final states with  $\ell + \text{jets}$  ( $\ell = e, \mu$ ),  $\ell\ell$ , and  $\tau\ell$  are examined. Upper limits on  $B(t \rightarrow bH^+)$  (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for  $B(H^+ \rightarrow \tau^+ \nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . For  $B(H^+ \rightarrow \tau^+ \nu) = 1$  also a simultaneous extraction of  $B(t \rightarrow bH^+)$  and the  $t\bar{t}$  cross section is performed, yielding a limit on  $B(t \rightarrow bH^+)$  between 0.12 and 0.26 for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . See their Figs. 5–8 for excluded regions in several MSSM scenarios.
- 48 ABAZOV 09P search for  $H^+$  production by  $q\bar{q}$  annihilation followed by  $H^+ \rightarrow t\bar{b}$  decay in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Cross section limits in several two-doublet models are given for  $m_{H^+} = 180\text{--}300 \text{ GeV}$ . A region with  $20 \lesssim \tan\beta \lesssim 70$  is excluded (95% CL) for  $180 \text{ GeV} \lesssim m_{H^+} \lesssim 184 \text{ GeV}$  in type-I models.
- 49 ABULENCIA 06E search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A fit is made for  $t\bar{t}$  production processes in dilepton, lepton + jets, and lepton +  $\tau$  final states, with the decays  $t \rightarrow W^+ b$  and  $t \rightarrow H^+ b$  followed by  $H^+ \rightarrow \tau^+ \nu, c\bar{s}, t^* \bar{b}$ , or  $W^+ H^0$ . Within the MSSM the search is sensitive to the region  $\tan\beta < 1$  or  $> 30$  in the mass range  $m_{H^\pm} = 80\text{--}160 \text{ GeV}$ . See Fig. 2 for the excluded region in a certain MSSM scenario.
- 50 ABDALLAH 04 search for  $e^+ e^- \rightarrow H^+ H^-$  with  $H^\pm$  decaying to  $\tau\nu, cs$ , or  $W^* A^0$  in Type-I two-Higgs-doublet models.
- 51 ABBIENDI 03 give a limit  $m_{H^\pm} > 1.28 \tan\beta \text{ GeV}$  (95%CL) in Type II two-doublet models.
- 52 ABAZOV 02B search for a charged Higgs boson in top decays with  $H^+ \rightarrow \tau^+ \nu$  at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . For  $m_{H^+} = 75 \text{ GeV}$ , the region  $\tan\beta > 32.0$  is excluded at 95%CL. The excluded mass region extends to over 140 GeV for  $\tan\beta$  values above 100.
- 53 BORZUMATI 02 point out that the decay modes such as  $b\bar{b}W, A^0 W$ , and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.
- 54 ABBIENDI 01Q give a limit  $\tan\beta/m_{H^\pm} < 0.53 \text{ GeV}^{-1}$  (95%CL) in Type II two-doublet models.
- 55 BARATE 01E give a limit  $\tan\beta/m_{H^\pm} < 0.40 \text{ GeV}^{-1}$  (90% CL) in Type II two-doublet models. An independent measurement of  $B \rightarrow \tau\nu X$  gives  $\tan\beta/m_{H^\pm} < 0.49 \text{ GeV}^{-1}$  (90% CL).
- 56 GAMBINO 01 use the world average data in the summer of 2001  $B(b \rightarrow s\gamma) = (3.23 \pm 0.42) \times 10^{-4}$ . The limit applies for Type-II two-doublet models.
- 57 AFFOLDER 00i search for a charged Higgs boson in top decays with  $H^+ \rightarrow \tau^+ \nu$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . The excluded mass region extends to over 120 GeV for  $\tan\beta$  values above 100 and  $B(\tau\nu) = 1$ . If  $B(t \rightarrow bH^+) \gtrsim 0.6$ ,  $m_{H^+}$  up to 160 GeV is excluded. Updates ABE 97L.
- 58 ABBOTT 99 search for a charged Higgs boson in top decays in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ , by comparing the observed  $t\bar{t}$  cross section (extracted from the data assuming the dominant decay  $t \rightarrow bW^+$ ) with theoretical expectation. The search is sensitive to regions of the domains  $\tan\beta \lesssim 1, 50 < m_{H^\pm} (\text{GeV}) \lesssim 120$  and  $\tan\beta \gtrsim 40, 50 < m_{H^\pm} (\text{GeV}) \lesssim 160$ . See Fig. 3 for the details of the excluded region.
- 59 ACKERSTAFF 99D measure the Michel parameters  $\rho, \xi, \eta$ , and  $\xi\delta$  in leptonic  $\tau$  decays from  $Z \rightarrow \tau\tau$ . Assuming  $e\text{--}\mu$  universality, the limit  $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$  (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.
- 60 ACCIARRI 97F give a limit  $m_{H^\pm} > 2.6 \tan\beta \text{ GeV}$  (90% CL) from their limit on the exclusive  $B \rightarrow \tau\nu X$  branching ratio.
- 61 AMMAR 97B measure the Michel parameter  $\rho$  from  $\tau \rightarrow e\nu\nu$  decays and assumes  $e\text{--}\mu$  universality to extract the Michel  $\eta$  parameter from  $\tau \rightarrow \mu\nu\nu$  decays. The measurement is translated to a lower limit on  $m_{H^\pm}$  in a two-doublet model  $m_{H^\pm} > 0.97 \tan\beta \text{ GeV}$  (90% CL).
- 62 COARASA 97 reanalyzed the constraint on the  $(m_{H^\pm}, \tan\beta)$  plane derived from the inclusive  $B \rightarrow \tau\nu X$  branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- 63 GUCHAIT 97 studies the constraints on  $m_{H^\pm}$  set by Tevatron data on  $\ell\tau$  final states in  $t\bar{t} \rightarrow (Wb)(Hb), W \rightarrow \ell\nu, H \rightarrow \tau\nu$ . See Fig. 2 for the excluded region.
- 64 MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large  $B_c \rightarrow \tau\nu X$  background to  $B_H \rightarrow \tau\nu X$  decays. Stronger limits are obtained.
- 65 STAHL 97 fit  $\tau$  lifetime, leptonic branching ratios, and the Michel parameters and derive limit  $m_{H^\pm} > 1.5 \tan\beta \text{ GeV}$  (90% CL) for a two-doublet model. See also STAHL 94.
- 66 ALAM 95 measure the inclusive  $b \rightarrow s\gamma$  branching ratio at  $T(4S)$  and give  $B(b \rightarrow s\gamma) < 4.2 \times 10^{-4}$  (95% CL), which translates to the limit  $m_{H^\pm} > [244 + 63/(\tan\beta)]^{1.3}$

See key on page 1171

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.  
 67 BUSKULIC 95 give a limit  $m_{H^\pm} > 1.9 \tan\beta$  GeV (90% CL) for Type-II models from  $b \rightarrow \tau\nu_\tau X$  branching ratio, as proposed in GROSSMAN 94.

### $H^\pm$ (charged Higgs) mass limits for $m_{H^\pm} > m(\text{top})$

Limits obtained at the LHC are given in the  $m_{H^\pm}^{\text{mod-}}$  benchmark scenario, see CARENA 13, and depend on the  $\tan\beta$  values.

1 AABOUD 18BW search for  $\bar{t}bH^\pm$  associated production in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See also their Fig. 9 for the excluded region in the hMSSM parameter space.

### $H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin  $T_3$  is thus restricted to two possibilities depending on lepton chiralities:  $T_3(H^{\pm\pm}) = \pm 1$ , with the coupling  $g_{\ell\ell}$  to  $\ell_L^- \ell_L^-$  and  $\ell_R^+ \ell_R^+$  ("left-handed") and  $T_3(H^{\pm\pm}) = 0$ , with the coupling to  $\ell_R^- \ell_R^-$  and  $\ell_L^+ \ell_L^+$  ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group  $SU(2)_L \times SU(2)_R \times U(1)$ , the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

1 AAD 23AI search for  $H^{++}H^{--}$  production using  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . Decay branching ratios  $B(H^{++} \rightarrow \ell^+ \ell'^+)$  for the six flavor combinations are assumed to be equal, adding up to unity. If the  $T_3 = 0$  states are degenerate with the  $T_3 = \pm 1$  states, the limit becomes 1080 GeV.

2 AABOUD 19K search for pair production of  $H^{++}H^{--}$  followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm$  in  $36.1 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to  $B(H^{\pm\pm} \rightarrow W^\pm W^\pm) = 1$ . See their Fig. 5 for limits on the cross section for  $m_{H^{++}}$  between 200 and 700 GeV.

3 See their Figs. 11(b) and 13 for limits with smaller branching ratios.

4 AAD 15AG search for  $H^{++}H^{--}$  production in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

5 AAD 15AP search for  $H^{++}H^{--}$  production in  $20.3 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.

6 CHATRCHYAN 12AU search for  $H^{++}H^{--}$  production with  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated  $H^{++}H^{--}$  production or assuming different scenarios.

7 ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+ \tau^+$ , or decaying outside the detector.

8 ABBIENDI 02c searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm \ell'^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ). The limit holds for  $\ell = \ell' = \tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .

9 AAD 21u search for pair production of  $H^{++}H^{--}$  followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to  $B(H^{\pm\pm} \rightarrow W^\pm W^\pm) = 1$ . See their Fig. 9(a) for limits on the cross section for  $m_{H^{++}}$  between 200 and 600 GeV.

10 AAD 21u search for associated production of  $H^{\pm\pm}H^\mp$  followed by the decays  $H^{\pm\pm} \rightarrow W^\pm W^\pm, H^\pm \rightarrow W^\pm Z$  in  $139 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ .  $H^{\pm\pm}$  and  $H^\pm$  are assumed to be degenerate in mass within 5 GeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to  $B(H^{\pm\pm} \rightarrow W^\pm W^\pm) = 1$ . See their Fig. 9(b) for limits on the cross section for  $m_{H^{++}}$  between 200 and 600 GeV.

11 SIRUNYAN 21w search for vector boson fusion production of  $H^{\pm\pm}$  decaying to  $H^{\pm\pm} \rightarrow W^\pm W^\pm \rightarrow \ell^\pm \nu \ell'^\pm \nu$  in  $137 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 8 for limits on cross section times branching ratio for  $m_{H^{++}}$  between 160 and 800 GeV.

12 SIRUNYAN 19cQ search for  $H^{\pm\pm}$  production by vector boson fusion followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm \rightarrow qq\ell\nu$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 5 for limits on cross section times branching ratio for  $m_{H^{\pm\pm}}$  between 0.6 and 2 TeV.

13 SIRUNYAN 18cc search for  $H^{\pm\pm}$  production by vector boson fusion followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm$  in  $35.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 13 \text{ TeV}$ . See their Fig. 3 for limits on cross section times branching ratio for  $m_{H^{\pm\pm}}$  between 200 and 1000 GeV.

14 KANEMURA 15 examine the case where  $H^{++}$  decays preferentially to  $W^{(*)}W^{(*)}$  and estimate that a lower mass limit of  $\sim 84 \text{ GeV}$  can be derived from the same-sign dilepton data of AAD 15AG if  $H^{++}$  decays with 100% branching ratio to  $W^{(*)}W^{(*)}$ .

15 KHACHATRYAN 15D search for  $H^{\pm\pm}$  production by vector boson fusion followed by the decay  $H^{\pm\pm} \rightarrow W^\pm W^\pm$  in  $19.4 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 8 \text{ TeV}$ . See their Fig. 4 for limits on cross section times branching ratio for  $m_{H^{++}}$  between 160 and 800 GeV.

16 KANEMURA 14 examine the case where  $H^{++}$  decays preferentially to  $W^{(*)}W^{(*)}$  and estimate that a lower mass limit of  $\sim 60 \text{ GeV}$  can be derived from the same-sign dilepton data of AAD 12cy.

17 AAD 13y search for  $H^{++}H^{--}$  production in a generic search of events with three charged leptons in  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.

18 AAD 12AY search for  $H^{++}H^{--}$  production with  $1.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.

19 AAD 12CQ search for  $H^{++}H^{--}$  production with  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

20 ABAZOV 12A search for  $H^{++}H^{--}$  production in  $7.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .

21 AALTONEN 11AF search for  $H^{++}H^{--}$  production in  $6.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.

22 AALTONEN 08AA search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.

23 ABAZOV 08v search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.

24 AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+ \mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141 \text{ GeV}$  (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.

25 ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\bar{p}$  collisions. The limit is valid for  $g_{\ell\ell} < 10^{-8}$  so that the Higgs decays outside the detector.

26 ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm \mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .

27 ABBIENDI 03q searches for single  $H^{\pm\pm}$  via direct production in  $e^+ e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via  $t$ -channel exchange in  $e^+ e^- \rightarrow e^+ e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160 \text{ GeV}$  (see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2 \text{ TeV}$  (see Fig. 8).

# Gauge & Higgs Boson Particle Listings

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

- <sup>28</sup> GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\overline{M}}/G_F < 0.14$  (90% CL), where  $G_{M\overline{M}}$  is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to  $m_{H^{++}} > 210$  GeV if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- <sup>29</sup> ASAKA 95 point out that  $H^{++}$  decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.
- <sup>30</sup> ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.
- <sup>31</sup> ACTON 92M from  $\Delta\Gamma_Z < 40$  MeV.
- <sup>32</sup> SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

(see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2$  TeV (see Fig. 8).

- <sup>17</sup> GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\overline{M}}/G_F < 0.14$  (90% CL), where  $G_{M\overline{M}}$  is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to  $m_{H^{++}} > 210$  GeV if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- <sup>18</sup> ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.
- <sup>19</sup> ACTON 92M from  $\Delta\Gamma_Z < 40$  MeV.
- <sup>20</sup> SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

- 1 AAD 23AI search for  $H^{++}H^{--}$  production using 139 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 13$  TeV. Decay branching ratios  $B(H^{++} \rightarrow \ell^+\ell^+)$  for the six flavor combinations are assumed to be equal, adding up to unity.
- 2 See their Figs. 12(b) and 14 for limits with smaller branching ratios.
- 3 AAD 15AG search for  $H^{++}H^{--}$  production in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.
- 4 AAD 15AP search for  $H^{++}H^{--}$  production in 20.3 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 8$  TeV. The limit assumes 100% branching ratio to the specified final state.
- 5 ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+\tau^+$ , or decaying outside the detector.
- 6 ACHARD 03F search for  $e^+e^- \rightarrow H^{++}H^{--}$  with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$ . The limit holds for  $\ell = e, \mu, \tau$ , and slightly different limits apply for other flavor combinations. The limit is valid for  $g_{\ell\ell} \gtrsim 10^{-7}$ .
- 7 ABBIENDI 02C searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ). the limit holds for  $\ell = \ell' = \tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .
- 8 AAD 12AY search for  $H^{++}H^{--}$  production with 1.6 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit assumes 100% branching ratio to the specified final state.
- 9 AAD 12CQ search for  $H^{++}H^{--}$  production with 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.
- 10 ABAZOV 12A search for  $H^{++}H^{--}$  production in 7.0 fb<sup>-1</sup> of  $p\overline{p}$  collisions at  $E_{cm} = 1.96$  TeV.
- 11 AALTONEN 11AF search for  $H^{++}H^{--}$  production in 6.1 fb<sup>-1</sup> of  $p\overline{p}$  collisions at  $E_{cm} = 1.96$  TeV.
- 12 ABAZOV 08V search for  $H^{++}H^{--}$  production in  $p\overline{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.
- 13 AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+\mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141$  GeV (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.
- 14 ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\overline{p}$  collisions. The limit is valid for  $g_{\ell\ell} < 10^{-8}$  so that the Higgs decays outside the detector.
- 15 ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm\mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .
- 16 ABBIENDI 03Q searches for single  $H^{\pm\pm}$  via direct production in  $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via  $t$ -channel exchange in  $e^+e^- \rightarrow e^+e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160$  GeV

Gauge & Higgs Boson Particle Listings
Charged Higgs Bosons (H± and H±±), Searches for, New Heavy Bosons

Table with 4 columns: Author(s), Year, Publication, and Contact Info. Includes GROSSMAN, STAHL, ACTON, SWARTZ, Y. Grossman, H. Haber, Y. Nir, A. Stahl, P.D. Acton et al., M.L. Swartz et al.

New Heavy Bosons (W', Z', leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axiguons. The latest unpublished results are described in "W' Searches" and "Z' Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

CONTENTS:

W'-Boson Searches

MASS LIMITS for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from p-pbar or pp -> W'X with W' decaying to the mode indicated in the comments. New decay channels (e.g., W' -> WZ) are assumed to be suppressed. The most recent preliminary results can be found in the "W'-boson searches" review above.

Table with 5 columns: VALUE (GeV), CL%, DOCUMENT ID, TECN, COMMENT. Lists mass limits for W' decays to various particles like WZ, tb, ZX, WH, etc.

Main table listing experimental searches for W' bosons. Columns include search number, author(s), experiment, and decay mode. Includes entries like 24 AABOUD 18AF ATLS W' -> tb, 25 AABOUD 18AI ATLS W' -> WH, etc.

••• We do not use the following data for averages, fits, limits, etc. •••

- 1 AAD 23AH search for resonances produced through Drell-Yan and vector-boson-fusion processes in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 7 and Fig. 8 for limits on  $\sigma \cdot B$ . The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$  produced mainly via Drell-Yan.
- 2 AAD 23CC search for resonances decaying to  $tb$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for right-handed  $W'$  assuming a  $W'$  coupling equal to the SM  $W$  coupling. The limit becomes  $M_{W'} > 4200$  GeV for left-handed  $W'$ . See their Figs. 12 and 13 for limits on  $\sigma \cdot B$ .
- 3 AAD 23L perform a generic search for resonances with events containing a  $Z$  decaying into  $e^+e^-$  or  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Figs. 6, 7, 8 for model independent limits on  $\sigma \cdot B$  for Gaussian-shaped resonances. The limit above is for heavy-vector-triplet  $W'$  decaying to  $WZ$  with  $g_V = 3$  as well as with  $g_V = 1$ .
- 4 AAD 23O search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2950$  GeV for  $g_V = 1$ .
- 5 TUMASYAN 23AP search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 4.8$  TeV assuming  $M_{W'} = M_{Z'}$ , and combining  $W' \rightarrow WZ, W' \rightarrow WH, Z' \rightarrow WW, Z' \rightarrow ZH$  channels.
- 6 TUMASYAN 23AP search for resonances decaying to  $WH$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 4.8$  TeV assuming  $M_{W'} = M_{Z'}$ , and combining  $W' \rightarrow WZ, W' \rightarrow WH, Z' \rightarrow WW, Z' \rightarrow ZH$  channels.
- 7 TUMASYAN 23AW search for SSM  $W'$  resonance decaying to  $\tau\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W-W'$  interference and bosonic decays of  $W'$  are not included. See their Fig. 6 for limits on  $\sigma \cdot B$ .
- 8 TUMASYAN 22Ac search for  $W'$  with SM-like couplings in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The diboson decays of  $W'$  are assumed to be suppressed. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 9 TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limits on  $\sigma \cdot B$ . The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$  produced mainly via Drell-Yan.
- 10 TUMASYAN 22J search for resonances produced through Drell-Yan and vector-boson-fusion processes in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ , produced mainly via Drell-Yan. See their Fig. 9 for limits on  $\sigma \cdot B$ .
- 11 TUMASYAN 22R search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  produced mainly via Drell-Yan. See their Fig. 8 for limits on  $\sigma \cdot B$ .
- 12 SIRUNYAN 21Y search for resonances decaying to  $tb$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 2 for limits on  $\sigma \cdot B(W' \rightarrow tb)$ .
- 13 AAD 20Aj search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2900$  GeV for  $g_V = 1$ . See their Fig. 6 for limits on  $\sigma \cdot B$ .
- 14 AAD 20AT search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 3900$  GeV for  $g_V = 1$ . See their Fig. 13 for limits on  $\sigma \cdot B$ .
- 15 AAD 20T search for  $W'$  with SM-like couplings in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 4(c) for limits on the product of the cross section, acceptance, and branching fraction.
- 16 SIRUNYAN 20Ai limit is for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 17 SIRUNYAN 20q search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ .
- 18 AABOUD 19E search for right-handed  $W'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limit on  $\sigma \cdot B$ .
- 19 AAD 19c search for  $W'$  with SM-like couplings in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Bosonic decays and  $W-W'$  interference are neglected. The limits on  $e$  and  $\mu$  separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on  $\sigma \cdot B$ .
- 20 AAD 19b search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 3400$  GeV for  $g_V = 1$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{W'} > 3800$  GeV and  $M_{W'} > 3500$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 9 for limits on  $\sigma \cdot B$ .

- 21 SIRUNYAN 19AY limits shown for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W-W'$  interference and bosonic decays of  $W'$  are not included. See their Fig. 5 for limits on  $\sigma \cdot B$ . Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on  $\sigma \cdot BA\epsilon$  can be seen in Fig. 8.
- 22 SIRUNYAN 19CP present a statistical combinations of searches for  $W'$  decaying to pairs of bosons or leptons in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . If we assume  $M_{W'} = M_{Z'}$ , the limit becomes  $M_{W'} > 4500$  GeV for  $g_V = 3$  and  $M_{W'} > 5000$  GeV for  $g_V = 1$ . See their Figs. 2 and 3 for limits on  $\sigma \cdot B$ .
- 23 SIRUNYAN 19I search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2800$  GeV if we assume  $M_{W'} = M_{Z'}$ .
- 24 AABOUD 18AF give the limit above for right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. These limits also exclude  $W$  bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level.  $W' \rightarrow \ell\nu_R$  is assumed to be forbidden. See their Fig. 5 for limits on  $\sigma \cdot B$  for both cases of left- and right-handed  $W'$ .
- 25 AABOUD 18Ai search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2670$  GeV for  $g_V = 1$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{W'} > 2930$  GeV and  $M_{W'} > 2800$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 26 AABOUD 18AK search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2800$  GeV for  $g_V = 1$ .
- 27 AABOUD 18AL search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2900$  GeV for  $g_V = 1$ .
- 28 AABOUD 18BG limit is for  $W'$  with SM-like couplings using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Bosonic decays of  $W'$  and  $W-W'$  interference are neglected. See Fig. 2 for limits on  $\sigma \cdot B$ .
- 29 AABOUD 18CH search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2260$  GeV for  $g_V = 1$ .
- 30 AABOUD 18F search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 3000$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{W'} > 3500$  GeV and  $M_{W'} > 3100$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 31 AABOUD 18K limit is for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W-W'$  interference and bosonic decays of  $W'$  are not included. See their Fig. 4 for limit on  $\sigma \cdot B$ .
- 32 SIRUNYAN 18I limit is for right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W' \rightarrow \ell\nu_R$  decay is assumed to be forbidden. The limit becomes  $M_{W'} > 3.4$  TeV if  $M_{\nu_R} \ll M_{W'}$ . See their Fig. 5 for exclusion limits on  $W'$  models having both left- and right-handed couplings.
- 33 SIRUNYAN 18AX search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . See their Fig. 6 for limits on  $\sigma \cdot B$ .
- 34 SIRUNYAN 18AZ limit is derived for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. No interference with SM  $W$  process is considered. The bosonic decays are assumed to be negligible. See their Fig. 6 for limits on  $\sigma \cdot B$ .
- 35 SIRUNYAN 18BK search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 3100$  GeV for  $g_V = 1$ .
- 36 SIRUNYAN 18Bo limit is for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 37 SIRUNYAN 18Dj search for resonances decaying to  $WZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2270$  GeV for  $g_V = 1$ .
- 38 SIRUNYAN 18ED search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{W'} > 2900$  GeV and  $M_{W'} > 2800$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively.
- 39 SIRUNYAN 18P give this limit for a heavy-vector-triplet  $W'$  with  $g_V = 3$ . If they assume  $M_{Z'} = M_{W'}$ , the limit increases to  $M_{W'} > 3800$  GeV.
- 40 AABOUD 17AK search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above is for a  $W'$  boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.
- 41 AABOUD 17Ao search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a  $W'$  in the heavy-vector-triplet model with  $g_V = 3$ . See their Fig. 4 for limits on  $\sigma \cdot B$ .
- 42 AABOUD 17B search for resonances decaying to  $HW$  ( $H \rightarrow b\bar{b}, c\bar{c}; W \rightarrow \ell\nu$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 1750$  GeV for  $g_V = 1$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{W'} > 2310$  GeV and  $M_{W'} > 1730$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 3 for limits on  $\sigma \cdot B$ .
- 43 KHACHATRYAN 17J search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\tau$  and hypothetical heavy neutrino  $N_\tau$ , with  $N_\tau$  decaying into  $\tau j$ . The quoted limit is for  $M_{N_\tau} = M_{W_R}/2$ . The limit becomes  $M_{W_R} > 2350$  GeV (1630 GeV) for  $M_{W_R}/M_{N_\tau} = 0.8$  (0.2). See their Fig. 4 for excluded regions in the  $M_{W_R}-M_{N_\tau}$  plane.
- 44 KHACHATRYAN 17w search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 45 KHACHATRYAN 17z limit is for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The bosonic decays of  $W'$  and the interference with SM  $W$  process are neglected.
- 46 SIRUNYAN 17A search for resonances decaying to  $WZ$  with  $WZ \rightarrow \ell\nu q\bar{q}, q\bar{q}q\bar{q}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V$

See key on page 1171

## Gauge & Higgs Boson Particle Listings New Heavy Bosons

- = 3. The limit becomes  $M_{W'} > 2000$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{W'} > 2400$  GeV and  $M_{W'} > 2300$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig.6 for limits on  $\sigma \cdot B$ .
- 47 SIRUNYAN 17AK search for resonances decaying to  $WZ$  or  $HW$  in  $pp$  collisions at  $\sqrt{s} = 8$  and 13 TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . The limit becomes  $M_{W'} > 2300$  GeV for  $g_V = 1$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{W'} > 2400$  GeV for both  $g_V = 3$  and  $g_V = 1$ . See their Fig.1 and 2 for limits on  $\sigma \cdot B$ .
- 48 SIRUNYAN 17H search for right-handed  $W'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W'$  is assumed to decay into  $\tau$  and a heavy neutrino  $N$ , with  $N$  decaying to  $\tau q \bar{q}$ . The limit above assumes  $M_N = M_{W'}/2$ .
- 49 SIRUNYAN 17I limit is for a right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit becomes  $M_{W'} > 2400$  GeV for  $M_{\nu R} \ll M_{W'}$ .
- 50 SIRUNYAN 17R search for resonances decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ . Mass regions  $M_{W'} < 2370$  GeV and  $2870 < M_{W'} < 2970$  GeV are excluded for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the excluded mass regions are  $1000 < M_{W'} < 2500$  GeV and  $2760 < M_{W'} < 3300$  GeV for  $g_V = 3$ ;  $1000 < M_{W'} < 2430$  GeV and  $2810 < M_{W'} < 3130$  GeV for  $g_V = 1$ . See their Fig.5 for limits on  $\sigma \cdot B$ .
- 51 AABOUD 16AE search for resonances decaying to  $VV$  ( $V = W$  or  $Z$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Results from  $\nu\nu q\bar{q}$ ,  $\nu\ell q\bar{q}$ ,  $\ell\ell q\bar{q}$  and  $qqq\bar{q}$  final states are combined. The quoted limit is for a heavy-vector-triplet  $W'$  with  $g_V = 3$  and  $M_{W'} = M_{Z'}$ .
- 52 AABOUD 16V limit is for  $W'$  with SM-like coupling using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The bosonic decays of  $W'$  and the interference with SM  $W$  process are neglected.
- 53 AAD 16R search for  $W' \rightarrow WZ$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $\ell\nu\ell'\ell'$ ,  $\ell\ell q\bar{q}$ ,  $\ell\nu q\bar{q}$ , and all hadronic channels are combined. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 54 AAD 16S search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a  $W'$  having SM-like couplings to quarks.
- 55 KHACHATRYAN 16AO limit is for a SM-like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit combines  $t \rightarrow q\bar{q}b$  and  $t \rightarrow \ell\nu b$  events.
- 56 KHACHATRYAN 16AP search for a resonance decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. Both  $H$  and  $W$  are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$ .
- 57 KHACHATRYAN 16BD search for resonance decaying to  $HW$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit is for heavy-vector-triplet (HVT)  $W'$  with  $g_V = 3$ . The HVT model  $m_{W'} = m_{Z'} > 1.8$  TeV is also obtained by combining  $W'/Z' \rightarrow WH/ZH \rightarrow \ell\nu b\bar{b}$ ,  $qq\tau\tau$ ,  $qqb\bar{b}$ , and  $qqqq\bar{q}q$  channels.
- 58 KHACHATRYAN 16K search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 59 KHACHATRYAN 16L search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.
- 60 KHACHATRYAN 16O limit is for  $W'$  having universal couplings. Interferences with the SM amplitudes are assumed to be absent.
- 61 AAD 15AU search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow q\bar{q}'$ ,  $Z \rightarrow \ell^+\ell^-$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 62 AAD 15AV limit is for a SM like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- 63 AAD 15AZ search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 64 AAD 15CP search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 65 AAD 15R limit is for a SM like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- 66 AAD 15V search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 67 KHACHATRYAN 15C search for  $W'$  decaying via  $WZ$  to fully leptonic final states using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = M_W M_Z/M_{W'}^2$ .
- 68 KHACHATRYAN 15T limit is for  $W'$  with SM-like coupling which interferes the SM  $W$  boson constructively using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. For  $W'$  without interference, the limit becomes  $> 3280$  GeV.
- 69 KHACHATRYAN 14O search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell j \bar{j}$ . The quoted limit is for  $M_{\nu eR} = M_{\nu \mu R} = M_{W_R}/2$ . See their Fig. 3 and Fig. 5 for excluded regions in the  $M_{W_R} - M_\nu$  plane.
- 70 AAD 23BF search for  $W'$  decaying to  $WZ'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The mass difference between  $W'$  and  $Z'$  is assumed to be 250 GeV. See their Fig. 9(a) for limits on  $\sigma \cdot B$  as a function of  $M_{W'}$ .
- 71 AAD 23CG search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell j \bar{j}$ . See their Fig. 9 for limits in  $m_N - m_{W_R}$  plane.
- 72 AAD 23CK search for a new resonance decaying to  $HX$  ( $H \rightarrow b\bar{b}$ ,  $X \rightarrow q\bar{q}'$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 12 for limits on  $\sigma \cdot B$ .
- 73 AAD 23U search for a narrow charged vector boson decaying to  $W\gamma$ . See their Fig. 8(d) for the exclusion limit in  $m_{W'} - \sigma \cdot B$  plane.
- 74 TUMASYAN 22 search for KK excited  $W$  decaying in cascade to three  $W$  via a scalar radion  $R$ . See their Fig. 4 for limits in  $M_{W'} - M_R$  plane.
- 75 TUMASYAN 22AL search for resonances decaying to  $tB$  or  $bT$  with vector-like quarks  $B$  ( $T$ ) subsequently decaying to  $bH$  or  $bZ$  ( $tH$  or  $tZ$ ). See their Fig. 7 for limits on  $\sigma \cdot B$ .
- 76 TUMASYAN 22B search for a narrow charged vector boson decaying to  $W\gamma$ . See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 77 TUMASYAN 22I search for KK excited  $W$  decaying in cascade to three  $W$  via a scalar radion  $R$ . See their Fig. 10 for limits in  $M_{W'} - M_R$  plane.
- 78 TUMASYAN 22P search for right handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying to  $\ell j \bar{j}$ . See their Fig. 7 for excluded regions in  $M_{W_R} - M_N$  plane.
- 79 AAD 20AD search for a narrow resonance decaying to a pair of large-radius-jets  $J_1$  and  $J_2$  employing a machine-learning procedure. See their Fig. 3 for limits on  $\sigma \cdot B$  depending on assumptions about invariant masses for  $J_1$ ,  $J_2$ , and  $J_1 J_2$ .
- 80 AAD 20W search for  $W'$  decaying to  $WZ'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 5(b) for limits on  $\sigma \cdot B$  as a function of  $m_{Z'}$ . The  $W' \rightarrow WZ'$  branching fraction was chosen to be 0.5 and the mass difference between the  $W'$  and  $Z'$  was set to 250 GeV.
- 81 AABOUD 19B search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying to  $\ell j \bar{j}$ . See their Figs. 7 and 8 for excluded regions in  $M_{W_R} - M_N$  plane.
- 82 AABOUD 19BB search for right handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\ell$  and a boosted hypothetical heavy neutrino  $N$ , with  $N$  decaying to  $\ell$  and a large radius jet  $j = q\bar{q}$ . See their Fig. 7 for excluded regions in  $M_{W_R} - M_N$  plane.
- 83 SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner  $B$  decaying to  $Hb$  (or a bottom quark and a heavy vector-like top partner  $T$  decaying to  $Ht$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limits on  $\sigma \cdot B$ .
- 84 AABOUD 18AA search for a narrow charged vector boson decaying to  $W\gamma$ . See their Fig. 9 for the exclusion limit in  $M_{W'} - \sigma \cdot B$  plane.
- 85 AABOUD 18AD search for resonances decaying to  $HX$  ( $H \rightarrow b\bar{b}$ ,  $X \rightarrow q\bar{q}'$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Figs. 3-5 for limits on  $\sigma \cdot B$ .
- 86 AABOUD 18CJ search for heavy-vector-triplet  $W'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for model with  $g_V = 3$  assuming  $M_{W'} = M_{Z'}$ . The limit becomes  $M_{W'} > 5500$  GeV for model with  $g_V = 1$ .
- 87 SIRUNYAN 18CV search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying to  $\ell j \bar{j}$ . The quoted limit is for  $M_N = M_{W_R}/2$ . See their Fig. 6 for excluded regions in the  $M_{W_R} - M_N$  plane.
- 88 KHACHATRYAN 17U search for resonances decaying to  $HW$  ( $H \rightarrow b\bar{b}$ ;  $W \rightarrow \ell\nu$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit on the heavy-vector-triplet model is  $M_{Z'} = M_{W'} > 2$  TeV for  $g_V = 3$ , in which constraints from the  $Z' \rightarrow HZ$  ( $H \rightarrow b\bar{b}$ ;  $Z \rightarrow \ell^+\ell^-$ ,  $\nu\bar{\nu}$ ) are combined. See their Fig.3 and Fig.4 for limits on  $\sigma \cdot B$ .
- 89 AAD 15BB search for  $W'$  decaying into  $WH$  with  $W \rightarrow \ell\nu$ ,  $H \rightarrow b\bar{b}$ . See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.
- 90 AALTONEN 15C limit is for a SM-like right-handed  $W'$  assuming  $W' \rightarrow \ell\nu$  decays are forbidden, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. See their Fig. 3 for limit on  $g_{W'}/g_W$ .
- 91 KHACHATRYAN 15V search new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 92 AAD 14AT search for a narrow charged vector boson decaying to  $W\gamma$ . See their Fig. 3a for the exclusion limit in  $m_{W'} - \sigma \cdot B$  plane.
- 93 AAD 14S search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell\ell$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 94 KHACHATRYAN 14 search for  $W'$  decaying into  $WZ$  final state with  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow q\bar{q}$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 95 KHACHATRYAN 14A search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow q\bar{q}$ , or  $W \rightarrow q\bar{q}$ ,  $Z \rightarrow \ell\ell$ .  $pp$  collisions data at  $\sqrt{s}=8$  TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass-width plane.
- 96 AAD 13AO search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu$ ,  $Z \rightarrow 2j$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 97 CHATRCHYAN 13AJ search for resonances decaying to  $WZ$  pair, using the hadronic decay modes of  $W$  and  $Z$ , in  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 7 for the limit on the cross section.
- 98 CHATRCHYAN 13AQ limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson using  $pp$  collisions at  $\sqrt{s}=7$  TeV.
- 99 CHATRCHYAN 13E limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson using  $pp$  collisions at  $\sqrt{s}=7$  TeV. For  $W'$  with right-handed coupling, the bound becomes  $>1850$  GeV ( $>1910$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes  $>1640$  GeV.
- 100 CHATRCHYAN 13U search for  $W'$  decaying to the  $WZ$  final state, with  $W$  decaying into jets, in  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 101 The AAD 12AV quoted limit is for a SM-like right-handed  $W'$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV.  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- 102 AAD 12BV use  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$ .
- 103 AAD 12CK search for  $pp \rightarrow tW'$ ,  $W' \rightarrow \bar{t}q$  events in  $pp$  collisions. See their Fig. 5 for the limit on  $\sigma \cdot B$ .
- 104 AAD 12CR use  $pp$  collisions at  $\sqrt{s}=7$  TeV.
- 105 AAD 12M search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell j \bar{j}$ . See their Fig. 4 for the limit in the  $m_N - m_{W_R}$  plane.
- 106 AALTONEN 12N search for  $p\bar{p} \rightarrow tW'$ ,  $W' \rightarrow \bar{t}d$  events in  $p\bar{p}$  collisions. See their Fig. 3 for the limit on  $\sigma \cdot B$ .

## Gauge &amp; Higgs Boson Particle Listings

## New Heavy Bosons

- <sup>107</sup> CHATRCHYAN 12AR search for  $pp \rightarrow tW'$ ,  $W' \rightarrow \bar{t}d$  events in  $pp$  collisions. See their Fig. 2 for the limit on  $\sigma \cdot B$ .
- <sup>108</sup> CHATRCHYAN 12BG search for right-handed  $W_R$  in  $pp$  collisions  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . See their Fig. 3 for the limit in the  $m_N - m_{W'}$  plane.
- <sup>109</sup> ABAZOV 11H use data from  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model.
- <sup>110</sup> ABAZOV 11L limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV. For  $W'$  with right-handed coupling, the bound becomes  $>885$  GeV ( $>890$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes  $>916$  GeV.
- <sup>111</sup> AALTONEN 10N use  $p\bar{p}$  collision data at  $\sqrt{s}=1.96$  TeV. The quoted limit assumes  $g_{W'WZ}/g_{WWZ} = (M_{W'}/M_W)^2$ . See their Fig. 4 for limits in mass-coupling plane.
- <sup>112</sup> AALTONEN 09AC search for new particle decaying to dijets using  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.
- <sup>113</sup> The ACOSTA 03B quoted limit is for  $M_{W'} \gg M_{\nu_R}$ , using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV. For  $M_{W'} < M_{\nu_R}$ ,  $M_{W'}$  between 225 and 566 GeV is excluded.
- <sup>114</sup> The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV. See their Fig. 2 for the limits on the production cross sections as a function of the  $W'$  width.
- <sup>115</sup> AFFOLDER 01i combine a new bound on  $W' \rightarrow e\nu$  of 754 GeV, using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV, with the bound of ABE 00 on  $W' \rightarrow \mu\nu$  to obtain quoted bound.
- <sup>116</sup> ABE 97c search for new particle decaying to dijets using  $p\bar{p}$  collisions at  $\sqrt{s}=1.8$  TeV.
- <sup>117</sup> For bounds on  $W_R$  with nonzero right-handed mass, see Fig. 5 from ABACHI 96c.
- <sup>118</sup> ABACHI 95E assume that the decay  $W' \rightarrow WZ$  is suppressed and that the neutrino from  $W'$  decay is stable and has a mass significantly less  $m_{W'}$ .
- <sup>119</sup> RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed  $K$  factor.

 **$W_R$  (Right-Handed  $W$  Boson) MASS LIMITS**

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91.  $g_R = g_L$  assumed. [Limits in the section MASS LIMITS for  $W'$  below are also valid for  $W_R$  if  $m_{\nu_R} \ll m_{W_R}$ .] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the  $W_L - W_R$  mixing angle  $\zeta$  are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

<sup>1</sup> The quoted limit is for manifest left-right symmetric model.

<sup>2</sup> CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

<sup>3</sup> PRIEELS 14 limit is from  $\mu^+ \rightarrow e^+ \nu \bar{\nu}$  decay parameter  $\xi''$ , which is determined by the positron polarization measurement.

<sup>4</sup> WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized  $^{60}\text{Co}$   $\beta$  decays. The listed limit assumes no mixing.

<sup>5</sup> ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.

<sup>6</sup> MELCONIAN 07 measure the neutrino angular asymmetry in  $\beta^+$ -decays of polarized  $^{37}\text{K}$ , stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the  $W_L - W_R$  mixing angle appreciably.

<sup>7</sup> SCHUMANN 07 limit is from measurements of the asymmetry  $\langle \bar{p}_\nu \cdot \sigma_n \rangle$  in the  $\beta$  decay of polarized neutrons. Zero mixing is assumed.

<sup>8</sup> CYBURT 05 limit follows by requiring that three light  $\nu_R$ 's decouple when  $T_{dec} > 140$  MeV. For different  $T_{dec}$ , the bound becomes  $M_{W_R} > 3.3$  TeV ( $T_{dec} / 140$  MeV) $^{3/4}$ .

<sup>9</sup> THOMAS 01 limit is from measurement of  $\beta^+$  polarization in decay of polarized  $^{12}\text{N}$ . The listed limit assumes no mixing.

<sup>10</sup> ACKERSTAFF 99D limit is from  $\tau$  decay parameters. Limit increase to 145 GeV for zero mixing.

<sup>11</sup> BARENBOIM 98 assumes minimal left-right model with Higgs of  $SU(2)_R$  in  $SU(2)_L$  doublet. For Higgs in  $SU(2)_L$  triplet,  $m_{W_R} > 1100$  GeV. Bound calculated from effect of corresponding  $Z_{LR}$  on electroweak data through Z-Z<sub>LR</sub> mixing.

<sup>12</sup> The quoted limit is from  $\mu$  decay parameters. BARENBOIM 97 also evaluate limit from  $K_L - K_S$  mass difference.

<sup>13</sup> STAHL 97 limit is from fit to  $\tau$ -decay parameters.

<sup>14</sup> ALLET 96 measured polarization-asymmetry correlation in  $^{12}\text{N}$   $\beta^+$  decay. The listed limit assumes zero L-R mixing.

<sup>15</sup> KUZNETSOV 95 limit is from measurements of the asymmetry  $\langle \bar{p}_\nu \cdot \sigma_n \rangle$  in the  $\beta$  decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

<sup>16</sup> KUZNETSOV 94B limit is from measurements of the asymmetry  $\langle \bar{p}_\nu \cdot \sigma_n \rangle$  in the  $\beta$  decay of polarized neutrons. Zero mixing assumed.

<sup>17</sup> BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of  $SU(2)_L \times SU(2)_R \times U(1)$  gauge model. The limit is for  $m_t = 200$  GeV and slightly improves for smaller  $m_t$ .

<sup>18</sup> SEVERIJNS 93 measured polarization-asymmetry correlation in  $^{107}\text{In}$   $\beta^+$  decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.

<sup>19</sup> IMAZATO 92 measure positron asymmetry in  $K^+ \rightarrow \mu^+ \nu_\mu$  decay and obtain  $\xi_P \mu > 0.990$  (90% CL). If  $W_R$  couples to  $u\bar{s}$  with full weak strength ( $V_{us}^R = 1$ ), the result corresponds to  $m_{W_R} > 653$  GeV. See their Fig. 4 for  $m_{W_R}$  limits for general  $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$ .

<sup>20</sup> POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming  $\zeta = 0$ . Supersedes POLAK 91.

<sup>21</sup> AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

<sup>22</sup> COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

<sup>23</sup> POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming  $\zeta = 0$ . Supersedes by POLAK 92B.

<sup>24</sup> BARBIERI 89B limit holds for  $m_{\nu_R} \leq 10$  MeV.

<sup>25</sup> LANGACKER 89B limit is for any  $\nu_R$  mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

<sup>26</sup> BALKE 88 limit is for  $m_{\nu_{eR}} = 0$  and  $m_{\nu_{\mu R}} \leq 50$  MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.

<sup>27</sup> JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point  $e^+$  spectrum in the decay of the highly polarized  $\mu^+$ .

<sup>28</sup> STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay  $e^+$  spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.

<sup>29</sup> BERGSM 83 set limit  $m_{W_2}/m_{W_1} > 1.9$  at CL = 90%.

<sup>30</sup> CARR 83 is TRIUMF experiment with a highly polarized  $\mu^+$  beam. Looked for deviation from V-A at the high momentum end of the decay  $e^+$  energy spectrum. Limit from previous world-average muon polarization parameter is  $m_{W_R} > 240$  GeV. Assumes a light right-handed neutrino.

<sup>31</sup> BEALL 82 limit is obtained assuming that  $W_R$  contribution to  $K_L^0 - K_S^0$  mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

**Limit on  $W_L - W_R$  Mixing Angle  $\zeta$** 

Lighter mass eigenstate  $W_1 = W_L \cos \zeta - W_R \sin \zeta$ . Light  $\nu_R$  assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

<sup>1</sup> ACKERSTAFF 99D limit is from  $\tau$  decay parameters.

<sup>2</sup> CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

<sup>3</sup> The quoted limit is from  $\mu$  decay parameters. BARENBOIM 97 also evaluate limit from  $K_L - K_S$  mass difference.

<sup>4</sup> MISHRA 92 limit is from the absence of extra large-x, large-y  $\bar{\nu}_\mu N \rightarrow \bar{\nu}_\mu X$  events at Tevatron, assuming left-handed  $\nu$  and right-handed  $\bar{\nu}$  in the neutrino beam. The result gives  $\zeta^2(1 - 2m_W^2/m_{W_2}^2) < 0.0015$ . The limit is independent of  $\nu_R$  mass.

See key on page 1171

**Z'-Boson Searches**

### MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

#### Limits for Z'<sub>SM</sub>

Z'<sub>SM</sub> is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

#### Limits for Z'<sub>LR</sub>

Z'<sub>LR</sub> is the extra neutral boson in left-right symmetric models. g<sub>L</sub> = g<sub>R</sub> is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

- 1 DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0012 < \theta < 0.0004$ .
- 2 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 3 TUMASYAN 23BE search for pair production of heavy Majorana neutrinos via the decay of a  $Z'$  boson in a final state with  $\ell^+\ell^-$  and at least two jets. For cases with  $m_N = M_{Z'}/4$ , their 95% CL limits are  $M_{Z'} > 3.59$  TeV ( $> 4.10$  TeV) in the dielectron (dimuon) channel. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 4 BOBOVNIKOV 18 use the ATLAS limits on  $\sigma(pp \rightarrow Z') \cdot B(Z' \rightarrow W^+W^-)$  to constrain the  $Z$ - $Z'$  mixing parameter  $\xi$ . See their Fig. 10 for limits in  $M_{Z'} - \xi$  plane.
- 5 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0006$ .
- 6 ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0028$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 7 ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00098 < \theta < 0.00190$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 8 CHEUNG 01b limit is derived from bounds on contact interactions in a global electroweak analysis.
- 9 ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 10 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 11 CHAY 00 also find  $-0.0003 < \theta < 0.0019$ . For  $g_R$  free,  $m_{Z'} > 430$  GeV.
- 12 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_{LR}$  and  $Z_\chi$ .
- 13 CASALBUONI 99 discuss the discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$ . It is shown that the data are better described in a class of models including the  $Z_{LR}$  model.
- 14 CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds  $|\theta| < 0.0042$ .
- 15 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0009 < \theta < 0.0017$ .
- 16 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $\text{SO}(10)$ , embedded in  $E_6$ .
- 17 BARENBOIM 98 also gives 68% CL limits on the  $Z$ - $Z'$  mixing  $-0.0005 < \theta < 0.0033$ . Assumes Higgs sector of minimal left-right model.
- 18 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 19 VILAIN 94b assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 20 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 21 GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1$  MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.
- 22 BARBIERI 89b limit holds for  $m_{\nu_R} \leq 10$  MeV. Bounds depend on assumed supernova core temperature.

### Limits for $Z_\chi$

$Z_\chi$  is the extra neutral boson in  $\text{SO}(10) \rightarrow \text{SU}(5) \times \text{U}(1)_\chi$ .  $g_\chi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 4 AABOUD 16u search for resonances decaying to  $\ell^+\ell^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 5 AAD 14v search for resonances decaying to  $e^+e^-, \mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 6 AAD 12cc search for resonances decaying to  $e^+e^-, \mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 7 AALTONEN 11i search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 8 ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 9 DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0011 < \theta < 0.0007$ .
- 10 AALTONEN 09v search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 11 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0016 < \theta < 0.0006$ .
- 12 ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0031$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 13 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 14 ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00099 < \theta < 0.00194$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 15 BARGER 03b limit is from the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150$  MeV is assumed. The limit with  $T_C = 400$  MeV is  $>4300$  GeV.
- 16 CHEUNG 01b limit is derived from bounds on contact interactions in a global electroweak analysis.
- 17 ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0017$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 18 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 19 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100$  GeV. See Fig. 3 for limits in the mass-mixing plane.
- 20 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_{LR}$  and  $Z_\chi$ .
- 21 ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_\chi$ .
- 22 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0020 < \theta < 0.0015$ .
- 23 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $\text{SO}(10)$ , embedded in  $E_6$ .
- 24 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 25 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 26  $Z$ - $Z'$  mixing is assumed to be zero.  $\sqrt{s} = 57.77$  GeV.
- 27 VILAIN 94b assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 28 FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos  $\Delta N_\nu < 0.5$  and is valid for  $m_{\nu_R} < 1$  MeV.
- 29 ABE 90f use data for  $R, R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90f fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.
- 30 Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1$  MeV).
- 31 GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1$  MeV. See also GRIFOLS 90D, RIZZO 91.

### Limits for $Z_\psi$

$Z_\psi$  is the extra neutral boson in  $E_6 \rightarrow \text{SO}(10) \times \text{U}(1)_\psi$ .  $g_\psi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 18 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0018 < \theta < 0.0009$ .
- 19 ABDALLAH 06C give 95% CL limit  $|\theta| < 0.0027$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 20 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 21 ABBIENDI 04G give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00129 < \theta < 0.00258$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 22 BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150$  MeV is assumed. The limit with  $T_C = 400$  MeV is  $> 1100$  GeV.
- 23 ABREU 00S give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 24 BARATE 00I search for deviations in cross section and asymmetries in  $e^+ e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 25 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100$  GeV. See Fig. 3 for limits in the mass-mixing plane.
- 26 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0024$ .
- 27 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 28 ABE 97S find  $\sigma(Z') \times B(e^+ e^-, \mu^+ \mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 29 VILAIN 94B assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.

- 30 ABE 90F use data for  $R, R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90F fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.
- 31 Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1$  MeV).
- 32 GRIFOLS 90D limit holds for  $m_{\nu_R} \lesssim 1$  MeV. See also RIZZO 91.

Limits for  $Z_\eta$ 

$Z_\eta$  is the extra neutral boson in  $E_6$  models, corresponding to  $Q_\eta = \sqrt{3/8} Q_X - \sqrt{5/8} Q_\psi$ .  $g_\eta = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

1 AAD 23O search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2800$  GeV for  $g_V = 1$ .

2 TUMASYAN 23AF search for resonance decaying to  $b\bar{b}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $Z'$  with  $g_V = 1$ . See their Fig. 4 for limits on  $\sigma_B$ .

3 TUMASYAN 23AP search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 4.8$  TeV assuming  $M_{W'} = M_{Z'}$  and combining  $W' \rightarrow WZ, W' \rightarrow WH, Z' \rightarrow WW, Z' \rightarrow ZH$  channels.

4 TUMASYAN 23AP search for resonances decaying to  $ZH$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 4.8$  TeV assuming  $M_{W'} = M_{Z'}$  and combining  $W' \rightarrow WZ, W' \rightarrow WH, Z' \rightarrow WW, Z' \rightarrow ZH$  channels.

5 TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limits on  $\sigma_B$ . The quoted limit is for heavy-vector-triplet  $W'$  with  $g_V = 3$  produced mainly via Drell-Yan.

6 SIRUNYAN 21X search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 3500$  GeV for  $g_V = 1$ .

7 AAD 20AJ search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2200$  GeV for  $g_V = 1$ . See their Fig. 6 for limits on  $\sigma_B$ .

8 AAD 20AM search for a resonance decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for a leptophobic top-color  $Z'$  with  $\Gamma_{Z'}/M_{Z'} = 0.01$ . The limit becomes  $M_{Z'} > 4700$  GeV for  $\Gamma_{Z'}/M_{Z'} = 0.03$ .

9 AAD 20AT search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 3500$  GeV for  $g_V = 1$ . See their Fig. 14 for limits on  $\sigma_B$ .

10 SIRUNYAN 20Q search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ .

11 AABOUD 19AS search for a resonance decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for a top-color  $Z'$  with  $\Gamma_{Z'}/M_{Z'} = 0.01$ . Limits are also set on  $Z'$  masses in simplified Dark Matter models.

See key on page 1171

## Gauge & Higgs Boson Particle Listings

### New Heavy Bosons

- 12 AAD 19d search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2900$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 3800$  GeV and  $M_{Z'} > 3500$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 9 for limits on  $\sigma \cdot B$ .
- 13 SIRUNYAN 19AA search for a resonance decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for a leptophobic top-color  $Z'$  with  $\Gamma_{Z'}/M_{Z'} = 0.01$ .
- 14 SIRUNYAN 19CP present a statistical combinations of searches for  $Z'$  decaying to pairs of bosons or leptons in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . If we assume  $M_{Z'} = M_{W'}$ , the limit becomes  $M_{Z'} > 4500$  GeV for  $g_V = 3$  and  $M_{Z'} > 5000$  GeV for  $g_V = 1$ . See their Figs. 2 and 3 for limits on  $\sigma \cdot B$ .
- 15 SIRUNYAN 19I search for resonances decaying to  $ZW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2800$  GeV if we assume  $M_{Z'} = M_{W'}$ .
- 16 AABOUD 18AB search for resonances decaying to  $b\bar{b}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a leptophobic  $Z'$  with SM-like couplings to quarks. See their Fig. 6 for limits on  $\sigma \cdot B$ . Additional limits on a  $Z'$  axial-vector mediator in a simplified dark-matter model are shown in Fig. 7.
- 17 AABOUD 18AI search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2650$  GeV for  $g_V = 1$ . If we assume  $M_{W'} = M_{Z'}$ , the limit increases  $M_{Z'} > 2930$  GeV and  $M_{Z'} > 2800$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 18 AABOUD 18AK search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2750$  GeV for  $g_V = 1$ .
- 19 AABOUD 18B search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 1$ . See their Fig.11 for limits on  $\sigma \cdot B$ .
- 20 AABOUD 18BI search for a resonance decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for a top-color assisted  $TC Z'$  with  $\Gamma_{Z'}/M_{Z'} = 0.01$ . The limits for wider resonances are available. See their Fig. 14 for limits on  $\sigma \cdot B$ .
- 21 AABOUD 18F search for resonances decaying to  $WW$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2200$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 3500$  GeV and  $M_{Z'} > 3100$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig.5 for limits on  $\sigma \cdot B$ .
- 22 SIRUNYAN 18ED search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 2900$  GeV and  $M_{Z'} > 2800$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively.
- 23 SIRUNYAN 18P give this limit for a heavy-vector-triplet  $Z'$  with  $g_V = 3$ . If they assume  $M_{Z'} = M_{W'}$ , the limit increases to  $M_{Z'} > 3800$  GeV.
- 24 AABOUD 17AK search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a leptophobic  $Z'$  boson having axial-vector coupling strength with quarks  $g_q = 0.2$ . The limit is 2100 GeV if  $g_q = 0.1$ .
- 25 AABOUD 17AO search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a  $Z'$  in the heavy-vector-triplet model with  $g_V = 3$ . See their Fig.4 for limits on  $\sigma \cdot B$ .
- 26 SIRUNYAN 17AK search for resonances decaying to  $WW$  or  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 8$  and 13 TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 2200$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 2400$  GeV for both  $g_V = 3$  and  $g_V = 1$ . See their Fig.1 and 2 for limits on  $\sigma \cdot B$ .
- 27 SIRUNYAN 17Q search for a resonance decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a resonance with relative width  $\Gamma_{Z'}/M_{Z'} = 0.01$ . Limits for wider resonances are available. See their Fig.6 for limits on  $\sigma \cdot B$ .
- 28 SIRUNYAN 17R search for resonances decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . Mass regions  $M_{Z'} < 1150$  GeV and  $1250$  GeV  $< M_{Z'} < 1670$  GeV are excluded for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the excluded mass regions are  $1000 < M_{Z'} < 2500$  GeV and  $2760 < M_{Z'} < 3300$  GeV for  $g_V = 3$ ;  $1000 < M_{Z'} < 2430$  GeV and  $2810 < M_{Z'} < 3130$  GeV for  $g_V = 1$ . See their Fig.5 for limits on  $\sigma \cdot B$ .
- 29 AAD 23BF search for a Dark Matter (DM) simplified  $Z'$  produced in association with  $W$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 9(c) for limits on  $\sigma \cdot B$  as a function of  $M_{Z'}$ .
- 30 AAD 23W set limits on a dark Higgs model with a spin-1 mediator  $Z'$  and a dark Higgs  $s$ . Dark Higgs  $s$  is assumed to decay into  $WW$ . See their Fig. 9 for limits in  $M_{Z'} - M_s$  plane.
- 31 AAD 23X set limits on  $L_\mu - L_\tau$  of  $Z'$  using four-muon final states in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 7 for limits in mass-coupling plane.
- 32 ADACHI 23B search for  $Z'$  produced in association with  $\mu^+ \mu^-$  and decaying invisibly in  $e^+ e^-$  collisions at  $\sqrt{s} = 10.58$  GeV. See their Fig. 3 and Fig. 4 for limits in mass-coupling plane.
- 33 ADACHI 23F search for resonances decaying to  $\tau^+ \tau^-$  in  $\mu^+ \mu^- \tau^+ \tau^-$  events in  $e^+ e^-$  collisions at  $\sqrt{s} = 10.58$  GeV. See their Fig. 3 for limits on  $\sigma \cdot B$ .
- 34 HAYRAPETYAN 23D search for  $\mu^+ \mu^-$  resonance produced in association with one or more  $b$ -jets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limits in the mass-coupling plane of the  $B_3 - L_2$   $Z'$  model.
- 35 HAYRAPETYAN 23G search for spin-0 and spin-1 resonances decaying to  $\mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV in the mass ranges of 1.1–2.6 GeV and 4.2–7.9 GeV. See their Fig. 5 for limits on  $\sigma \cdot B$ .
- 36 Li 23I limits on light  $Z'$  couplings are derived from the steller cooling bounds in the mass range of  $10^4 - 10^6$  eV. See their Fig. 4 for limits on dark photon,  $B-L$ ,  $L_\mu - L_\tau$ , and  $L_e - L_\mu(\tau)$  models.
- 37 MANZARI 23 study supernova cooling induced by the emission of light dark fermions  $\chi$  assumed to couple with leptons via a new massive vector boson  $Z'$ . See their Figs. 4 and 5 for limits in mass-coupling plane.
- 38 AAD 22 search for  $b\bar{b}Z'$  productions in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay into  $b\bar{b}$ . See their Fig.4 for limits on  $\sigma \cdot B$ .
- 39 AAD 22b search for DM mediator  $Z'$  produced in association with a  $Z$  boson in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay invisibly  $Z' \rightarrow \chi\chi$ . See their Fig. 4 for limits in  $M_{Z'} - M_\chi$  plane.
- 40 ANDREEV 22 search for missing energy in CERN NA64-e experiment. See their Fig. 7 for limits on couplings of  $U(1)$  gauge  $L_\mu - L_\tau$   $Z'$  models, in the mass range of 1 MeV  $< M_{Z'} < 600$  MeV with the kinetic  $Z' - \gamma$  mixing being determined by  $\mu$  and  $\tau$  loops.
- 41 BONET 22 obtain limits on  $Z'$  coupling from  $\nu$ -nucleus scattering data collected by the CONUS experiment at the nuclear power plant in Brokkdorf. See their Fig. 5 for limits in mass-coupling plane.
- 42 COLOMA 22 set limits on  $Z'$  coupling from  $\nu$ -nucleus and  $\nu$ -e scattering data collected by a Ge detector at the Dresden-II power reactor and the COHERENT experiment. See their Fig. 6 for limits in mass-coupling plane in the mass range of 1 keV  $< M_{Z'} < 5$  GeV.
- 43 COLOMA 22A use Borexino Phase-II spectral data to constrain  $Z'$  couplings. See their Fig. 7 for limits in mass-coupling plane in the mass range of 10 keV  $< M_{Z'} < 100$  MeV.
- 44 CZANK 22 search for  $Z'$  produced in association with  $\mu^+ \mu^-$  in  $e^+ e^-$  collisions at and near  $T$  resonances.  $Z'$  is assumed to decay into  $\mu^+ \mu^-$ . See their Fig. 8 for limits on  $Z' \mu\mu$  couplings.
- 45 TUMASYAN 22AA search for  $Z'$  production in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay into two "semivisible" jets (SVJ), i.e., collimated mixtures of visible and invisible particles. See their Fig. 7 and 8 for limits on  $\sigma \cdot B$ .
- 46 AAD 21AQ limits are for a  $B - L$  gauge boson model derived from their measurements on four-lepton differential cross sections. See their Fig. 13 for exclusion limits on the  $B - L$  breaking Higgs boson mass.
- 47 AAD 21AZ search for DM mediator  $Z'$  produced in association with a SM Higgs boson in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay invisibly  $Z' \rightarrow \chi\chi$ . See their Fig. 7 for limits in  $M_{Z'} - M_\chi$  plane.
- 48 AAD 21BB search for  $Z'$  productions in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay into a SM Higgs boson  $H$  and an invisible particle  $A$ . See their Fig.7 for limits in  $M_{Z'} - M_A$  plane.
- 49 AAD 21D set limits on a dark Higgs model with a spin-1 mediator  $Z'$  and a scalar dark Higgs boson  $s$ . Dark Higgs  $s$  is assumed to decay into  $WW$  or  $ZZ$ . See their Fig.4 for limits in  $M_{Z'} - M_s$  plane.
- 50 AAD 21K search for  $\gamma + \cancel{E}_T$  events in  $pp$  collision at  $\sqrt{s} = 13$  TeV. See their Fig. 5 for limits on  $Z'$  particle invisibly decaying to  $\chi\chi$ .
- 51 BURAS 21 performed global fit to leptophilic  $Z'$  models using a large number of observables.
- 52 CADEDDU 21 obtain limits on  $Z'$  coupling  $g_{Z'}$  from coherent  $\nu$ -nucleus scattering data collected by COHERENT experiment. For limits in the  $M_{Z'} - g_{Z'}$  plane, see their Figures 3 and 4 for the universal  $Z'$  model and Figures 5 and 6 for the  $B - L$  model.
- 53 COLARESI 21 obtain limits on  $Z'$  coupling from coherent  $\nu$ -nucleus scattering data collected by a Ge detector at the Dresden-II power reactor. See their Fig.7 for limits in mass-coupling plane.
- 54 KRIBS 21 set decay-agnostic limits on kinetic mixing parameter between  $U(1)_Y$  field and new heavy abelian vector boson (dark photon) field using the HERA  $ep$  collision data. See their Fig. 3 for limits in mass-mixing plane.
- 55 TUMASYAN 21D search for energetic jets +  $\cancel{E}_T$  events in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  $Z'$  is assumed to decay into a pair of invisible particles  $\chi\chi$ . See their Fig. 7 for limits on signal strength in  $M_{Z'} - M_\chi$  plane, and Fig. 8 for limits on signal strength in quark and dark matter coupling vs mediator mass.
- 56 AAD 20AF search for resonances decaying to  $H\gamma$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 1c for limits on  $\sigma \cdot B$  for the mass range  $0.7 < m_{Z'} < 4$  TeV.
- 57 AAD 20T search for Dark Matter mediator  $Z'$  decaying invisibly or decaying to  $q\bar{q}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 5 for limits in  $M_{Z'} - g_q$  plane from the inclusive category. See their Fig. 7(a) for limits on the product of the cross section, acceptance,  $b$ -tagging efficiency, and branching fraction from the 2  $b$ -tag category.
- 58 AAD 20W search for a Dark Matter (DM) simplified model  $Z'$  produced in association with  $W$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 5 for limits on  $Z'$  production cross section.
- 59 AAIJ 20AL search for spin-0 and spin-1 resonances decaying to  $\mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV in the mass regions  $M_{Z'} < 60$  GeV, with non-negligible widths considered above 20 GeV. See their Figs. 7, 8, and 9 for limits on  $\sigma \cdot B$ .
- 60 ADACHI 20 search for production of  $Z'$  in  $e^+ e^-$  collisions. The  $Z'$  is assumed to decay invisibly. See their Fig. 3 and Fig. 5 for limits on  $Z'$  coupling and  $\sigma(e^+ e^- \rightarrow e^+ \mu^+ \bar{\nu} Z')$ .
- 61 SIRUNYAN 20AI search for broad resonances decaying into dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 11 for exclusion limits in mass-coupling plane.
- 62 SIRUNYAN 20AQ search for a narrow resonance lighter than 200 GeV decaying to  $\mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 3 for limits on  $Z'$  kinetic mixing coefficient.
- 63 SIRUNYAN 20M search for a narrow resonance with a mass between 350 and 700 GeV in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig.3 for exclusion limits in mass-coupling plane.
- 64 AABOUD 19AJ search in  $pp$  collisions at  $\sqrt{s} = 13$  TeV for a new resonance decaying to  $q\bar{q}$  and produced in association with a high  $p_T$  photon. For a leptophobic axial-vector  $Z'$  in the mass region  $250$  GeV  $< M_{Z'} < 950$  GeV, the  $Z'$  coupling with quarks  $g_q$  is constrained below 0.18. See their Fig.2 for limits in  $M_{Z'} - g_q$  plane.
- 65 AABOUD 19D search in  $pp$  collisions at  $\sqrt{s} = 13$  TeV for a new resonance decaying to  $q\bar{q}$  and produced in association with a high- $p_T$  photon or jet. For a leptophobic axial-vector  $Z'$  in the mass region  $100$  GeV  $< M_{Z'} < 220$  GeV, the  $Z'$  coupling with quarks  $g_q$  is constrained below 0.23. See their Fig. 6 for limits in  $M_{Z'} - g_q$  plane.
- 66 AABOUD 19V search for Dark Matter simplified  $Z'$  decaying invisibly or decaying to fermion pair in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

- 67 AAD 19L search for resonances decaying to  $\ell^+ \ell^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.
- 68 LONG 19 uses the weak charge data of Cesium and proton to constrain mass of  $Z'$  in the 3-3-1 models.
- 69 PANDEY 19 obtain limits on  $Z'$  induced neutrino non-standard interaction (NSI) parameter  $\epsilon$  from LHC and IceCube data. See their Fig.2 for limits in  $M_{Z'} - \epsilon$  plane, where  $\epsilon = g_q g_\nu v^2 / (2 M_{Z'}^2)$ .
- 70 SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for limits on  $Z'$  production cross section.
- 71 SIRUNYAN 19AN search for a Dark Matter (DM) simplified model  $Z'$  decaying to  $H$  DM DM in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 7 for limits on the signal strength modifiers.
- 72 SIRUNYAN 19CB search in  $pp$  collisions at  $\sqrt{s} = 13$  TeV for a new resonance decaying to  $q\bar{q}$ . For a leptophobic  $Z'$  in the mass region 50–300 GeV, the  $Z'$  coupling with quarks  $g'_q$  is constrained below 0.2. See their Figs. 4 and 5 for limits on  $g'_q$  in the mass range  $50 < M_{Z'} < 450$  GeV.
- 73 SIRUNYAN 19CD search in  $pp$  collisions at  $\sqrt{s}=13$  TeV for a leptophobic  $Z'$  produced in association of high  $p_T$  ISR photon and decaying to  $q\bar{q}$ . See their Fig. 2 for limits on the  $Z'$  coupling strength  $g'_q$  to  $q\bar{q}$  in the mass range between 10 and 125 GeV.
- 74 SIRUNYAN 19D search for a narrow neutral vector resonance decaying to  $H\gamma$ . See their Fig. 3 for exclusion limit in  $M_{Z'} - \sigma \cdot B$  plane. Upper limits on the production of  $H\gamma$  resonances are set as a function of the resonance mass in the range of 720–3250 GeV.
- 75 AABOUD 18AA search for a narrow neutral vector boson decaying to  $H\gamma$ . See their Fig. 10 for the exclusion limit in  $M_{Z'} - \sigma \cdot B$  plane.
- 76 AABOUD 18CJ search for heavy-vector-triplet  $Z'$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for model with  $g_V = 3$  assuming  $M_{Z'} = M_{W'}$ . The limit becomes  $M_{Z'} > 5500$  GeV for model with  $g_V = 1$ .
- 77 AABOUD 18N search for a narrow resonance decaying to  $q\bar{q}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the  $Z'$  mass range 450–1800 GeV.
- 78 AAIJ 18AQ search for spin-0 and spin-1 resonances decaying to  $\mu^+ \mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on  $\sigma \cdot B$ .
- 79 SIRUNYAN 18DR searches for  $\mu^+ \mu^-$  resonances produced in association with  $b$ -jets in the  $pp$  collision data with  $\sqrt{s} = 8$  TeV and 13 TeV. An excess of events near  $m_{\mu\mu} = 28$  GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at  $\sqrt{s} = 8$  TeV and the 95% CL upper limits at  $\sqrt{s} = 13$  TeV.
- 80 SIRUNYAN 18G search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.
- 81 SIRUNYAN 18I search for a narrow resonance decaying to  $b\bar{b}$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV using dedicated  $b$ -tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on  $\sigma \cdot B$  in the  $Z'$  mass range 325–1200 GeV.
- 82 AABOUD 17B search for resonances decaying to  $HZ$  ( $H \rightarrow b\bar{b}, c\bar{c}, Z \rightarrow \ell^+ \ell^-, \nu\bar{\nu}$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 1490$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 2310$  GeV and  $M_{Z'} > 1730$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig.3 for limits on  $\sigma \cdot B$ .
- 83 KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 84 KHACHATRYAN 17U search for resonances decaying to  $HZ$  ( $H \rightarrow b\bar{b}, Z \rightarrow \ell^+ \ell^-, \nu\bar{\nu}$ ) in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit on the heavy-vector-triplet model is  $M_{Z'} = M_{W'} > 2$  TeV for  $g_V = 3$ , in which constraints from the  $W' \rightarrow HW$  ( $H \rightarrow b\bar{b}, W \rightarrow \ell\nu$ ) are combined. See their Fig.3 and Fig.4 for limits on  $\sigma \cdot B$ .
- 85 SIRUNYAN 17A search for resonances decaying to  $WW$  with  $WW \rightarrow \ell\nu q\bar{q}, q\bar{q}q\bar{q}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ . The limit becomes  $M_{Z'} > 1600$  GeV for  $g_V = 1$ . If we assume  $M_{Z'} = M_{W'}$ , the limit increases  $M_{Z'} > 2400$  GeV and  $M_{Z'} > 2300$  GeV for  $g_V = 3$  and  $g_V = 1$ , respectively. See their Fig.6 for limits on  $\sigma \cdot B$ .
- 86 SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar  $H$  and a light pseudo scalar  $A$ .  $A$  is assumed to decay invisibly. See their Fig.9 for limits on  $\sigma \cdot B$ .
- 87 SIRUNYAN 17T search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.
- 88 SIRUNYAN 17V search for a new resonance decaying to a top quark and a heavy vector-like top partner  $T$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their table 5 for limits on the  $Z'$  production cross section for various values of  $M_{Z'}$  and  $M_T$  in the range of  $M_{Z'} = 1500$ –2500 GeV and  $M_T = 700$ –1500 GeV.
- 89 AABOUD 16 search for a narrow resonance decaying into  $b\bar{b}$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a leptophobic  $Z'$  with SM-like couplings to quarks. See their Fig.6 for limits on  $\sigma \cdot B$ .
- 90 AAD 16L search for  $Z' \rightarrow a\gamma, a \rightarrow \gamma\gamma$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See their Table 6 for limits on  $\sigma \cdot B$ .
- 91 AAD 16S search for a new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above is for a leptophobic  $Z'$  having coupling strength with quark  $g_q = 0.3$  and is taken from their Figure 3.
- 92 KHACHATRYAN 16AP search for a resonance decaying to  $HZ$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. Both  $H$  and  $Z$  are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet  $Z'$  with  $g_V = 3$ .
- 93 KHACHATRYAN 16E search for a leptophobic top-color  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The quoted limit assumes that  $\Gamma_{Z'}/m_{Z'} = 0.012$ . Also  $m_{Z'} < 2.9$  TeV is excluded for wider topcolor  $Z'$  with  $\Gamma_{Z'}/m_{Z'} = 0.1$ .
- 94 AAD 15AO search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See Fig. 11 for limit on  $\sigma \cdot B$ .
- 95 AAD 15AT search for monotop production plus large missing  $E_T$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV and give constraints on a  $Z'$  model having  $Z' u\bar{t}$  coupling.  $Z'$  is assumed to decay invisibly. See their Fig. 6 for limits on  $\sigma \cdot B$ .
- 96 AAD 15CD search for decays of Higgs bosons to 4  $\ell$  states via  $Z'$  bosons,  $H \rightarrow ZZ' \rightarrow 4\ell$  or  $H \rightarrow Z'Z' \rightarrow 4\ell$ . See Fig. 5 for the limit on the signal strength of the  $H \rightarrow Z'Z' \rightarrow 4\ell$  process and Fig. 16 for the limit on  $H \rightarrow Z'Z' \rightarrow 4\ell$ .
- 97 KHACHATRYAN 15F search for monotop production plus large missing  $E_T$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV and give constraints on a  $Z'$  model having  $Z' u\bar{t}$  coupling.  $Z'$  is assumed to decay invisibly. See Fig. 3 for limits on  $\sigma \cdot B$ .
- 98 KHACHATRYAN 15O search for narrow  $Z'$  resonance decaying to  $ZH$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. See their Fig. 6 for limit on  $\sigma \cdot B$ .
- 99 AAD 14AT search for a narrow neutral vector boson decaying to  $Z\gamma$ . See their Fig. 3b for the exclusion limit in  $m_{Z'} - \sigma \cdot B$  plane.
- 100 KHACHATRYAN 14A search for new resonance in the  $WW$  ( $\ell\nu q\bar{q}$ ) and the  $ZZ$  ( $\ell\ell q\bar{q}$ ) channels using  $pp$  collisions at  $\sqrt{s}=8$  TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.
- 101 MARTINEZ 14 use various electroweak data to constrain the  $Z'$  boson in the 3-3-1 models.
- 102 AAD 13AQ search for a leptophobic top-color  $Z'$  decaying to  $t\bar{t}$ . The quoted limit assumes that  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 103 CHATRCHYAN 13BM search for top-color  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=8$  TeV. The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 104 CHATRCHYAN 13AP search for top-color leptophobic  $Z'$  decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 105 AAD 12BV search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 7 for limit on  $\sigma \cdot B$ .
- 106 AAD 12K search for narrow resonance decaying to  $t\bar{t}$  using  $pp$  collisions at  $\sqrt{s}=7$  TeV. See their Fig. 5 for limit on  $\sigma \cdot B$ .
- 107 AALTONEN 12AR search for chromophilic  $Z'$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. See their Fig. 5 for limit on  $\sigma \cdot B$ .
- 108 AALTONEN 12N search for  $p\bar{p} \rightarrow tZ', Z' \rightarrow T\bar{u}$  events in  $p\bar{p}$  collisions. See their Fig. 3 for the limit on  $\sigma \cdot B$ .
- 109 ABAZOV 12R search for top-color  $Z'$  boson decaying exclusively to  $t\bar{t}$ . The quoted limit is for  $\Gamma_{Z'}/m_{Z'} = 0.012$ .
- 110 CHATRCHYAN 12AI search for  $pp \rightarrow t\bar{t}$  events and give constraints on a  $Z'$  model having  $Z' t\bar{t}$  coupling. See their Fig. 4 for the limit in mass-coupling plane.
- 111 Search for resonance decaying to  $t\bar{t}$ . See their Fig. 6 for limit on  $\sigma \cdot B$ .
- 112 Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 4 for limit on  $\sigma \cdot B$ .
- 113 Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 3 for limit on  $\sigma \cdot B$ .
- 114 CHATRCHYAN 11O search for same-sign top production in  $pp$  collisions induced by a hypothetical FCNC  $Z'$  at  $\sqrt{s} = 7$  TeV. See their Fig. 3 for limit in mass-coupling plane.
- 115 Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 3 for limit on  $\sigma \cdot B$ .
- 116 Search for narrow resonance decaying to  $t\bar{t}$ . See their Fig. 2 for limit on  $\sigma \cdot B$ .
- 117 BARGER 03b use the nucleosynthesis bound on the effective number of light neutrino  $\delta N_{\nu}$ . See their Figs.4–5 for limits in general  $E_6$  motivated models.
- 118 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H=100$  GeV. See Fig. 2 for limits in general  $E_6$ -motivated models.
- 119 CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no  $Z$ - $Z'$  mixing.
- 120 Search for  $Z'$  decaying to dijets at  $\sqrt{s}=1.8$  TeV. For  $Z'$  with electromagnetic strength coupling, no bound is obtained.

### Searches for $Z'$ with Lepton-Flavor-Violating decays

The following limits are obtained from  $p\bar{p}$  or  $pp \rightarrow Z' X$  with  $Z'$  decaying to the mode indicated in the comments.

- 1 CABARCAS 24 use constraints on the non-standard neutrino interactions reported by ANTARES and IceCube experiments to constrain  $Z'$  models with  $\mu\tau$  coupling. See their Figs. 1 and 2 for limits in mass-coupling plane.
- 2 AAD 23CB search for a new particle with lepton-flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Figs.4, 5, and 6 for limits on  $\sigma \cdot B$ .
- 3 TUMASYAN 23H search for a new particle with lepton-flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 4 for limits on  $\sigma \cdot B$ .
- 4 AABOUD 18CM search for a new particle with lepton-flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Figs. 4, 5, and 6 for limits on  $\sigma \cdot B$ .
- 5 SIRUNYAN 18AT search for a narrow resonance  $Z'$  decaying into  $e\mu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig.5 for limit on  $\sigma \cdot B$  in the range of  $600 \text{ GeV} < M_{Z'} < 5000$  GeV.
- 6 AABOUD 16P search for new particle with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Figs.2, 3, and 4 for limits on  $\sigma \cdot B$ .
- 7 KHACHATRYAN 16BE search for new particle  $Z'$  with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 8$  TeV in the range of  $200 \text{ GeV} < M_{Z'} < 2000$  GeV. See their Fig.4 for limits on  $\sigma \cdot B$  and their Table 5 for bounds on various masses.
- 8 AAD 15O search for new particle  $Z'$  with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 8$  TeV in the range of  $500 \text{ GeV} < M_{Z'} < 3000$  GeV. See their Fig. 2 for limits on  $\sigma \cdot B$ .
- 9 AAD 11H search for new particle  $Z'$  with lepton flavor violating decay in  $pp$  collisions at  $\sqrt{s} = 7$  TeV in the range of  $700 \text{ GeV} < M_{Z'} < 1000$  GeV. See their Fig. 3 for limits on  $\sigma \cdot B$ .

- 10 AAD 11z search for new particle Z' with lepton flavor violating decay in pp collisions at sqrt(s) = 7 TeV in the range 700 GeV < M\_Z' < 2000 GeV.
11 ABULENCIA 06M search for new particle Z' with lepton flavor violating decay in pp collisions at sqrt(s) = 1.96 TeV in the range of 100 GeV < M\_Z' < 800 GeV.

Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the Z boson or photon in d=1 extra dimension. These bounds can also be interpreted as a lower bound on 1/R, the size of the extra dimension.

Table with columns: VALUE (TeV), CL%, DOCUMENT ID, TECN, COMMENT. Lists various constraints from MUECK, CORNET, DELGADO, RIZZO, MARCIANO, MASIP, NATH, STRUMIA.

- 1 MUECK 02 limit is 2sigma and is from global electroweak fit ignoring correlations among observables.
2 Bound is derived from limits on e nu qq' contact interaction, using data from HERA and the Tevatron.
3 Bound holds only if first two generations of quarks lives on separate branes.

See the related review(s): Leptoquarks

MASS LIMITS for Leptoquarks from Pair Production

Table with columns: VALUE (GeV), CL%, DOCUMENT ID, TECN, COMMENT. Lists mass limits for various leptoquarks from AAD, TUMASYAN, SIRUNYAN, etc.

Table with columns: VALUE, CL%, DOCUMENT ID, TECN, COMMENT. Lists various Higgs boson listings from SIRUNYAN, AABOUD, KHACHATRY, etc.

- 1 AAD 23B search for scalar leptoquarks decaying to  $c\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 8 for exclusion limit on  $\sigma$  as function of  $M_{LQ}$ .
- 2 AAD 23C search for scalar and vector leptoquarks decaying to  $b\tau$ . The limit quoted above is for scalar leptoquark. See their Fig. 9 for limits on leptoquark pair production cross sections.
- 3 AAD 23C search for scalar and vector leptoquarks decaying to  $b\tau$ . The limit quoted above is for vector leptoquark with  $\kappa = 1$ . The limit becomes  $M_{LQ} > 1650$  for vector leptoquark with  $\kappa = 0$ . See their Fig. 9 for limits on leptoquark pair production cross sections.
- 4 AAD 23F search for scalar leptoquarks decaying to  $t\nu$  and  $b\mu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 9 for exclusion contour in  $B(b\mu) - M_{LQ}$  plane.
- 5 AAD 23F search for scalar leptoquarks decaying to  $t\nu$  and  $b\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 9 for exclusion contour in  $B(b\tau) - M_{LQ}$  plane.
- 6 AAD 23F search for scalar leptoquarks decaying to  $t\mu$  and  $b\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 9 for exclusion contour in  $B(t\mu) - M_{LQ}$  plane.
- 7 AAD 23F search for scalar leptoquarks decaying to  $t\tau$  and  $b\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 9 for exclusion contour in  $B(t\tau) - M_{LQ}$  plane.
- 8 AAD 23F search for  $\kappa = 1$  (YM coupling) vector leptoquarks decaying to  $t\nu$  and  $b\mu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. If  $\kappa = 0$  (minimal coupling) is assumed, the limit becomes  $M_{LQ} > 1710$  GeV. See their Fig. 10 for exclusion contour in  $B(b\mu) - M_{LQ}$  plane.
- 9 AAD 23F search for  $\kappa = 1$  (YM coupling) vector leptoquarks decaying to  $t\nu$  and  $b\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. If  $\kappa = 0$  (minimal coupling) is assumed, the limit becomes  $M_{LQ} > 1620$  GeV. See their Fig. 10 for exclusion contour in  $B(b\tau) - M_{LQ}$  plane.
- 10 TUMASYAN 22H search for scalar leptoquarks decaying to  $t\tau$ . See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of  $M_{LQ}$ .
- 11 TUMASYAN 22H search for scalar leptoquarks decaying to  $t\mu$ . See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of  $M_{LQ}$ .
- 12 TUMASYAN 22H search for scalar leptoquarks decaying to  $t\tau$ . See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of  $M_{LQ}$ .
- 13 AAD 21AG search for scalar leptoquarks decaying to  $t\tau$ . See their Fig. 6 for exclusion limit on  $B(t\tau)$  as function of  $M_{LQ}$ .
- 14 AAD 21AG search for scalar leptoquarks decaying to  $t\mu$ . See their Fig. 6 for exclusion limit on  $B(t\mu)$  as function of  $M_{LQ}$ .
- 15 AAD 21AW search for scalar leptoquarks decaying to  $b\tau$ . See their Fig. 9 for exclusion contour in  $B(b\tau) - M_{LQ}$  plane.
- 16 AAD 21AW search for scalar leptoquarks decaying to  $t\tau$ . See their Fig. 9 for exclusion contour in  $B(t\tau) - M_{LQ}$  plane.
- 17 AAD 21AW search for  $\kappa = 1$  vector leptoquarks decaying to  $b\tau$ . See their Fig. 10 for exclusion contour in  $B(b\tau) - M_{LQ}$  plane and for limit on  $\kappa = 0$  vector leptoquarks.
- 18 AAD 21s search for scalar leptoquarks decaying to  $b\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(b\nu) = 1$ . For  $B(b\nu) = 0.05$ , the limit becomes 400 GeV.
- 19 AAD 21t search for scalar leptoquarks decaying to  $t\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(t\tau) = 1$ . For  $B(t\tau) = 0.5$ , the limit becomes 1220 GeV. See their Fig. 15b for limits on  $B(t\tau)$  as a function of leptoquark mass.
- 20 SIRUNYAN 21J search for scalar leptoquarks decaying to  $t\tau$  and  $b\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 21 SIRUNYAN 21J search for vector leptoquarks decaying to  $t\nu$  and  $b\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above assumes  $\kappa = 1$ . If we assume  $\kappa = 0$ , the limit becomes  $M_{LQ} > 1290$  GeV.
- 22 AAD 20AK search for scalar leptoquarks decaying to  $e q, e b, e c, \mu q, \mu b, \mu c$ . The quoted limit assumes  $B(e q) = 1$ . See their Fig. 9 for limits on  $B(e q), B(e b), B(e c), B(\mu q), B(\mu b), B(\mu c)$  as a function of leptoquark mass.
- 23 AAD 20AK search for scalar leptoquarks decaying to  $e q, e b, e c, \mu q, \mu b, \mu c$ . The quoted limit assumes  $B(\mu q) = 1$ . See their Fig. 9 for limits on  $B(e q), B(e b), B(e c), B(\mu q), B(\mu b), B(\mu c)$  as a function of leptoquark mass.
- 24 AAD 20s search for scalar leptoquarks decaying to  $t\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 25 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes scalar leptoquark with  $B(\nu b) = 1$ .
- 26 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes scalar leptoquark with  $B(\nu t) = 1$ .
- 27 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes scalar leptoquark with  $B(\nu q) = 1$ .
- 28 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes vector leptoquark with  $B(\nu b) = 1$  and  $\kappa = 1$ . If we assume  $\kappa = 0$ , the limit becomes  $M_{LQ} > 1560$  GeV.
- 29 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes vector leptoquark with  $B(\nu t) = 1$  and  $\kappa = 1$ . If we assume  $\kappa = 0$ , the limit becomes  $M_{LQ} > 1475$  GeV.
- 30 SIRUNYAN 20A search for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$  ( $q = u, d, s, c$ ). The limit quoted above assumes vector leptoquark with  $B(\nu q) = 1$  and  $\kappa = 1$ . If we assume  $\kappa = 0$ , the limit becomes  $M_{LQ} > 1560$  GeV.
- 31 AABOUD 19AX search for leptoquarks using  $e e j j$  events in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(e q) = 1$ .
- 32 AABOUD 19AX search for leptoquarks using  $\mu \mu j j$  events in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(\mu q) = 1$ .
- 33 AABOUD 19X search for scalar leptoquarks decaying to  $t\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 34 AABOUD 19x search for scalar leptoquarks decaying to  $b\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 35 AABOUD 19x search for scalar leptoquarks decaying to  $b\nu$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 36 AABOUD 19x search for scalar leptoquarks decaying to  $t\tau$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.
- 37 SIRUNYAN 19B search for a pair of scalar leptoquarks decaying to  $\mu \mu j j$  and  $\nu \nu j j$  final states in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Limits are shown as a function of  $\beta$  where  $\beta$  is the branching fraction to a muon and a quark. For  $\beta = 1.0$  (0.5) LQ masses up to 1530 (1285) GeV are excluded. See Fig. 9 for exclusion limits in the plane of  $\beta$  and LQ mass.
- 38 SIRUNYAN 19B search for a pair of scalar leptoquarks decaying to  $e e j j$  and  $e \nu j j$  final states in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Limits are shown as a function of the branching fraction  $\beta$  to an electron and a quark. For  $\beta = 1.0$  (0.5) LQ masses up to 1435 (1270) GeV are excluded. See Fig. 9 for exclusion limits in the plane of  $\beta$  and LQ mass.
- 39 SIRUNYAN 19y search for a pair of third generation scalar leptoquarks, each decaying to  $\tau$  and a jet. Assuming  $B(\tau b) = 1$ , leptoquark masses below 1.02 TeV are excluded.
- 40 SIRUNYAN 18cz search for scalar leptoquarks decaying to  $\tau t$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(\tau t) = 1$ .
- 41 SIRUNYAN 18ec set limits for scalar and vector leptoquarks decaying to  $\mu t, \tau t$ , and  $\nu b$ . The limit quoted above assumes scalar leptoquark with  $B(\mu t) = 1$ .
- 42 SIRUNYAN 18ec set limits for scalar and vector leptoquarks decaying to  $\mu t, \tau t$ , and  $\nu b$ . The limit quoted above assumes vector leptoquark with all possible combinations of branching fractions to  $\mu t, \tau t$ , and  $\nu b$ .
- 43 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ . The limit quoted above assumes scalar leptoquark with  $B(b\nu) = 1$ . Vector leptoquarks with  $\kappa = 1$  are excluded below masses of 1810 GeV.
- 44 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ . The limit quoted above assumes scalar leptoquark with  $B(q\nu) = 1$ . Vector leptoquarks with  $\kappa = 1$  are excluded below masses of 1790 GeV.
- 45 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ . The limit quoted above assumes scalar leptoquark with  $B(\nu t) = 1$ . Vector leptoquarks with  $\kappa = 1$  are excluded below masses of 1780 GeV.
- 46 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ .  $\kappa = 1$  and  $LQ \rightarrow b\nu$  are assumed.
- 47 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ .  $\kappa = 1$  and  $LQ \rightarrow q\nu$  with  $q = u, d, s, c$  are assumed.
- 48 SIRUNYAN 18u set limits for scalar and vector leptoquarks decaying to  $t\nu, b\nu$ , and  $q\nu$ .  $\kappa = 1$  and  $LQ \rightarrow t\nu$  are assumed.
- 49 KHACHATRYAN 17j search for scalar leptoquarks decaying to  $\tau b$  using  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- 50 SIRUNYAN 17H search for scalar leptoquarks using  $\tau\tau b b$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- 51 AAD 16c search for scalar leptoquarks using  $e e j j$  events in collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(e q) = 1$ .
- 52 AAD 16c search for scalar leptoquarks using  $\mu \mu j j$  events in collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\mu q) = 1$ .
- 53 AAD 16c search for scalar leptoquarks decaying to  $b\nu$ . The limit above assumes  $B(b\nu) = 1$ .
- 54 AAD 16c search for scalar leptoquarks decaying to  $t\nu$ . The limit above assumes  $B(t\nu) = 1$ .
- 55 KHACHATRYAN 16AF search for scalar leptoquarks using  $e e j j$  and  $e \nu j j$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(e q) = 1$ . For  $B(e q) = 0.5$ , the limit becomes 850 GeV.
- 56 KHACHATRYAN 16AF search for scalar leptoquarks using  $\mu \mu j j$  and  $\mu \nu j j$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 760 GeV.
- 57 KHACHATRYAN 15AJ search for scalar leptoquarks using  $\tau\tau t t$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\tau t) = 1$ .
- 58 KHACHATRYAN 14T search for scalar leptoquarks decaying to  $\tau b$  using  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\tau b) = 1$ . See their Fig. 5 for the exclusion limit as function of  $B(\tau b)$ .
- 59 SIRUNYAN 19bc search for scalar leptoquark (LQ) pair production in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. One LQ is assumed to decay to  $\mu q$ , while the other decays to dark matter pair and SM particles. See their Fig. 4 for limits in  $M_{LQ} - M_{DM}$  plane.
- 60 AAD 13AE search for scalar leptoquarks using  $\tau\tau b b$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- 61 CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to  $\tau b$  in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above is for scalar leptoquarks with  $B(\tau b) = 1$ .
- 62 AAD 12H search for scalar leptoquarks using  $e e j j$  and  $e \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(e q) = 1$ . For  $B(e q) = 0.5$ , the limit becomes 607 GeV.
- 63 AAD 12o search for scalar leptoquarks using  $\mu \mu j j$  and  $\mu \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 594 GeV.
- 64 CHATRCHYAN 12AG search for scalar leptoquarks using  $e e j j$  and  $e \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(e q) = 1$ . For  $B(e q) = 0.5$ , the limit becomes 640 GeV.
- 65 CHATRCHYAN 12AG search for scalar leptoquarks using  $\mu \mu j j$  and  $\mu \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 650 GeV.
- 66 CHATRCHYAN 12Bo search for scalar leptoquarks decaying to  $\nu b$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- 67 AAD 11d search for scalar leptoquarks using  $e e j j$  and  $e \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(e q) = 1$ . For  $B(e q) = 0.5$ , the limit becomes 319 GeV.
- 68 AAD 11d search for scalar leptoquarks using  $\mu \mu j j$  and  $\mu \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 362 GeV.
- 69 ABAZOV 11v search for scalar leptoquarks using  $e \nu j j$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(e q) = 0.5$ .
- 70 CHATRCHYAN 11N search for scalar leptoquarks using  $e \nu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(e q) = 0.5$ .
- 71 KHACHATRYAN 11D search for scalar leptoquarks using  $e e j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(e q) = 1$ .
- 72 KHACHATRYAN 11E search for scalar leptoquarks using  $\mu \mu j j$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ .
- 73 ABAZOV 10L search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- 74 ABAZOV 09 search for scalar leptoquarks using  $\mu \mu j j$  and  $\mu \nu j j$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 270 GeV.
- 75 ABAZOV 09AF search for scalar leptoquarks using  $e e j j$  and  $e \nu j j$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(e q) = 1$ . For  $B(e q) = 0.5$  the bound becomes 284 GeV.
- 76 AALTONEN 08P search for vector leptoquarks using  $\tau^+ \tau^- b\bar{b}$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is  $> 317$  GeV (251 GeV) at 95% CL for  $B(\tau b) = 1$ .

- 77 Search for pair production of scalar leptoquark state decaying to  $\tau b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- 78 Search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu q) = 1$ .
- 79 ABAZOV 07J search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- 80 ABAZOV 06A search for scalar leptoquarks using  $\mu\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 204 GeV.
- 81 ABAZOV 06L search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and at 1.96 TeV. The limit above assumes  $B(\nu q) = 1$ .
- 82 ABULENCIA 06T search for scalar leptoquarks using  $\mu\mu jj$ ,  $\mu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted limit assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$  or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of  $B(\mu q)$ .
- 83 ABAZOV 05H search for scalar leptoquarks using  $ee jj$  and  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  the bound becomes 234 GeV.
- 84 ACOSTA 05P search for scalar leptoquarks using  $ee jj$ ,  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.
- 85 ABBIENDI 03R search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s} = 189-209$  GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquark with  $B(\ell q) = 1$ . See their table 12 for other cases.
- 86 ABAZOV 02 search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.
- 87 ABAZOV 01D search for scalar leptoquarks using  $e\nu jj$ ,  $ee jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit above assumes  $B(eq)=1$ . For  $B(eq)=0.5$  and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.
- 88 ABBIENDI 00M search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s}=183$  GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquarks with  $B(\ell q)=1$ . See their Table 8 and Figs. 6-9 for other cases.
- 89 ABBOTT 00c search for scalar leptoquarks using  $\mu\mu jj$ ,  $\mu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit above assumes  $B(\mu q)=1$ . For  $B(\mu q)=0.5$  and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.
- 90 AFFOLDER 00k search for scalar leptoquark using  $\nu\nu cc$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The quoted limit assumes  $B(\nu c)=1$ . Bounds for vector leptoquarks are also given.
- 91 AFFOLDER 00k search for scalar leptoquark using  $\nu\nu bb$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The quoted limit assumes  $B(\nu b)=1$ . Bounds for vector leptoquarks are also given.
- 92 ABBOTT 99j search for leptoquarks using  $\mu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The quoted limit is for a scalar leptoquark with  $B(\mu q) = B(\nu q) = 0.5$ . Limits on vector leptoquarks range from 240 to 290 GeV.
- 93 ABBOTT 98E search for scalar leptoquarks using  $e\nu jj$ ,  $ee jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit above assumes  $B(eq)=1$ . For  $B(eq)=0.5$  and 0, the bound becomes 204 and 79 GeV, respectively.
- 94 ABBOTT 98j search for charge  $-1/3$  third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\nu b)=1$ .
- 95 ABE 98s search for scalar leptoquarks using  $\mu\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit is for  $B(\mu q) = 1$ . For  $B(\mu q)=B(\nu q)=0.5$ , the limit is  $> 160$  GeV.
- 96 GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97x and ABBOTT 98E.
- 97 ABE 97f search for third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\tau b) = 1$ .
- 98 ABE 97x search for scalar leptoquarks using  $ee jj$  events in  $p\bar{p}$  collisions at  $E_{cm}=1.8$  TeV. The limit is for  $B(eq)=1$ .
- 99 Limit is for charge  $-1/3$  isospin-0 leptoquark with  $B(\ell q) = 2/3$ .
- 100 First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- 101 Limits are for charge  $-1/3$ , isospin-0 scalar leptoquarks decaying to  $\ell^- q$  or  $\nu q$  with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.
- 102 KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of  $d e^+$  and  $u \bar{p}$  ( $s \mu^+$  and  $c \bar{p}$ ). See paper for limits for specific branching ratios.
- 103 BARTEL 87b limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint  $B(X \rightarrow c \bar{\mu}) + B(X \rightarrow s \mu^+) = 1$ .
- 104 BEHREND 86b assumed that a charge 2/3 spinless leptoquark,  $\chi$ , decays either into  $s \mu^+$  or  $c \bar{\mu}$ .  $B(\chi \rightarrow s \mu^+) + B(\chi \rightarrow c \bar{\mu}) = 1$ .

- 1 AAD 23bz search for single production of charge 4/3 scalar leptoquarks decaying to  $b\tau^-$ , and charge 2/3 vector leptoquarks decaying to  $\bar{b}\tau^-$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above assumes a scalar leptoquark with  $B(b\tau) = 1$  and the leptoquark coupling strength  $\lambda = 1.0$ . The limit becomes  $M_{LQ} > 1530$  GeV for  $\lambda = 2.5$ .
- 2 SIRUNYAN 21J search for single production of charge  $-1/3$  scalar leptoquarks decaying to  $t\tau^-$  and  $b\nu$ , and charge 2/3 vector leptoquarks decaying to  $t\nu$  and  $b\tau^+$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit quoted above assumes a scalar leptoquark with  $B(\tau) = B(b\nu) = 0.5$  and the leptoquark coupling strength  $\lambda = 1.5$ . The limit becomes  $M_{LQ} > 750$  GeV for  $\lambda = 2.5$ .
- 3 SIRUNYAN 18bJ search for single production of charge 2/3 scalar leptoquarks decaying to  $\tau b$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The limit above assumes  $B(\tau b) = 1$  and the leptoquark coupling strength  $\lambda = 1$ .
- 4 KHACHATRYAN 16AG search for single production of charge  $\pm 1/3$  scalar leptoquarks using  $ee j$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(eq) = 1$  and the leptoquark coupling strength  $\lambda = 1$ .
- 5 KHACHATRYAN 16AG search for single production of charge  $\pm 1/3$  scalar leptoquarks using  $\mu\mu j$  events in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The limit above assumes  $B(\mu q) = 1$  and the leptoquark coupling strength  $\lambda = 1$ .
- 6 ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Figs. 12-17 and Table 4 for states with different quantum numbers.
- 7 Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes  $B(\ell q) = 2/3$ . The limit is 77 GeV if first and second leptoquarks are degenerate.
- 8 AAD 22E leptoquarks decaying both to  $ue^-$  and  $c\mu^-$  are constrained from the comparison of the production cross sections for  $e^+ \mu^-$  and  $e^- \mu^+$  in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. Scalar leptoquarks with  $M_{LQ} < 1880$  GeV are excluded for  $g^{eu} = g^{\mu c} = 1$ .
- 9 TUMASYAN 21D search for energetic jets +  $E_T$  events in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. The branching fraction for the decay of the leptoquark into an electron neutrino and up quark is assumed to be 100% ( $\beta = 0$ ). See their Fig. 12 for exclusion limits in mass-coupling plane.
- 10 DEY 16 use the 2010-2012 IceCube PeV energy data set to constrain the leptoquark production cross section through the  $\nu q \rightarrow LQ \rightarrow \nu q$  process. See their Figure 4 for the exclusion limit in the mass-coupling plane.
- 11 AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2-3 and Tables 1-4 for detailed limits.
- 12 The quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Figs. 3-5 for limits on states with different quantum numbers.
- 13 ABAZOV 07E search for leptoquark single production through  $qg$  fusion process in  $p\bar{p}$  collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.
- 14 AKTAS 05B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Fig. 3 for limits on states with different quantum numbers.
- 15 CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6-7 and Tables 1-8 for detailed limits.
- 16 CHEKANOV 03B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Figs. 11-12 and Table 5 for limits on states with different quantum numbers.
- 17 For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.
- 18 CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6-7 and Tables 5-6 for detailed limits.
- 19 For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.
- 20 See their Fig. 14 for limits in the mass-coupling plane.
- 21 BREITWEG 00E search for  $F=0$  leptoquarks in  $e^+p$  collisions. For limits in mass-coupling plane, see their Fig. 11.
- 22 ABREU 99G limit obtained from process  $e\gamma \rightarrow LQ+q$ . For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.
- 23 For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96b.
- 24 DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5-8 and Table 1 for detailed limits.
- 25 DERRICK 93 search for single leptoquark production in  $ep$  collisions with the decay  $e q$  and  $\nu q$ . The limit is for leptoquark coupling of electromagnetic strength and assumes  $B(eq) = B(\nu q) = 1/2$ . The limit for  $B(eq) = 1$  is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

**MASS LIMITS for Leptoquarks from Single Production**

These limits depend on the  $q$ - $\ell$  leptoquark coupling  $g_{LQ}$ . It is often assumed that  $g_{LQ}^2/4\pi=1/137$ . Limits shown are for a scalar, weak isoscalar, charge  $-1/3$  leptoquark.

1 CALABRESE 23 obtain limits on leptoquark coupling from coherent  $\nu$ -nucleus scattering data collected by COHERENT experiment. See their Fig. 3 for limits in mass-coupling plane.

2 TUMASYAN 23AV search for  $\tau\nu$  events mediated by  $t$ -channel leptoquark exchange in  $pp$  collisions at  $\sqrt{s}=13$  TeV. See their Fig. 10 for limits in mass-coupling plane.

3 TUMASYAN 23s search for leptoquark induced  $b\bar{b} \rightarrow \tau^+\tau^-$  process in  $pp$  collisions at  $\sqrt{s}=13$  TeV. See their Fig. 12 for limits on a vector  $b\tau$  leptoquark in mass-coupling plane.

4 CRIVELLIN 21A set limits on coupling strengths of scalar and vector leptoquarks using  $K \rightarrow \pi\nu\nu, K \rightarrow \pi e^+e^-, K^0 - \bar{K}^0$  and  $D^0 - \bar{D}^0$  mixings, and weak neutral current measurements. See their Fig. 2 and Fig. 3 for the limits in mass-coupling plane.

5 AEBISCHER 20 explain the  $B$  decay anomalies using four-fermion operator Wilson coefficients. See their Table 1. These Wilson coefficients may be generated by a  $U_1$  vector leptoquark with  $U_1$  transforming as  $(3,1)_{2/3}$  under the SM gauge group. See their Figures 6, 7, 8 for the regions of the LQ parameter space which explains the  $B$  anomalies and avoids the indirect low energy constraints.

6 DEPPISCH 20 limits on the lepton-number-violating higher-dimensional-operators are derived from  $K \rightarrow \pi\nu\nu$  in the standard model effective field theory. These higher-dimensional-operators may be induced from leptoquark-exchange diagrams.

7 ABRAMOWICZ 19 obtain a limit on  $\lambda/M_{LQ} > 1.16 \text{ TeV}^{-1}$  for weak isotriplet spin-0 leptoquark  $S_1^L$ . We obtain the limit quoted above by converting the limit on  $\lambda/M_{LQ}$  for  $S_1^L$  assuming  $\lambda = \sqrt{4\pi}$ . See their Table 5 for the limits of leptoquarks with different quantum numbers. These limits are derived from bounds of  $eq$  contact interactions.

8 MANDAL 19 give bounds on leptoquarks from  $\tau$ -decays, leptonic dipole moments, lepton-flavor-violating processes, and  $K$  decays.

9 ZHANG 18A give bounds on leptoquark induced four-fermion interactions from  $D \rightarrow K\ell\nu$ . The authors inform us that the shape parameter of the vector form factor in both the abstract and the conclusions of ZHANG 18A should be  $r_{+1} = 2.16 \pm 0.07$  rather than  $\pm 0.07$ . The numbers listed in their Table 7 are correct.

10 BARRANCO 16 give bounds on leptoquark induced four-fermion interactions from  $D \rightarrow K\ell\nu$  and  $D_S \rightarrow \ell\nu$ .

11 KUMAR 16 gives bound on SU(2) singlet scalar leptoquark with charge  $-1/3$  from  $K^0 - \bar{K}^0$  mixing,  $K \rightarrow \pi\nu\bar{\nu}, K_L^0 \rightarrow \mu^+\mu^-$ , and  $K_L^0 \rightarrow \mu^\pm e^\mp$  decays.

12 BESSAA 15 obtain limit on leptoquark induced four-fermion interactions from the ATLAS and CMS limit on the  $q\bar{q}e\bar{e}$  contact interactions.

13 SAHOO 15A obtain limit on leptoquark induced four-fermion interactions from  $B_{s,d} \rightarrow \mu^+\mu^-$  for  $\lambda \simeq O(1)$ .

14 SAKAKI 13 explain the  $B \rightarrow D^{(*)}\tau\bar{\nu}$  anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.

15 KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from  $b \rightarrow s\ell^+\ell^-$  decays.

16 AARON 11C limit is for weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of  $eq$  contact interactions.

17 DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from  $K, B, \tau$  decays, meson mixings, LFV,  $g=2$  and  $Z \rightarrow b\bar{b}$ .

18 AKTAS 07A search for lepton-flavor violation in  $e p$  collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

19 SCHAEEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.

20 SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from  $K \rightarrow e\mu, B \rightarrow e\tau$  decays.

21 CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

22 ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on  $e^\pm q$  contact interactions.

23 The bound is derived from  $B(B^0 \rightarrow e^\pm\mu^\mp) < 1.7 \times 10^{-7}$ .

24 CHEKANOV 02 search for lepton-flavor violation in  $e p$  collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

25 CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.

26 ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.

27 ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling,  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 2.

28 ADLOFF 00 limits are from the  $Q^2$  spectrum measurement of  $e^+p \rightarrow e^+X$ .

29 BARATE 00I search for deviations in cross section and jet-charge asymmetry in  $e^+e^- \rightarrow \bar{q}q$  due to  $t$ -channel exchange of a leptoquark at  $\sqrt{s}=130$  to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

30 BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.

31 GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.

32 ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.

33 ABBIENDI 99 limits are from  $e^+e^- \rightarrow q\bar{q}$  cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

34 ABE 98V quoted limit is from  $B(B_S \rightarrow e^\pm\mu^\mp) < 8.2 \times 10^{-6}$ . ABE 98V also obtain a similar limit on  $M_{LQ} > 20.4$  TeV from  $B(B_d \rightarrow e^\pm\mu^\mp) < 4.5 \times 10^{-6}$ . Both bounds assume the non-canonical association of the  $b$  quark with electrons or muons under SU(4).

35 ACCIARRI 98J limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=130$ –172 GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

36 ACKERSTAFF 98V limits are from  $e^+e^- \rightarrow q\bar{q}$  and  $e^+e^- \rightarrow b\bar{b}$  cross sections at  $\sqrt{s}=130$ –172 GeV, which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

37 DEANDREA 97 limit is for  $\bar{R}_2$  leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange.

38 DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

39 DERRICK 97 search for lepton-flavor violation in  $e p$  collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

40 GROSSMAN 97 estimate the upper bounds on the branching fraction  $B \rightarrow \tau^+\tau^-(X)$  from the absence of the  $B$  decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

41 JADACH 97 limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=172.3$  GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

42 KUZNETSOV 95B use  $\pi, K, B, \tau$  decays and  $\mu e$  conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from  $K_L \rightarrow \mu e$  decay assuming zero mixing.

43 MIZUKOSHI 95 calculate the one-loop radiative correction to the  $Z$ -physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

44 BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the  $Z$ .  $m_H=250$  GeV,  $\alpha_s(m_Z)=0.12$ ,  $m_t=180$  GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to  $\bar{\nu}_L t_R, \bar{\nu}_L, \bar{\nu}_L$  and  $\bar{\nu}_L$ , see Fig. 2 in BHATTACHARYYA 94b erratum and Fig. 3.

45 DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from  $\pi, K, D, B, \mu, \tau$  decays and meson mixings, etc. See Table 15 of DAVIDSON 94 for detail.

46 KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on  $\pi^0 \rightarrow \bar{\nu}\nu$ .

47 LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in  $\pi_{\ell 2}$  decay provides a much more stringent bound.

48 MAHANTA 94 gives bounds of  $P$ - and  $T$ -violating scalar-leptoquark couplings from atomic and molecular experiments.

49 From  $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$  ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling  $4g^2/M^2 (\bar{\nu}_L u_R) (\bar{\nu}_L e_R)$  with  $g=0.004$  for spin-0 leptoquark and  $g^2/M^2 (\bar{\nu}_L e_L u_L) (\bar{\nu}_R \gamma^\mu e_R)$  with  $g \simeq 0.6$  for spin-1 leptoquark.

See key on page 1171

1 SIRUNYAN 20A1 search for resonances decaying into dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  
 2 SIRUNYAN 18B0 search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.

- 3 KHACHATRYAN 17W search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  
 4 KHACHATRYAN 16K search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 13$  TeV.  
 5 KHACHATRYAN 16L search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.  
 6 KHACHATRYAN 15V search for resonances decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  
 7 KHACHATRYAN 17Y search for pair production of color-octet gauge boson  $g_A$  each decaying to  $4j$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  
 8 AAD 16W search for a new resonance decaying to a pair of  $b$  and  $B_H$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The vector-like quark  $B_H$  is assumed to decay to  $bH$ . See their Fig. 3 and Fig. 4 for limits on  $\sigma \cdot B$ .  
 9 KHACHATRYAN 16E search for KK gluon decaying to  $t\bar{t}$  in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  
 10 KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles ( $\Theta^0$ ), decaying to  $b\bar{b}$ ,  $Zg$  or  $\gamma g$ , in  $pp$  collisions at  $\sqrt{s} = 8$  TeV. The  $\Theta^0$  particle is often predicted in coloron ( $G'$ , color-octet gauge boson) models and appear in the  $pp$  collisions through  $G' \rightarrow \Theta^0 \Theta^0$  decays. Assuming  $B(\Theta^0 \rightarrow b\bar{b}) = 0.5$ , they give limits  $m_{\Theta^0} > 623$  GeV (426 GeV) for  $m_{G'} = 2.3 m_{\Theta^0}$  ( $m_{G'} = 5 m_{\Theta^0}$ ).  
 11 AALTONEN 13R search for new resonance decaying to  $\sigma\sigma$ , with hypothetical strongly interacting  $\sigma$  particle subsequently decaying to 2 jets, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV, using data corresponding to an integrated luminosity of  $6.6 \text{ fb}^{-1}$ . For  $50 \text{ GeV} < m_\sigma < m_{g_A}/2$ , axigluons in mass range 150–400 GeV are excluded.  
 12 CHATRCHYAN 13A search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  
 13 CHATRCHYAN 13AS search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.  
 14 CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to  $q\bar{q}$  pairs in  $pp$  collisions. The quoted limit is for  $B(g_A \rightarrow q\bar{q}) = 1$ .  
 15 ABAZOV 12R search for massive color octet vector particle decaying to  $t\bar{t}$ . The quoted limit assumes  $g_A$  couplings with light quarks are suppressed by 0.2.  
 16 CHATRCHYAN 11Y search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  
 17 AALTONEN 10L search for massive color octet non-chiral vector particle decaying into  $t\bar{t}$  pair with mass in the range  $400 \text{ GeV} < M < 800 \text{ GeV}$ . See their Fig. 6 for limit in the mass-coupling plane.  
 18 KHACHATRYAN 10 search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  
 19 AALTONEN 09AC search for new narrow resonance decaying to dijets.  
 20 CHOUDHURY 07 limit is from the  $t\bar{t}$  production cross section measured at CDF.  
 21 DONCHESKI 98 compare  $\alpha_s$  derived from low-energy data and that from  $\Gamma(Z \rightarrow \text{hadrons})/\Gamma(Z \rightarrow \text{leptons})$ .  
 22 ABE 97G search for new particle decaying to dijets.  
 23 ABE 95N assume axigluons decaying to quarks in the Standard Model only.  
 24 ABE 93G assume  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 10$ .  
 25 CUYPERS 91 compare  $\alpha_s$  measured in  $T$  decay and that from  $R$  at PEP/PETRA energies.  
 26 ABE 90H assumes  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 5$  ( $\Gamma(g_A) = 0.09 m_{g_A}$ ). For  $N = 10$ , the excluded region is reduced to 120–150 GeV.  
 27 ROBINETT 89 result demands partial-wave unitarity of  $J = 0$   $t\bar{t} \rightarrow t\bar{t}$  scattering amplitude and derives a limit  $m_{g_A} > 0.5 m_t$ . Assumes  $m_t > 56 \text{ GeV}$ .  
 28 ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution.  $\Gamma(g_A) < 0.4 m_{g_A}$  assumed. See also BAGGER 88.  
 29 CUYPERS 88 requires  $\Gamma(T \rightarrow g g_A) < \Gamma(T \rightarrow g g g)$ . A similar result is obtained by DONCHESKI 88.  
 30 DONCHESKI 88B requires  $\Gamma(T \rightarrow g q\bar{q})/\Gamma(T \rightarrow g g g) < 0.25$ , where the former decay proceeds via axigluon exchange. A more conservative estimate of  $< 0.5$  leads to  $m_{g_A} > 21 \text{ GeV}$ .

### MASS LIMITS for Color-Octet Scalar Bosons

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
none 1800–3700	95	1 SIRUNYAN 20A1	CMS	$pp \rightarrow S_8 X, S_8 \rightarrow gg$

- RAINBOLT 19 limits are from  $B(Z \rightarrow \ell^+\ell^-\ell^+\ell^-)$ . See their Figs. 5 and 6 for limits in mass-coupling plane.
- SIRUANYAN 19AZ search for  $pp \rightarrow Z \rightarrow X^0\mu^+\mu^- \rightarrow \mu^+\mu^-\mu^+\mu^-$  events in  $pp$  collisions at  $\sqrt{s} = 13$  TeV. See their Fig. 5 for limits on  $\sigma(pp \rightarrow X^0\mu^+\mu^-) \cdot B(X^0 \rightarrow \mu^+\mu^-)$ .
- BARATE 98U obtain limits on  $B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \ell\bar{\ell}, q\bar{q}, gg, \gamma\gamma, \nu\bar{\nu})$ . See their Fig. 17.
- See Fig. 4 of ACCIARRI 97Q for the upper limit on  $B(Z \rightarrow \gamma X^0; E_\gamma > E_{\min})$  as a function of  $E_{\min}$ .
- ACTON 93E give  $\sigma(e^+e^- \rightarrow X^0\gamma) \cdot B(X^0 \rightarrow \gamma\gamma) < 0.4$  pb (95%CL) for  $m_{X^0} = 60 \pm 2.5$  GeV. If the process occurs via  $s$ -channel  $\gamma$  exchange, the limit translates to  $\Gamma(X^0) \cdot B(X^0 \rightarrow \gamma\gamma)^2 < 20$  MeV for  $m_{X^0} = 60 \pm 1$  GeV.
- ABREU 92D give  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (3-10)$  pb for  $m_{X^0} = 10-78$  GeV. A very similar limit is obtained for spin-1  $X^0$ .
- ADRIANI 92F search for isolated  $\gamma$  in hadronic  $Z$  decays. The limit  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (2-10)$  pb (95%CL) is given for  $m_{X^0} = 25-85$  GeV.
- ACTON 91 searches for  $Z \rightarrow Z^* X^0, Z^* \rightarrow e^+e^-, \mu^+\mu^-, \text{ or } \nu\bar{\nu}$ . Excludes any new scalar  $X^0$  with  $m_{X^0} < 9.5$  GeV/c if it has the same coupling to  $ZZ^*$  as the MSM Higgs boson.
- ACTON 91B limits are for  $m_{X^0} = 60-85$  GeV.
- ADEVA 91D limits are for  $m_{X^0} = 30-89$  GeV.
- ADEVA 91D limits are for  $m_{X^0} = 30-86$  GeV.
- AKRAWY 90J give  $\Gamma(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < 1.9$  MeV (95%CL) for  $m_{X^0} = 32-80$  GeV. We divide by  $\Gamma(Z) = 2.5$  GeV to get product of branching ratios. For nonresonant transitions, the limit is  $B(Z \rightarrow \gamma q\bar{q}) < 8.2$  MeV assuming three-body phase space distribution.

### MASS LIMITS for a Heavy Neutral Boson Coupling to $e^+e^-$

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
none 55-61		1 ODAKA	89 VNS	$\Gamma(X^0 \rightarrow e^+e^-) \cdot B(X^0 \rightarrow \text{had.}) \gtrsim 0.2$ MeV

		4 BERGER	85B PLUT	
none 39.8-45.5		5 ADEVA	84 MRKJ	$\Gamma(X^0 \rightarrow e^+e^-) = 10$ keV
>47.8	95	5 ADEVA	84 MRKJ	$\Gamma(X^0 \rightarrow e^+e^-) = 4$ MeV
none 39.8-45.2		5 BEHREND	84c CELL	
>47	95	5 BEHREND	84c CELL	$\Gamma(X^0 \rightarrow e^+e^-) = 4$ MeV

- ODAKA 89 looked for a narrow or wide scalar resonance in  $e^+e^- \rightarrow$  hadrons at  $E_{\text{cm}} = 55.0-60.8$  GeV.
- DERRICK 86 found no deviation from the Standard Model Bhabha scattering at  $E_{\text{cm}} = 29$  GeV and set limits on the possible scalar boson  $e^+e^-$  coupling. See their figure 4 for excluded region in the  $\Gamma(X^0 \rightarrow e^+e^-) \cdot m_{X^0}$  plane. Electronic chiral invariance requires a parity doublet of  $X^0$ , in which case the limit applies for  $\Gamma(X^0 \rightarrow e^+e^-) = 3$  MeV.
- ADEVA 85 first limit is from  $2\gamma, \mu^+\mu^-,$  hadrons assuming  $X^0$  is a scalar. Second limit is from  $e^+e^-$  channel.  $E_{\text{cm}} = 40-47$  GeV. Supersedes ADEVA 84.
- BERGER 85B looked for effect of spin-0 boson exchange in  $e^+e^- \rightarrow e^+e^-$  and  $\mu^+\mu^-$  at  $E_{\text{cm}} = 34.7$  GeV. See Fig. 5 for excluded region in the  $m_{X^0} - \Gamma(X^0)$  plane.
- ADEVA 84 and BEHREND 84c have  $E_{\text{cm}} = 39.8-45.5$  GeV. MARK-J searched  $X^0$  in  $e^+e^- \rightarrow$  hadrons,  $2\gamma, \mu^+\mu^-, e^+e^-$  and CELLO in the same channels plus  $\tau$  pair. No narrow or broad  $X^0$  is found in the energy range. They also searched for the effect of  $X^0$  with  $m_X > E_{\text{cm}}$ . The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for  $\Gamma(X^0 \rightarrow e^+e^-) = 2$  MeV if  $X^0$  is a spin-0 doublet. The second limit of BEHREND 84c was read off from their figure 2. The original papers also list limits in other channels.

### Search for $X^0$ Resonance in $e^+e^-$ Collisions

The limit is for  $\Gamma(X^0 \rightarrow e^+e^-) \cdot B(X^0 \rightarrow f)$ , where  $f$  is the specified final state. Spin 0 is assumed for  $X^0$ .

VALUE (keV)	CL%	DOCUMENT ID	TECN	COMMENT

A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

Table showing mass limits for Axions from Astrophysics and Cosmology. Columns include VALUE (MeV), DOCUMENT ID, TECN, and COMMENT. Lists experiments like BARROSO, RAFFELT, DICUS.

1 ADACHI 23k quoted limit is for m\_X0 approx 3 GeV, ctau\_X0 = 1 cm, and the decay channel X0 -> e+e-. See their Fig. 2 for limits with different lifetimes and decay channels.
2 ADACHI 23k quoted limit is for m\_X0 approx 2 GeV, ctau\_X0 = 1 cm, and the decay channel X0 -> e+e-. See their Fig. 2 for limits with different lifetimes and decay channels.
3 CORTINA-GIL 23B limit extends over 10-170 MeV in mass. Quoted limit is at 155 MeV.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>4</sup> LEES 22B quoted limit is for  $m_{A^0} = 3.9$  GeV, assuming the promptly decaying axion. Limits of  $O(10^{-7})$  are obtained for  $m_{A^0} = 0.175\text{--}4.78$  GeV. See their Figs.3 and 4 for mass and lifetime dependent limits.
- <sup>5</sup> ABRATENKO 21 quoted limit is for  $m_{X^0} = 150$  MeV and the lifetime  $c\tau_{X^0} = 80$  m. See their Fig. 4 for the limits in the range of  $m_{X^0} = 10\text{--}210$  MeV.
- <sup>6</sup> CORTINA-GIL 21 quoted limit is for  $m_{X^0} = 370$  MeV. Limits from  $O(10^{-5})$  and  $O(10^{-6})$  are obtained for  $m_{X^0} = 10\text{--}370$  MeV (see their Fig. 7).
- <sup>7</sup> CORTINA-GIL 21A quoted limit is for  $m_{X^0} = 160\text{--}250$  MeV. Limits between  $5 \times 10^{-11}$  and  $2 \times 10^{-10}$  are obtained in the range of  $m_{X^0} = 0\text{--}110$  and  $154\text{--}260$  MeV, assuming stable or invisibly decaying  $X^0$ . See their Fig. 4 for mass- and lifetime-dependent limits.
- <sup>8</sup> CORTINA-GIL 21C quoted limit is for  $m_{X^0} = 130\text{--}140$  MeV, and limits of  $9 \times 10^{-10}\text{--}6 \times 10^{-7}$  are obtained in the mass range of  $m_{X^0} = 110\text{--}155$  MeV, assuming  $X^0$  escapes detection. See their Fig. 6 for mass- and lifetime-dependent limits.
- <sup>9</sup> PARK 21 look for dark photons produced by decays of  $B^0$  through off-shell Higgs-dark Higgs mixing. See their Fig. 5 for limits in the range of  $m_{X^0} = 0.01\text{--}2.62$  GeV.
- <sup>10</sup> AHN 19 is an update of AHN 17 from a new data set. See their Fig. 4 for the limits in the range of  $m_{X^0} = 0\text{--}250$  MeV.
- <sup>11</sup> AAIJ 17AQ limit is for  $\tau_{X^0} = 10$  ps. See their Fig. 4 for limits in the range of  $m_{X^0} = 250\text{--}4700$  MeV and  $\tau_{X^0} = 0.1\text{--}1000$  ps.
- <sup>12</sup> AHN 17 limit as a function of  $m_{X^0}$  from 0 to 250 MeV is provided in their Fig. 5.
- <sup>13</sup> BATLEY 17 limit is for  $m_{X^0} = 216$  MeV and  $\tau_{X^0} \leq 10$  ps. See their Fig. 4(c) for limits in the range of  $m_{X^0} = 211\text{--}354$  MeV and longer lifetimes.
- <sup>14</sup> WON 16 look for a vector boson coupled to baryon number. Derived limits on  $\alpha' < 10^{-3}\text{--}10^{-2}$  for  $m_{X^0} = 290\text{--}520$  MeV at 95% CL. See their Fig. 4 for mass-dependent limits.
- <sup>15</sup> AAIJ 15AZ limit is for  $\tau_{X^0} = 10$  ps and  $m_{X^0} = 214\text{--}4350$  MeV. See their Fig. 4 for mass- and lifetime-dependent limits.
- <sup>16</sup> ADLARSON 13 limits between  $2.0 \times 10^{-5}$  and  $1.5 \times 10^{-6}$  are obtained for  $m_{X^0} = 20\text{--}100$  MeV (see their Fig. 8). Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .
- <sup>17</sup> BABUSCI 13B limit is for  $B(\phi \rightarrow \eta X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies to  $m_{X^0} = 410$  MeV. It is derived by analyzing  $\eta \rightarrow \pi^0 \rho^0 \pi^0$  and  $\pi^- \pi^+ \pi^0$ . Limits between  $1 \times 10^{-6}$  and  $2 \times 10^{-8}$  are obtained for  $m_{X^0} \leq 450$  MeV (see their Fig. 6).
- <sup>18</sup> ARCHILLI 12 analyzed  $\eta \rightarrow \pi^+ \pi^- \pi^0$  decays. Derived limits on  $\alpha'/\alpha < 2 \times 10^{-5}$  for  $m_{X^0} = 50\text{--}420$  MeV at 90% CL. See their Fig. 8 for mass-dependent limits.
- <sup>19</sup> GNINENKO 12A limit is for  $B(\pi^0 \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 90$  MeV and  $\tau_{X^0} \approx 1 \times 10^{-8}$  sec. Limits between  $10^{-8}$  and  $2 \times 10^{-15}$  are obtained for  $m_{X^0} = 3\text{--}120$  MeV and  $\tau_{X^0} = 1 \times 10^{-11}\text{--}1$  sec. See their Fig. 3 for limits at different masses and lifetimes.
- <sup>20</sup> GNINENKO 12B limit is for  $B(\eta \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 100$  MeV and  $\tau_{X^0} \approx 6 \times 10^{-9}$  sec. Limits between  $10^{-5}$  and  $3 \times 10^{-14}$  are obtained for  $m_{X^0} \lesssim 550$  MeV and  $\tau_{X^0} = 10^{-10}\text{--}10$  sec. See their Fig. 5 for limits at different mass and lifetime and for  $\eta'$  decays.
- <sup>21</sup> ADLER 04 limit applies for a mass near 180 MeV. For other masses in the range  $m_{X^0} = 150\text{--}250$  MeV the limit is less restrictive, but still improves ADLER 02c and ATIYA 93B.
- <sup>22</sup> ANISIMOVSKY 04 bound is for  $m_{X^0} = 0$ .
- <sup>23</sup> ADLER 02c bound is for  $m_{X^0} < 60$  MeV. See Fig. 2 for limits at higher masses.
- <sup>24</sup> The quoted limit is for  $m_{X^0} = 0\text{--}80$  MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.
- <sup>25</sup> ALTEGOER 98 looked for  $X^0$  from  $\pi^0$  decay which penetrate the shielding and convert to  $\pi^0$  in the external Coulomb field of a nucleus.
- <sup>26</sup> KITCHING 97 limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} \approx 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>27</sup> ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable  $X^0$  particles and extends to  $m_{X^0} = 80$  MeV at the same level. See paper for dependence on finite lifetime.
- <sup>28</sup> AMSLER 94b and AMSLER 96b looked for a peak in missing-mass distribution.
- <sup>29</sup> MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of  $X^0$  decay modes. It applies to  $\tau(X^0) > 10^{-23}$  sec.
- <sup>30</sup> ATIYA 93b looked for a peak in missing mass distribution. The bound applies for stable  $X^0$  of  $m_{X^0} = 150\text{--}250$  MeV, and the limit becomes stronger ( $10^{-8}$ ) for  $m_{X^0} = 180\text{--}240$  MeV.
- <sup>31</sup> NG 93 studied the production of  $X^0$  via  $\gamma\gamma \rightarrow \pi^0 \rightarrow \gamma X^0$  in the early universe at  $T \approx 1$  MeV. The bound on extra neutrinos from nucleosynthesis  $\Delta N_\nu < 0.3$  (WALKER 91) is employed. It applies to  $m_{X^0} \ll 1$  MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier  $X^0$ .
- <sup>32</sup> ALLIEGRO 92 limit applies for  $m_{X^0} = 150\text{--}340$  MeV and is the branching ratio times the decay probability. Limit is  $< 1.5 \times 10^{-8}$  at 99% CL.
- <sup>33</sup> ATIYA 92 looked for a peak in missing mass distribution. The limit applies to  $m_{X^0} = 0\text{--}130$  MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires  $X^0$  to be a vector particle.
- <sup>34</sup> BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between  $1 \times 10^{-12}$  and  $1 \times 10^{-7}$  are obtained for  $3 < m_{X^0} < 40$  MeV.
- <sup>35</sup> Limits between  $1 \times 10^{-12}$  and 1 are obtained for  $4 < m_{X^0} < 69$  MeV.
- <sup>36</sup> Limits between  $1 \times 10^{-11}$  and  $5 \times 10^{-3}$  are obtained for  $4 < m_{X^0} < 63$  MeV.
- <sup>37</sup> Limits between  $1 \times 10^{-14}$  and 1 are obtained for  $3 < m_{X^0} < 82$  MeV.
- <sup>38</sup> MEIJERDREES 92 limit applies for  $\tau_{X^0} = 10^{-23}\text{--}10^{-11}$  sec. Limits between  $2 \times 10^{-4}$  and  $4 \times 10^{-6}$  are obtained for  $m_{X^0} = 25\text{--}120$  MeV. Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .

- <sup>39</sup> ATIYA 90b limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} = 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are also provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>40</sup> KORENCHENKO 87 limit assumes  $m_{A^0} = 1.7$  MeV,  $\tau_{A^0} \lesssim 10^{-12}$  s, and  $B(A^0 \rightarrow e^+ e^-) = 1$ .
- <sup>41</sup> EICHLER 86 looked for  $\pi^+ \rightarrow e^+ \nu A^0$  followed by  $A^0 \rightarrow e^+ e^-$ . Limits on the branching fraction depend on the mass and lifetime of  $A^0$ . The quoted limits are valid when  $\tau(A^0) \gtrsim 3 \times 10^{-10}$  s if the decays are kinematically allowed.
- <sup>42</sup> YAMAZAKI 84 looked for a discrete line in  $K^+ \rightarrow \pi^+ X$ . Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
- <sup>43</sup> ASANO 82 at KEK set limits for  $B(K^+ \rightarrow \pi^+ X^0)$  for  $m_{X^0} < 100$  MeV as  $BR < 4 \times 10^{-8}$  for  $\tau(X^0 \rightarrow n\gamma\text{'s}) > 1 \times 10^{-9}$  s,  $BR < 1.4 \times 10^{-6}$  for  $\tau < 1 \times 10^{-9}$  s.
- <sup>44</sup> ASANO 81B is KEK experiment. Set  $B(K^+ \rightarrow \pi^+ X^0) < 3.8 \times 10^{-8}$  at CL = 90%.
- <sup>45</sup> ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ( $3 < m < 40$  MeV) contradicts experimental muon anomalous magnetic moments.

### $A^0$ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

$< 3.0 \times 10^{-4}$	90	2 ASAI	94 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} = 30\text{--}500$ keV
$< 2.8 \times 10^{-5}$	90	3 AKOPYAN	91 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma (A^0 \rightarrow \gamma\gamma), m_{A^0} < 30$ keV
$< 1.1 \times 10^{-6}$	90	4 ASAI	91 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 800$ keV
$< 3.8 \times 10^{-4}$	90	GNINENKO	90 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 30$ keV
$< (1\text{--}5) \times 10^{-4}$	95	5 TSUCHIYAKI	90 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} = 300\text{--}900$ keV
$< 6.4 \times 10^{-5}$	90	6 ORITO	89 CNTR	$o\text{-Ps} \rightarrow A^0 \gamma, m_{A^0} < 30$ keV
		7 AMALDI	85 CNTR	Ortho-positronium
		8 CARBONI	83 CNTR	Ortho-positronium
1 BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.				
2 The ASAI 94 limit is based on inclusive photon spectrum and is independent of $A^0$ decay modes.				
3 The AKOPYAN 91 limit applies for a short-lived $A^0$ with $\tau_{A^0} < 10^{-13}$ $m_{A^0}$ [keV] s.				
4 ASAI 91 limit translates to $g_{A^0 e^+ e^-}^2 / 4\pi < 1.1 \times 10^{-11}$ (90% CL) for $m_{A^0} < 800$ keV.				
5 The TSUCHIYAKI 90 limit is based on inclusive photon spectrum and is independent of $A^0$ decay modes.				
6 ORITO 89 limit translates to $g_{A^0 e^+ e^-}^2 / 4\pi < 6.2 \times 10^{-10}$ . Somewhat more sensitive limits are obtained for larger $m_{A^0}$ : $B < 7.6 \times 10^{-6}$ at 100 keV.				
7 AMALDI 85 set limits $B(A^0 \gamma) / B(\gamma\gamma) < (1\text{--}5) \times 10^{-6}$ for $m_{A^0} = 900\text{--}100$ keV which are about 1/10 of the CARBONI 83 limits.				
8 CARBONI 83 looked for ortho-positronium $\rightarrow A^0 \gamma$ . Set limit for $A^0$ electron coupling squared, $g(eA^0)^2 / (4\pi) < 6 \times 10^{-10}\text{--}7 \times 10^{-9}$ for $m_{A^0}$ from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from $g\text{--}2$ experiments.				

See key on page 1171

## Axions ( $A^0$ ) and Other Very Light Bosons

### $A^0$ (Axion) Search in Photoproduction

VALUE	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc. • • •		
	<sup>1</sup> ADHIKARI 22c	GLUX	$m_{A^0} = 180-480, 600-720$ MeV
	<sup>2</sup> BASSOMPIERRE... 95		$m_{A^0} = 1.8 \pm 0.2$ MeV
<sup>1</sup> ADHIKARI 22c	search for $A^0 \rightarrow \gamma\gamma$ and $A^0 \rightarrow \pi^+\pi^-\pi^0$ decays, and set limits of $f_{A^0} \lesssim 0.5-14$ GeV at 90% CL. See their Fig. 4 for mass-dependent limits.		
<sup>2</sup> BASSOMPIERRE 95	is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of $e^+e^-$ pairs in the region $m_{e^+e^-} = 1.8 \pm 0.2$ MeV. They obtained bounds on the production rate $A^0$ for $\tau(A^0) = 10^{-18}-10^{-9}$ sec. They also found an excess of events in the range $m_{e^+e^-} = 2.1-3.5$ MeV.		

### $A^0$ (Axion) Production in Hadron Collisions

Limits are for  $\sigma(A^0) / \sigma(\pi^0)$ .

<sup>1</sup>ACCIARRI 23 search for axions in the NuMI neutrino beam target, which are produced through mixings with mesons due to the coupling with gluons, and exclude  $f_{A^0}$  around tens of TeV for  $m_{A^0} = 0.2-0.9$  GeV. They assume a slightly suppressed axion coupling to muons. See their Fig. 4 for the limits.  
<sup>2</sup>BERTUZZO 23 employs an analysis analogous to ACCIARRI 23. They search for lepton-like axions primarily produced via  $\pi \rightarrow \mu A^0$  and  $\tau \rightarrow e A^0$ , and exclude  $f_{A^0}$  around  $1 \times 10^6-6 \times 10^7$  GeV for  $m_{A^0} = 0.2-1.7$  GeV. See their Fig. 2 for the limits.

<sup>3</sup>AAD 22j set upper limits for the cross sections of  $H \rightarrow A^0A^0 \rightarrow 4\mu$  and  $H \rightarrow ZA^0 \rightarrow 2E2\mu$ . See their Figs. 14 and 17 for the respective mass-dependent limits.  
<sup>4</sup>TUMASYAN 22AH set the limits of  $O(10^{-6})$  with respect to the product of the branching fractions of  $H \rightarrow A^0A^0$  and  $A^0 \rightarrow e^+e^-, \mu^+\mu^-$ . They also derive limits on the effective axion couplings contributing to  $H \rightarrow A^0A^0$  and  $H \rightarrow ZA^0$ . See their Figs. 5 and 7 for the limits.  
<sup>5</sup>TUMASYAN 22R is analogous to GAVELA 20, and set a limit on the products of the axion couplings to gluons and Z bosons as  $G_{AZZ} G_{Agg} < 6.64 \times 10^{-7} \text{ GeV}^{-2}$  at 95% CL for  $f_{A^0} = 3$  TeV and  $m_{A^0} < 100$  GeV. Here we use  $c_G^- = G_{Agg} f_{A^0}/4$  and  $c_Z^- = G_{AZZ} f_{A^0}/4$  to translate their limits. They also set a limit on the product of the axion couplings to gluons and ZH. See their Fig. 9 for the  $f_{A^0}$ -dependent limits.  
<sup>6</sup>AAD 21F look for axion production with an energetic jet and large missing  $p_T$ , and set a limit on the axion coupling to gluons,  $c_G^-/f_{A^0} < 8 \times 10^{-6} \text{ GeV}^{-1}$  at 95% CL for  $m_{A^0} = 1$  MeV. Using  $c_G^- = \alpha_s/8\pi$ , we interpret the limit as  $f_{A^0} > 0.4$  TeV for  $\alpha_s \approx 0.08$ .  
<sup>7</sup>AAD 21K look for axion production with an energetic photon and large missing  $p_T$ , and set a limit on the axion coupling to a Z boson and photon,  $G_{AZ\gamma} < 5.1 \times 10^{-4} \text{ GeV}^{-1}$  at 95% CL for  $m_{A^0} = 1$  MeV and assuming  $G_{A\gamma\gamma} = 0$ .  
<sup>8</sup>AAD 21N look for axion production using the measurement of light-by-light scattering based on Pb+Pb collision data. They set the limit on the axion-photon coupling,  $G_{A\gamma\gamma} < 5.3 \times 10^{-5}-3.4 \times 10^{-4} \text{ GeV}^{-1}$  at 95% CL for  $m_{A^0} = 6-100$  GeV. Here we use  $\Lambda_a = G_{A\gamma\gamma}^{-1}$  to translate their limits. See their Fig. 9 for mass-dependent limits.  
<sup>9</sup>CARRA 21 is analogous to GAVELA 20, and they use the differential cross sections for WW and Z $\gamma$  production measured with the ATLAS detector to set limits on the product of the axion couplings to gauge bosons as  $G_{AWW} G_{Agg} < 6.2 \times 10^{-7} \text{ GeV}^{-2}$  and  $G_{AZ\gamma} G_{Agg} < 3.7 \times 10^{-7} \text{ GeV}^{-2}$  at 95% CL for  $m_{A^0} \lesssim 100$  GeV.  
<sup>10</sup>AAIJ 20AL look for a light new boson decaying into a pair of muons using the LHCb data with an integrated luminosity of 5.1 fb<sup>-1</sup>, and set limits on the cross section over a range of  $m_{X^0} = 0.22-3$  and 20-60 GeV. See Figs. 8 and 9 for mass-dependent limits.  
<sup>11</sup>GAVELA 20 focus on the axion production as an s-channel off shell mediator, and use the Run 2 CMS public data to set limits on the product of the axion couplings to gluons and photons as well as Z bosons as  $G_{A\gamma\gamma} G_{Agg} < 2.8 \times 10^{-7} \text{ GeV}^{-2}$  and  $G_{AZZ} G_{Agg} < 9.8 \times 10^{-7} \text{ GeV}^{-2}$  for  $m_{A^0} \lesssim 200$  GeV. See their Fig.3 for the limits.  
<sup>12</sup>SIRUNYAN 19BQ look for the pair production of a new light boson decaying into a pair of muons, and set limits on the product of the production cross section times branching fraction to dimuons squared times acceptance over a range of  $m_{X^0} = 0.25-8.5$  GeV. See the right panel of their Fig. 1 for mass-dependent limits.  
<sup>13</sup>JAIN 07 claims evidence for  $A^0 \rightarrow e^+e^-$  produced in 207Pb collision on nuclear emulsion (Ag/Br) for  $m(A^0) = 7 \pm 1$  or  $19 \pm 1$  MeV and  $\tau(A^0) \leq 10^{-13}$  s.  
<sup>14</sup>AHMAD 97 reports a result of APEX Collaboration which studied positron production in  $^{238}\text{U}+^{232}\text{Ta}$  and  $^{238}\text{U}+^{181}\text{Ta}$  collisions, without requiring a coincident electron. No narrow lines were found for  $250 < E_{e^+} < 750$  keV.  
<sup>15</sup>LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy  $e^+e^-$  line at  $\approx 635$  keV in  $^{238}\text{U}+^{181}\text{Ta}$  collision. Limits on the production probability for a narrow sum-energy  $e^+e^-$  line are set. See their Table 2.  
<sup>16</sup>GANZ 96 (EPOS II Collaboration) has placed upper bounds on the production cross section of  $e^+e^-$  pairs from  $^{238}\text{U}+^{181}\text{Ta}$  and  $^{238}\text{U}+^{232}\text{Th}$  collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of  $e^+e^-$  pairs. These limits rule out the existence of peaks in the  $e^+e^-$  sum-energy distribution, reported by an earlier version of this experiment.  
<sup>17</sup>KAMEL 96 looked for  $e^+e^-$  pairs from the collision of  $^{32}\text{S}$  (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity  $m_{e^+e^-} > 2$  MeV.  
<sup>18</sup>BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of  $e^+e^-$  or  $\mu^+\mu^-$  from the produce  $A^0$ . See Fig. 5 for the excluded region in  $m_{A^0}$ -x plane. For the standard axion,  $0.3 < x < 25$  is excluded at 95% CL. If combined with BLUEMLEIN 91,  $0.008 < x < 32$  is excluded.  
<sup>19</sup>MEIJERDREES 92 give  $\Gamma(\pi^- p \rightarrow nA^0)/\Gamma(\pi^- p \rightarrow \text{all}) < 10^{-5}$  (90% CL) for  $m_{A^0} = 100$  MeV,  $\tau_{A^0} = 10^{-11}-10^{-23}$  sec. Limits ranging from  $2.5 \times 10^{-3}$  to  $10^{-7}$  are given for  $m_{A^0} = 25-136$  MeV.  
<sup>20</sup>BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for  $A^0 \rightarrow e^+e^-, 2\gamma$  are found. Fig. 6 gives the excluded region in  $m_{A^0}$ -x plane ( $x = \tan\beta = v_2/v_1$ ). Standard axion is excluded for  $0.2 < m_{A^0} < 3.2$  MeV for most  $x > 1$ , 0.2-11 MeV for most  $x < 1$ .  
<sup>21</sup>FAISSNER 89 searched for  $A^0 \rightarrow e^+e^-$  in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass  $2m_e-20$  MeV is excluded. Lower limit on  $f_{A^0}$  of  $\approx 10^4$  GeV is given for  $m_{A^0} = 2m_e-20$  MeV.  
<sup>22</sup>DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass  $\sim 1.1, \sim 2.1$ , and  $\sim 9$  MeV, lifetimes  $10^{-16}-10^{-15}$  s decaying to  $e^+e^-$  and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with  $\pi^0$  Dalitz decay. DEBOER 89B is a reply which contests the criticism.  
<sup>23</sup>EL-NADI 88 claim the existence of a neutral particle decaying into  $e^+e^-$  with mass  $1.60 \pm 0.59$  MeV, lifetime  $(0.15 \pm 0.01) \times 10^{-14}$  s, which is produced in heavy ion interactions with emulsion nuclei at  $\sim 4$  GeV/c/nucleon.  
<sup>24</sup>FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for  $A^0 \rightarrow \gamma\gamma$ . A standard axion decaying to  $2\gamma$  is excluded except for a region  $x \approx 1$ . Lower limit on  $f_{A^0}$  of  $10^2-10^3$  GeV is given for  $m_{A^0} = 0.1-1$  MeV.  
<sup>25</sup>BADIER 86 did not find long-lived  $A^0$  in 300 GeV  $\pi^-$  Beam Dump Experiment that decays into  $e^+e^-$  in the mass range  $m_{A^0} = (20-200)$  MeV, which excludes the  $A^0$  decay constant  $f(A^0)$  in the interval (60-600) GeV. See their figure 6 for excluded region on  $f(A^0)$ - $m_{A^0}$  plane.  
<sup>26</sup>BERGSMA 85 look for  $A^0 \rightarrow 2\gamma, e^+e^-, \mu^+\mu^-$ . First limit above is for  $m_{A^0} = 1$  MeV; second is for 200 MeV. See their figure 4 for excluded region on  $f_{A^0}$ - $m_{A^0}$  plane.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- where  $f_{A^0}$  is  $A^0$  decay constant. For Peccei-Quinn PECCEI 77  $A^0$ ,  $m_{A^0} < 180$  keV and  $\tau > 0.037$  s. (CL = 90%). For the axion of FAISSNER 81b at 250 keV, BERGSM 85 expect 15 events but observe zero.
- 27 FAISSNER 83 observed 19  $1-\gamma$  and 12  $2-\gamma$  events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.
- 28 FAISSNER 83b extrapolate SIN  $\gamma$  signal to LAMPF  $\nu$  experimental condition. Resulting 370  $\gamma$ 's are not at variance with LAMPF upper limit of 450  $\gamma$ 's. Derived from LAMPF limit that  $[d\sigma(A^0)/d\omega \text{ at } 90^\circ] m_{A^0} / \tau_{A^0} < 14 \times 10^{-35} \text{ cm}^2 \text{ sr}^{-1} \text{ MeV ms}^{-1}$ . See comment on FRANK 83b.
- 29 FRANK 83b stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450  $\gamma$ 's. See comment on FAISSNER 83b.
- 30 HOFFMAN 83 set CL = 90% limit  $d\sigma/dt \text{ B}(e^+e^-) < 3.5 \times 10^{-32} \text{ cm}^2/\text{GeV}^2$  for  $140 < m_{A^0} < 160$  MeV. Limit assumes  $\tau(A^0) < 10^{-9}$  s.
- 31 FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since  $2-\gamma$  peak rate remarkably decreases if iron wall is set in front of the decay region.
- 32 FAISSNER 81 see excess  $\mu e$  events. Suggest axion interactions.
- 33 FAISSNER 81b is SIN 590 MeV proton beam dump. Observed  $14.5 \pm 5.0$  events of  $2\gamma$  decay of long-lived neutral penetrating particle with  $m_{2\gamma} \lesssim 1$  MeV. Axion interpretation with  $\eta-A^0$  mixing gives  $m_{A^0} = 250 \pm 25$  keV,  $\tau(2\gamma) = (7.3 \pm 3.7) \times 10^{-3}$  s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83b, FRANK 83b, and BERGSM 85. Also see in the next subsection ALEKSEEV 82b, CAVIGNAC 83, and ANANEV 85.
- 34 KIM 81 analyzed 8 candidates for  $A^0 \rightarrow 2\gamma$  obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is  $(0.86 \sim 5.6) \times 10^{-3}$  s depending on models. Faisner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.
- 35 FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for  $A^0 \rightarrow e^+e^-$  decay. Assuming  $A^0/m^0 = 5.5 \times 10^{-7}$ , obtained decay rate limit  $20/(A^0 \text{ mass})$  MeV/s (CL = 90%), which is about  $10^{-7}$  below theory and interpreted as upper limit to  $m_{A^0} < 2m_{e^-}$ .
- 36 JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events  $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68} \text{ cm}^4, \text{ CL} = 90\%]$ . Second limit is from nonobservation of axion decays into  $2\gamma$ 's or  $e^+e^-$ , and for axion mass a few MeV.
- 37 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
- 38 BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either  $2\gamma$  or  $e^+e^-$ . No signal found. CL = 90% limits for model parameter(s) are given.
- 39 COTEUS 79 is a beam dump experiment at BNL.
- 40 DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.
- 41 BELLOTTI 78 first value comes from search for  $A^0 \rightarrow e^+e^-$ . Second value comes from search for  $A^0 \rightarrow 2\gamma$ , assuming mass  $< 2m_{e^-}$ . For any mass satisfying this, limit is above value  $\times (\text{mass}^{-4})$ . Third value uses data of PL 60B 401 and quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67} \text{ cm}^4$ .
- 42 BOSETTI 78b quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67} \text{ cm}^4$ .
- 43 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
- 44 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
- 45 VYSOTSKI 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

### $A^0$ (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1	CHANG 07		Primakoff or Compton
2	ALTMANN 95	CNTR	Reactor; $A^0 \rightarrow e^+e^-$
3	KETOV 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
4	KOCH 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
5	DATAR 82	CNTR	Light water reactor
6	VUILLEUMIER 81	CNTR	Reactor; $A^0 \rightarrow 2\gamma$

- 1 CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products  $G_{A\gamma\gamma} G_{ANN}$  and  $G_{Aee} G_{ANN}$  for  $m(A^0)$  less than the MeV range.
- 2 ALTMANN 95 looked for  $A^0$  decaying into  $e^+e^-$  from the Bugey5 nuclear reactor. They obtain an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma) \times \text{B}(A^0 \rightarrow e^+e^-) < 10^{-16}$  for  $m_{A^0} = 1.5$  MeV at 90% CL. The limit is weaker for heavier  $A^0$ . In the case of a standard axion, this limit excludes a mass in the range  $2m_e < m_{A^0} < 4.8$  MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances  $Z^0$  in the  $(m_{\chi^0}, f_{\chi^0})$  plane.
- 3 KETOV 86 searched for  $A^0$  at the Rovno nuclear power plant. They found an upper limit on the  $A^0$  production probability of  $0.8 [100 \text{ keV}/m_{A^0}]^6 \times 10^{-6}$  per fission. In the standard axion model, this corresponds to  $m_{A^0} > 150$  keV. Not valid for  $m_{A^0} \gtrsim 1$  MeV.
- 4 KOCH 86 searched for  $A^0 \rightarrow \gamma\gamma$  at nuclear power reactor Biblis A. They found an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$  (CL=95%). Standard axion with  $m_{A^0} = 250$  keV gives  $10^{-5}$  for the ratio. Not valid for  $m_{A^0} > 1022$  keV.

- 5 DATAR 82 looked for  $A^0 \rightarrow 2\gamma$  in neutron capture ( $np \rightarrow dA^0$ ) at Tarapur 500 MW reactor. Sensitive to sum of  $l = 0$  and  $l = 1$  amplitudes. With ZEHNDER 81 [ $(l = 0) - (l = 1)$ ] result, assert nonexistence of standard  $A^0$ .
- 6 VUILLEUMIER 81 is at Grenoble reactor. Set limit  $m_{A^0} < 280$  keV.

### $A^0$ (Axion) and Other Light Boson ( $X^0$ ) Searches in Nuclear Transitions

Limits are for branching ratio.

- 1 DERBIN 23 use a thallium garnet bolometric detector to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of  $^{169}\text{Tm}$ . Their limits are equivalent to an upper bound on the KSVZ and DFSZ axion masses of 141 eV and 244 eV, respectively.
- 2 DERBIN 02 looked for the axion emission in an M1 transition in  $^{125m}\text{Te}$  decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.
- 3 DEBOER 97c reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into  $e^+e^-$  would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.
- 4 TSUNODA 95 looked for axion emission when  $^{252}\text{Cf}$  undergoes a spontaneous fission, with the axion decaying into  $e^+e^-$ . The bound is for  $m_{A^0} = 40$  MeV. It improves to  $2.5 \times 10^{-5}$  for  $m_{A^0} = 200$  MeV.
- 5 MINOWA 93 studied chain process,  $^{139}\text{Ce} \rightarrow ^{139}\text{La}^*$  by electron capture and M1 transition of  $^{139}\text{La}^*$  to the ground state. It does not assume decay modes of  $A^0$ . The bound applies for  $m_{A^0} < 166$  keV.
- 6 HICKS 92 bound is applicable for  $\tau_{X^0} < 4 \times 10^{-11}$  sec.
- 7 The ASANUMA 90 limit is for the branching fraction of  $X^0$  emission per  $^{241}\text{Am}$   $\alpha$  decay and valid for  $\tau_{X^0} < 3 \times 10^{-11}$  s.
- 8 The DEBOER 90 limit is for the branching ratio  $^8\text{Be}^* (18.15 \text{ MeV}, 1^+) \rightarrow ^8\text{Be} A^0$ ,  $A^0 \rightarrow e^+e^-$  for the mass range  $m_{A^0} = 4-15$  MeV.
- 9 The BINI 89 limit is for the branching fraction of  $^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O} X^0$ ,  $X^0 \rightarrow e^+e^-$  for  $m_{X^0} = 1.5-3.1$  MeV.  $\tau_{X^0} \lesssim 10^{-11}$  s is assumed. The spin-parity of  $X^0$  is restricted to  $0^+$  or  $1^-$ .
- 10 AVIGNONE 88 looked for the 1115 keV transition  $\text{C}^* \rightarrow \text{Cu} A^0$ , either from  $A^0 \rightarrow 2\gamma$  in-flight decay or from the secondary  $A^0$  interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for  $m_{A^0} < 1.1$  MeV.
- 11 DATAR 88 rule out light pseudoscalar particle emission through its decay  $A^0 \rightarrow e^+e^-$  in the mass range 1.02-2.5 MeV and lifetime range  $10^{-13}-10^{-8}$  s. The above limit is for  $\tau = 5 \times 10^{-13}$  s and  $m = 1.7$  MeV; see the paper for the  $\tau$ - $m$  dependence of the limit.
- 12 The limit is for the branching fraction of  $^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow ^{16}\text{O} X^0$ ,  $X^0 \rightarrow e^+e^-$  against internal pair conversion for  $m_{X^0} = 1.7$  MeV and  $\tau_{X^0} < 10^{-11}$  s. Similar limits are obtained for  $m_{X^0} = 1.3-3.2$  MeV. The spin parity of  $X^0$  must be either  $0^+$  or  $1^-$ . The limit at 1.7 MeV is translated into a limit for the  $X^0$ -nucleon coupling constant:  $g_{X^0 NN}^2/4\pi < 2.3 \times 10^{-9}$ .
- 13 The DOEHNER 88 limit is for  $m_{A^0} = 1.7$  MeV,  $\tau(A^0) < 10^{-10}$  s. Limits less than  $10^{-4}$  are obtained for  $m_{A^0} = 1.2-2.2$  MeV.
- 14 SAVAGE 88 looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in  $^{14}\text{N}$ , 17.64 MeV state  $J^P = 1^+$  in  $^9\text{Be}$ , and the 18.15 MeV state  $J^P = 1^+$  in  $^8\text{Be}$ . This experiment constrains the isovector coupling of  $A^0$  to hadrons, if  $m_{A^0}$

See key on page 1171

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- $= (1.1 \rightarrow 2.2)$  MeV and the isoscalar coupling of  $A^0$  to hadrons, if  $m_{A^0} = (1.1 \rightarrow 2.6)$  MeV. Both limits are valid only if  $\tau(A^0) \lesssim 1 \times 10^{-11}$  s.
- <sup>15</sup> Limits are for  $\Gamma(A^0(1.8 \text{ MeV})/\Gamma(\pi M1))$ ; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of  $e^+e^-$  pairs. Valid for  $\tau_{A^0} < 2 \times 10^{-11}$  s. <sup>6</sup>Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the <sup>10</sup>B and <sup>14</sup>N isoscalar decay data strongly reject PECCEI 86 model II and III.
- <sup>16</sup> SAVAGE 86B looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in <sup>14</sup>N. Limit on the branching fraction is valid if  $\tau_{A^0} \lesssim 1 \times 10^{-11}$  s for  $m_{A^0} = (1.1-1.7)$  MeV. This experiment constrains the iso-vector coupling of  $A^0$  to hadrons.
- <sup>17</sup> ANANEV 85 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% masses below 470 keV (Li\* decay) and below  $2m_e$  for deuteron\* decay.
- <sup>18</sup> CAVAINAC 83 at Bugey reactor exclude axion at any  $m_{97}\text{Nb}^*$  decay and axion with  $m_{A^0}$  between 275 and 288 keV (deuteron\* decay).
- <sup>19</sup> ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% mass-ranges  $m_{A^0} < 400$  keV (Li\* decay) and  $330 \text{ keV} < m_{A^0} < 2.2$  MeV. (deuteron\* decay).
- <sup>20</sup> LEHMANN 82 obtained  $A^0 \rightarrow 2\gamma$  rate  $< 6.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0}$  between 100 and 1000 keV.
- <sup>21</sup> ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check  $A^0$  production. No  $2\gamma$  peak in Li\*, Nb\* decay (both single  $p$  transition) nor in  $n$  capture (combined with previous Ba\* negative result) rules out standard  $A^0$ . Set limit  $m_{A^0} < 60$  keV for any  $A^0$ .
- <sup>22</sup> ZEHNDER 81 looked for  $\text{Ba}^* \rightarrow A^0\text{Ba}$  transition with  $A^0 \rightarrow 2\gamma$ . Obtained  $2\gamma$  coincidence rate  $< 2.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0} > 160$  keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- <sup>23</sup> CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

### $A^0$ (Axion) Limits from Its Electron Coupling

Limits are for  $\tau(A^0 \rightarrow e^+e^-)$ .

VALUE (s)	CL%	DOCUMENT ID	TECN	COMMENT
• • •				We do not use the following data for averages, fits, limits, etc. • • •
1		ANDREEV 21	NA64	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow \text{invisible}$ )
2		ANDREEV 21B	NA64	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
3	90	BROSS 91	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
4		GUO 90	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
5		BJORKEN 88	CALO	$A \rightarrow e^+e^-$ or $2\gamma$
6		BLINOV 88	MD1	$ee \rightarrow eeA^0$ ( $A^0 \rightarrow ee$ )
7	90	RIORDAN 87	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
8	90	BROWN 86	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
9	95	DAVIER 86	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )
10	90	KONAKA 86	BDMP	$eN \rightarrow eA^0N$ ( $A^0 \rightarrow ee$ )

- <sup>1</sup> ANDREEV 21 look for invisible decays of axions coupled to electrons, and set limits on  $g_{Aee} < 4.6 \times 10^{-6} - 3.1 \times 10^{-3}$  for  $m_{A^0} = 10^{-3} - 1$  GeV. This limits the axion contribution to the electron  $g-2$  to an order of magnitude less than the current experimental uncertainty. See their Figs. 3 and 4 for mass-dependent limits.
- <sup>2</sup> ANDREEV 21B set limits on  $g_{Aee}$  in the range of  $6.3 \times 10^{-6} - 1.6 \times 10^{-3}$  for  $m_{A^0} = 2-17$  MeV at 90% CL. This excludes  $6.6 \times 10^{-5} < g_{Aee} < 1 \times 10^{-4}$  at  $m_{A^0} = 16.7$  MeV corresponding to the ATOMKI anomaly. See their Fig. 2 for mass-dependent limits.
- <sup>3</sup> The listed BROSS 91 limit is for  $m_{A^0} = 1.14$  MeV.  $B(A^0 \rightarrow e^+e^-) = 1$  assumed. Excluded domain in the  $\tau_{A^0} - m_{A^0}$  plane extends up to  $m_{A^0} \approx 7$  MeV (see Fig. 5). Combining with electron  $g-2$  constraint, axions coupling only to  $e^+e^-$  ruled out for  $m_{A^0} < 4.8$  MeV (90% CL).
- <sup>4</sup> GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with  $g-2$  constraint, axions coupling only to  $e^+e^-$  are ruled out for  $m_{A^0} < 2.7$  MeV (90% CL).
- <sup>5</sup> BJORKEN 88 reports limits on axion parameters ( $f_A, m_A, \tau_A$ ) for  $m_{A^0} < 200$  MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.
- <sup>6</sup> BLINOV 88 assume zero spin,  $m = 1.8$  MeV and lifetime  $< 5 \times 10^{-12}$  s and find  $\Gamma(A^0 \rightarrow \gamma\gamma)B(A^0 \rightarrow e^+e^-) < 2$  eV (CL=90%).
- <sup>7</sup> Assumes  $A^0\gamma\gamma$  coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for  $m_{A^0} < 15$  MeV.
- <sup>8</sup> Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for  $m_{A^0} < 15$  MeV are shown in their figure 3.
- <sup>9</sup>  $m_{A^0} = 1.8$  MeV assumed. The excluded domain in the  $\tau_{A^0} - m_{A^0}$  plane extends up to  $m_{A^0} \approx 14$  MeV, see their figure 4.
- <sup>10</sup> The limits are obtained from their figure 3. Also given is the limit on the  $A^0\gamma\gamma - A^0e^+e^-$  coupling plane by assuming Primakoff production.

### Search for $A^0$ (Axion) Resonance in Bhabha Scattering

The limit is for  $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$ .

		10 VONWIMMER.87	CNTR	

- <sup>1</sup> HALLIN 92 quote limits on lifetime,  $8 \times 10^{-14} - 5 \times 10^{-13}$  sec depending on mass, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 91 overstated their sensitivity by a factor of 3.
- <sup>2</sup> HENDERSON 92c exclude axion with lifetime  $\tau_{A^0} = 1.4 \times 10^{-12} - 4.0 \times 10^{-10}$  s, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . HENDERSON 92c also exclude a vector boson with  $\tau = 1.4 \times 10^{-12} - 6.0 \times 10^{-10}$  s.
- <sup>3</sup> WU 92 quote limits on lifetime  $> 3.3 \times 10^{-13}$  s assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 89 overestimate the limit by a factor of  $\pi/2$ . WU 92 also quote a bound for vector boson,  $\tau > 8.2 \times 10^{-13}$  s.
- <sup>4</sup> WIDMANN 91 bound applies exclusively to the case  $B(A^0 \rightarrow e^+e^-) = 1$ , since the detection efficiency varies substantially as  $\Gamma(A^0)_{\text{total}}$  changes. See their Fig. 6.
- <sup>5</sup> JUDGE 90 excludes an elastic pseudoscalar  $e^+e^-$  resonance for  $4.5 \times 10^{-13}$  s  $< \tau(A^0) < 7.5 \times 10^{-12}$  s (95% CL) at  $m_{A^0} = 1.832$  MeV. Comparable limits can be set for  $m_{A^0} = 1.776-1.856$  MeV.
- <sup>6</sup> See also TSERTOS 88B in references.
- <sup>7</sup> The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.
- <sup>8</sup> VANKLINKEN 88 looked for relatively long-lived resonance ( $\tau = 10^{-10} - 10^{-12}$  s). The sensitivity is not sufficient to exclude such a narrow resonance.
- <sup>9</sup> MAIER 87 obtained limits  $R\Gamma \lesssim 60$  eV (100 eV) at  $m_{A^0} \approx 1.64$  MeV (1.83 MeV) for energy resolution  $\Delta E_{\text{cm}} \approx 3$  keV, where  $R$  is the resonance cross section normalized to that of Bhabha scattering, and  $\Gamma = \Gamma_{ee}^2/\Gamma_{\text{total}}$ . For a discussion implying that  $\Delta E_{\text{cm}} \approx 10$  keV, see TSERTOS 89.
- <sup>10</sup> VONWIMMERSPERG 87 measured Bhabha scattering for  $E_{\text{cm}} = 1.37-1.86$  MeV and found a possible peak at 1.73 with  $\int \sigma dE_{\text{cm}} = 14.5 \pm 6.8$  keV-b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

### Search for $A^0$ (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for  $\Gamma(A^0 \rightarrow e^+e^-)\Gamma(A^0 \rightarrow \gamma\gamma)/\Gamma_{\text{total}}$

<79	97	CONNELL 88	CNTR	$m_{A^0} = 1.832$ MeV
		1 TRZASKA 91		also give limits in the range $(6.6-30) \times 10^{-3}$ eV (95%CL) for $m_{A^0} = 1.6-2.0$ MeV.
		2 FOX 89		measured positron annihilation with an electron in the source material into two photons and found no signal at 1.062 MeV ( $< 9 \times 10^{-5}$ of two-photon annihilation at rest).
		3		Similar limits are obtained for $m_{A^0} = 1.045-1.085$ MeV.

### Search for $X^0$ (Light Boson) Resonance in $e^+e^- \rightarrow \gamma\gamma\gamma$

The limit is for  $\Gamma(X^0 \rightarrow e^+e^-)\Gamma(X^0 \rightarrow \gamma\gamma\gamma)/\Gamma_{\text{total}}$ . C invariance forbids spin-0  $X^0$  coupling to both  $e^+e^-$  and  $\gamma\gamma\gamma$ .

- • • We do not use the following data for averages, fits, limits, etc. • • •
- <sup>1</sup> MITSUI 96 looked for a monochromatic  $\gamma$ . The bound applies for a vector  $X^0$  with  $C=-1$  and  $m_{X^0} < 200$  keV. They derive an upper bound on  $eX^0$  coupling and hence on the branching ratio  $B(\rho\text{-Ps} \rightarrow \gamma\gamma X^0) < 6.2 \times 10^{-6}$ . The bounds weaken for heavier  $X^0$ .
- <sup>2</sup> SKALSEY 95 looked for a monochromatic  $\gamma$  without an accompanying  $\gamma$  in  $e^+e^-$  annihilation. The bound applies for scalar and vector  $X^0$  with  $C = -1$  and  $m_{X^0} = 100\text{--}1000$  keV.
- <sup>3</sup> SKALSEY 95 reinterpreted the bound on  $\gamma A^0$  decay of  $\rho$ -Ps by ASA1 91 where 3% of delayed annihilations are not from  $^3S_1$  states. The bound applies for scalar and vector  $X^0$  with  $C = -1$  and  $m_{X^0} = 0\text{--}800$  keV.
- <sup>4</sup> ADACHI 94 looked for a peak in the  $\gamma\gamma$  invariant mass distribution in  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} = 70\text{--}800$  keV.
- <sup>5</sup> ADACHI 94 looked for a peak in the missing-mass mass distribution in  $\gamma\gamma$  channel, using  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} < 800$  keV.
- <sup>6</sup> ADACHI 94 looked for a peak in the missing mass distribution in  $\gamma\gamma\gamma\gamma$  channel, using  $\gamma\gamma\gamma\gamma$  production from  $e^+e^-$  annihilation. The bound applies for  $m_{X^0} = 200\text{--}900$  keV.

### Searches for Goldstone Bosons ( $X^0$ )

- <sup>1</sup> ADACHI 23A set limits in the range of  $1.1 \times 10^{-3}\text{--}9.7 \times 10^{-3}$  for  $0 < m_{X^0} < 1.6$  GeV on  $B(\tau^- \rightarrow e^- X^0)/B(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau)$ . See their Fig. 2 for mass-dependent limits.
- <sup>2</sup> ADACHI 23A set limits in the range of  $7 \times 10^{-4}\text{--}1.22 \times 10^{-2}$  for  $0 < m_{X^0} < 1.6$  GeV on  $B(\tau^- \rightarrow \mu^- X^0)/B(\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau)$ . See their Fig. 2 for mass-dependent limits.

- <sup>3</sup> FIORILLO 23 used data from Kamiokande-II and IMB on the neutrino flux from SN1987A to constrain the universal neutrino Majoron Yukawa coupling,  $g$ . They set an upper limit of  $g m_{X^0} \lesssim 10^{-9}$  MeV for Majoron masses  $100 \text{ eV} \lesssim m_{X^0} \lesssim 100 \text{ MeV}$ , using neutrino coalescence as production of Majorons which then decay back to neutrinos. See their Fig. 1 for the mass-dependent limits.
- <sup>4</sup> SANDNER 23 study Majoron production via neutrino inverse decay and use Planck data to constrain the neutrino Majoron Yukawa coupling to  $g \lesssim 2 \times 10^{-13}\text{--}1 \times 10^{-12}$  for Majoron masses  $m_{X^0} = 1\text{--}10 \text{ eV}$ . See their Fig. 1 for mass-dependent limits.
- <sup>5</sup> COLOMA 22A used the spectral data of Borexino Phase II to constrain the neutrino non-standard interaction with electrons mediated by a scalar or a pseudoscalar. Limits on the universal coupling to neutrinos and electrons between  $2 \times 10^{-6}$  and  $10^{-4}$  are obtained for  $m_{X^0} \lesssim 30\text{--}40 \text{ MeV}$ . See their Fig. 6 for mass-dependent limits.
- <sup>6</sup> AGUILAR-AREVALO 21A quoted limit applies to  $m_{X^0} = 33.9 \text{ MeV}$ . Limits between  $4.3 \times 10^{-6}$  and  $7.5 \times 10^{-5}$  are obtained for  $0 < m_{X^0} < 33.9 \text{ MeV}$ . The lifetime of  $X^0$  is assumed to be long enough. See their Fig. 6 for mass-dependent limits.
- <sup>7</sup> AGUILAR-AREVALO 21A quoted limit applies to  $m_{X^0} = 85 \text{ MeV}$ . Limits between  $5.2 \times 10^{-8}$  and  $1.4 \times 10^{-6}$  are obtained for  $0 < m_{X^0} < 120 \text{ MeV}$ , which improve the limits of PICCIOTTO 88 by an order of magnitude. The lifetime of  $X^0$  is assumed to be long enough. See their Fig. 4 for mass-dependent limits.
- <sup>8</sup> AGUILAR-AREVALO 20 obtained limits of order  $10^{-5}$  for  $m_{X^0} = 47.8\text{--}95.1 \text{ MeV}$ . The quoted limit applies to  $m_{X^0} = 75 \text{ MeV}$ . See their Fig. 1 for mass-dependent limits.
- <sup>9</sup> BALDINI 20 obtained limits for  $m_{X^0} = 20\text{--}45 \text{ MeV}$  and  $\tau_{X^0} < 40 \text{ ps}$ , and supersedes BOLTON 88 for  $m_{X^0} = 20\text{--}40 \text{ MeV}$ . See their Fig. 17 for mass-dependent limits.
- <sup>10</sup> BAYES 15 limits are the average over  $m_{X^0} = 13\text{--}80 \text{ MeV}$  for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit  $< 58 \times 10^{-6}$  at 90% CL for massless familons and for the same asymmetry as normal muon decay, a case not covered by JODIDIO 86.
- <sup>11</sup> LATTANZI 13 use WMAP 9 year data as well as X-ray and  $\gamma$ -ray observations to derive limits on decaying majoron dark matter. A limit on the decay width  $\Gamma(X^0 \rightarrow \nu\bar{\nu}) < 6.4 \times 10^{-19} \text{ s}^{-1}$  at 95% CL is found if majorons make up all of the dark matter.
- <sup>12</sup> LESSA 07 consider decays of the form Meson  $\rightarrow \ell\nu$  Majoron and  $\ell \rightarrow \ell'\nu\bar{\nu}$  Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings  $g_{\alpha\beta}$  ( $\alpha, \beta = e, \mu, \tau$ ). Their best limits are  $|g_{e\alpha}|^2 < 5.5 \times 10^{-6}$ ,  $|g_{\mu\alpha}|^2 < 4.5 \times 10^{-5}$ ,  $|g_{\tau\alpha}|^2 < 5.5 \times 10^{-2}$  at CL = 90%.
- <sup>13</sup> FARZAN 03 set limits on the neutrino Majoron Yukawa coupling,  $|g_{e\alpha}| < 4 \times 10^{-7}$ , by considering the SN cooling due to the massless Majoron emission via neutrino coalescence. They also exclude values around  $10^{-5}$  for both  $g_{e\mu}$  and  $g_{\mu\mu}$  using the process  $\nu\nu \rightarrow X^0 X^0$ . See also their Figs. 3 and 4 for mass-dependent limits.
- <sup>14</sup> DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay  $Z \rightarrow H^0 A^0 \rightarrow X^0 X^0 X^0 X^0$  and  $e^+e^- \rightarrow Z H^0$  with  $H^0 \rightarrow X^0 X^0$ .
- <sup>15</sup> BOBRKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit  $x_e^2 < 2 \times 10^{-4}$  (95%CL) is found for the effective anomalous magneton parameterized as  $x_e(G_F/8\pi\sqrt{2})^{1/2}$ .
- <sup>16</sup> ALBRECHT 90E limits are for  $B(\tau \rightarrow \ell X^0)/B(\tau \rightarrow \ell\nu\bar{\nu})$ . Valid for  $m_{X^0} < 100 \text{ MeV}$ . The limits rise to 7.1% (for  $\mu$ ), 5.0% (for  $e$ ) for  $m_{X^0} = 500 \text{ MeV}$ .
- <sup>17</sup> ATIYA 90 limit is for  $m_{X^0} = 0$ . The limit  $B < 1 \times 10^{-8}$  holds for  $m_{X^0} < 95 \text{ MeV}$ . For the reduction of the limit due to finite lifetime of  $X^0$ , see their Fig. 3.
- <sup>18</sup> BALKE 88 limits are for  $B(\mu^+ \rightarrow e^+ X^0)$ . Valid for  $m_{X^0} < 80 \text{ MeV}$  and  $\tau_{X^0} > 10^{-8} \text{ sec}$ .
- <sup>19</sup> BOLTON 88 limit corresponds to  $F > 3.1 \times 10^9 \text{ GeV}$ , which does not depend on the chirality property of the coupling.
- <sup>20</sup> CHANDA 88 find  $\nu_T < 10 \text{ MeV}$  for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and  $\nu_S > 5.8 \times 10^6 \text{ GeV}$  in the singlet Majoron model.
- <sup>21</sup> CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling  $h$  in the range  $2 \times 10^{-5} < h < 3 \times 10^{-4}$  for the interaction  $L_{\text{int}} = \frac{1}{2} i h \bar{\psi}_\nu \gamma_5 \psi_\nu \phi_X$ . For several families of neutrinos, the limit applies for  $(\Sigma h_i^4)^{1/4}$ .
- <sup>22</sup> PICCIOTTO 88 limit applies when  $m_{X^0} < 55 \text{ MeV}$  and  $\tau_{X^0} > 2 \text{ ns}$ , and it decreases to  $4 \times 10^{-7}$  at  $m_{X^0} = 125 \text{ MeV}$ , beyond which no limit is obtained.
- <sup>23</sup> GOLDMAN 87 limit corresponds to  $F > 2.9 \times 10^9 \text{ GeV}$  for the family symmetry breaking scale from the Lagrangian  $L_{\text{int}} = (1/F) \bar{\psi}_\mu \gamma^\mu (a + b\gamma_5) \psi_e \theta_\mu \phi_X$  with  $a^2 + b^2 = 1$ . This is not as sensitive as the limit  $F > 9.9 \times 10^9 \text{ GeV}$  derived from the search for  $\mu^+ \rightarrow e^+ X^0$  by JODIDIO 86, but does not depend on the chirality property of the coupling.
- <sup>24</sup> Limits are for  $\Gamma(\mu \rightarrow e X^0)/\Gamma(\mu \rightarrow e\nu\bar{\nu})$ . Valid when  $m_{X^0} = 0\text{--}93.4, 98.1\text{--}103.5 \text{ MeV}$ .
- <sup>25</sup> EICHLER 86 looked for  $\mu^+ \rightarrow e^+ X^0$  followed by  $X^0 \rightarrow e^+ e^-$ . Limits on the branching fraction depend on the mass and lifetime of  $X^0$ . The quoted limits are valid when  $\tau_{X^0} \lesssim 3 \times 10^{-10} \text{ s}$  if the decays are kinematically allowed.
- <sup>26</sup> JODIDIO 86 corresponds to  $F > 9.9 \times 10^9 \text{ GeV}$  for the family symmetry breaking scale with the parity-conserving effective Lagrangian  $L_{\text{int}} = (1/F) \bar{\psi}_\mu \gamma^\mu \psi_e \theta^\mu \phi_X$ .
- <sup>27</sup> BALTRUSAITIS 85 search for light Goldstone boson ( $X^0$ ) of broken U(1). CL = 95% limits are  $B(\tau \rightarrow \mu^+ X^0)/B(\tau \rightarrow \mu^+ \nu\bar{\nu}) < 0.125$  and  $B(\tau \rightarrow e^+ X^0)/B(\tau \rightarrow e^+ \nu\bar{\nu}) < 0.04$ . Inferred limit for the symmetry breaking scale is  $m > 3000 \text{ TeV}$ .
- <sup>28</sup> The primordial heavy neutrino must decay into  $\nu$  and familon,  $f_A$ , early so that the red-shifted decay products are below critical density, see their table. In addition,  $K \rightarrow \pi f_A$  and  $\mu \rightarrow e f_A$  are unseen. Combining these excludes  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and  $5 \times 10^{-4} \text{ MeV}$  ( $\mu$  decay) and  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and  $0.1 \text{ MeV}$  ( $K$ -decay).

Majoron Searches in Neutrinoless Double  $\beta$  Decay

Limits are for the half-life of neutrinoless  $\beta\beta$  decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported.

- 1 BERNATOWICZ 92 studied double- $\beta$  decays of <sup>128</sup>Te and <sup>130</sup>Te, and found the ratio  $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$  in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of <sup>128</sup>Te of  $(7.7 \pm 0.4) \times 10^{24}$  year. We calculated 90% CL limit as  $(7.7-1.28 \times 0.4=7.2) \times 10^{24}$ .
- 2 AZZOLINI 23 use 9.95 kg-yr of data, collected by the CUPID-0 experiment, to place a limit on the single Majoron mode of the 0 $\nu\beta\beta$  decay of <sup>82</sup>Se. Various limits on modes involving the emission of multiple Majorons are given too. The resulting constraint on the Majoron-neutrino coupling constant is  $g_{\nu\chi} < 1.8-4.4 \times 10^{-5}$ . The range is due to the variability of the used nuclear matrix elements.
- 3 AGOSTINI 22 use 32.8 kg-yr of GERDA phase 2 data to derive a limit of  $g_{\nu\chi} < 1.8-4.4 \times 10^{-5}$  on the neutrino-Majoron coupling. The range reflects the author's evaluation of the spread of nuclear matrix elements.
- 4 AL-KHARUSI 21 utilize the complete dataset of the EXO-200 experiment, corresponding to an exposure of 234 kg yr, to place a limit on the one Majoron mode of the neutrinoless double beta decay of <sup>136</sup>Xe. Several limits are reported, the one given here corresponds to a spectral index of 1, resulting in a limit of  $g_{\nu\chi} < 0.4-0.9 \times 10^{-5}$  on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- 5 ARNOLD 19 uses the NEMO-3 tracking calorimeter to determine limits for the Majoron emitting double beta decay, with spectral index  $n = 3$ . The limit corresponds to the range of the  $g_{ee}$  coupling of 0.013-0.035; depending on the nuclear matrix elements used.
- 6 ARNOLD 18 use the NEMO-3 tracking detector. The limit corresponds to  $\langle g_{ee} \rangle < 3.2-8.0 \times 10^{-5}$ ; the range corresponds to different nuclear matrix element calculations.
- 7 AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine  $g_{\nu\chi} < 3.4-8.7 \times 10^{-5}$  on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- 8 ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to  $g_{\nu\chi} < 1.6-3.0 \times 10^{-4}$ . The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.
- 9 ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the  $g_{\nu\chi} < 0.8-1.7 \times 10^{-5}$  on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.
- 10 GANDO 12 use the KamLAND-Zen detector to obtain the limit on the 0 $\nu\chi$  decay with Majoron emission. It implies that the coupling constant  $g_{\nu\chi} < 0.8-1.6 \times 10^{-5}$  depending on the nuclear matrix elements used.
- 11 ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant  $g_{\nu\chi} < 0.6-1.6 \times 10^{-4}$  depending on the nuclear matrix element used. Supersedes ARNABOLDI 03.
- 12 ARGYRADES 10 use the NEMO-3 tracking detector and <sup>96</sup>Zr to derive the reported limit. No limit for the Majoron electron coupling is given.
- 13 ARGYRADES 09 use <sup>150</sup>Nd data taken with the NEMO-3 tracking detector. The reported limit corresponds to  $\langle g_{\nu\chi} \rangle < 1.7-3.0 \times 10^{-4}$  using a range of nuclear matrix elements that include the effect of nuclear deformation.

- 14 ARNOLD 06 use <sup>100</sup>Mo data taken with the NEMO-3 tracking detector. The reported limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.4-1.8) \times 10^{-4}$  using a range of matrix element calculations. Supersedes by ARNOLD 15.
- 15 NEMO-3 tracking calorimeter is used in ARNOLD 06. Reported half-life limit for <sup>82</sup>Se corresponds to  $\langle g_{\nu\chi} \rangle < (0.66-1.9) \times 10^{-4}$  using a range of matrix element calculations. Supersedes ARNOLD 04.
- 16 ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.5-0.9)10^{-4}$  using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03. Supersedes by ARNOLD 06.
- 17 ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to  $\langle g_{\nu\chi} \rangle < (0.7-1.6)10^{-4}$  using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.
- 18 Supersedes ALESSANDRELLO 00. Array of TeO<sub>2</sub> crystals in high resolution cryogenic calorimeter. Some enriched in <sup>130</sup>Te. Derive  $\langle g_{\nu\chi} \rangle < 17-33 \times 10^{-5}$  depending on matrix element.
- 19 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.
- 20 Limit for the 0 $\nu\chi$  decay with Majoron emission of <sup>116</sup>Cd using enriched CdWO<sub>4</sub> scintillators.  $\langle g_{\nu\chi} \rangle < 4.6-8.1 \times 10^{-5}$  depending on the matrix element. Supersedes DANEVICH 00.
- 21 Limit for the 0 $\nu$ 2 $\chi$  decay of <sup>116</sup>Cd. Supersedes DANEVICH 00.
- 22 BERNABEI 02b obtain limit for 0 $\nu\chi$  decay with Majoron emission of <sup>136</sup>Xe using liquid Xe scintillation detector. They derive  $\langle g_{\nu\chi} \rangle < 2.0-3.0 \times 10^{-5}$  with several nuclear matrix elements.
- 23 Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the 0 $\nu\chi$  decay by means of tracking calorimeter ELEGANT V. Considering various nuclear element calculations, a range of limits for the Majoron-neutrino coupling is given:  $\langle g_{\nu\chi} \rangle < (6.3-360) \times 10^{-5}$ .
- 24 ASHITKOV 01 result for 0 $\nu\chi$  of <sup>100</sup>Mo is less stringent than ARNOLD 00.
- 25 DANEVICH 01 obtain limit for the 0 $\nu\chi$  decay with Majoron emission of <sup>160</sup>Gd using Gd<sub>2</sub>SiO<sub>5</sub>:Ce crystal scintillators.
- 26 DANEVICH 01 obtain limit for the 0 $\nu$ 2 $\chi$  decay with 2 Majoron emission of <sup>160</sup>Gd.
- 27 ARNOLD 00 reports limit for the 0 $\nu\chi$  decay with Majoron emission derived from tracking calorimeter NEMO 2. Using <sup>82</sup>Se source:  $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$ . Matrix element from GUENTHER 96.
- 28 Using <sup>96</sup>Zr source:  $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$ . Matrix element from ARNOLD 99.
- 29 ARNOLD 00 reports limit for the 0 $\nu$ 2 $\chi$  decay with two Majoron emission derived from tracking calorimeter NEMO 2.
- 30 ARNOLD 98 determine the limit for 0 $\nu\chi$  decay with Majoron emission of <sup>82</sup>Se using the NEMO-2 tracking detector. They derive  $\langle g_{\nu\chi} \rangle < 2.3-4.3 \times 10^{-4}$  with several nuclear matrix elements.
- 31 LUESCHER 98 report a limit for the 0 $\nu$  decay with Majoron emission of <sup>136</sup>Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on  $\langle g_{\nu\chi} \rangle$  of  $2.0 \times 10^{-4}$ .
- 32 See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.

Invisible  $A^0$  (Axion) MASS LIMITS from Astrophysics and Cosmology

$v_1 = v_2$  is usually assumed ( $v_j =$  vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

- 1 CHENG 23 employ an improved approximation of the boson cloud eigenfrequency to calculate the superradiance rate. They find that sensitivity depends on initial spin distribution and the merger timescale, and identify two preferred ranges for boson mass centered at  $1.78 \times 10^{-12}$  and  $7.94 \times 10^{-13}$  eV.
- 2 DELLA-MONICA 23 consider the solitonic core implied by ultralight scalar dark matter in the centre of the Milky Way and the effect its presence would have on the precisely tracked orbits of the stars orbiting our galaxy's central supermassive black hole, Sagittarius A\*.
- 3 DERBIN 23 employ a thulium garnet crystal bolometer to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of thulium-169,  $^{169}\text{Tm}$ . Mass bound applies to KSVZ axions, value for DFSZ is 244 eV.
- 4 NOTARI 23 improved the evaluation of axion production from pion scatterings by using pion-pion scattering data and incorporating the momentum dependence of the Boltzmann equation. The limit is based on the Planck 2018, BAO, and Pantheon SN Ia data.
- 5 ROGERS 23 use the CMB and BOSS galaxy-clustering data to set limits on the abundance of ultralight axion DM. They obtained  $\Omega_{A^0} < 0.002$  for  $m_{A^0} = 10^{-30}$ - $10^{-28}$  eV and set upper limits ranging from 0.002 to 0.07 for  $m_{A^0} = 10^{-32}$ - $10^{-25}$  eV. See their Fig. 22 for mass-dependent limits.
- 6 SMARRA 23 is the European Pulsar Timing Array's constraint on the contribution of ultralight DM to the DM density in our local galactic neighbourhood. Ultralight DM cannot saturate the known DM density of 0.3 GeV/cc for masses inside this mass interval of  $10^{-24.5}$ - $10^{-23}$  eV.
- 7 XIA 23 is analogous to PORAYKO 18 and use the Fermi-LAT pulsar timing array. They set a bound on the local density as  $\rho_{A^0} \lesssim 8 \text{ GeV/cm}^3$  for  $m_{A^0} \lesssim 10^{-23}$  eV at 95% CL, with weaker constraints up to  $10^{-22}$  eV. See their Fig. 1 for the mass-dependent limits.
- 8 LAGUE 22 used the BOSS galaxy-clustering data to set limits on the abundance of ultralight axion dark matter. When combined with the CMB data, they obtained  $\Omega_{A^0} h^2 < 0.004$  for  $m_{A^0} = 10^{-31}$ - $10^{-26}$  eV. See their Figs. 1 and 15 for mass-dependent limits.
- 9 YUAN 22a use the data of Advanced LIGO and Advanced Virgo's first three observing runs to search for stochastic GW background produced by scalar bosonic clouds formed by the BH superradiant instability. They set the limit, taking into account all the unstable modes.
- 10 BANIK 21 use the subhalo mass function inferred from the analyses of the GD-1 and Pal 5 stellar streams. The limit is strengthened to  $2.2 \times 10^{-21}$  eV when adding dwarf satellite counts.
- 11 BAUMHOLZER 21 study the freeze-in production of axion dark matter through couplings to photons, and set the limit using Lyman- $\alpha$  forest data and the observed number of Milky Way subhalos.

- 12 CROON 21 study the supernova cooling effect of the axion-muon coupling, taking account of semi-Compton scattering and muon-proton bremsstrahlung, as well as the loop-induced axion-photon coupling, and exclude the range of  $g_{A\mu\mu} \simeq 7 \times 10^{-3}$ - $2 \times 10^{-10}$  for  $m_{A^0} < 0.5$  GeV. See their Fig. 8 for mass-dependent limits.
- 13 FUJIKURA 21 use the EROS-2 survey and the Subaru HSC observation to set limits on spherically symmetric axion clumps, taking account of the finite lens and source size effects.  $f_{A^0} \gtrsim 10^{12}$  GeV can be constrained depending on the fraction of the axion dark matter collapsed into clumps, and the clump densities. See their Figs. 7-10 for the limits.
- 14 MARTINCAMALICH 21 considered axion emission from a supernova core through the  $\Lambda$  hyperon decay, and set the limit on  $B(\Lambda \rightarrow nA^0) \lesssim 8 \times 10^{-9}$ , or equivalently,  $f_{A^0}/c_{sd} \gtrsim 2.6 \times 10^9$  GeV in terms of the flavor-violating axion coupling to the down and strange quarks.
- 15 NG 21 use the binary black holes reported by LIGO and Virgo to determine the black hole spin distribution at formation and the scalar boson mass simultaneously, neglecting the boson self-interaction.
- 16 ROGERS 21 set the limit by using a framework involving Bayesian emulator optimization to accurately forward-model the Lyman- $\alpha$  flux power spectrum, and comparing this with small-scale data to constrain the predicted suppression of cosmic structure growth.
- 17 TSUKADA 21 look for a stochastic GW background produced by extragalactic BH-hidden photon cloud systems through the superradiant instability. They assume a uniform spin distribution at birth of isolated BHs from 0 to 1.
- 18 IRSIC 20 used the Lyman- $\alpha$  forest constraint on small-scale isocurvature perturbation to derive limits on the axion mass and decay constant, assuming that the axion makes up all dark matter in the post-inflationary scenario. See their Fig. 1 for other astrophysical limits as well as the limits on the case of the temperature-dependent axion mass.
- 19 PODDAR 20 used the observed decay in orbital period of four compact binary systems to derive a limit on the emission of axions with  $m_{A^0} < 1 \times 10^{-19}$  eV, assuming they couple to nucleons and the strong CP phase vanishes at the potential minimum. They exclude  $f_{A^0} \lesssim 10^{11}$  GeV for such axions.
- 20 SCHUTZ 20 set a limit on fuzzy dark matter based on the existing limits for warm dark matter derived from the inferred subhalo mass function.
- 21 SUN 20 look for quasimonochromatic gravitational waves emitted from boson clouds around the Cygnus X-1 black hole. The quoted limit assume the black hole age of  $5 \times 10^6$  years. A mass range of  $9.6$ - $15.5 \times 10^{-13}$  eV is disfavored when repeated induction of bosonova for string axions with decay constant  $f_{A^0} \simeq 10^{15}$  GeV prevents the superradiance from being saturated.
- 22 DAVOUDIASH 19 used the observed data of M87\* by the Event Horizon Telescope to set the limit. A mass range of  $0.85$ - $4.6 \times 10^{-21}$  eV is disfavored for a spin-1 boson.
- 23 MARSH 19 considered heating of star clusters due to the stochastic oscillations of the core and granular quasiparticles in the outer halo. The limit was derived by requiring the survival of the old star cluster in Eridanus II, where the lower end is set by the validity of diffusion approximation. The effect of tidal stripping is also discussed for lower masses.
- 24 PALOMBA 19 used the LIGO O2 dataset to derive limits on nearly monochromatic gravitational waves emitted by boson clouds formed around a stellar-mass black hole. They exclude boson masses in a range of  $1.1 \times 10^{-13}$  and  $4 \times 10^{-13}$  eV for high initial black hole spin, and  $1.2 \times 10^{-13}$  and  $1.8 \times 10^{-13}$  eV for moderate spin. See their Figs. 2 and 3 for limits based on various values of black hole initial spin, boson cloud age, and distance.
- 25 CHANG 18 update axion bremsstrahlung emission rates in nucleon-nucleon collisions, shifting the excluded mass range to higher values. They rule out the hadronic axion with mass up to a few hundred eV, closing the hadronic axion window. See their Fig. 11 for results based on several different choices of the temperature and density profile of the proto-neutron star.
- 26 PORAYKO 18 look for time-dependent oscillations in the gravitational potential generated by ultralight scalar dark matter, and set a bound on its local density as  $\rho_{A^0} \lesssim 6 \text{ GeV/cm}^3$  for  $m_{A^0} \lesssim 10^{-23}$  eV at 95% CL. See their Fig. 4 for the limits.
- 27 ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-year data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.
- 28 CADAMURO 11 use the deuterium abundance to show that the  $m_{A^0}$  range 0.7 eV - 300 keV is excluded for axions, complementing HANNESTAD 10.
- 29 DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of  $^{169}\text{Tm}$ , constraining the axion-electron  $\times$  axion-nucleon couplings.
- 30 ANDRIAMONJE 10 search for solar axions produced from  $^7\text{Li}$  (478 keV) and  $D(p,\gamma)^3\text{He}$  (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for  $m_A < 100$  eV.
- 31 This is an update of HANNESTAD 08 including 7 years of WMAP data.
- 32 ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of  $^{57}\text{Fe}$ . They show limits on the axion-nucleon  $\times$  axion-photon coupling assuming  $m_A < 0.03$  eV.
- 33 DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of  $^{169}\text{Tm}$ , constraining the axion-photon  $\times$  axion-nucleon couplings.
- 34 KEKEZ 09 look at axio-electric effect of solar axions in HPGE detectors. The one-loop axion-electron coupling for hadronic axions is used.
- 35 This is an update of HANNESTAD 07 including 5 years of WMAP data.
- 36 This is an update of HANNESTAD 05a with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman- $\alpha$  data are left out, in contrast to HANNESTAD 05a and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.
- 37 MELCHIORRI 07A is analogous to HANNESTAD 05a, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman- $\alpha$  data, a conservative limit is 1.4 eV.
- 38 HANNESTAD 05a puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large scale structure, Lyman  $\alpha$ , and the prior Hubble parameter from HST Key Project. A  $\chi^2$  statistic is used. Neutrinos are assumed not to contribute to hot dark matter.

See key on page 1171

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>39</sup> MOROJ 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent  $g_{A\gamma}$  is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.
- <sup>40</sup> BORISOV 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-13}$  from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.
- <sup>41</sup> KACHELRIESS 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-10}$  from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit,  $g_{ae} < 9 \times 10^{-13}$  which is strongly dependent on the strength of the magnetic field in white dwarfs.
- <sup>42</sup> KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.
- <sup>43</sup> RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- <sup>44</sup> ALTHERR 94 bound is on the axion-electron coupling  $g_{ae} < 1.5 \times 10^{-13}$ , from energy loss via axion emission.
- <sup>45</sup> CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in  $z=m_{\psi}/m_{\phi}$  (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window  $f_A=3 \times 10^5-3 \times 10^6$  GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.
- <sup>46</sup> BERSHADY 91 searched for a line at wave length from 3100-8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.
- <sup>47</sup> KIM 91c argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.
- <sup>48</sup> RAFFELT 91b argue that previous SN1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- <sup>49</sup> RESSELL 91 uses absence of any intracuster line emission to set limit.
- <sup>50</sup> ENGEL 90 rule out  $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$ , which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to  $2.5 \times 10^{-3} \text{ eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^4 \text{ eV}$ . The constraint is loose in the middle of the range, i.e. for  $g_{AN} \sim 10^{-6}$ .
- <sup>51</sup> RAFFELT 90d is a re-analysis of DEARBORN 86.
- <sup>52</sup> The region  $m_{A^0} \gtrsim 2 \text{ eV}$  is also allowed.
- <sup>53</sup> ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- <sup>54</sup> MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2-4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88b.
- <sup>55</sup> RAFFELT 88b derives a limit for the energy generation rate by exotic processes in helium-burning stars  $\epsilon < 100 \text{ erg g}^{-1} \text{ s}^{-1}$ , which gives a firmer basis for the axion limits based on red giant cooling.
- <sup>56</sup> RAFFELT 87 also gives a limit  $g_{A\gamma} < 1 \times 10^{-10} \text{ GeV}^{-1}$ .
- <sup>57</sup> DEARBORN 86 also gives a limit  $g_{A\gamma} < 1.4 \times 10^{-11} \text{ GeV}^{-1}$ .
- <sup>58</sup> RAFFELT 86 gives a limit  $g_{A\gamma} < 1.1 \times 10^{-10} \text{ GeV}^{-1}$  from red giants and  $< 2.4 \times 10^{-9} \text{ GeV}^{-1}$  from the sun.
- <sup>59</sup> KAPLAN 85 says  $m_{A^0} < 23 \text{ eV}$  is allowed for a special choice of model parameters.
- <sup>60</sup> FUKUGITA 82 gives a limit  $g_{A\gamma} < 2.3 \times 10^{-10} \text{ GeV}^{-1}$ .

### Search for Relic Invisible Axions

Limits are for the dimensionless quantity  $[G_{A\gamma\gamma}/m_{A^0}]^2 \rho_A$  where  $G_{A\gamma\gamma}$  denotes the axion two-photon coupling,  $L_{int} = -\frac{G_{A\gamma\gamma}}{4} \phi_A F_{\mu\nu} \tilde{F}^{\mu\nu} = G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}$ , and  $\rho_A$  is the axion energy density near the earth, unless otherwise stated. Notice that for QCD axions  $G_{A\gamma\gamma}/m_{A^0}$  does not depend on  $m_{A^0}$ . For the reference values  $m_{A^0} = 1 \mu\text{eV}$ ,  $G_{A\gamma\gamma} = 3.9 \times 10^{-16} \text{ GeV}^{-1}$  (that would apply to KSVZ axions at that mass), and  $\rho_A = 300 \text{ MeV}/\text{cm}^3$  one finds  $[G_{A\gamma\gamma}/m_{A^0}]^2 \rho_A = 3.5 \times 10^{-43}$ .

- <sup>1</sup> ADACHI 23D is analogous to ADE 21. They used POLARBEAR data, and take account of a stochastic local axion field amplitude with the time-averaged local axion density  $\rho_A = 0.3 \text{ GeV}/\text{cm}^3$ . Limits are set at  $G_{A\gamma\gamma} < 2.4 \times 10^{-11} \text{ GeV}^{-1}$  ( $m_{A^0}/10^{-21} \text{ eV}$ ), which is 2.2 times larger than the deterministic case. See Fig. 5 for mass-dependent limits.
- <sup>2</sup> DI-VORA 23 searches for axions in a narrow mass window using an 8T haloscope and a travelling wave parametric amplifier to achieve noise close to the quantum limit. This is an improvement on their previous scan at the same mass, ALESINI 21. See Fig. 7 for mass-dependent limits and a comparison.
- <sup>3</sup> JEWELL 23 is an update of BRUBAKER 17. See their Fig. 11 for the mass-dependent limits.
- <sup>4</sup> JEWELL 23 correct an underestimation of intermediate frequency noise in BACKES 21. See their Fig. 11 for the mass-dependent limits.
- <sup>5</sup> KIM 23 is an update of KWON 21 on the CAPP-PACE experiment. See their Fig. 4 for mass-dependent limits.
- <sup>6</sup> OSHIMA 23 report first limits from the DANCE experiment. This experiment is based on a novel bow-tie cavity design that searches for the oscillating rotation of polarised laser light driven by the DM axion-photon mixing at low frequencies. See their Fig. 6 for mass-dependent limits.
- <sup>7</sup> THOMSON 23 used an AC microwave cavity to search for dark matter axions. The axion signal is resonantly enhanced when the axion mass matches the difference between a cavity which is pumped with power and another resonant mode close in frequency that is used to read out the signal. See their Fig. 7 for the mass-dependent limits.
- <sup>8</sup> YANG 23 extends the first phase of CAPP 18T to KSVZ axions between 4.8077 and 4.8181 GHz. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits. Quoted value is for their limit derived with a Bayesian method.
- <sup>9</sup> YI 23 is analogous to LEE 20A, using the CAPP-12TB haloscope. See their Fig. 4 for mass-dependent limits.
- <sup>10</sup> YI 23A used the same data as YI 23, but instead of the standard halo model, they searched for axion dark matter in the Sagittarius tidal stream with a velocity  $v = 300 \text{ km/sec}$  and a velocity dispersion  $\delta v = 20 \text{ km/sec}$ . See their Fig. 4 for mass-dependent limits.
- <sup>11</sup> ADE 22 is an update of ADE 21 based on the expanded data of the 2012-2015 observing seasons. See their Fig. 3 for mass-dependent limits over the extended mass range  $1 \times 10^{-23}-6 \times 10^{-19} \text{ eV}$ .
- <sup>12</sup> ALESINI 22 is an update of ALESINI 21, using the TM030 mode of the cylindrical dielectric cavity. See their Fig. 8 for mass-dependent limits.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- 13 BATTYE 22 is analogous to DARLING 20A, and use plasma ray tracing technique to analyze the propagation of radio photons converted from axion dark matter in the magnetosphere of PSR J1745-2900. The quoted limit assumes  $\rho_A = 6.5 \times 10^4 \text{ GeV/cm}^3$  in the vicinity of the magnetar. See their Fig. 1 for mass-dependent limits.
- 14 CHANG 22 used a microwave cavity detector to search for dark matter axions. See Fig. 3 for the mass-dependent limits.
- 15 FERGUSON 22 is analogous to ADE 21. They use the data of the SPT-3G's 2019 observing season. See their Fig. 5 for mass-dependent limits over the extended mass range  $0.047\text{--}9.5 \times 10^{-20} \text{ eV}$ .
- 16 LEE 22 is analogous to LEE 20A. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits.
- 17 QUICKAMP 22 is a 15.28 to 16.23 GHz microwave cavity haloscope with 11.5 T B-field. See Fig. 4 for mass-dependent limits.
- 18 YOON 22 analyzed the data from LEE 22 and changed from a frequentist to a Bayesian method to set limits. See their Fig. 27 for mass-dependent limits.
- 19 ZHOU 22 is analogous to DARLING 20A, and they use the data from the MeerKAT radio telescope's observation of the neutron star J0806.4-4123, which is 250 pc from Earth. See their Fig.3 for mass-dependent limits.
- 20 ADE 21 looks for a time-variable global rotation of the CMB polarization induced by the harmonic oscillations of local axion-like dark matter and uses data from the 2012 observing season of the Keck Array, part of the BICEP program. The limits get 25% weaker for  $m_{A^0} = 4.8 \times 10^{-20}\text{--}5.7 \times 10^{-19} \text{ eV}$ . See their Eq. (80) and Fig. 6 for mass-dependent limits.
- 21 ALESINI 21 is an update of ALESINI 19. See their Figs. 5 and 6 for the mass-dependent limits.
- 22 BARTRAM 21A is analogous to DU 18. See their Fig.4 for mass-dependent limits.
- 23 DEVLIN 21 use the superconducting resonant detection circuit of a cryogenic Penning trap with a single antiproton. See their Fig. 3 for mass-dependent limits.
- 24 GRAMOLIN 21 use two detection channels, each consisting of two stacked toroids to look for the axion-induced oscillating magnetic field. The quoted limit applies at  $m_{A^0} = 0.02 \text{ neV}$ . See their Fig. 4 for mass-dependent limits.
- 25 KWON 21 is analogous to LEE 20A. They also obtain weaker limits in the range of  $m_{A^0} = 10.16\text{--}11.37 \mu\text{eV}$ . See their Fig. 4 for mass-dependent limits.
- 26 MELCON 21 use a radio frequency cavity consisting of 5 sub-cavities coupled by inductive irises installed inside the CAST dipole magnet to look for higher axion masses. See their Fig. 9 for mass-dependent limits.
- 27 SALEMI 21 is an update of OUELLET 19A. See their Fig. 4 for mass-dependent limits.
- 28 THOMSON 21 use a resonant cavity supporting two spatially overlapping microwave modes, which is sensitive to the axion mass corresponding to the sum or difference of the two resonant frequencies. The original limit was retracted due to a sign error. See their Fig. 2 in the erratum for the corrected limits.
- 29 YUAN 21 use polarimetric observations of Sgr A\* taken by the Event Horizon Telescope to search for periodic oscillation of the polarization induced by axion dark matter, assuming a solitonic core near the Galactic center. They obtained limits in the range of  $G_{A\gamma\gamma} = 8 \times 10^{-13}\text{--}3 \times 10^{-11} \text{ GeV}^{-1}$ .
- 30 BRAINE 20 is analogous to DU 18. See Fig. 4 for their mass-dependent limits.
- 31 CRISOSTO 20 used a resonant LC circuit to look for lighter axion dark matter. They obtained a similar, slightly weaker limit for  $m_{A^0} = 174.98\text{--}175.19$  and  $177.34\text{--}177.38 \text{ neV}$ . See their Fig. 4 for mass-dependent limits.
- 32 DARLING 20A use VLA data to look for radio-frequency radiation converted from axion dark matter in the magnetosphere of the Galactic Center magnetar PSR J1745-2900. They extended the results of DARLING 20, which used only data with the highest angular resolution, by adding sub-optimal data. They use  $\rho_A = 6.5 \times 10^4 \text{ GeV/cm}^3$  in the vicinity of the magnetar. See their Fig. 2 for mass-dependent limits.
- 33 FOSTER 20 look for radio-frequency radiation converted from axion dark matter in the magnetic field around neutron stars. They use the observed data of isolated local neutron stars and in the Galactic center. The quoted limit applies to  $m_{A^0} \simeq 7 \mu\text{eV}$ . See their Fig. 2 for mass-dependent limits.
- 34 JEONG 20 is analogous to LEE 20A, and they use a double-cell cavity to look for axions with mass  $> 10 \mu\text{eV}$ . See their Fig. 5 for mass-dependent limits.
- 35 KENNEDY 20 is analogous to BRANCA 17, and they compare the frequency ratios of the Si cavity measured by a Sr optical lattice clock and by a H maser. Assuming the local density of moduli dark matter,  $\rho_S = 0.3 \text{ GeV/cm}^3$ , they obtain a limit  $G_{S\gamma\gamma} < 5.8 \times 10^{-24} \text{ GeV}^{-1}$  at  $m_{S^0} = 2 \times 10^{-19} \text{ eV}$ . See their Fig. 2 for mass-dependent limits as well as limits on the modulus coupling to electrons.
- 36 LEE 20A used a microwave cavity detector at the IBS/CAPP to search for dark matter axions. See Fig. 3 for the mass-dependent limits.
- 37 ALESINI 19 used a superconducting resonant cavity made of NbTi to increase the quality factor. The limit applies to a mass range of  $0.2 \text{ neV}$  around  $m_{A^0} = 37.5 \mu\text{eV}$ .
- 38 FUJITA 19 look for photon birefringence under the oscillating axion background using the polarimetric imaging observation of a protoplanetary disk, AB Aur. See their Fig. 2 for a more conservative limit taking account of possible systematic effects.
- 39 OUELLET 19A look for the axion-induced oscillating magnetic field generated by a toroidal magnetic field. The quoted limit applies at  $m_{A^0} = 8 \text{ neV}$ . See their Fig. 3 for the mass-dependent limits.
- 40 BOUTAN 18 use a small high frequency cavity installed above the main ADMX cavity to look for heavier axion dark matter. See their Fig. 4 for mass-dependent limits.
- 41 DU 18 is analogous to DUFFY 06. They upgraded a dilution refrigerator to reduce the system noise. The quoted limit is around  $m_{A^0} = 2.69 \mu\text{eV}$  for the boosted Maxwellian axion line shape. See Fig. 4 for their mass-dependent limits.
- 42 ZHONG 18 is analogous to BRUBAKER 17. The quoted limit applies at  $m_{A^0} = 23.76 \mu\text{eV}$ . See Fig. 4 for their mass-dependent limits.
- 43 BRANCA 17 look for modulations of the fine-structure constant and the electron mass due to moduli dark matter by using the cryogenic resonant-mass AURIGA detector. The limit on the assumed dilatonic coupling implies  $G_{S\gamma\gamma} < 1.5 \times 10^{-24} \text{ GeV}^{-1}$  for the scalar to two-photon coupling. See Fig. 5 for the mass-dependent limits.
- 44 BRUBAKER 17 used a microwave cavity detector at the Yale Wright Laboratory to search for dark matter axions. See Fig. 3 for the mass-dependent limits.
- 45 CHOI 17 used a microwave cavity detector with toroidal geometry. See Fig. 4 for their mass-dependent limits.
- 46 MCALLISTER 17 used a high-frequency microwave cavity haloscope at 26.6 GHz in a 7 T magnetic field. See Fig. 4 for mass-dependent limits.

- 47 HOSKINS 16 is analogous to DUFFY 06. See Fig. 12 for mass-dependent limits in terms of the local dark matter density.
- 48 BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review B70 180503 (2004)] is interpreted in terms of subdominant dark matter axions with  $m_{A^0} = 0.11 \text{ meV}$ .
- 49 HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.
- 50 ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the  $m_{A^0}$  dependence of the limit.
- 51 DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.
- 52 ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than  $0.45 \text{ GeV/cm}^3$  in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.
- 53 KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of  $G_{A\gamma\gamma}$  and hence the bound from relic axion search.
- 54 HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.
- 55 WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with  $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2 \times 10^{-14} \text{ MeV}^{-4}$  (the three generation DFSZ model) and  $\rho_A = 300 \text{ MeV/cm}^3$  that makes up galactic halos gives  $(G_{A\gamma\gamma}/m_{A^0})^2 \rho_A = 4 \times 10^{-44}$ . Note that our definition of  $G_{A\gamma\gamma}$  is  $(1/4\pi)$  smaller than that of WUENSCH 89.

### Invisible $A^0$ (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling  $G_{A\gamma\gamma}$  defined by  $L = -G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}$ . For scalars  $S^0$  the limit is on the coupling constant in  $L = G_{S\gamma\gamma} \phi_S (\mathbf{E}^2 - \mathbf{B}^2)$ . The relation between  $G_{A\gamma\gamma}$  and  $m_{A^0}$  is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.

none $6.0 \times 10^{-9}-1.3 \times 10^{-5}$		56 LUCENTE	20a	ASTR	$m_{A^0} < 270$ MeV					
$<2.6 \times 10^{-11}$	95	57 MEYER	20	FLAT	$m_{A^0} < 3 \times 10^{-10}$ eV					1 PANT 24 searches for the imprint of axion-photon oscillations in the very-high-energy gamma-ray spectrum of the quasar QSO B1420+326 observed by the MAGIC telescope. Three small disconnected regions of mass-coupling parameter space below 1 neV are ruled out. See Fig. 4 for the limits.
$<8.4 \times 10^{-8}$	99	58 YAMAMOTO	20	COSM	$m_{A^0} < 4 \times 10^{-6}$ eV					2 BATTYE 23 look for dark-matter axions falling into pulsar magnetospheres and converting into narrow radio lines. Unlike the earlier FOSTER 22 they search for evidence of conversion in the time-domain signal of a single pulsar, using 1 hour of MeerKAT data on the pulsar PSR J2144-3933. The quoted limit applies to an assumed magnetic field of $2 \times 10^{12}$ G and a dark matter density of 0.45 GeV/cm <sup>3</sup> .
$<1 \times 10^{-3}$	95	59 ALONI	19	PRMX	$m_{A^0} = 0.16$ GeV					3 BEAUFORT 23 extends DEROCOCO 22 who searched for the X-ray decay of axions that build up in the gravitational well of the Sun over its lifetime, the 'solar basin'. They use data from NuSTAR and SpHinx telescopes and extends the previous study by accounting for the axion production via photon coalescence.
$<1.4 \times 10^{-14}$	95	60 CAPUTO	19	ASTR	$m_{A^0} < 5 \times 10^{-24}$ eV					4 BERNAL 23 use gamma-ray data from 739 blazars observed by FermiLAT and 38 blazars by Cherenkov observatories. They estimate optical depth, subtract the astrophysical component, and attribute the residual to axion two-photon decay. The quoted limit is for $m_{A^0} \approx 25$ eV. See their Fig. 3 for the mass-dependent limits.
$<9.6 \times 10^{-14}$	95	61 FEDDERKE	19	CMB	$m_{A^0} = 10^{-22}$ eV					5 CAPOZZI 23 use Planck CMB and Lyman-alpha observations to set limits on early energy injection by decaying dark matter axions that would affect CMB anisotropies and the reionisation history of the Universe. The quoted limit applies to $m_{A^0} = 100$ eV and the reionization model of Fauchere-Giguere. See Fig.4 for mass-dependent constraints from different reionization models.
$<7 \times 10^{-13}$	95	62 IVANOV	19	ASTR	$m_{A^0} = 5 \times 10^{-23}$ eV					6 CAPOZZI 23a search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 100 MeV but the limit does not extend to arbitrarily large couplings. See Fig. 7 for mass-dependent limits.
$<4 \times 10^{-11}$	95	63 LIANG	19	ASTR	$m_{A^0} = 1.2 \times 10^{-7}$ eV					7 DAVIES 23 is analogous to AJELLO 16, and use the Fermi-LAT data from three quasars (3C454.3, CTA 102, and 3C279), considering the blazar jets as the regions where the axion-photon oscillations occur. See Fig. 8 for the mass-dependent limits.
$<3 \times 10^{-12}$		64 FORTIN	18	ASTR	Axion-like particles					8 DIAMOND 23 demonstrate that a window of decaying 10-MeV-mass ALP parameter space previously thought to be excluded by the lack of gamma-ray emission from the SN 1987A explosion is actually unconstrained because of the formation of a fireball that would prevent decay photons from escaping. They nevertheless re-exclude this window by considering the non-detection of the sub-MeV emission by the Pioneer Venus Orbiter. The quoted limit is at $m_{A^0} = 56$ MeV. See their Fig. 2 for mass-dependent limits.
$<5.0 \times 10^{-3}$	90	66 YAMAJI	18	LSW	$m_{A^0} = 46-1020$ eV					9 FILZINGER 23 searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequency ratio between the E3 and E2 transitions of <sup>171</sup> Yb <sup>+</sup> . They assume the local dark matter density $\rho_S = 0.4$ GeV/cm <sup>3</sup> . The quoted limit is set at $m_{S^0} \approx 4 \times 10^{-23}$ eV. See their Fig. 4 for the limits over $m_{S^0} = 1 \times 10^{-24}-1 \times 10^{-17}$ eV.
$<1 \times 10^{-11}$	99.9	67 ZHANG	18	ASTR	$m_{A^0} = 0.6-4$ neV					10 HOOF 23 consider axions emitted from SN1987A converting to gamma rays in Galactic magnetic fields, using temporal information of the Solar Maximum Mission data. They set a limit $G_{A\gamma\gamma} \lesssim 5 \times 10^{-12}$ for masses $m_{A^0} \lesssim 2 \times 10^{-10}$ eV. See left panel in Fig. 3 for mass-dependent limits.
$<6.6 \times 10^{-11}$	95	68 ADE	17	CMB	Axion-like particles					11 HOOF 23 look for gamma rays resulting from the decay of axions produced from SN1987A, using the Solar Maximum Mission data. See right panel in Fig. 3 for mass-dependent limits.
$<2.51 \times 10^{-4}$	95	69 ANASTASSO...	17	CAST	$m_{A^0} < 0.02$ eV					12 JACOBSEN 23 search for the imprints of axion-photon mixing on the TeV spectra of several blazars using data from the HAWC air shower detector.
$>1.5 \times 10^{-11}$	95	70 DOLAN	17	RVUE	Axion-like particles					13 LI 23h look for gamma-ray spectral irregularities induced by axion-photon oscillations from AGN VER J0521+211, using the Fermi-LAT and VERITAS data. See their Fig. 4 for mass-dependent limits.
$<2.6 \times 10^{-12}$	95	71 INADA	17	LSW	$m_{A^0} < 0.1$ eV					14 NOORDHUIS 23 places strong constraints on the axion-photon coupling over a broad mass window using the fact that the polar cap regions of pulsars can generate a population of axions, which would then convert into an observable outgoing radio flux in the presence of the neutron star's B-field. They search for this signal in 27 pulsars and set mass-dependent limits shown in their Fig. 2.
$<6 \times 10^{-13}$	95	72 KOHRI	17	ASTR	$m_{A^0} = 0.7-50$ neV					15 PANT 23 study the effect of axion-photon oscillations on the gamma-ray spectrum from the extragalactic neutrino source, TXS 0506+056. The quoted limit is at $m_{A^0} \approx 2.7 \times 10^{-7}$ eV. See their Fig. 2 for mass-dependent limits.
$<7.4 \times 10^{-12}$	95	73 MARSH	17	ASTR	$m_{A^0} \leq 10^{-13}$ eV					16 SHERRILL 23 search for scalar dilaton-like dark matter via oscillations in the fundamental constants. Their most competitive constraint is on the scalar photon coupling (Fig. 6, upper panel) that affects the fine-structure constant, which they extract using an optical-to-optical clock comparison between <sup>171</sup> Yb <sup>+</sup> and <sup>87</sup> Sr. Quoted limit applies at the smallest mass in their search window for this case of $10^{-20}$ eV.
$<6 \times 10^{-13}$	95	74 TIWARI	17	COSM	$m_{A^0} \leq 10^{-15}$ eV					17 SULAI 23 looked for ultralight axion dark matter using the "Earth as a transducer" concept over the 0.5 to 5 Hz frequency range. They situate several magnetometers at magnetically quiet places and search for spatially-correlated magnetic field patterns induced by axion dark matter interacting in the effective cavity formed between the Earth's surface and the ionosphere. See their Fig. 12 for mass-dependent limits in context. This limit extends to higher-frequencies than their previous limit using archival geomagnetic field data collected by the SuperMAG collaboration, see ARZA 22
$<5 \times 10^{-12}$	95	75 AJELLO	16	COSM	$m_{A^0} = 0.5-5$ neV					18 YAO 23 study an optical circular polarization in blazars induced by the axion-photon mixing. The quoted limit assumes the transverse magnetic field at the jet's emission site, with $B_T = 1$ G, and this limit inversely scales with $B_T$ . See their Fig. 3 for the limits' dependence on $B_T$ and electron density.

## Axions ( $A^0$ ) and Other Very Light Bosons

- 19 ZHANG 23A searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequencies of a hyperfine-structure transition in  $^{87}\text{Rb}$  and an electronic transition in  $^{164}\text{Dy}$ , and by comparing them with that of a quartz oscillator. They assume the local dark matter density  $\rho_S \simeq 0.4 \text{ GeV}/\text{cm}^3$ . The quoted limit is set at  $m_{S0} \simeq 1 \times 10^{-17} \text{ eV}$ . See their Fig. 3 for the limits over  $m_{S0} = 1 \times 10^{-17} - 8.3 \times 10^{-13} \text{ eV}$ .
- 20 APRILE 22B is an update of APRILE 20 based on a similar solar axion modeling to DENT 20A and GAO 20. They exclude the XENONIT excess found in APRILE 20. The quoted limit holds for small  $g_{Aee}$ . See Fig. 6 for correlation between  $G_{A\gamma\gamma}$  and  $g_{Aee}$ .
- 21 ARQUIST 22 is analogous to AVIGNONE 98, and supersedes ANASTASSOPOULOS 17 for  $m_{A0} \gtrsim 1.2 \text{ eV}$ .
- 22 ARZA 22 search for low-mass axions as dark matter using the Earth as a transducer for axion-photon conversion. The concept works because the region between the Earth and the ionosphere forms an insulating cavity that parametrically enhances the axion signal by the radius of the Earth. The result is an oscillating and spatially correlated magnetic field induced via the interaction between axion dark matter and the geomagnetic field, which they searched for using archival magnetometer field data over 20 years compiled by the SuperMAG collaboration. Quoted limit applies for masses  $3-4 \times 10^{-17} \text{ eV}$ , see Fig. 1 for mass-dependent limits.
- 23 BERNAL 22 explored the possibility that the excess in the cosmic optical background measured by New Horizons Long Range Reconnaissance Imager was due to axion dark matter decaying into monoenergetic photons. See their Fig. 2 for the axion-photon coupling to explain the excess.
- 24 CALORE 22 update CALORE 20 by evaluating axion fluxes from progenitors of various masses and performing a template-based analysis using 12 years of Fermi-LAT data in the energy range from 50 MeV to 500 GeV. See their Fig. 10 for mass-dependent limits.
- 25 CAPUTO 22 study the effect of energy deposition by radiative decay of axions produced via the Primakoff process and photon coalescence in the supernova core, and set the limits by the radiative energy deposition  $< 10^{50} \text{ erg}$  and progenitor radius  $= 5 \times 10^{13} \text{ cm}$ . The quoted limit is at  $m_{A0} = 150 \text{ MeV}$ . See their Fig. 2 for mass-dependent limits.
- 26 CASTILLO 22 update CAPUTO 19 using the polarization measurements of the Crab Pulsar by the QUIJOTE MFI instrument and 20 Galactic pulsars from the PPTA project. See their Table 1 for the assumed local axion energy density  $\rho_A$  for each pulsar and their Fig. 7 for the mass-dependent limits in the range of  $3 \times 10^{-23} \text{ eV} \leq m_{A0} \leq 10^{-19} \text{ eV}$ .
- 27 DEROCO 22 uses the NuSTAR data to search for monochromatic X-ray lines produced by the decay of solar axions trapped on bound orbits. The quoted limit applies to  $m_{A0} \simeq 9 \text{ keV}$ . They also derive limits in the plane of  $g_{Aee}$  and  $G_{A\gamma\gamma}$ . See their Figs. 2 and 4 for mass-dependent limits.
- 28 DESSERT 22A look for an axion-induced linear polarization using data from multiple magnetic white dwarf stars. See their Figs. 1 and 8 for the mass-dependent limits.
- 29 ECKNER 22 set limits by using sub-PeV diffuse gamma-ray data from HAWC and Tibet AS $\gamma$  by assuming that gamma rays produced simultaneously with high-energy neutrinos from extragalactic sources suggested by IceCube are converted to axions in the magnetic field at the source and reconverted to gamma rays in the Galactic magnetic field. See their Fig. 4 for mass-dependent limits.
- 30 FOSTER 22 is an update of FOSTER 20 in the list of limits on relic invisible axions. They search for axion-photon transitions generated by neutron stars in the Galactic center region. They use improved population models of the Galactic center neutron stars and a Navarro-Frenk-White (NFW) model of the galactic dark matter distribution. The quoted limit applies to  $m_{A0} \simeq 17-25 \mu\text{eV}$ . See their Fig. 1 for mass-dependent limits.
- 31 KIRITA 22 update HOMMA 21 by increasing the laser energy and developing a background discrimination method using the beam cross-section dependence of the background originated from optical elements. The quoted limits applies to  $m_{A0} = 0.18 \text{ eV}$ . See their Fig. 11 for mass-dependent limits.
- 32 LANGHOFF 22 set limits by considering the freeze-in production of axions coupled only to photons. The quoted limit applies to  $m_{A0} = 2 \text{ MeV}$  for the reheating temperature equal to 5 MeV. See their Fig. 1 for mass-dependent limits.
- 33 LI 22 is analogous to LI 21B, and use the spectra of the blazar FSRQ 4C+21.35 measured by MAGIC, VERITAS, and Fermi-LAT. The quoted limit applies to  $m_{A0} \simeq 8 \times 10^{-10} \text{ eV}$ . See their Fig. 1 for mass-dependent limits.
- 34 LI 22C is analogous to LI 21B, and use the spectra of the blazars Mrk 421 and PG 1553+113 measured by MAGIC and Fermi-LAT. The quoted limit applies to  $m_{A0} \simeq 1 \times 10^{-8} \text{ eV}$ . See their Fig. 4 for mass-dependent limits.
- 35 LUCENTE 22 developed a method to correctly incorporate the effects of axions decaying into photons inside the core of horizontal-branch stars. They update ARENZA 20 by evaluating axion energy transfer in the range of axion mean free path where the diffusive energy transport and free streaming approximations are not applicable. See their Fig. 1 for the limits.
- 36 BASU 21 searched for birefringence induced by axion dark matter using multiple images of the polarized source in the strongly gravitationally lensed system CLASS B1152+199. They assume the axion makes up all dark matter, and used the axion density in the emitting region,  $\rho_A = 20 \text{ GeV}/\text{cm}^3$ . Limits between  $9.2 \times 10^{-11} - 7.7 \times 10^{-8} \text{ GeV}^{-1}$  are obtained for  $m_{A0} = 3.6 \times 10^{-21} - 4.6 \times 10^{-18} \text{ eV}$ . See their Fig. 2 for mass-dependent limits.
- 37 BI 21 look for the gamma-ray spectral distortions induced by axion-photon oscillations in the presence of the Galactic magnetic field, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet AS $\gamma$  and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 3 for mass-dependent limits.
- 38 DOLAN 21A study the effect of axion production on the evolution of asymptotic giant branch stars, and use the white-dwarf initial-final mass relation to set the limits. See their Fig. 1 for mass-dependent limits.
- 39 GUO 21 is analogous to AJELLO 16, and use the Fermi-LAT and H.E.S.S. II measurements of PG 1553+113 and PKS 2155-304. See their Fig. 6 for mass-dependent limits.
- 40 HOMMA 21 look for the production of axion resonance states and their subsequent stimulated decays by combining linearly polarized creation laser pulses and circularly polarized inducing laser pulses. The quoted limit is at  $m_{A0} \simeq 0.178 \text{ eV}$ . See their Fig. 14 for mass-dependent limits.
- 41 LI 21B is analogous to AJELLO 16, and use the spectra of the blazar Mrk 421 measured by ARGO-YBJ and Fermi-LAT. They consider ALP-photon mixing in the magnetic fields of both the blazar jet and the Galaxy. The quoted limit applies to  $m_{A0} \simeq 1 \times 10^{-9} \text{ eV}$ . See their Fig. 5 for mass-dependent limits.
- 42 LLOYD 21 is analogous to FORTIN 18, and set limits on the product of the axion couplings to photons and nucleons as  $g_{ANN} G_{A\gamma\gamma} \lesssim 4.6 \times 10^{-19} \text{ GeV}^{-1}$  for  $m_{A0} \lesssim 10^{-5} \text{ eV}$  by using the quiescent soft gamma-ray flux upper limits in five magnetars. We use  $g_{ANN} = G_{AN} 2m_N$  to translate their limits. See their Table II and Fig. 3 for the limits.
- 43 REGIS 21 look for monochromatic photons from axion decay, using the MUSE spectroscopic data on the Leo T dwarf spheroidal galaxy. They assume that axions make up all of dark matter and use the integrated dark matter density along the line of sight determined by observations.
- 44 XIAO 21 use X-ray data from Betelgeuse to look for signals from axions produced in the stellar core that were converted to X-rays by the Galactic magnetic field. See their Fig. 1 for the mass-dependent limit.
- 45 ABUDINEN 20 look for the process  $e^+e^- \rightarrow \gamma A^0$  ( $A^0 \rightarrow \gamma\gamma$ ) and set upper limits of around  $10^{-3}$  over the mass range. The quoted limit is at  $m_{A0} = 0.3 \text{ GeV}$ . See their Fig. 5 for mass dependent limits.
- 46 BANERJEE 20A look for axions produced from high-energy bremsstrahlung photons through the Primakoff effect with the electric field of the target nuclei. They exclude  $G_{A\gamma\gamma} = 2 \times 10^{-4} - 5 \times 10^{-2} \text{ GeV}^{-1}$  for  $m_{A0} < 55 \text{ MeV}$ . See their Fig. 5 for mass-dependent limits.
- 47 BUEHLER 20 look for the  $\gamma$ -ray transparency due to axion-photon oscillations using high-energy photon events from 79 sources in the Second Fermi-LAT Catalog of High-Energy Sources. The quoted limit is for the intergalactic magnetic field strength and coherence length of  $B = 1 \text{ nG}$  and  $s = 1 \text{ Mpc}$ . See their Figs. 4 and 5 for mass-dependent limits and for different magnetic-field parameters.
- 48 CALORE 20 use the isotropic diffuse  $\gamma$ -ray background measured by the Fermi-LAT to constrain the  $\gamma$ -ray flux converted in the Galactic magnetic field from axions produced from past core-collapse supernovae. They also derive a limit on a heavier axion with  $m_{A0} \gtrsim \text{keV}$  decaying into two photons of  $G_{A\gamma\gamma} \lesssim 5 \times 10^{-11} \text{ GeV}^{-1}$  for  $m_{A0} = 5 \text{ keV}$ . See their Figs. 5 and 7 for the limits as well as limits in the presence of axion-nucleon couplings.
- 49 ARENZA 20 extend the globular cluster bound of AYALA 14 to heavier masses ( $m_{A0} \leq$  a few 100 keV) by taking account of the coalescence process  $\gamma + \gamma \rightarrow A^0$  as well as the decay of the ALP inside the stellar core. See their Fig. 4 for mass-dependent limits.
- 50 DENT 20A is analogous to GAO 20. The quoted limit is from their arXiv:2006.15118v3 (v2 is their published version), using the relativistic Hartree-Fock form factor. The limit is up to two times weaker than the published one. See Fig. 4 in their arXiv version 3 for the correlation between  $G_{A\gamma\gamma}$  and  $g_{Aee}$  corresponding to the excess reported in APRILE 20.
- 51 DEPTA 20 correct the underestimated D abundance in MILLEA 15, and derive robust cosmological bounds by allowing the reheating temperature,  $N_{\text{eff}}$ , and neutrino chemical potential to vary. See their Fig. 6 for mass-dependent limits.
- 52 DESSERT 20A use the NuSTAR data of the Quintuplet and Westerlund 1 super star clusters to look for X-rays converted in the Galactic magnetic field from the axions produced in stellar cores. See their Fig. 3 for the mass-dependent limits.
- 53 ESTEBAN 20 show that the two anomalous ANITA events can be explained by the reflected radio pulses that are resonantly produced in the ionosphere via axion-photon conversion for  $m_{A0} \lesssim 1 \times 10^{-7} \text{ eV}$ , if an axion clump passes the Earth about once a month. See their Fig. 5 for the region consistent with this interpretation for different values of the axion density inside the clumps.
- 54 GAO 20 correct the limit of APRILE 20 by including inverse Primakoff scattering in the XENONIT detector. The quoted limit is from their arXiv:2006.14598v4 (v3 is their published version), taking account of the atomic form factor of Xe as pointed out in ABE 201. The limit is weaker by a factor of 1.5-2 than the published one. See Fig. 3 in their arXiv version 4 for correlation between  $G_{A\gamma\gamma}$  and  $g_{Aee}$  corresponding to the excess reported in APRILE 20.
- 55 KOROCHKIN 20 assume the axion makes up all dark matter, and look for a dip in the observed gamma-ray spectrum of the blazar 1ES 1218+304 by Fermi/LAT and VERITAS due to the extragalactic background light produced by the axion decay. Their analysis favors nonzero axion-induced absorption with  $G_{A\gamma\gamma} = 3 \times 10^{-11} - 2 \times 10^{-10} \text{ GeV}^{-1}$  over a range of  $m_{A0} = 2-18 \text{ eV}$ . See their Fig. 1 for mass-dependent limits between  $0.25 < m_{A0} < 25 \text{ eV}$ .
- 56 LUCENTE 20A study the SN 1987A energy-loss argument on the axion-like particle production. In addition to the Primakoff process, they take account of photon coalescence as well as gravitational trapping that become relevant at  $m_{A0} > 100 \text{ MeV}$ . See their Fig. 12 for the mass-dependent limit.
- 57 MEYER 20 look for prompt  $\gamma$ -rays converted in the Galactic magnetic fields from axions produced via the Primakoff process in a sample of 20 extragalactic core-collapse supernovae. The limits assume a progenitor mass of 10 times the solar mass and certain models for the optical emission and the galactic magnetic field. See their Figs. 2 and 6 in the erratum for mass- and model-dependent limits.
- 58 YAMAMOTO 20 look for X-ray photons converted by the Earth's magnetic field from the axions produced by the two-body decay of dark matter, and set the limits by using the Suzaku data. The quoted limit is for the monochromatic X-ray line from the galactic dark matter with lifetime  $\tau = 4.32 \times 10^{17} \text{ sec}$ . They also derive limits on the continuum spectrum from the extragalactic component. See their Fig. 7 for the limits.
- 59 ALONI 19 used the data collected by the PRIMEX experiment to derive a limit based on a data-driven method. See their Fig. 2 for mass-dependent limits.
- 60 CAPUTO 19 look for an oscillating variation of the polarization angle of the pulsar J0437-4715, where they assume the local axion energy density  $\rho_A = 0.3 \text{ GeV}/\text{cm}^3$ . See their Fig. 2 for mass-dependent limits for  $5 \times 10^{-24} \text{ eV} \leq m_{A0} \leq 2 \times 10^{-19} \text{ eV}$ .
- 61 FEDDERKE 19 look for a uniform reduction of the CMB polarization at large scales, which is induced by the oscillating axion background during CMB decoupling. The quoted limit is based on the assumption that axions make up all of the dark matter. See their Fig. 3 for mass-dependent limits for  $m_{A0} = 10^{-22} - 10^{-19} \text{ eV}$ .
- 62 IVANOV 19 look for the axion-induced periodic changes in the polarization angle of parsec-scale jets in active galactic nuclei observed by the MOJAVE program, where they use the axion energy density  $\rho_A = 20 \text{ GeV}/\text{cm}^3$ . See their Fig. 6 for mass-dependent limits for  $5 \times 10^{-23} \text{ eV} \leq m_{A0} \leq 1.2 \times 10^{-21} \text{ eV}$ .
- 63 LIANG 19 look for spectral irregularities in the spectrum of 10 bright H.E.S.S. sources in the Galactic plane, assuming photon-ALP mixing in the Galactic magnetic fields. See their Fig. 2 for mass-dependent limits with different Galactic magnetic field models.

See key on page 1171

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>64</sup>FORTIN 18 studied the conversion of axion-like particles produced in the core of a magnetar to hard X-rays in the magnetosphere. See their Fig. 5 for mass-dependent limits with different values of the magnetar core temperature.
- <sup>65</sup>JAECKEL 18 study axions produced through the Primakoff process from SN 1987A, which subsequently decay into photon pairs. See their Fig. 1 for the mass-dependent limits in the range of  $m_{A^0} = 0.01\text{--}100$  MeV.
- <sup>66</sup>YAMAJI 18 search for axions with an x-ray LSW at Spring-8, using the Laue-case conversion in a silicon crystal. They also obtain  $G_{A\gamma\gamma} < 4.2 \times 10^{-3} \text{ GeV}^{-1}$  for  $m_{A^0} < 10$  eV. See their Fig. 5 for mass-dependent limits.
- <sup>67</sup>ZHANG 18 look for spectral irregularities in the spectrum of PKS 2155-304 measured by Fermi LAT, assuming photon-ALP mixing in the intercluster and Galactic magnetic fields. See their Figs. 2 and 3 for mass-dependent limits with different values of the intercluster magnetic field parameters.
- <sup>68</sup>ADE 17 look for cosmic birefringence from axion-like particles using CMB polarization data taken by the BICEP2 and Keck Array experiments. They set a limit  $G_{A\gamma\gamma} H_I < 7.2 \times 10^{-2}$  at 95%CL for  $m_{A^0} < 10^{-28}$  eV, where  $H_I$  is the Hubble parameter during inflation.
- <sup>69</sup>ANASTASSOPOULOS 17 looked for solar axions by the CAST axion helioscope in the vacuum phase, and supersedes ANDRIAMONJE 07.
- <sup>70</sup>DOLAN 17 update existing limits on  $G_{A\gamma\gamma}$  for axion-like particles. The limits from the proton beam dump experiments in their Fig. 2 contained an error, and the corrected version is shown in Fig. 1 of DOLAN 21.
- <sup>71</sup>INADA 17 search for axions with an x-ray LSW at Spring-8. See their Fig. 4 for mass-dependent limits.
- <sup>72</sup>KOHR1 17 attributed to axion-photon oscillations the excess of cosmic infrared background observed by the CIBER experiment. See their Fig. 5 for the region preferred by their scenario.
- <sup>73</sup>MARSH 17 is similar to WOUTERS 13, using Chandra observations of M87. See their Fig. 6 for mass-dependent limits.
- <sup>74</sup>TIWARI 17 use observed limits of the cosmic distance-duality relation to constrain the photon-ALP mixing based on 3D simulations of the magnetic field configuration. The quoted value is for the averaged magnetic field of 1nG with a coherent length of 1 Mpc. See their Fig. 5 for mass-dependent limits.
- <sup>75</sup>AJELLO 16 look for irregularities in the energy spectrum of the NGC1275 measured by Fermi LAT, assuming photon-ALP mixing in the intra-cluster and Galactic magnetic fields. See their Fig. 2 for mass-dependent limits.
- <sup>76</sup>DELLA-VALLE 16 look for the birefringence induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
- <sup>77</sup>DELLA-VALLE 16 look for the dichroism induced by axion-like particles. See their Fig. 14 for mass-dependent limits.
- <sup>78</sup>JAECKEL 16 use the LEP data of  $Z \rightarrow 2\gamma$  and  $Z \rightarrow 3\gamma$  to constrain the ALP production via  $e^+e^- \rightarrow Z \rightarrow A^0\gamma (A^0 \rightarrow \gamma\gamma)$ , assuming the ALP coupling with two hypercharge bosons. See their Fig. 4 for mass-dependent limits.
- <sup>79</sup>LEEFER 16 derived limits by using radio-frequency spectroscopy of dysprosium and atomic clock measurements. See their Fig. 1 for mass-dependent limits as well as limits on Yukawa-type couplings of the scalar to the electron and nucleons.
- <sup>80</sup>ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.
- <sup>81</sup>ARIK 15 is analogous to ARIK 09, and search for solar axions for  $m_{A^0}$  around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.
- <sup>82</sup>Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>83</sup>BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.
- <sup>84</sup>HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons  $G_{S\gamma\gamma} < 2.62 \times 10^{-4} \text{ GeV}^{-1}$  at  $m_{S^0} = 0.15$  eV. See their Figs. 11 and 12 for mass-dependent limits.
- <sup>85</sup>MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.
- <sup>86</sup>VANTILBURG 15 look for harmonic variations in the dysprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits,  $G_{S\gamma\gamma} < 6 \times 10^{-27} \text{ GeV}^{-1}$  at  $m_{S^0} = 6 \times 10^{-23}$  eV. See their Fig. 4 for mass-dependent limits between  $1 \times 10^{-24} < m_{S^0} < 1 \times 10^{-15}$  eV.
- <sup>87</sup>VINOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.
- <sup>88</sup>ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.
- <sup>89</sup>AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.
- <sup>90</sup>DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.
- <sup>91</sup>EJLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.
- <sup>92</sup>PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>93</sup>REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.
- <sup>94</sup>ABRAMOWSKI 13a look for irregularities in the energy spectrum of the BL Lac object PKS 2155-304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.
- <sup>95</sup>ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.
- <sup>96</sup>BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.
- <sup>97</sup>FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7-12 solar masses.
- <sup>98</sup>MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy  $\gamma$ -rays with respect to predictions based on extragalactic background light models. See their Fig.4 for mass-dependent lower limits for various magnetic field configurations.
- <sup>99</sup>WOUTERS 13 look for irregularities in the X-ray spectrum of the Hydra cluster observed by Chandra. See their Fig. 4 for mass-dependent limits.
- <sup>100</sup>CADAMURO 12 derived cosmological limits on  $G_{A\gamma\gamma}$  for axion-like particles. See their Fig. 1 for mass-dependent limits.
- <sup>101</sup>PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.
- <sup>102</sup>ARIK 11 search for solar axions using  $^3\text{He}$  buffer gas in CAST, continuing from the  $^4\text{He}$  version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.
- <sup>103</sup>ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.
- <sup>104</sup>AHMED 09a is analogous to AVIGNONE 98.
- <sup>105</sup>ARIK 09 is the  $^4\text{He}$  filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.
- <sup>106</sup>CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at 3 $\sigma$  the range  $2.6 \times 10^{-7} \text{ GeV}^{-1} < G_{A\gamma\gamma} < 4.2 \times 10^{-6} \text{ GeV}^{-1}$  for vacuum  $m_{A^0}$  roughly below 6 meV for density scaling index exceeding 0.8.
- <sup>107</sup>GONDOL0 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.
- <sup>108</sup>LIPSS photon regeneration experiment, assuming scalar particle  $S^0$ . See Fig. 4 for mass-dependent limits.
- <sup>109</sup>CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
- <sup>110</sup>FOUCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
- <sup>111</sup>INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
- <sup>112</sup>ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
- <sup>113</sup>ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
- <sup>114</sup>ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
- <sup>115</sup>ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
- <sup>116</sup>INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X ray.
- <sup>117</sup>MORALES 02b looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
- <sup>118</sup>BERNABE 01b looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
- <sup>119</sup>ASTIER 00b looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
- <sup>120</sup>MASSO 00 studied limits on axion-photon coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound  $g_{p\bar{p}\gamma}^2/4\pi < 1.7 \times 10^{-9}$  for the coupling  $g_{p\bar{p}\gamma}^2 \rho \phi_A$ .
- <sup>121</sup>AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
- <sup>122</sup>Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
- <sup>123</sup>Experiment based on proposal by MAIANI 86.
- <sup>124</sup>Experiment based on proposal by VANBIBBER 87.
- <sup>125</sup>LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
- <sup>126</sup>RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
- <sup>127</sup>SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to  $m_{A^0} = 4 \times 10^{-3}$  where  $G_{A\gamma\gamma} < 1 \times 10^{-4} \text{ GeV}^{-1}$ .

### Limit on Invisible $A^0$ (Axion) Electron Coupling

The limit is for  $g_{Aee} \phi_A \bar{e}(i\gamma_5)e$ , or equivalently, the dipole-dipole potential

$$-\frac{g_{Aee}^2}{16\pi m_{A^0}^2} ((\sigma_1 \cdot \sigma_2) - 3(\sigma_1 \cdot \mathbf{n})(\sigma_2 \cdot \mathbf{n}))/r^3 \text{ where } \mathbf{n} = \mathbf{r}/r \text{ and the sign of the potential was corrected based on DAIDO 17.}$$

<sup>1</sup> AALBERS 23A look for solar axions from the ABC processes. See their Fig. 6 for the limits.

<sup>2</sup> AALBERS 23A look for absorption of axion dark matter. The quoted limit is for  $m_{A^0} \simeq 1.4$  keV. The local density  $\rho_A = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 7 for mass-dependent limits.

<sup>3</sup> ADHIKARI 23 is an update of ADHIKARI 19B.

<sup>4</sup> ADHIKARI 23A look for absorption and Compton-like processes of axion dark matter. The quoted limit is for  $m_{A^0} \simeq 37$  keV. See their Fig. 4 for mass-dependent limits.

<sup>5</sup> AGNES 23A look for absorption of axion dark matter. The quoted limit is for  $m_{A^0} \simeq 0.25$  keV. The local density  $\rho_A = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 2 for mass-dependent limits.

<sup>6</sup> APRILE 23B look for an absorption signal of axions within  $\pm 500$  seconds of the GW signals, including the neutron star merger GW170817. They set a 90% CL upper limit on the product of coincident fluence and cross section of axions to be less than  $10^{-29}$  cm<sup>2</sup>/cm<sup>2</sup> in the recoil energy range of 5.5–210 keV<sub>ee</sub>.

<sup>7</sup> CAPOZZI 23A search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 1 MeV. See Fig. 8 for mass-dependent limits.

<sup>8</sup> WADEKAR 23 use the Leo T dwarf galaxy's interstellar medium to derive limits, requiring the heating rate from axion dark matter absorption into hydrogen atoms and two-photon decay to be less than the astrophysical cooling rate. See Fig. 2 for limits over  $m_{A^0} = 1\text{--}100$  keV, which loosen for lighter masses.

<sup>9</sup> APRILE 22 extend APRILE 19D to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to  $m_{A^0} = 0.1$  keV. See their Fig. 15 for mass-dependent limits.

<sup>10</sup> APRILE 22B is an update of APRILE 20, and set the limit,  $g_{Aee} \lesssim 9 \times 10^{-15}\text{--}3 \times 10^{-13}$ . The quoted limit applies to  $m_{A^0} = 2$  keV. They exclude the XENON1T excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.

<sup>11</sup> APRILE 22B is an update of APRILE 20. They exclude the XENON1T excess found in APRILE 20. The quoted limit holds for small  $G_{A\gamma\gamma}$ . See their Fig. 6 for correlation between  $g_{Aee}$  and  $G_{A\gamma\gamma}$ .

<sup>12</sup> DESSERT 22 is an update of DESSERT 19. They used the Chandra observation of the magnetic white dwarf RE J0317-853 to look for converted X-rays in the magnetosphere from axions produced in the core through electron bremsstrahlung. They obtained the limit,  $g_{Aee} \cdot G_{A\gamma\gamma} < 1.3 \times 10^{-25}$  GeV<sup>-1</sup> at 95% CL for  $m_{A^0} \lesssim 10^{-5}$  eV. See their Fig. 1 for mass-dependent limits.

<sup>13</sup> IKEDA 22 look for magnons excited by dark matter axions, using data taken with a hybrid quantum system consisting of a superconducting qubit and a spherical ferromagnetic crystal. The quoted limit assumes the local dark matter density  $\rho_A = 0.45$  GeV/cm<sup>3</sup> and the velocity  $v = 220$  km/sec. See their Fig. 4 for the limits.

<sup>14</sup> LANGHOFF 22 set limits by considering the freeze-in production of axions coupled to electrons without anomalous coupling to photons. The quoted limit applies to  $m_{A^0} = 15$  MeV for the reheating temperature equal to 5 MeV. See their Fig. 2 for mass-dependent limits.

<sup>15</sup> WANG 22c use the spin-amplifier based on hyperpolarized <sup>129</sup>Xe to set limits on the product of the axion couplings to electrons and nucleons as  $g_{Aee} g_{ANN} < 4 \times 10^2$  (95 % CL) at  $m_{A^0} = 0.1$  meV. Here  $g_{ANN}$  is the dimensionless axion-neutron coupling. See their Fig. 4 for the mass-dependent limits.

<sup>16</sup> XIAO 22 extend XIAO 21 in the list of photon coupling limits by including the production of axions from Compton and bremsstrahlung processes, and set limits on the product of the axion couplings to electrons and photons as  $G_{A\gamma\gamma} g_{Aee} < 0.4\text{--}2.8 \times 10^{-24}$  GeV<sup>-1</sup> (95 % CL) for  $m_{A^0} < 3.5 \times 10^{-11}$  eV. See their Fig. 5 for the limits. They are comparable to those of DESSERT 19 and more restrictive than the CAST bounds of BARTH 13.

<sup>17</sup> CALORE 21 consider the production of axions from Galactic and extragalactic SNe via nucleon-nucleon bremsstrahlung and their subsequent decay into electron-positron pairs, and exclude the range of  $g_{Aee} \simeq 10^{-19}\text{--}10^{-11}$  at  $g_{APP} = 10^{-9}$  for  $m_{A^0} = 3\text{--}30$  MeV. See their Fig. 7 for the limits.

<sup>18</sup> LUCENTE 21 study the axion production in a supernova via electron-proton bremsstrahlung and electron-positron fusion, and exclude the range of  $g_{Aee} \simeq 10^{-10}\text{--}10^{-8}$  for  $m_{A^0} = 1\text{--}160$  MeV. The quoted limit is at  $m_{A^0} = 120$  MeV. See their Fig. 12 for the mass-dependent limits.

<sup>19</sup> AGOSTINI 20 is analogous to AHMED 09A. The quoted limit applies to  $m_{A^0} = 150$  keV. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.

<sup>20</sup> AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter axion absorption. The quoted limit is for  $m_{A^0} \simeq 17$  eV. The local density  $\rho_A = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 3 for mass-dependent limits.

<sup>21</sup> APRILE 20 is an update of APRILE 17B where they look for an absorption signal of axion dark matter. They obtained the limit,  $g_{Aee} \lesssim 2 \times 10^{-14}\text{--}1 \times 10^{-12}$  at 90% CL for  $m_{A^0} = 1\text{--}200$  keV. They also found an excess over known backgrounds, which favors the mass  $m_{A^0} = 2.3 \pm 0.2$  keV with a 3  $\sigma$  significance. See their Fig. 10 for mass-dependent limits.

<sup>22</sup> APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of <sup>57</sup>Fe, and set limits on  $g_{Aee}$ ,  $G_{A\gamma\gamma}$ ,  $g_{ANN}$ , and their products. An excess is observed at low energies between 2 and 3 keV. See their Fig. 8 for correlation between the couplings. The quoted limit applies to the case of vanishing  $G_{A\gamma\gamma}$  and  $g_{ANN}$ .

<sup>23</sup> ARALIS 20 is analogous to AHMED 09A. The quoted limit applies to  $m_{A^0} = 0.3$  keV. The limits at masses above 3 keV in their Fig. 9 was later found to be incorrect due to an error in their analysis. See Fig. 2 in ARALIS 21 for the corrected limits.

<sup>24</sup> CAPOZZI 20 obtains a limit on the axion-electron coupling from the brightness of the tip of the red-giant branch in  $\omega$  Centauri. A similar limit of  $< 1.6 \times 10^{-13}$  is obtained in NGC 4258.

<sup>25</sup> CRESCINI 20 is an update of CRESCINI 18. They assume a local axion dark matter density,  $\rho_A = 0.3$  GeV/cm<sup>3</sup>. See their Fig. 4 for the limits.

<sup>26</sup> GHOSH 20A study thermal production of axion via coupling to leptons in the early universe and estimate its contribution to  $\Delta N_{\text{eff}}$ . The quoted limit is for  $\Delta N_{\text{eff}} < 0.5$ . See their Fig. 7 for their mass-dependent limits.

<sup>27</sup> STRANIERO 20 is analogous to CAPOZZI 20, with 22 galactic globular clusters used to derive the limit.

<sup>28</sup> WANG 20A is an update of LIU 17A. See their Fig. 9.

<sup>29</sup> WANG 20A is an update of LIU 17A. They assume a local axion dark matter density,  $\rho_A = 0.3$  GeV/cm<sup>3</sup>. See their Fig. 10 for limits between  $0.185 < m_{A^0} < 10$  keV.

<sup>30</sup> ADHIKARI 19B is analogous to LIU 17A.

<sup>31</sup> APRILE 19D is analogous to APRILE 17B, but they use only ionization signals. The quoted limit applies to  $m_{A^0} = 0.7$  keV. See their Fig. 5(e) for mass-dependent limits.

<sup>32</sup> DESSERT 19 used the Suzaku observations of a magnetic white dwarf (RE J0317-853) to look for X-ray signatures converted from axions in the surrounding magnetic fields. They obtained the limit,  $g_{Aee} \cdot G_{A\gamma\gamma} < 1.6 \times 10^{-24}$  GeV<sup>-1</sup> at 95% CL for  $m_{A^0} \lesssim 10^{-5}$  eV. See their Fig. 2 for mass-dependent limits.

<sup>33</sup> TERRANO 19 look for the axion-induced oscillating magnetic field acting on the electron spin, using data taken with a rotating torsion pendulum containing polarized electrons.

See key on page 1171

Gauge & Higgs Boson Particle Listings  
Axions ( $A^0$ ) and Other Very Light Bosons

Reference	Technique	Limit	Particle	Comment
The quoted limit applies to $m_{A^0} = 10^{-23}$ – $10^{-18}$ eV and assumes a local axion dark matter density, $\rho_A = 0.45$ GeV/cm <sup>3</sup> . See their Fig. 5 for mass-dependent limits.		$< 0.016$	95	4 BUSCHMANN 22 ASTR Neutron star cooling
34 ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{A^0} = 60$ keV. See their Fig. 5 for mass-dependent limits.		$< 320$	90	5 GAVRILYUK 22 CNTR Solar axion
35 ARMENGAUD 18 is analogous to LIU 17A.				6 SCHULTHESS 22 Neutron EDM
36 ARMENGAUD 18 is analogous to AHMED 09A. See the left panel of Fig. 5 for mass-dependent limits.				7 AYBAS 21 CASP Nucleon EDM
37 CRESCINI 18 look for collective excitations of the electron spins caused by dark matter axions. The quoted limit assumes the local dark matter density, $\rho_A = 0.45$ GeV/cm <sup>3</sup> .				8 BHUSAL 21 Solar axion
38 FICEK 18 use the measurements of the hyperfine structure of antiprotonic helium to constrain a dipole-dipole potential between electron and antiproton. See their Fig. 3 for limits on various spin- and velocity-dependent potentials.		$< 24$	90	9 JIANG 21 NMR Axion dark matter
39 ABGRALL 17 is analogous to AHMED 09A using the MAJORANA DEMONSTRATOR. See their Fig. 2 for limits between 6 keV $< m_{A^0} < 97$ keV.		$< 7.3$	90	10 ROUSSY 21 Molecular EDM
40 AKERIB 17B is analogous to LIU 17A.		$< 0.03$		11 ZHANG 21B ASTR Neutron star inspiral
41 AKERIB 17B is analogous to AHMED 09A. See their Fig. 7 for mass-dependent limits.		$< 9.6 \times 10^{-3}$	95	12 ABDELHAME...20 CNTR Solar axion
42 APRILE 17B is analogous to AHMED 09A. They found a bug in their code and needed to correct the limits in Fig. 7 of APRILE 14B. See their Fig. 1 for the corrected limits between 1 keV $< m_{A^0} < 40$ keV.		$< 65$	95	13 ABDELHAME...20 CNTR Solar axion
43 FICEK 17 look for spin-dependent interactions between electrons by comparing precision spectroscopic measurements in <sup>4</sup> He with theoretical calculations. See their Fig. 1 for limits up to $m_{A^0} = 10$ keV.		$< 6.6$	90	14 APRILE 20 XE1T Solar axion
44 FU 17A is analogous to LIU 17A. See their Fig. 3 for mass-dependent limits.		$< 0.085$	90	15 KLIMCHITSK...20 Casimir effect
45 FU 17A is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.		$< 12.7$	95	16 WANG 20A CDEX Solar axion
46 LIU 17A is analogous to AHMED 09A. See their Fig. 9 for limits between 0.25 keV $< m_{A^0} < 20$ keV.		$< 0.01$		17 LEINSON 19 ASTR Neutron star cooling
47 LIU 17A look for solar axions produced from Compton, bremsstrahlung, atomic-recombination and deexcitation channels, and set a limit for $m_{A^0} < 1$ keV.		$< 93$	90	18 LLOYD 19 ASTR $\gamma$ -rays from NS
48 LUO 17 use a recent measurement of the dipole-dipole interaction between two iron atoms at the nanometer scale and set a limit for $m_{A^0} < 1$ keV. See their Fig. 3 for mass-dependent limits.		$< 4$	90	19 SMORRA 19 $\bar{p}$ g-factor
49 BATTICH 16 is analogous to CORSICO 16 and used the pulsating DB white dwarf PG 1351+489.		$< 177$	90	20 WU 19 NMR Axion dark matter
50 CORSICO 16 studied the cooling rate of the pulsating DA white dwarf L19-2 based on an asteroseismic model.		$< 0.079$	95	21 AKHMATOV 18 CNTR Solar axion
51 YOON 16 look for solar axions with the axio-electric effect in Cs(Tl) crystals and set a limit for $m_{A^0} < 1$ keV.		$< 100$	95	22 ARMENGAUD 18 EDE3 Solar axion
52 TERRANO 15 used a torsion pendulum and rotating attractor with 20-pole electron-spin distributions. See their Fig. 4 for a mass-dependent limit up to $m_{A^0} = 500$ $\mu$ eV.		$< 8.6 \times 10^3$	90	23 BEZNOGOV 18 ASTR Neutron star cooling
53 ABE 14F set limits on the axioelectric effect in the XMASS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between $m_{A^0} = 40$ – $120$ keV.		$< 1.4 \times 10^4$	90	24 GAVRILYUK 18 CNTR Solar axion
54 APRILE 14B look for solar axions using the XENON100 detector.		$< 145$	95	25 HAMAGUCHI 18 ASTR Neutron star cooling
55 APRILE 14B is analogous to AHMED 09A. Their Fig. 7 was later found to be incorrect due to a bug in their code. See Fig. 1 in APRILE 17B for the corrected limits.				26 ABEL 17 Neutron EDM
56 DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.				27 ABGRALL 17 HPGE Solar axion
57 MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.				28 FU 17A PNDX Solar axion
58 ABE 13D is analogous to DERBIN 12, using the XMASS detector.				29 KLIMCHITSK...17A Casimir effect
59 ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between 3 keV $< m_{A^0} < 100$ keV.				30 LIU 17A CDEX Solar axion
60 ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.				31 BERENJI 16 ASTR $\gamma$ -rays from NS
61 BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 8.1 \times 10^{-23}$ GeV <sup>-1</sup> at 95% CL.				32 GAVRILYUK 15 CNTR Solar axion
62 DERBIN 13 looked for 5.5 MeV solar axions produced in $pd \rightarrow {}^3\text{He } A^0$ in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.				33 KLIMCHITSK...15 Casimir-less
63 HECKEL 13 studied the influence of 2 or 4 stationary sources each containing $6.0 \times 10^{24}$ polarized electrons, on a rotating torsion pendulum containing $9.8 \times 10^{24}$ polarized electrons. See their Fig. 4 for mass-dependent limits.				34 BEZERRA 14 Casimir effect
64 VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.				35 BEZERRA 14A Casimir effect
65 CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with $g_{Aee} \simeq 4.8 \times 10^{-13}$ .				36 BEZERRA 14B Casimir effect
66 DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.				37 BEZERRA 14C Casimir effect
67 AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.				38 BLUM 14 COSM <sup>4</sup> He abundance
68 AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.				39 LEINSON 14 ASTR Neutron star cooling
69 DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.				40 ALESSANDRIA 13 CNTR Solar axion
70 These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor. The sign of the limit set by CHUI 93 is opposite to that of the axion-mediated dipole-dipole potential.				41 ARMENGAUD 13 EDEL Solar axion
71 These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them. The limits reflect the corrected sign of the dipole-dipole potential.				42 BELLI 12 CNTR Solar axion
72 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.				43 BELLINI 12B BORX Solar axion
				44 DERBIN 11 CNTR Solar axion
				45 BELLINI 08 CNTR Solar axion
				46 ADELBERGER 07 Test of Newton's law
1 LELLA 24 update constraints on the axion-proton coupling from supernova 1987A based on the SN cooling argument (including a treatment of the trapping regime) as well as the non-observation of any coincident axion-induced events in the Kamiokande II neutrino detector. They exclude QCD axion models above 0.01 eV, and axion-like particles in a window that extends up to 300 MeV. See their Fig. 3 for mass-dependent limits.				
2 KARANATH 23 utilized an in-plane polarized deuteron beam in a storage ring to constrain the axion-induced oscillating EDM of the deuteron for $m_{A^0} = 0.496$ – $0.502$ neV. Assuming axions account for all dark matter with $\rho_A \simeq 0.55$ GeV/cm <sup>3</sup> , they derived constraints on axion couplings to the deuteron EDM operator, gluons, and the deuteron spin. For detailed limits, see their Figs. 19–21.				
3 LEE 23 analyzed data from a K– <sup>3</sup> He comagnetometer, accounting for stochastic effects, to limit the axion-neutron coupling $g_{Ann} < 2.4 \times 10^{-10}$ GeV <sup>-1</sup> at 95% CL for $m_{A^0} = 0.4$ – $4$ feV. They assumed axions form all dark matter with a density of 0.3 GeV/cm <sup>3</sup> . See their Fig. 5 for the limits.				
4 BUSCHMANN 22 studied the axion emission from five neutron stars with ages $\sim 10^5$ – $10^6$ years, comparing the simulation with axions to age and luminosity measurements. The mass bound assumes the KSVZ axion model with $C_p = -0.47$ and $C_n = -0.02$ . See their Fig. 3 for the limits on the DFSZ axion model.				
5 GAVRILYUK 22 look for solar axions from the ABC interactions with the experimental setup similar to GAVRILYUK 15. The mass bound assumes the KSVZ axion model, $S = 0.5$ , and $m_H/m_d = 0.56$ .				
6 SCHULTHESS 22 look for a time-oscillating neutron EDM caused by the coupling between axion dark matter and gluons, using a Ramsey-type apparatus for a cold neutron beam. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-19}$ – $4 \times 10^{-12}$ eV.				
7 AYBAS 21 limits the axion couplings to the nucleon EDM and the nucleons as $g_{AN\gamma} < 9.5 \times 10^{-4}$ GeV <sup>-2</sup> and $g_{ANN}/2m_N < 0.28$ GeV <sup>-1</sup> (95% CL) for $m_{A^0} = 162$ – $166$ neV, based on a measurement of <sup>207</sup> Pb solid-state NMR in a polarized ferroelectric crystal. Here $m_N$ is the nucleon mass and $g_{ANN}$ is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.46$ GeV/cm <sup>3</sup> . See their Fig. 3 for the limits.				
8 BHUSAL 21 looked for 5.5 MeV solar axions produced by $pd \rightarrow {}^3\text{He } A^0$ through the axion-induced dissociation of deuterons by using SNO data, and set a limit on the isovector axion-nucleon coupling, $ g_{a,N}^3  < 2 \times 10^{-5}$ GeV <sup>-1</sup> , which is equivalent to $ g_{Ann} - g_{App}  < 4 \times 10^{-5}$ in terms of the dimensionless axion-nucleon couplings.				
9 JIANG 21 use the spin-amplifier based on hyperpolarized <sup>129</sup> Xe gas to set limits on the axion couplings to nucleons as $g_{ANN}/2m_N < 3.2 \times 10^{-9}$ GeV <sup>-1</sup> (95% CL) at $m_{A^0} = 52.94$ feV, and comparable limits in the mass range of 8.3–744 feV. Here $m_N$ is the nucleon mass and $g_{ANN}$ is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.4$ GeV/cm <sup>3</sup> . See their Fig. 4b for the limits.				
10 ROUSSY 21 look for a time-oscillating EDM of molecular ions HFF <sup>+</sup> induced by axion dark matter couplings to gluons. See their Fig. 3 for limits in the range of $m_{A^0} = 10^{-22}$ – $10^{-15}$ eV.				

Invisible  $A^0$  (Axion) Limits from Nucleon Coupling

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- 11** ZHANG 21B use the gravitational waves from the binary neutron star inspiral GW170817 to look for a type of axion whose mass is suppressed due to cancellation with additional contributions. They exclude  $1.6 \times 10^{16} < f_A < 10^{18}$  GeV at  $3\sigma$  for  $m_{A^0} \lesssim 10^{-13}$  eV. See their Fig. 1 for mass-dependent limits.
- 12** ABDELHAMEED 20 look for the resonant excitation of  $^{169}\text{Tm}$  (8.41 keV) by solar axions produced via the Primakoff effect. The mass bound assumes the KSVZ axion model,  $S = 0.5$ , and  $m_U/m_d = 0.56$ . They set a limit on the product of axion couplings to photons and nucleons as  $G_{A\gamma\gamma} \cdot g_{A\text{pp}} < 1.44 \times 10^{-14}$  GeV $^{-1}$  (90% CL).
- 13** ABDELHAMEED 20 look for the resonant excitation of  $^{169}\text{Tm}$  (8.41 keV) by solar axions produced via the axion-electron coupling. They set a limit on the product of axion couplings to electrons and nucleons as  $g_{Aee} \cdot g_{A\text{pp}} < 2.81 \times 10^{-16}$  (90% CL).
- 14** APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of  $^{57}\text{Fe}$ . An excess is observed at low energies between 2 and 3 keV. See their Fig. 8 for correlation between the couplings.
- 15** KLIMCHITSKAYA 20 use the measurement of the Casimir force between a Au-coated microsphere and a SiC plate to constrain the force due to two-axion exchange for  $17.8 < m_{A^0} < 100$  eV. See their Fig. 2 for mass-dependent limits.
- 16** WANG 20A is an update of LIU 17A. The limit assumes the DFSZ axion. See their Fig. 7 for the limit on product of axion couplings to electrons and nucleons.
- 17** LEINSON 19 is analogous to BEZNOGOV 18, but estimating the axion luminosity based on the Tolman's analytic solution to the Einstein equations of spherical fluids in hydrostatic equilibrium. The dimensionless axion-neutron coupling is constrained as  $g_{Ann} < 1.0 \times 10^{-10}$ .
- 18** LLOYD 19 is analogous to BERENJI 16. They highlight that the limit obtained with this technique strongly depends on the assumed NS core temperature.
- 19** SMORRA 19 look for spin-precession effects from ultra-light axion dark matter in the  $\bar{p}$  spin-flip resonance data. Assuming  $\rho_A = 0.4$  GeV/cm $^3$ , they constrain the dimensionless axion-antiproton coupling as  $g_{A\bar{p}p} < 2-9$  at 95% CL for  $m_{A^0} = 2 \times 10^{-23}-4 \times 10^{-17}$  eV. See the right panel of their Fig. 3.
- 20** WU 19 look for axion-induced time-oscillating features of the NMR spectrum of acetonitrile- $2,13\text{C}$ . Assuming  $C_p = C_n$  and  $\rho_A = 0.4$  GeV/cm $^3$ , they constrain the dimensionless axion-nucleon coupling as  $g_{ANN} < 6 \times 10^{-5}$  for  $m_{A^0} = 10^{-21}-1.3 \times 10^{-17}$  eV. Note that the limits for  $m_{A^0} < 10^{-21}$  eV in their Fig. 3(a) should be weaker than those for heavier masses. See ADELBERGER 19 and WU 19c on this issue.
- 21** AKHMATOV 18 is an update of GAVRILYUK 15.
- 22** ARMENGAUD 18 is analogous to ALESSANDRIA 13. The quoted limit assumes the DFSZ axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
- 23** BEZNOGOV 18 constrain the axion-neutron coupling by assuming that thermal evolution of the hot neutron star HESS J1731-347 is dominated by the lowest possible neutrino emission. The quoted limit assumes the KSVZ axion with the effective Peccei-Quinn charge of the neutron  $C_n = -0.02$ . The dimensionless axion-neutron coupling is constrained as  $g_{Ann} < 2.8 \times 10^{-10}$ .
- 24** GAVRILYUK 18 look for the resonant excitation of  $^{83}\text{Kr}$  (9.4 keV) by solar axions produced via the Primakoff effect. The mass bound assumes  $m_U/m_d = 0.56$  and  $S = 0.5$ .
- 25** HAMAGUCHI 18 studied the axion emission from the neutron star in Cassiopeia A based on the minimal cooling scenario which explains the observed rapid cooling rate. The quoted limit corresponds to  $f_A > 5 \times 10^8$  GeV obtained for the KSVZ axion with  $C_p = -0.47$  and  $C_n = -0.02$ .
- 26** ABEL 17 look for a time-oscillating neutron EDM and an axion-wind spin-precession effect respectively induced by axion dark matter couplings to gluons and nucleons. See their Fig. 4 for limits in the range of  $m_{A^0} = 10^{-24}-10^{-17}$  eV.
- 27** ABGRALL 17 limit assumes the hadronic axion model used in ALESSANDRIA 13. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
- 28** FU 17A look for the 14.4 keV  $^{57}\text{Fe}$  solar axions. The limit assumes the DFSZ axion model. See their Fig. 3 for mass-dependent limits on the axion-electron coupling. Notice that in this figure the DFSZ and KSVZ lines should be interchanged.
- 29** KLIMCHITSKAYA 17A use the differential measurement of the Casimir force between a Ni-coated sphere and Au and Ni sectors of the structured disc to constrain the axion coupling to nucleons for  $2.61 \text{ meV} < m_{A^0} < 0.9$  eV. See their Figs. 1 and 2 for mass dependent limits.
- 30** LIU 17 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 6(b) for the limit on product of axion couplings to electrons and nucleons.
- 31** BERENJI 16 used the Fermi LAT observations of neutron stars to look for photons from axion decay. They assume the effective Peccei-Quinn charge of the neutron  $C_n = 0.1$  and a neutron-star core temperature of 20 MeV.
- 32** GAVRILYUK 15 look for solar axions emitted by the M1 transition of  $^{83}\text{Kr}$  (9.4 keV). The mass bound assumes  $m_U/m_d = 0.56$  and  $S = 0.5$ .
- 33** KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for  $1.7 \times 10^{-3} < m_{A^0} < 0.9$  eV. See their Figs. 1 and 2 for mass dependent limits.
- 34** BEZERRA 14 use the measurement of the thermal Casimir-Polder force between a Bose-Einstein condensate of  $^{87}\text{Rb}$  atoms and a  $\text{SiO}_2$  plate to constrain the force mediated by exchange of two pseudoscalars for  $0.1 \text{ meV} < m_{A^0} < 0.3$  eV. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.
- 35** BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for  $1 \times 10^{-3} \text{ eV} < m_{A^0} < 15$  eV. See their Figs. 1 and 2 for the mass-dependent limit.
- 36** BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for  $1 \text{ eV} < m_{A^0} < 20$  eV. See their Figs. 1-3 for mass-dependent limits.
- 37** BEZERRA 14c is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for  $3 \times 10^{-5} \text{ eV} < m_{A^0} < 1$  eV. See their Figs. 1, 3, and 4 for the mass-dependent limits.

- 38** BLUM 14 studied effects of an oscillating strong CP phase induced by axion dark matter on the primordial  $^4\text{He}$  abundance. See their Fig. 1 for mass-dependent limits.
- 39** LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found  $C_n^2 m_{A^0}^2 \simeq 5.7 \times 10^{-6} \text{ eV}^2$ , where  $C_n$  is the effective Peccei-Quinn charge of the neutron.
- 40** ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited  $^{57}\text{Fe}$  nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
- 41** ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.
- 42** BELLINI 12 looked for solar axions emitted by the M1 transition of  $^7\text{Li}^*$  (478 keV) after the electron capture of  $^7\text{Be}$ , using the resonant excitation  $^7\text{Li}$  in the LiF crystal. The mass bound assumes  $m_U/m_d = 0.55$ ,  $m_U/m_S = 0.029$ , and the flavor-singlet axial vector matrix element  $S = 0.4$ .
- 43** BELLINI 12b looked for 5.5 MeV solar axions produced in the  $p\bar{d} \rightarrow ^3\text{He} A^0$ . The limit assumes the hadronic axion model. See their Figs. 6 and 7 for mass-dependent limits on product of axion couplings to photons, electrons, and nucleons.
- 44** DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited  $^{57}\text{Fe}$  nuclei in the Sun, using their possible resonant capture on  $^{57}\text{Fe}$  in the laboratory. The mass bound assumes  $m_U/m_d = 0.56$  and the flavor-singlet axial vector matrix element  $S = 3F - D \simeq 0.5$ .
- 45** BELLINI 08 consider solar axions emitted in the M1 transition of  $^7\text{Li}^*$  (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For  $m_{A^0} < 450$  keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- 46** ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for  $m_{A^0}$  below about 1 meV.

### Axion Limits from $T$ -violating Medium-Range Forces

The limit is for the coupling  $g = g_p g_s$  in a  $T$ -violating potential between nucleons,

nucleon and electron, or electrons of the form  $V = \frac{g\hbar^2}{8\pi m_p} (\boldsymbol{\sigma} \cdot \boldsymbol{\tau}) \left( \frac{1}{r^2} + \frac{1}{\lambda r} \right) e^{-r/\lambda}$ , where  $g_s$  and  $g_p$  are dimensionless scalar and pseudoscalar coupling constants,  $m_p$  is the fermion mass with the pseudoscalar coupling (whereas the mass  $m_s$  of the fermion with the scalar coupling does not explicitly appear), and  $\lambda = \hbar/(m_A c)$  is the range of the force.

1	AYRES	23	at PSI use their neutron EDM setup to look for a mm to micron-range spin-dependent force between ultracold spin-polarized neutrons stored in vacuum and the unpolarised nucleons in the surrounding apparatus. They constrain a nucleon-neutron monopole-dipole interaction parameterised by the coupling $g_s^N g_p^N$ . They set a limit of $g_s^N g_p^N < 10^{-20}$ (95% CL) for a 1 meV mass axion, see Fig. 6.
2	PODDAR	23	search for long-range monopole-dipole forces between the polarized population of electrons inside the Earth and the unpolarised nucleons in the Sun, which would affect the precession of orbital perihelion. However, the most competitive limit is obtained by combining the monopole-monopole force constraints on $g_s^N$ from planetary precession with the strongest stellar bound on the pseudoscalar electron coupling ( $g_p^e$ ), shown in Fig. 5.
3	ZHANG	23	look for changes of the ratio of precession frequencies between $^{129}\text{Xe}$ and $^{131}\text{Xe}$ as the bias field is flipped in Earth's gravitational field after Earth rotation effect is subtracted. They find $g_p^N g_s^N < 1 \times 10^{-26}-3.7 \times 10^{-36}$ for $\lambda = 0.3-1 \times 10^{10}$ m. See their Fig. 4 for limits as a function of $\lambda$ .

## Axions ( $A^0$ ) and Other Very Light Bosons

4 CRESCINI 22 is an update of CRESCINI 17, and find $g_p^e g_s^N \leq 5.7 \times 10^{-32}$ and $g_p^e g_s^e \leq 1.6 \times 10^{-31}$ for $\lambda \gtrsim 10$ cm at 95% CL. See their Fig. 4 for limits as a function of $\lambda$ .	< 4	$\times 10^{-6}$	90	1 ABREU	24	FASR	$m_{\gamma} \approx 50$ MeV
5 FENG 22 look for changes of the ratio of precession frequencies between $^{129}\text{Xe}$ and $^{131}\text{Xe}$ when a BGO crystal is positioned near the atomic cell. They find $g_p^e g_s^N < 2 \times 10^{-20} - 3 \times 10^{-24}$ for $\lambda = 0.11-0.55$ mm. See their Fig. 4 for limits as a function of $\lambda$ .	< 1	$\times 10^{-3}$	90	2 AAD	23b	ATLS	$m_{\gamma} = 5-40$ GeV
6 AFACH 21 look for axion domain walls coupled to atomic spins by using the global network of optical magnetometers. Assuming that the axion domain walls make up all dark matter, they exclude the effective decay constant below $4 \times 10^5$ GeV for $m_{A^0}$ in the range of $10^{-15}-10^{-11}$ eV. See their Fig. 4 for the mass-dependent limits.	< 1.3	$\times 10^{-8}$	90	3 AAD	23i	ATLS	$m_{\gamma} = 0.017-15$ GeV
7 DZUBA 18 used atomic EDM measurements to derive limits on the product of the pseudoscalar coupling to nucleon and the scalar coupling to electron, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV. See their Fig. 1 for mass-dependent limits.	< 1	$\times 10^{-16}$	90	4 AAD	23t	ATLS	$m_{\gamma} \lesssim 40$ GeV
8 STADNIK 18 used atomic and molecular EDM experiments to derive limits on the product of the pseudoscalar couplings to electron and the scalar coupling to nucleon and electron. See their Fig. 2 for mass-dependent limits, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV.	< 1.6	$\times 10^{-3}$	90	5 AALBERS	23a	LZ	$m_{\gamma} = 1-17$ keV
9 CRESCINI 17 use the QUAX- $g_p g_s$ experiment to look for variation of a paramagnetic GSO crystal magnetization when rotating lead disks are positioned near the crystal, and find $g = g_p^e g_s^N < 4.3 \times 10^{-30}$ for $\lambda = 0.1-0.2$ m at 95% CL. See their Fig. 6 for limits as a function of $\lambda$ .	< 6	$\times 10^{-14}$	90	6 ABLIKIM	23af	BES3	$m_{\gamma} = 1.5-2.9$ GeV
10 AFACH 15 look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find $g < 2.2 \times 10^{-27}$ ( $\text{m}/\lambda$ ) <sup>2</sup> at 95% CL for $1 \mu\text{m} < \lambda < 5$ mm. See their Fig. 3 for their limits.	< 2.1	$\times 10^{-3}$	95	7 ABUDINEN	23b	BEL2	$m_{\gamma} = 4-9.7$ GeV
11 STADNIK 15 studied proton and neutron spin contributions for nuclei and derive the limits $g < 10^{-28}-10^{-23}$ for $\lambda > 3 \times 10^{-4}$ m using the data of TULLNEY 13. See their Figs. 1 and 2 for $\lambda$ -dependent limits.	< 1.1	$\times 10^{-16}$	90	8 ADHIKARI	23	C100	$m_{\gamma} = 215$ eV
12 TERRANO 15 used a torsion pendulum and rotating attractor, and derived a restrictive limit on the product of the pseudoscalar coupling to electron and the scalar coupling to nucleons, $g < 9 \times 10^{-29}-5 \times 10^{-26}$ for $m_{A^0} < 1.5-400$ $\mu\text{eV}$ . See their Fig. 5 for mass-dependent limits.	< 2	$\times 10^{-14}$	68	9 ADHIKARI	23a	C100	$m_{\gamma} = 10-1000$ keV
13 BULATOWICZ 13 looked for NMR frequency shifts in polarized $^{129}\text{Xe}$ and $^{131}\text{Xe}$ when a zirconia rod is positioned near the NMR cell, and find $g < 1 \times 10^{-19}-1 \times 10^{-24}$ for $\lambda = 0.01-1$ cm. See their Fig. 4 for their limits.	< 2.1	$\times 10^{-3}$	95	10 ADRIAN	23	HPS	$m_{\gamma} = 19-81$ MeV
14 CHU 13 look for a shift of the spin precession frequency of polarized $^3\text{He}$ in the presence of an unpolarized mass, in analogy to YODIN 96. See Fig. 3 for limits on $g$ in the approximate $m_{A^0}$ range 0.02-2 MeV.	< 1.1	$\times 10^{-16}$	90	11 AGNES	23a	D550	$m_{\gamma} = 0.03-20$ keV
15 TULLNEY 13 look for a shift of the precession frequency difference between the colocated $^3\text{He}$ and $^{129}\text{Xe}$ in the presence an unpolarized mass, and derive limits $g < 3 \times 10^{-29}-2 \times 10^{-22}$ for $\lambda > 3 \times 10^{-4}$ m. See their Fig. 3 for $\lambda$ -dependent limits.	< 2	$\times 10^{-12}$	95	12 AN	23a		$m_{\gamma} = 4.1-6.2$ $\mu\text{eV}$
16 RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on $g$ . See their Figs. 2 and 3 for results.	< 5	$\times 10^{-6}$	90	13 ANDREEV	23	NA64	$m_{\gamma} = 10^{-3}-1.5$ GeV
17 HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on $g$ in the approximate $m_{A^0}$ range 0.03-10 MeV.	< 5.0	$\times 10^{-14}$	68	14 BAJJALI	23	BRAS	$m_{\gamma} = 49.63-74.44$ $\mu\text{eV}$
18 PETUKHOV 10 use spin relaxation of polarized $^3\text{He}$ and find $g < 3 \times 10^{-23}$ ( $\text{cm}/\lambda$ ) <sup>2</sup> at 95% CL for the force range $\lambda = 10^{-4}-1$ cm.	< 2	$\times 10^{-7}$	90	15 CORTINA-GIL	23c	NA62	$m_{\gamma} = 10-700$ MeV
19 SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find $g < 2 \times 10^{-21}$ ( $\text{cm}/\lambda$ ) <sup>2</sup> at 95% CL for the force range $\lambda = 10^{-4}-1$ cm.	< 2.2	$\times 10^{-3}$	90	16 HAYRAPETY...	23g	CMS	$m_{\gamma} = 1.1-7.9$ GeV
20 IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show $\lambda$ -dependent limits in their Fig. 1.	< 3	$\times 10^{-11}$	95	17 KOTAKA	23	DORR	$m_{\gamma} = 74-110$ $\mu\text{eV}$
21 SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96 \times 10^{-21}$ ( $\text{cm}/\lambda$ ) <sup>2</sup> for the force range $\lambda = 10^{-3}-1$ cm and $g < 3.9 \times 10^{-22}$ ( $\text{cm}/\lambda$ ) <sup>2</sup> for $\lambda = 10^{-4}-10^{-3}$ cm, each time at 95% CL, significantly improving on BAESSLER 07.	< 2	$\times 10^{-15}$	90	18 LI	23i	ASTR	$m_{\gamma} = 10^{-3}-10^5$ eV
22 BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain $g$ for an interaction range $1 \mu\text{m}$ -a few mm. See their Fig. 3 for results.	< 2	$\times 10^{-15}$	90	19 RAMANATH...	23	QULP	$m_{\gamma} = 19.7-30.5$ $\mu\text{eV}$
23 HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about $9 \times 10^{22}$ polarized electrons. See their Fig. 4 for limits on $g$ as a function of interaction range.	< 5	$\times 10^{-17}$	90	20 ROMANENKO	23	LSW	$m_{\gamma} = 0.21-5.7$ $\mu\text{eV}$
24 NI 99 searched for a $T$ -violating medium-range force acting on paramagnetic $\text{Tb F}_3$ salt. See their Fig. 1 for the result.	< 1	$\times 10^{-2}$	90	21 XIA	23	ASTR	$m_{\gamma} \lesssim 10^{-23}$ eV
25 POSPELOV 98 studied the possible contribution of $T$ -violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate CP. The size of the force among nucleons must be smaller than gravity by a factor of $2 \times 10^{-10}$ ( $1 \text{ cm}/\lambda_A$ ), where $\lambda_A = h/m_A c$ .	< 1	$\times 10^{-15}$	68	22 AAD	22j	ATLS	$m_{\gamma} = 1-60$ GeV
26 YODIN 96 compared the precession frequencies of atomic $^{199}\text{Hg}$ and $\text{Cs}$ when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.	< 1	$\times 10^{-15}$	90	23 AAD	22s	ATLS	$m_{\gamma} \lesssim 10$ GeV
27 RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.	(4.6 $\pm$ 0.5 $\pm$ 0.4)	$\times 10^{-15}$	68	24 APRILE	22	XE1T	$m_{\gamma} = 0.9$ keV

**Hidden Photons: Kinetic Mixing Parameter Limits**

Limits are on the kinetic mixing parameter  $\chi$  which is defined by the Lagrangian

$$L = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{1}{4} F'_{\mu\nu} F'^{\mu\nu} - \frac{\chi}{2} F_{\mu\nu} F'^{\mu\nu} + \frac{m^2}{2} A'_\mu A'^\mu,$$

where  $A_\mu$  and  $A'_\mu$  are the photon and hidden-photon fields with field strengths  $F_{\mu\nu}$  and  $F'_{\mu\nu}$ , respectively, and  $m_{\gamma'}$  is the hidden-photon mass.

- 1 ABREU 24 look for hidden photons produced from the  $pp$  collision in the decay channel  $\gamma' \rightarrow e^+e^-$ , and exclude at 90% CL the region of  $\chi = 4 \times 10^{-6}\text{--}2 \times 10^{-4}$  and  $m_{\gamma\prime} = 10\text{--}80$  MeV, with the newly excluded region near the higher values of  $\chi$ . See their Fig. 7 for mass-dependent limits.
- 2 AAD 23B0 look for rare decays of the  $Z$  boson,  $Z \rightarrow \gamma' + H'$ , with dark Higgs decaying into a pair of hidden photons, assuming that at least two of the hidden photons decay into  $e^+e^-$  or  $\mu^+\mu^-$ . The quoted limit assumes the hidden fine structure constant  $\alpha_D = 0.1$  and the dark Higgs mass ranging 20 to 70 GeV. See their Fig. 5 for the mass-dependent limits.
- 3 AAD 23I look for exotic decays of the SM-like Higgs boson,  $H \rightarrow \gamma'\gamma'$  with hidden photons decaying into displaced lepton or light quark pairs, and set limits on the kinetic mixing within  $1 \times 10^{-4}\text{--}1 \times 10^{-8}$  for the given mass range. The quoted limit is for  $m_{\gamma\prime} \approx 13$  GeV with a branching fraction of 0.1 for the Higgs decaying into hidden photon pairs. See their Fig. 13 for the mass-dependent limits.
- 4 AAD 23T is analogous to AAD 22s, but using the  $ZH$  production mode, and set the upper limit on the branching ratio  $B(H \rightarrow \gamma'\gamma')$  within 0.0219–0.0252 (95% CL).
- 5 AALBERS 23A look for an absorption of hidden photon dark matter. The quoted limit is for  $m_{\gamma\prime} = 1.4$  keV. The local density  $\rho_{\gamma\prime} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 7 for mass-dependent limits.
- 6 ABLIKIM 23AF look for invisible decays of hidden photons produced in the reaction  $e^+e^- \rightarrow \gamma'\gamma'$ . They set limits within the  $1.6 \times 10^{-3}\text{--}5.7 \times 10^{-3}$ . See their Fig. 3 for mass-dependent limits.
- 7 ABUDINEN 23B look for hidden photons in the dark Higgsstrahlung process,  $e^+e^- \rightarrow \gamma' H'$  ( $\gamma' \rightarrow \mu^+\mu^-$ ) with  $H'$  being invisible. They set upper limits on the product of the kinetic mixing and the hidden gauge coupling,  $\chi^2 \cdot \alpha_D$ , in the range of  $1.7 \times 10^{-8}\text{--}2 \times 10^{-6}$  at 90% CL for a 1 GeV dark Higgs mass. See their Fig. 3 for the mass-dependent limits.
- 8 ADHIKARI 23 look for the annual modulation signal induced by solar flux of hidden photons. See their Fig. 10 for mass-dependent limits.
- 9 ADHIKARI 23A look for absorption and Compton-like processes of hidden photon dark matter. The quoted limit is for  $m_{\gamma\prime} \approx 12$  keV. Limits between  $6 \times 10^{-14}\text{--}3 \times 10^{-11}$  are obtained. See their Fig. 4 for mass-dependent limits.
- 10 ADRIAN 23 is an update of ADRIAN 18, and use the data from the 2016 engineering run at 2.3 GeV. The quoted limit is at  $m_{\gamma\prime} \approx 74$  MeV. See their Fig. 28 for the mass-dependent limits.
- 11 AGNES 23A look for an absorption of hidden photon dark matter. The quoted limit is for  $m_{\gamma\prime} = 0.03$  keV. The local density  $\rho_{\gamma\prime} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 2 for mass-dependent limits.
- 12 AN 23A look for absorption of hidden photon dark matter at radio telescopes, setting limits based on data from the FAST telescope. The local density  $\rho_{\gamma\prime} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 1 for mass-dependent limits.
- 13 ANDREEV 23 is an update of ANDREEV 21 and ANDREEV 21A. The quoted limit applies to  $m_{\gamma\prime} = 1$  MeV. See their Fig. 3 for mass-dependent limits.
- 14 BAJJALI 23 look for hidden photon dark matter by using a 12–18 GHz dish antenna at U. Hamburg that is sensitive to vertically aligned hidden photon polarizations. They assume a local density of  $\rho_{\gamma\prime} = 0.3$  GeV/cm<sup>3</sup>. See their Figure 12 for mass-dependent limits in the range of  $m_{\gamma\prime} = 50\text{--}75$   $\mu\text{eV}$  under the assumption of randomly aligned hidden photon polarizations, defined as "1 sigma sensitivity". The run is labelled BRASS-p.
- 15 CORTINA-GIL 23c NA62 beam dump experiment searches for hidden photons decaying to  $\mu^+\mu^-$ , extending their previous search CORTINA-GIL 19. The quoted limit applies at 300 MeV but does not extend to arbitrarily large kinetic mixing parameters. See Fig. 4 for mass-dependent limits.
- 16 HAYRAPETYAN 23G search for kinetically mixed hidden photons in proton-proton collisions at the LHC that would generate a narrow peak in the mass spectrum of dimuon events. The mass window between 2.6 and 4.2 GeV is left unconstrained to avoid  $J/\psi$  and  $\psi(2S)$  resonances. Mass dependent limits given in their Fig. 6.
- 17 KOTAKA 23 is an update of TOMITA 20, and set limits  $\chi < 0.3\text{--}2 \times 10^{-10}$  for the quoted mass range. The local density  $\rho_{\gamma\prime} = 0.39$  GeV/cm<sup>3</sup> is assumed. See their Fig. 5 for mass-dependent limits.
- 18 LI 23I set cooling bounds on the emission of hidden photons from the Sun, red giant, and horizontal branch stars, including emission of both the transverse and longitudinal modes. Cooling bounds are computed assuming a static model as opposed to considering the impact on stellar evolution. The result is comparable to earlier estimates of the same bound e.g. REDONDO 13. Limit applies at the most constraining mass around 200 eV for the solar bound.
- 19 RAMANATHAN 23 look for hidden photon dark matter using a gold-plated copper dish antenna cooled to 20 mK. The local density  $\rho_{\gamma\prime} = 0.45$  GeV/cm<sup>3</sup> is assumed. Limits between  $7.9 \times 10^{-13}$  and  $3.81 \times 10^{-12}$  are obtained. See their Fig. 5 for mass-dependent limits.
- 20 ROMANENKO 23 employed two superconducting radio frequency cavities with a high quality factor, optimized for detecting the longitudinal polarization of the hidden photon. The quoted limit is set at  $m_{\gamma\prime} \approx 5$   $\mu\text{eV}$ . See their Fig. 4 for the mass-dependent limits.
- 21 XIA 23 is analogous to WU 22A and use the Fermi-LAT pulsar timing array. They set a bound on the local density as  $\rho_{\gamma\prime} \lesssim 7$  GeV/cm<sup>3</sup> for  $m_{\gamma\prime} \lesssim 10^{-23}$  eV at 95% CL, with weaker constraints up to  $10^{-22}$  eV. See their Fig. 1 for the mass-dependent limits.

See key on page 1171

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

- 22 AAD 22i look for exotic decays of the SM-like Higgs boson,  $H \rightarrow \gamma' \gamma' \rightarrow 4\ell$  and  $H \rightarrow Z \gamma' \rightarrow 4\ell$ , and set limits on the kinetic mixing and the Higgs portal coupling. See their Figs. 19 and 20 for the mass-dependent limits.
- 23 AAD 22s look for decays of a Higgs boson into  $\gamma$  and  $\gamma'$  using the VBF production mode, and set the upper limit on the branching ratio at 0.018 (95% CL) for the 125 GeV Higgs boson. For the quoted mass range, the signal acceptance changes by less than 1%.
- 24 APRILE 22 is analogous to AN 20, and set limits  $\chi < 3 \times 10^{-13}$  (eV/ $m_{\gamma'}$ ) for  $m_{\gamma'} < 3$  eV (90% C.L.). For  $m_{\gamma'} > 3$  eV, see their Fig. 16 for mass-dependent limits.
- 25 APRILE 22 extend APRILE 19 to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to  $m_{\gamma'} = 0.09$  keV. See their Fig. 15 for mass-dependent limits.
- 26 APRILE 22b is an update of APRILE 20, and set limits  $\chi \lesssim 5 \times 10^{-17} - 2 \times 10^{-13}$ . The quoted limit applies to  $m_{\gamma'} = 1$  keV. They exclude the XENONIT excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.
- 27 BATTAGLIERI 22 is analogous to BATELL 14, and derived limits from the electron beam dump experiment at Jefferson Lab (BDX-MINI). Limits at the level of  $7 \times 10^{-5} - 1 \times 10^{-2}$  are obtained for the dark matter mass  $m_{\gamma'}/3$  and the hidden gauge coupling  $\alpha_D = 0.1$ . See their Fig. 11.
- 28 BOLTON 22 use the Ly- $\alpha$  forest at  $z \simeq 0.1$  as a calorimeter for heating in the intergalactic medium by the resonant conversion of hidden photon dark matter to photons, which is assumed to be responsible for the tension between the predicted and observed Ly- $\alpha$  absorption linewidths.
- 29 CERVANTES 22 use a dielectrically loaded Fabry-Perot open cavity to look for hidden photon dark matter. The local density  $\rho_{\gamma'} = 0.45$  GeV/cm<sup>3</sup> is assumed. See their Fig. 5 for mass-dependent limits.
- 30 CHILES 22 look for hidden photon dark matter by using a layered dielectric target and a superconducting nanowire single-photon detector. The local density  $\rho_{\gamma'} = 0.4$  GeV/cm<sup>3</sup> is assumed. See their Fig. 4 for mass-dependent limits.
- 31 HOCHBERG 22 update HOCHBERG 19. The quoted limit applies to  $m_{A^0} \simeq 11$  eV. See their Fig. 5 for mass-dependent limits.
- 32 LEES 22 look for a hidden fermion-fermion bound state decaying into three hidden photons, which subsequently decay into  $e^+e^-$ ,  $\mu^+\mu^-$ , or  $\pi^+\pi^-$ . For the bound-state mass in the range of 0.05–9.5 GeV, limits at the level of  $5 \times 10^{-5} - 1 \times 10^{-3}$  are obtained. See their Fig. 6 for mass-dependent limits.
- 33 LU 22 derive the limit by studying the effect of photons oscillating into hidden photons on the surface luminosity of the neutron star RX J1856.6-3754.
- 34 MARENTI 22 look for hidden photon dark matter by using a multilayer dielectric haloscope. Limits between  $6.86 \times 10^{-11}$  and  $5 \times 10^{-8}$  are obtained for  $m_{\gamma'} \simeq 1.1-3.1$  eV. See their Fig. 11 for mass-dependent limits.
- 35 THOMAS 22 improved KRIBS 21 by taking account of the changes in the parton distribution functions due to the inclusion of hidden photons. The quoted limit is at  $m_{\gamma'} \simeq 4$  GeV. Limits in the range of  $3 \times 10^{-2} - 9 \times 10^{-2}$  are obtained for  $m_{\gamma'} = 1-80$  GeV. See their Fig. 1 for the limits.
- 36 TUMASYAN 22AH look for exotic decays of the SM-like Higgs boson,  $H \rightarrow Z \gamma' \rightarrow 4\ell$ , and set limits on the Higgs portal coupling. See their Fig. 6 for the limits.
- 37 TUMASYAN 22N look for exotic decays of the SM-like Higgs boson,  $H \rightarrow \gamma' \gamma' (\gamma' \rightarrow \mu^+ \mu^-)$ , and set limits on the branching fraction product. See their Fig. 7 for mass- and lifetime-dependent limits.
- 38 WU 22A look for direction-dependent oscillations in the gravitational potential generated by ultralight hidden photon dark matter, and set a bound on its local density as  $\rho_{\gamma'} \lesssim 5$  GeV/cm<sup>3</sup> for  $m_{\gamma'} \lesssim 10^{-23}$  eV at 95% CL.
- 39 ANDREEV 21 is analogous to BANERJEE 18A. The quoted limit applies to  $m_{\gamma'} = 1$  MeV. See their Fig. 3 for mass-dependent limits.
- 40 ANDREEV 21A extends the limits of BANERJEE 19 by taking account of production through the resonant annihilation of secondary positrons with atomic electrons. The quoted limit is at  $m_{\gamma'} = 0.23$  GeV, assuming the fermion dark matter of mass  $m_{\gamma'}/3$  and the hidden gauge coupling  $\alpha_D = 0.1$ . See their Fig.3 for mass-dependent limits.
- 41 BI 21 look for the gamma-ray spectral attenuation due to scattering with hidden photons constituting all dark matter, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet AS $\gamma$  and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 4 for mass-dependent limits.
- 42 CAZZANIGA 21 look for semi-visible decays of hidden photons,  $\gamma' \rightarrow \chi_1 \chi_2 (\chi_2 \rightarrow \chi_1 e^+ e^-)$ , where  $\chi_1$  and  $\chi_2$  are hidden fermions. They exclude  $3 \times 10^{-5} \lesssim \chi \lesssim 2 \times 10^{-2}$  assuming the hidden gauge coupling  $\alpha_D = 0.1$ , and the fermion masses  $m_{\chi_1} = m_{\gamma'}/3$ ,  $(m_{\chi_2} - m_{\chi_1})/m_{\chi_1} = 0.4$ . See their Fig. 4 for mass-dependent limits.
- 43 DIXIT 21 look for hidden photon dark matter by using a superconducting transmon qubit dispersively coupled to a high Q storage cavity. The local density  $\rho_{\gamma'} = 0.4$  GeV/cm<sup>3</sup> is assumed. See their Fig.4 for mass-dependent limits.
- 44 GHOSH 21 use existing haloscope axion search limits to set limits on hidden photon dark matter, considering the polarization of hidden photons. The quoted limit is at  $m_{\gamma'} \simeq 3$   $\mu$ eV. See their Fig. 1 for mass-dependent limits.
- 45 GODFREY 21 look for hidden photon dark matter by using a wideband antenna, and set  $5\sigma$  limits on  $\chi$ . The local density  $\rho_{\gamma'} = 0.38$  GeV/cm<sup>3</sup> is assumed. See their updated Fig. 12 in arXiv:2101.02805v4 for mass-dependent limits in the range of  $m_{\gamma'} = 0.207-1.24$   $\mu$ eV.
- 46 KOPYLOV 21A is an update of KOPYLOV 19, but use Ne gas instead of Ar. The quoted limit applies to  $m_{\gamma'} = 12$  eV. See their Fig. 4 for mass-dependent limits.
- 47 KRIBS 21 used the HERA data on neutral current deep inelastic  $e p$  scattering to derive the limits, which become weaker for heavier masses. See their Fig. 3 for mass-dependent limits.
- 48 SCHMIDT 21 use the microscopic Parton-Hadron-String Dynamics approach to extract limits by comparing the theoretically calculated dilepton spectra with the HADES data on the search for  $\gamma' \rightarrow e^+ e^-$ . See their Fig. 5 for the mass-dependent limits for various allowed surplus of the hidden photon contribution over the standard model yield.
- 49 TSAI 21 update the limits from the CHARM and NuCal experiments, taking account of additional production channels from proton bremsstrahlung and  $\eta$  meson decays, respectively. Limits between  $3 \times 10^{-8}$  and  $1 \times 10^{-4}$  are obtained for  $0.01 < m_{\gamma'} < 0.8$  GeV (see their Fig. 1).
- 50 AAIJ 20c look for hidden photons produced from the  $pp$  collision in the decay channel  $\gamma' \rightarrow \mu^+ \mu^-$ . For prompt decaying hidden photons, limits at the level of  $10^{-4}-10^{-3}$  are obtained for  $m_{\gamma'} = 0.214-30$  GeV. See their Fig. 2 for mass-dependent limits.
- 51 AAIJ 20c look for hidden photons produced from the  $pp$  collision in the decay channel  $\gamma' \rightarrow \mu^+ \mu^-$ . For hidden photons with lifetimes of order ps, limits at the level of  $10^{-5}$  are obtained for  $m_{\gamma'} = 218-315$  MeV. See their Fig. 4 for mass-dependent limits.
- 52 ABLIKIM 20AB search for  $J/\psi \rightarrow \eta' \gamma' (\gamma' \rightarrow \gamma \pi^0)$ , and set the upper limit on the product branching fraction of order  $10^{-7}$ . See their Fig. 7 for mass-dependent limits.
- 53 AGOSTINI 20 is analogous to ABE 14f. The quoted limit applies to  $m_{\gamma'} = 150$  keV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.
- 54 AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter hidden photon absorption. The quoted limit is for  $m_{\gamma'} \simeq 17$  eV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 3 for mass-dependent limits.
- 55 AN 20 updates the direct detection limit of AN 13c on solar flux of hidden photons;  $\chi < 1.6 \times 10^{-12}$  (eV/ $m_{\gamma'}$ ) for  $m_{\gamma'} < 6$  eV (90% C.L.). For  $m_{\gamma'} > 6$  eV, see their Fig. 1 for mass-dependent limits.
- 56 ANDRIANAVALOMAHEFA 20 is analogous to SUZUKI 15, but uses a mirror that is about one order of magnitude larger than in similar studies in the past. Limits at the level of  $10^{-12}$  are obtained for  $m_{\gamma'} = 2.5-7$  eV. See their Fig.23 and Table III for mass-dependent limits.
- 57 APRILE 20 is analogous to ABE 14f, and set limits  $\chi \lesssim 10^{-16}-10^{-12}$ . The quoted limit applies to  $m_{\gamma'} = 1$  keV. They also found an excess over known backgrounds, which favors the mass  $m_{\gamma'} = 2.3 \pm 0.2$  keV with a  $3\sigma$  significance. See their Fig. 10 for mass-dependent limits.
- 58 ARALIS 20 is analogous to ABE 14f. The quoted limit applies to  $m_{\gamma'} = 0.1$  keV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. The limits at masses above 3 keV in their Fig. 10 was later found to be incorrect due to an error in their analysis. See Fig. 3 in ARALIS 21 for the corrected limits.
- 59 ARGUELLES 20 examine hidden-photon production in atmospheric cosmic-ray showers and its decay in IceCube and Super-Kamiokande. The quoted limit assumes a lifetime of  $\tau = 0.1$  km. See their Fig. 16 for mass- and lifetime-dependent limits.
- 60 ARNAUD 20 look for the absorption signal of hidden photon dark matter in a Ge detector. The quoted limit applies to  $m_{\gamma'} \simeq 9$  eV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 3 for mass-dependent limits.
- 61 BANERJEE 20 is an update of BANERJEE 18. They exclude  $8.2 \times 10^{-5} \lesssim \chi \lesssim 1 \times 10^{-2}$  for  $m_{\gamma'} = 1.5-24$  MeV. In particular, they exclude  $\chi = 1.2 \times 10^{-4} - 6.8 \times 10^{-4}$  for the 16.7 MeV gauge boson. See their Fig. 5 for mass-dependent limits.
- 62 BARAK 20 is analogous to AGUILAR-AREVALO 19A, and look for hidden photon dark matter by using the Skipper CCD. The quoted limit applies to  $m_{\gamma'} = 12.8$  eV. See their Fig. 4 for mass-dependent limits.
- 63 KRASNIKOV 20 showed that the limit of BANERJEE 20 combined with the measured anomalous magnetic moment of the electron exclude the 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment if it has pure vector or axial-vector interactions.
- 64 SHE 20 look for solar hidden photons. The quoted limit applies to  $m_{\gamma'} = 180$  eV. See their Fig. 4 for mass-dependent limits.
- 65 SHE 20 look for hidden photon dark matter and set limits  $\chi < 1.3 \times 10^{-15} - 2.8 \times 10^{-14}$  for the quoted mass range. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 6 for mass-dependent limits.
- 66 SIRUNYAN 20Aq look for a narrow resonance decaying into a pair of muons. For  $m_{\gamma'} < 45$  GeV, they use dedicated high-rate dimuon triggers to reduce the muon transverse momentum thresholds. The quoted limit applies to  $m_{\gamma'} = 50$  GeV, and limits of order  $10^{-3}$  are obtained for the quoted mass range. See their Fig. 3 for mass-dependent limits.
- 67 TOMITA 20 look for hidden photon dark matter using a planar metal plate and cryogenic receiver and set limits  $\chi < 1.8-4.3 \times 10^{-10}$  for the quoted mass range. The local density  $\rho_{\gamma'} = 0.39$  GeV/cm<sup>3</sup> is assumed. See their Fig. 7 for mass-dependent limits.
- 68 WANG 20A is analogous to ABE 14f. The quoted limit applies to  $m_{\gamma'} = 185$  eV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 11 for mass-dependent limits.
- 69 AABOUD 19G look for  $h \rightarrow \gamma' \gamma' (\gamma' \rightarrow \mu^+ \mu^-)$  and exclude a kinetic mixing around  $10^{-9}-10^{-8}$  for  $B(h \rightarrow \gamma' \gamma') = 0.01$  and 0.1. See their Fig. 9 for mass-dependent limits.
- 70 ABLIKIM 19A look for  $J/\psi \rightarrow \gamma' \eta (\gamma' \rightarrow e^+ e^-)$ . Limits between  $6 \times 10^{-3}$  and  $5 \times 10^{-2}$  are obtained (see their Fig. 8).
- 71 ABLIKIM 19H look for  $J/\psi \rightarrow \gamma' \eta' (\gamma' \rightarrow e^+ e^-)$ . Limits between  $3.4 \times 10^{-3}$  and  $2.6 \times 10^{-2}$  are obtained. See their Fig. 5 for mass-dependent limits.
- 72 AGUILAR-AREVALO 19A look for the absorption signal of hidden photon dark matter by using a CCD. The quoted limit applies to  $m_{\gamma'} = 17$  eV. The local density  $\rho_{\gamma'} = 0.3$  GeV/cm<sup>3</sup> is assumed. See their Fig. 4 for mass-dependent limits.
- 73 APRILE 19D is analogous to ABE 14f. The quoted limit applies to  $m_{\gamma'} = 0.7$  keV. See their Fig. 5(f) for mass-dependent limits.
- 74 BANERJEE 19 is an update of BANERJEE 18A. The quoted limit is at  $m_{\gamma'} = 1$  MeV. See their Fig. 3 for mass-dependent limits.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>75</sup> BHOONAH 19 examine heating of Galactic Center gas clouds by hidden photon dark matter. The quoted limit applies to  $m_{\gamma'} \simeq 10^{-12}$  eV. See their Fig. 2 for mass-dependent limits.
- <sup>76</sup> BRUN 19 is analogous to SUZUKI 15. The limit is derived under an assumption that hidden photons constitute the local dark matter density  $\rho_{\gamma'} = 0.3 \text{ GeV}/\text{cm}^3$ .
- <sup>77</sup> CORTINA-GIL 19 look for an invisible hidden photon in the reaction  $K^+ \rightarrow \pi^+ \pi^0 (\pi^0 \rightarrow \gamma\gamma')$ . The quoted limit applies to  $m_{\gamma'} = 62.5\text{--}65 \text{ MeV}$ . See their Figs. 6 and 7 for mass-dependent limits.
- <sup>78</sup> DANILOV 19 examined the hidden photon production in nuclear reactors, correctly taking account of the effective photon mass in the reactor and detector. The limit gets weaker for  $m_{\gamma'}$  less than the effective photon mass in proportion to  $1/m_{\gamma'}^2$ . See their Fig. 1 for mass-dependent limits.
- <sup>79</sup> HOCHBERG 19 look for the absorption signal of hidden photon dark matter by using superconducting-nanowire single-photon detectors. The quoted limit applies to  $m_{\gamma'} \simeq 1 \text{ eV}$ . The local density  $\rho_{\gamma'} = 0.3 \text{ GeV}/\text{cm}^3$  is assumed. See their Fig. 4 for mass-dependent limits.
- <sup>80</sup> KOPYLOV 19 look for hidden-photon dark matter using a counter with an aluminum cathode and derive limits assuming it constitute all the local dark matter. The quoted limit applies to  $m_{\gamma'} = 12 \text{ eV}$ . See their Fig. 7 for mass-dependent limits.
- <sup>81</sup> KOVETZ 19 examine heating of the early Universe plasma by hidden photon dark matter, and derive the limits by requiring that the cosmic mean 21 cm brightness temperature relative to the CMB temperature satisfy  $T_{21} > -100 \text{ mK}$ . The quoted limit applies to  $m_{\gamma'} \simeq 2 \times 10^{-14} \text{ eV}$ . See their Fig. 3 for mass-dependent limits.
- <sup>82</sup> NGUYEN 19 look for hidden photon dark matter with a resonant cavity, and set limits  $\sim 10^{-12}$  for  $m_{\gamma'} = 0.2\text{--}2.07 \mu\text{eV}$ . The quoted limit applies to  $m_{\gamma'} = 1.3 \mu\text{eV}$ . The local density  $\rho_{\gamma'} = 0.3 \text{ GeV}/\text{cm}^3$  is assumed. See their Fig. 19 for mass-dependent limits.
- <sup>83</sup> ABE 18f is an update of ABE 14f. The quoted limit applies to  $m_{\gamma'} \simeq 40 \text{ keV}$ . See their Fig. 5 for mass-dependent limits.
- <sup>84</sup> ADRIAN 18 look for a hidden photon resonance in the reaction  $e^- Z \rightarrow e^- Z \gamma' (\gamma' \rightarrow e^+ e^-)$ . The quoted limit applies to  $m_{\gamma'} = 40 \text{ MeV}$ . See their Fig. 4 for mass-dependent limits.
- <sup>85</sup> ANASTASI 18b look for a hidden photon resonance in the reaction  $e^+ e^- \rightarrow \gamma' \gamma' (\gamma' \rightarrow \mu^+ \mu^-)$ . The quoted limit is obtained by combining the result of ANASTASI 16 and it applies to  $m_{\gamma'} \simeq 519\text{--}987 \text{ MeV}$ . See their Fig. 9 for mass-dependent limits.
- <sup>86</sup> ARMENGAUD 18 is analogous to ABE 14f. The quoted limits applies to  $m_{\gamma'} = 1.6 \text{ keV}$ . See the right panel of Fig. 5 for mass-dependent limits.
- <sup>87</sup> BANERJEE 18 look for hidden photons produced in the reaction  $e^- Z \rightarrow e^- Z \gamma' (\gamma' \rightarrow e^+ e^-)$ , and exclude  $9.2 \times 10^{-5} \lesssim \chi \lesssim 1 \times 10^{-2}$  for  $m_{\gamma'} = 1\text{--}23 \text{ MeV}$ . They also set a limit on the electron coupling to a 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment. See their Fig. 3 for mass-dependent limits.
- <sup>88</sup> BANERJEE 18a look for invisible decays of hidden photons produced in the reaction  $e^- Z \rightarrow e^- Z \gamma'$ . The quoted limit is at  $m_{\gamma'} = 1 \text{ MeV}$ . See their Fig. 15 for mass-dependent limits.
- <sup>89</sup> KNIRCK 18 is analogous to SUZUKI 15. See their Fig. 5 for mass-dependent limits.
- <sup>90</sup> ABRGALL 17 is analogous to ABE 14f using the MAJORANA DEMONSTRATOR. See their Fig. 3 for limits between  $6 \text{ keV} < m_{\gamma'} < 97 \text{ keV}$ .
- <sup>91</sup> ABLIKIM 17AA look for  $e^+ e^- \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^- \text{ or } \mu^+ \mu^-)$ . Limits between  $10^{-3}$  and  $10^{-4}$  are obtained (see their Fig. 3).
- <sup>92</sup> ANGLÖHER 17 is analogous to ABE 14f. The quoted limit is at  $m_{\gamma'} = 0.7 \text{ keV}$ . See their Fig. 8 for mass-dependent limits.
- <sup>93</sup> BANERJEE 17 look for invisible decays of hidden photons produced in the reaction  $e^- Z \rightarrow e^- Z \gamma'$ . The quoted limit applies to  $m_{\gamma'} = 2 \text{ MeV}$ . See their Fig. 3 for mass-dependent limits.
- <sup>94</sup> CHANG 17 examine the hidden photon emission from SN1987A, including the effects of finite temperature and density on  $\chi$  and obtain limits  $\chi (m_{\gamma'}/\text{MeV}) \lesssim 3 \times 10^{-9}$  for  $m_{\gamma'} < 15 \text{ MeV}$  and  $\chi \lesssim 10^{-9}$  for  $m_{\gamma'} = 15\text{--}120 \text{ MeV}$ .
- <sup>95</sup> DUBININA 17 look for  $\mu^+ \rightarrow e^+ \bar{\nu}_\mu \nu_e \gamma' (\gamma' \rightarrow e^+ e^-)$  in a nuclear photoemulsion. The quoted limit applies to  $m_{\gamma'} = 1.1 \text{ MeV}$ . Limits between  $4.5 \times 10^{-3}$  and  $10^{-2}$  are obtained (see their Fig. 3).
- <sup>96</sup> LEES 17E look for invisible decays of hidden photons produced in the reaction  $e^+ e^- \rightarrow \gamma \gamma'$ . See their Fig. 5 for limits in the mass range  $m_{\gamma'} \leq 8 \text{ GeV}$ .
- <sup>97</sup> AAD 16AG look for hidden photons promptly decaying into collimated electrons and/or muons, assuming that they are produced in the cascade decays of squarks or the Higgs boson. See their Fig. 10 and Fig.13 for their limits on the cross section times branching fractions.
- <sup>98</sup> ANASTASI 16 look for the decay  $\gamma' \rightarrow \pi^+ \pi^-$  in the reaction  $e^+ e^- \rightarrow \gamma \gamma'$ . Limits between  $4.3 \times 10^{-3}$  and  $4.4 \times 10^{-4}$  are obtained for  $527 < m_{\gamma'} < 987 \text{ MeV}$  (see their Fig. 9).
- <sup>99</sup> KHACHATRYAN 16 look for  $\gamma' \rightarrow \mu^+ \mu^-$  in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into  $\gamma'$  and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.
- <sup>100</sup> AAD 15cd look for  $H \rightarrow Z \gamma' \rightarrow 4\ell$  with the ATLAS detector at LHC and find  $\chi < 4\text{--}17 \times 10^{-2}$  for  $m_{\gamma'} = 15\text{--}55 \text{ GeV}$ . See their Fig. 6.
- <sup>101</sup> ADARE 15 look for a hidden photon in  $\pi^0, \eta^0 \rightarrow \gamma e^+ e^-$  at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.
- <sup>102</sup> AN 15A derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is  $\chi < 1.3 \times 10^{-10}$  at  $m_{\gamma'} = 18 \text{ eV}$ . See their Fig. 1 for mass-dependent limits.
- <sup>103</sup> ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than  $m_{\gamma'}$  escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.
- <sup>104</sup> ANASTASI 15A look for the decay  $\gamma' \rightarrow e^+ e^-$  in the reaction  $e^+ e^- \rightarrow e^+ e^- \gamma'$ . Limits between  $1.7 \times 10^{-3}$  and  $1 \times 10^{-2}$  are obtained for  $m_{\gamma'} = 5\text{--}320 \text{ MeV}$  (see their Fig. 7).
- <sup>105</sup> BATLEY 15A look for  $\pi^0 \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^-)$  at the NA48/2 experiment. Limits between  $4.2 \times 10^{-4}$  and  $8.8 \times 10^{-3}$  are obtained for  $m_{\gamma'} = 9\text{--}120 \text{ MeV}$  (see their Fig. 4).
- <sup>106</sup> JAEGLE 15 look for the decay  $\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-, \text{ or } \pi^+ \pi^-$  in the dark Higgsstrahlung channel,  $e^+ e^- \rightarrow \gamma' H' (H' \rightarrow \gamma \gamma')$  at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.
- <sup>107</sup> KAZANAS 15 set limits by studying the decay of hidden photons  $\gamma' \rightarrow e^+ e^-$  inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.
- <sup>108</sup> SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are  $\chi < 6 \times 10^{-12}$  for  $m_{\gamma'} = 1.9\text{--}4.3 \text{ eV}$ . See their Fig. 7 for mass-dependent limits.
- <sup>109</sup> VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits  $\chi m_{\gamma'} < 1.8 \times 10^{-12} \text{ eV}$  for  $m_{\gamma'} = 3 \times 10^{-5}\text{--}8 \text{ eV}$ . See their Fig. 11.
- <sup>110</sup> ABE 14f look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between  $2 \times 10^{-13}$  and  $1 \times 10^{-12}$  are obtained, where the relation  $\chi^2 = \alpha'/\alpha$  is used to translate the original bound on the ratio of the hidden and EM fine-structure constants. See their Fig. 3 for mass-dependent limits.
- <sup>111</sup> AGA KISHIEV 14 look for hidden photons  $\gamma' \rightarrow e^+ e^-$  at the HADES experiment, and set limits on  $\chi$  for  $m_{\gamma'} = 0.02\text{--}0.6 \text{ GeV}$ . See their Fig. 5 for mass-dependent limits.
- <sup>112</sup> BABUSCI 14 look for the decay  $\gamma' \rightarrow \mu^+ \mu^-$  in the reaction  $e^+ e^- \rightarrow \mu^+ \mu^- \gamma'$ . Limits between  $4 \times 10^{-3}$  and  $9.0 \times 10^{-4}$  are obtained for  $520 \text{ MeV} < m_{\gamma'} < 980 \text{ MeV}$  (see their Fig. 7).
- <sup>113</sup> BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of  $10^{-4}\text{--}10^{-1}$  are obtained for  $m_{\gamma'} = 10^{-3}\text{--}1 \text{ GeV}$ , depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).
- <sup>114</sup> BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for  $\gamma'$ -bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded region.
- <sup>115</sup> FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.
- <sup>116</sup> LEES 14i look for hidden photons in the reaction  $e^+ e^- \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^-, \mu^+ \mu^-)$ . Limits at the level of  $10^{-4}\text{--}10^{-3}$  are obtained for  $0.02 \text{ GeV} < m_{\gamma'} < 10.2 \text{ GeV}$ . See their Fig. 4 for mass-dependent limits.
- <sup>117</sup> MERKEL 14 look for  $\gamma' \rightarrow e^+ e^-$  at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.
- <sup>118</sup> AN 13b examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.
- <sup>119</sup> AN 13c use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find  $\chi m_{\gamma'} < 3 \times 10^{-12} \text{ eV}$  for  $m_{\gamma'} < 1 \text{ eV}$ . See their Fig. 2 for mass-dependent limits.
- <sup>120</sup> DIAMOND 13 analyzed the beam dump data taken at the SLAC millicharge experiment to constrain a hidden photon invisibly decaying into lighter long-lived particles, which undergo elastic scattering off nuclei in the detector. Limits between  $8 \times 10^{-4}\text{--}2 \times 10^{-2}$  are obtained. The quoted limit is applied when the dark gauge coupling is set equal to the electromagnetic coupling. See their Fig.4 for mass-dependent limits.
- <sup>121</sup> GNINENKO 13 used the data taken at the SINDRUM experiment to constrain the decay,  $\pi^0 \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^-)$  to derive limits. See their Fig. 2 for their mass-dependent excluded region.
- <sup>122</sup> HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.
- <sup>123</sup> INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.
- <sup>124</sup> MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.
- <sup>125</sup> PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig.5 for mass-dependent limits.
- <sup>126</sup> PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.
- <sup>127</sup> REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13b, and also updated stellar-energy loss arguments. See their Fig.3 for mass-dependent limits, including a review of the currently best limits from other arguments.
- <sup>128</sup> GNINENKO 12a obtained bounds on  $B(\pi^0 \rightarrow \gamma \gamma') \cdot B(\gamma' \rightarrow e^+ e^-)$  from the NOMAD and PS191 neutrino experiments, and derived limits between  $8 \times 10^{-8}\text{--}2 \times 10^{-4}$ . See their Fig.4 for mass-dependent excluded regions.
- <sup>129</sup> GNINENKO 12b used the data taken at the CHARM experiment to constrain the decay,  $\eta(\eta') \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^-)$ , and derived limits between  $1 \times 10^{-7}\text{--}1 \times 10^{-4}$ . See their Fig.4 for mass-dependent excluded region.
- <sup>130</sup> ABRAHAMYAN 11 look for  $\gamma' \rightarrow e^+ e^-$  in the electron-nucleon fixed-target experiment at the Jefferson Laboratory (APEX). See their Fig. 5 for mass-dependent limits.
- <sup>131</sup> BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for  $\pi^0 \rightarrow \gamma \gamma' (\gamma' \rightarrow e^+ e^-)$ . See their Fig. 5 for mass-dependent limits.
- <sup>132</sup> BJORKEN 09 analyzed the beam dump data taken at E137, E141, and E774 to constrain a hidden photon produced by bremsstrahlung, subsequently decaying into  $e^+ e^-$ , and

$$J = \frac{1}{2}$$

e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (10 <sup>-6</sup> u)	DOCUMENT ID	TECN	COMMENT
<b>548.579909065 ± 0.000000016</b>	TIESINGA 21	RVUE	2018 CODATA value

<sup>2</sup>FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped <sup>12</sup>C<sup>6+</sup> ion.

e MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is: 1 u = 931.494 102 42(28) MeV/c<sup>2</sup> (2018 CODATA value, TIESINGA 21). The conversion error dominates the uncertainty of the masses given below.

<sup>1</sup>FAN 23 report the most accurate measurement of the electron magnetic moment. A one-electron quantum cyclotron is used. We do not propagate at the moment this measurement to the fine structure and other physical constants. When discrepancies in the independent determinations of alpha are resolved, the new measurement uncertainty of 0.13 ppt is available for precise tests for BSM physics.  
<sup>2</sup>MOHR 08 average is dominated by ODOM 06.  
<sup>3</sup>Superseded by HANNEKE 08 per private communication with Gerald Gabrielse.  
<sup>4</sup>This VANDYCK 87 result is for a positron. We do not take it into account for the average to avoid the assumption of CPT invariance.

$$(g_{e^+} - g_{e^-}) / g_{average}$$

A test of CPT invariance.

## e<sup>-</sup> MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in  $e^- \rightarrow \nu_e \gamma$ , (b) the (K) shell x-ray produced when an electron decays without additional energy deposit, e.g.,  $e^- \rightarrow \nu_e \bar{\nu}_e \nu_e$  ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best  $e^- \rightarrow \nu_e \gamma$  limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

## μ

$$J = \frac{1}{2}$$

## μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium ( $\mu^+ e^-$  atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (u)	DOCUMENT ID	TECN	COMMENT

<sup>2</sup> COHEN 87 make use of other 1986 CODATA entries below.

## μ MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is:  $1 u = 931.494 102 42(28) \text{ MeV}/c^2$  (2018 CODATA value, TIESINGA 21). The conversion error contributes significantly to the uncertainty of the masses given below.

$\mu/p$  MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error  $> 0.00001$  have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

Muon Anomalous Magnetic Moment

$\mu$  MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency  $\omega_3$  between the muon spin precession and the orbital angular frequency ( $e/m_\mu c$ )( $B$ ) is measured, as is the free proton NMR frequency  $\omega_p$ , thus determining the ratio  $R = \omega_3/\omega_p$ . Given the magnetic moment ratio  $\lambda = \mu_\mu/\mu_p$  (from hyperfine structure in muonium),  $(g-2)/2 = R/(\lambda-R)$ .

$\mu_\mu/(e\hbar/2m_\mu) - 1 = (g_\mu - 2)/2$

0.8 ± 4.3		BAILEY 78	CNTR	-	Storage ring

<sup>1</sup> This is the combination of the two BENNETT 09 measurements quoted here separately for  $\mu^+$  and  $\mu^-$ . The result is also presented as a measurement of  $(0.0 \pm 0.9) \times 10^{-19}$  e cm.

<sup>2</sup> EMA 22 determine indirect constraints on  $|\mu_{EDM}^\mu|$  from EDM measurements performed on heavy atoms and molecules, based on the muon-loop induced light-by-light CP-odd amplitude.

<sup>3</sup> Also reported as the limit of  $|d(\mu^+)| < 2.1 \times 10^{-19}$  e cm at 95% CL.

<sup>4</sup> Also reported as the limit of  $|d(\mu^-)| < 1.5 \times 10^{-19}$  e cm at 95% CL.

<sup>5</sup> This is the combination of the two BAILEY 78 results quoted here separately for  $\mu^+$  and  $\mu^-$ . BAILEY 78 uses the convention  $d = 1/2 \cdot (d_{\mu^+} - d_{\mu^-})$  and reports  $3.7 \pm 3.4$ . We convert their result to use the same convention as BENNETT 09.

MUON-ELECTRON CHARGE RATIO ANOMALY  $q_{\mu^+}/q_{e^-} - 1$

VALUE	DOCUMENT ID	TECN	CHG	COMMENT
<b><math>(1.1 \pm 2.1) \times 10^{-9}</math></b>				
1.1 ± 2.1	<sup>1</sup> MEYER 00	CNTR	+	1s-2s muonium interval

<sup>1</sup> MEYER 00 measure the 1s-2s muonium interval, and then interpret the result in terms of muon-electron charge ratio  $q_{\mu^+}/q_{e^-}$ .

$\mu^-$  DECAY MODES

$\mu^+$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $e^- \bar{\nu}_e \nu_\mu$	$\approx 100\%$	
$\Gamma_2$ $e^- \bar{\nu}_e \nu_\mu \gamma$	[a] $(6.0 \pm 0.5) \times 10^{-8}$	
$\Gamma_3$ $e^- \bar{\nu}_e \nu_\mu e^+ e^-$	[b] $(3.4 \pm 0.4) \times 10^{-5}$	

Lepton Family number (LF) violating modes

$\Gamma_4$ $e^- \nu_e \bar{\nu}_\mu$	LF [c] < 1.2	%	90%
$\Gamma_5$ $e^- \gamma$	LF	< 4.2	$\times 10^{-13}$
$\Gamma_6$ $e^- e^+ e^-$	LF	< 1.0	$\times 10^{-12}$
$\Gamma_7$ $e^- 2\gamma$	LF	< 7.2	$\times 10^{-11}$

[a] This only includes events with energy of  $e > 45$  MeV and energy of  $\gamma > 40$  MeV. Since the  $e^- \bar{\nu}_e \nu_\mu$  and  $e^- \bar{\nu}_e \nu_\mu \gamma$  modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] A test of additive vs. multiplicative lepton family number conservation.

<sup>1</sup>This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).

<sup>2</sup>KAULARD 98 obtained these same limits using the unified classical analysis of FELDMAN 98.

<sup>3</sup>This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.

<sup>4</sup>Assuming a giant-resonance-excitation model.

LIMIT ON MUONIUM  $\rightarrow$  ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

$R_g = G_C / G_F$

The effective Lagrangian for the  $\mu^+ e^- \rightarrow \mu^- e^+$  conversion is assumed to be

$\mathcal{L} = 2^{-1/2} G_C [\bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] [\bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e] + \text{h.c.}$

The experimental result is then an upper limit on  $G_C/G_F$ , where  $G_F$  is the Fermi coupling constant.

Table with columns: VALUE, CL%, EVTS, DOCUMENT ID, TECN, CHG, COMMENT. Includes entries for WILLMANN 99, GORDEEV 97, ABELA 96, NI 93, MATTHIAS 91, HUBER 90b, BEER 86, MARSHALL 82.

- 1 WILLMANN 99 quote both probability  $P_{MM} < 8.3 \times 10^{-11}$  at 90% CL in a 0.1 T field and  $R_g = G_C/G_F$ .
2 GORDEEV 97 quote limits on both  $f = G_{MM}/G_F$  and the probability  $W_{MM} < 4.7 \times 10^{-7}$  (90% CL).
3 ABELA 96 quote both probability  $P_{MM} < 8 \times 10^{-9}$  at 90% CL and  $R_g = G_C/G_F$ .

- • • We do not use the following data for averages, fits, limits, etc. • • •
1 BAYES 11 obtains the limit  $> 0.99909$  (90% CL) with the constraint that  $\xi \times (\mu$  LONGITUDINAL POLARIZATION)  $\times \delta / \rho \leq 1.0$ .
2 JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the erratum.
3 STOKER 85 find  $(\xi P_\mu \delta / \rho) > 0.9955$  and  $> 0.9966$ , where the first limit is from new  $\mu$  spin-rotation data and the second is from combination with CARR 83 data. In V-A theory,  $(\delta / \rho) = 1.0$ .

$\xi' =$  LONGITUDINAL POLARIZATION OF  $e^+$

(V-A) theory predicts the longitudinal polarization =  $\pm 1$  for  $e^\pm$ , respectively. We have flipped the sign for  $e^-$  so our programs can average.

Table with columns: VALUE, EVTS, DOCUMENT ID, TECN, CHG, COMMENT. Includes entries for BURKARD 85, SCHWARTZ 67, BLOOM 64, DUCLOS 64, BUHLER 63.

$\xi''$  PARAMETER

Table with columns: VALUE, EVTS, DOCUMENT ID, TECN, CHG, COMMENT. Includes entries for PRIEELS 14, BURKARD 85.

- 1 BURKARD 85 measure  $(\xi'' - \xi \xi') / \xi$  and  $\xi'$  and set  $\xi = 1$ .

TRANSVERSE  $e^+$  POLARIZATION IN PLANE OF  $\mu$  SPIN,  $e^+$  MOMENTUM

Table with columns: VALUE (units  $10^{-3}$ ), EVTS, DOCUMENT ID, TECN, CHG, COMMENT. Includes entries for DANNEBERG 05, BURKARD 85b.

TRANSVERSE  $e^+$  POLARIZATION NORMAL TO PLANE OF  $\mu$  SPIN,  $e^+$  MOMENTUM

Zero if T invariance holds.

Table with columns: VALUE (units  $10^{-3}$ ), EVTS, DOCUMENT ID, TECN, CHG, COMMENT. Includes entries for DANNEBERG 05, BURKARD 85b.

$\tau$

$$J = \frac{1}{2}$$

$\tau$  discovery paper was PERL 75.  $e^+e^- \rightarrow \tau^+\tau^-$  cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out  $J = 3/2$ . KIRKBY 79 also ruled out  $J$ =integer,  $J = 3/2$ .

<sup>1</sup> AAD 23BM measurement is derived from  $\gamma\gamma \rightarrow \tau^+\tau^-$  total cross-section from 1.44 nb<sup>-1</sup> LHC Pb-Pb collisions at  $\sqrt{s_{NN}} = 5.02$  TeV. Authors report both the measured value and the corresponding 95% CL limit.

## Lepton Particle Listings

 $\tau$ 

- <sup>2</sup> Measurement ill-suited for a standard average because its likelihood appears to be remarkably non-Gaussian and asymmetric according to the model-dependent extraction procedure and the reported 95% CL limits.
- <sup>3</sup> TUMASYAN 23As measurement is derived from  $\gamma\gamma \rightarrow \tau^+\tau^-$  total cross-section from 404  $\mu\text{b}^{-1}$  LHC Pb-Pb collisions at  $\sqrt{s_{NN}} = 5.02$  TeV.
- <sup>4</sup> ABDALLAH 04k measurement is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 183 and 208 GeV. In addition to the measurement, the authors also quote 95% CL limits of  $> -0.052$  and  $< 0.013$ .
- <sup>5</sup> ACHARD 04G limit is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.
- <sup>6</sup> GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero.
- <sup>7</sup> ACCIARRI 98E use  $Z \rightarrow \tau^+\tau^-\gamma$  events. In addition to the limits, the authors also quote a value of  $0.004 \pm 0.027 \pm 0.023$ .
- <sup>8</sup> ACKERSTAFF 98N use  $Z \rightarrow \tau^+\tau^-\gamma$  events. The limit applies to an average of the form factor for off-shell  $\tau$ 's having  $p^2$  ranging from  $m_\tau^2$  to  $(M_Z - m_\tau)^2$ .
- <sup>9</sup> ESCRIBANO 97 use preliminary experimental results.
- <sup>10</sup> ESCRIBANO 93 limit derived from  $\Gamma(Z \rightarrow \tau^+\tau^-)$ , and is on the absolute value of the magnetic moment anomaly.
- <sup>11</sup> SILVERMAN 83 limit is derived from  $e^+e^- \rightarrow \tau^+\tau^-$  total cross-section measurements for  $q^2$  up to  $(37 \text{ GeV})^2$ .

 $\tau$  ELECTRIC DIPOLE MOMENT ( $d_\tau$ )A nonzero value is forbidden by both  $T$  invariance and  $P$  invariance.The  $q^2$  dependence is expected to be small providing no thresholds are nearby.Re( $d_\tau$ )

### Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes

L means lepton number violation (e.g.  $\tau^- \rightarrow e^+\pi^-\pi^-$ ). Following common usage, LF means lepton family violation and not lepton number violation (e.g.  $\tau^- \rightarrow e^-\pi^+\pi^-$ ). B means baryon number violation.

$\Gamma_{186}$	$e^-\gamma$	LF	< 3.3	$\times 10^{-8}$	CL=90%

CONSTRAINED FIT INFORMATION

An overall fit to 85 branching ratios uses 170 measurements and one constraint to determine 46 parameters. The overall fit has a  $\chi^2 = 135.0$  for 125 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

Table of correlation coefficients for parameters x5, x9, x10, x14, x16, x20, x23, x27, x28, x30, x36, x38, x41, x43, x45, x48, x49, x52, x56, x61, x70, x78, x85, x89, x97, x103, x106, x107, x119, x120, x126, x127, x150, x151, x152, x154, x156, x160, x170, x173, x178, x179, x180, x182, x185. Includes column labels x3, x5, x9, x10, x14, x16, x20, x23, x27, x28.

### $\tau^-$ BRANCHING RATIOS

$$\Gamma(\text{particle}^- \geq 0 \text{ neutrals} \geq 0 K_S^0 \nu_\tau \text{ ("1-prong")}) / \Gamma_{\text{total}} \quad \Gamma_1 / \Gamma$$

$$\Gamma_1 / \Gamma = \Gamma_3 + \Gamma_5 + \Gamma_9 + \Gamma_{10} + \Gamma_{14} + \Gamma_{16} + \Gamma_{20} + \Gamma_{23} + \Gamma_{27} + \Gamma_{28} + \Gamma_{30} + \Gamma_{36} + \Gamma_{38} + \Gamma_{41} + \Gamma_{43} + \Gamma_{45} + \Gamma_{48} + \Gamma_{49} + \Gamma_{50} + \Gamma_{52} + \Gamma_{56} + \Gamma_{57} + 0.7196\Gamma_{150} + 0.7196\Gamma_{152} + 0.7196\Gamma_{154} + 0.7196\Gamma_{156} + 0.339\Gamma_{170} + 0.0835\Gamma_{178} + 0.0835\Gamma_{179} + 0.0835\Gamma_{180} / \Gamma$$

The charged particle here can be  $e$ ,  $\mu$ , or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below.

<sup>6</sup> Error correlated with BALTRUSAITIS 85  $e \nu \bar{\nu}$  value.

$\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma) / \Gamma_{\text{total}}$   $\Gamma_4 / \Gamma$

Table with columns: VALUE (%), EVTS, DOCUMENT ID, TECN, COMMENT. Includes 'OUR AVERAGE' and data from SHIMIZU, LEES, BERGFELD, ALEXANDER, WU.

- • • We do not use the following data for averages, fits, limits, etc. • • •
1 SHIMIZU 18A impose requirements on detected  $\gamma$ 's corresponding to a  $\tau$ -rest-frame energy cutoff  $E_\gamma^* > 10$  MeV.
2 LEES 15G impose requirements on detected  $\gamma$ 's corresponding to a  $\tau$ -rest-frame energy cutoff  $E_\gamma^* > 10$  MeV.
3 BERGFELD 00 impose requirements on detected  $\gamma$ 's corresponding to a  $\tau$ -rest-frame energy cutoff  $E_\gamma^* > 10$  MeV. For  $E_\gamma^* > 20$  MeV, they quote  $(3.04 \pm 0.14 \pm 0.30) \times 10^{-3}$ .
4 ALEXANDER 96S impose requirements on detected  $\gamma$ 's corresponding to a  $\tau$ -rest-frame energy cutoff  $E_\gamma > 20$  MeV.
5 WU 90 reports  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma) / \Gamma(\mu^- \bar{\nu}_\mu \nu_\tau) = 0.013 \pm 0.006$ , which is converted to  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma) / \Gamma_{\text{total}}$  using  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma) / \Gamma_{\text{total}} = 17.35\%$ . Requirements on detected  $\gamma$ 's correspond to a  $\tau$  rest frame energy cutoff  $E_\gamma > 37$  MeV.

$\Gamma(e^- \bar{\nu}_e \nu_\tau) / \Gamma_{\text{total}}$   $\Gamma_5 / \Gamma$

To minimize the effect of experiments with large systematic errors, we exclude experiments which together would contribute 5% of the weight in the average.

- BARATE 98E reconstruct  $K^0$ 's using  $K_S^0 \rightarrow \pi^+ \pi^-$  decays. They determine the  $\bar{K}^0 \rho^-$  fraction in  $\tau^- \rightarrow \pi^- \bar{K}^0 \pi^0 \nu_\tau$  decays to be  $(0.64 \pm 0.09 \pm 0.10)$  and multiply their  $B(\pi^- \bar{K}^0 \pi^0 \nu_\tau)$  measurement by this fraction to obtain the quoted result.

$\Gamma(K^- K^0 \pi^0 \nu_\tau) / \Gamma_{\text{total}}$   $\Gamma_{43} / \Gamma$

<sup>1</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type  $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \bar{\nu}_\tau)$ , and their charged conjugates.  
<sup>2</sup> ABE 97O assume  $\eta = 0$  in their fit. Letting  $\eta$  vary in the fit gives a  $\rho$  value of  $0.69 \pm 0.13 \pm 0.05$ .  
<sup>3</sup> Value is from a simultaneous fit for the  $\rho$  and  $\eta$  decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E  $\rho(e \text{ or } \mu)$  value which assumes  $\eta = 0$ . Result is strongly correlated with ALBRECHT 95C.  
<sup>4</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.

**$\rho(e)$  PARAMETER**

## Heavy Charged Lepton Searches

### Charged Heavy Lepton MASS LIMITS

#### Sequential Charged Heavy Lepton ( $L^\pm$ ) MASS LIMITS

These experiments assumed that a fourth generation  $L^\pm$  decayed to a fourth generation  $\nu_L$  (or  $L^0$ ) where  $\nu_L$  was stable, or that  $L^\pm$  decays to a light  $\nu_L$  via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, i.e.  $L^{*0} \rightarrow \ell\gamma$ . See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

- ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass  $> 40$  GeV.
- The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels  $L^- \rightarrow e\gamma$ ,  $L^- \rightarrow \nu W^-$ ,  $L^- \rightarrow eZ$ ; and  $L^0 \rightarrow \nu\gamma$ ,  $L^0 \rightarrow e^- W^+$ ,  $L^- \rightarrow \nu Z$ , where the  $W$  decays to  $\ell\nu_\ell$ , or to jets, and  $Z$  decays to  $\ell^+ \ell^-$  or jets.
- RILES 90 limits were the result of a special analysis of the data in the case where the mass difference  $m_{L^-} - m_{L^0}$  was allowed to be quite small, where  $L^0$  denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced  $m_{L^\pm}$  range, the mass difference extends to about 4 GeV.
- STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton ( $L^+$ ) mass for the generalized case in which the corresponding neutral heavy lepton ( $L^0$ ) in the SU(2) doublet is not of negligible mass.
- ABE 88 search for  $L^+$  and  $L^- \rightarrow$  hadrons looking for acoplanar jets. The bound is valid for  $m_\nu < 10$  GeV.
- ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy.  $E_{cm}^{ee} = 52$  GeV.
- Assumes associated neutrino is approximately massless.
- ADEVA 85 analyze one-isolated-muon data and sensitive to  $\tau < 10$  nanosec. Assume  $B(\text{lepton}) = 0.30$ .  $E_{cm} = 40\text{--}47$  GeV.
- BARTEL 83 limit is from PETRA  $e^+e^-$  experiment with average  $E_{cm} = 34.2$  GeV.
- BERGER 81B is DESY DORIS and PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .
- BRANDELIK 81 is DESY-PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .
- AZIMOV 80 estimated probabilities for  $M + N$  type events in  $e^+e^- \rightarrow L^+L^-$  deducing semi-hadronic decay multiplicities of  $L$  from  $e^+e^-$  annihilation data at  $E_{cm} = (2/3)m_L$ . Obtained above limit comparing these with  $e^+e^-$  data (BRANDELIK 80).
- BARBER 80B looked for  $e^+e^- \rightarrow L^+L^-$ ,  $L \rightarrow \nu^+ X$  with MARK-J at DESY-PETRA.
- ROTHE 69 examines previous data on  $\mu$  pair production and  $\pi$  and  $K$  decays.

## Neutrino Properties

## NEUTRINO PROPERTIES

Revised July 2023 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The Neutrino Properties Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, so far only limits, actually concern superpositions of the mass eigenstates  $\nu_i$ , which are in turn related to the weak eigenstates  $\nu_\ell$ , via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i} |\nu_i\rangle.$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a “dominant eigenstate” approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot therefore associate any particular state  $|\nu_i\rangle$  with any particular lepton label  $e, \mu$  or  $\tau$ . Nevertheless, note that in the standard labeling the  $|\nu_1\rangle$  has the largest  $|\nu_e\rangle$  component ( $\sim 2/3$ ),  $|\nu_2\rangle$  contains  $\sim 1/3$  of the  $|\nu_e\rangle$  component and  $|\nu_3\rangle$  contains only a small  $\sim 2.5\%$   $|\nu_e\rangle$  component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and

charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters  $|U_{\ell i}|^2$ , but to some extent also on experimental conditions (e.g., on energy resolution). Many of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos and are unaffected by  $CP$  phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity  $m_{\nu_e}^{2(eff)} = \sum_i |U_{ei}|^2 m_{\nu_i}^2$  is determined or constrained, where the sum is over all mass eigenvalues  $m_{\nu_i}$  that are too close together to be resolved experimentally. (The quantity  $m_{\nu_e}^{eff} \equiv \sqrt{m_{\nu_e}^{2(eff)}}$  is often denoted  $\langle m_\beta \rangle$  in the literature.) If the energy resolution is better than  $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$ , the corresponding heavier  $m_{\nu_i}$  and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

The dependence of  $m_{\nu_e}$  on the mass of the lightest neutrino is shown in Fig. 14.11 of the *Neutrino Masses, Mixing, and Oscillations* review. In the case of inverted ordering there is a minimum possible value of  $m_{\nu_e}^{eff}$ , approximately  $\sqrt{(\Delta m_{32}^2)} \sim 50$  meV. If  $m_{\nu_e}^{eff}$  is found to be larger than this value, it is impossible, based on this information only, to decide which ordering is realized in nature. On the other hand, if the  $m_{\nu_e}^{eff}$  is less than  $\sim 50$  meV, only the normal mass ordering is possible.

A limit on  $m_{\nu_e}^{2(eff)}$  implies an upper limit on the minimum value  $m_{min}^2$  of  $m_{\nu_i}^2$ , independent of the mixing parameters  $U_{ei}$ :  $m_{min}^2 \leq m_{\nu_e}^{2(eff)}$ . However, if and when the value of  $m_{\nu_e}^{2(eff)}$  is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences  $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$ , including eventually also their signs, and the mixing parameters  $|U_{ei}|^2$ , the individual neutrino mass squares  $m_{\nu_j}^2 = m_{\nu_e}^{2(eff)} - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$  can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting, i.e. sterile, neutrino species that might be observable since they couple, albeit weakly, to the flavor neutrinos  $|\nu_l\rangle$ . In that case, the neutrino mixing matrix would be  $n \times n$  unitary matrix with  $n > 3$ .

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given  $|\Delta m_{ij}^2|$  a limit on  $m_{\nu_e}^{2(eff)}$  from beta decay defines an upper limit on the maximum value  $m_{max}$  of  $m_{\nu_i}$ :  $m_{max}^2 \leq m_{\nu_e}^{2(eff)} + \sum_{i < j} |\Delta m_{ij}^2|$ . The analysis of the low energy

See key on page 1171

# Lepton Particle Listings

## Neutrino Properties

beta decay of tritium, combined with the oscillation results, thus limits *all* active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay  $\pi^+ \rightarrow \mu^+ + \nu_\mu$  or the shape of the spectrum of decay products of the  $\tau$  lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the  $\mu$  and  $\tau$  based neutrino mass. After the determination of the  $|\Delta m_{ij}^2|$ 's and the mixing angles  $\theta_{ij}$ , the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to  $\langle m_\beta \rangle \equiv \sqrt{m_{\nu_e}^{2(eff)}}$ . This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint, or eventually a value, of the sum of the neutrino masses  $m_{tot}$  can be determined from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table ( Sum of Neutrino Masses,  $m_{tot}$ ). Obviously,  $m_{tot}$  represents an upper limit for all  $m_i$  values. Note that many reported  $m_{tot}$  limits are considerably more stringent than the listed  $m_{\nu_e}^{eff}$  limits. Discussion concerning the model dependence of the  $m_{tot}$  limit is continuing.

### $\bar{\nu}$ MASS (electron based)

Those limits given below are for the square root of  $m_{\nu_e}^{2(eff)} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ . Limits that come from the kinematics of  ${}^3\text{H} \beta^- \bar{\nu}$  decay are the square roots of the limits for  $m_{\nu_e}^{2(eff)}$ . Obtained from the measurements reported in the Listings for " $\bar{\nu}$  Mass Squared," below.

<sup>1</sup> AKER 22 derive an upper limit on the kinematical neutrino mass using Tritium  $\beta$ -decay and the KATRIN spectrometer. The constraint is based on combining the first two science runs. Supersedes AKER 19.

<sup>2</sup> ESFAHANI 23 report the first continuous-spectrum measurement of  ${}^3\text{H} \beta$  decay, using cyclotron radiation emission spectroscopy (CRES) and a small demonstration detector. The energy resolution at the endpoint is demonstrated using  ${}^{83m}\text{Kr}$  and a kinematical neutrino mass limit derived from the spectral shape. A frequentist analysis obtained a limit of <15.2 eV.

- <sup>3</sup> AKER 19 report a neutrino mass limit, derived from the first month of data collected by the KATRIN tritium endpoint experiment. The analysis of the electron kinematics shows no evidence for neutrino mass. The quoted result is based on a frequentist analysis of the data following the method described in LOKHOV 15. Using the method of Feldman and Cousins, the derived upper limit is < 0.8 eV at 90% C.L. Superseded by AKER 22.
- <sup>4</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of  $m_\nu$ , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for  $m_\nu^2$ . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.
- <sup>5</sup> PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.
- <sup>6</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.
- <sup>7</sup> ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using  $\beta$ -decay of  ${}^{187}\text{Re}$ . Bolometric AgReO<sub>4</sub> micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium  $\beta$ -decays but has different systematic uncertainties.
- <sup>8</sup> LOREDO 02 updates LOREDO 89.
- <sup>9</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to  $m_\nu^2$ , making unambiguous interpretation difficult. See the footnote under " $\bar{\nu}$  Mass Squared."
- <sup>10</sup> WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable  $m_\nu^2$ . We report the most conservative limit, but the other is nearly the same. See the footnote under " $\bar{\nu}$  Mass Squared."
- <sup>11</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium source. A fit to a normal Kurie plot above 18300-18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7-15 eV below the endpoint yields  $m_\nu^2 = -4.1 \pm 10.9 \text{ eV}^2$ , leading to this Bayesian limit.
- <sup>12</sup> CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of  $m_\nu^2$  is given.
- <sup>13</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean  $m_\nu^2 = 221 \pm 4244 \text{ eV}^2$  from the two runs listed below.
- <sup>14</sup> STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the  $m_\nu^2$  errors given below but with  $m_\nu^2$  set equal to 0. The anomalous endpoint accumulation leads to a value of  $m_\nu^2$  which is negative by more than 5 standard deviations.
- <sup>15</sup> WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- <sup>16</sup> HOLZSCHUH 92B (Zurich) result is obtained from the measurement  $m_\nu^2 = -24 \pm 48 \pm 61$  ( $1\sigma$  errors), in  $\text{eV}^2$ , using the PDG prescription for conversion to a limit in  $m_\nu$ .
- <sup>17</sup> KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the  $m_\nu^2$  limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.
- <sup>18</sup> ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_\nu$  lies between 17 and 40 eV. However, the probability of a positive  $m^2$  is only 3% if statistical and systematic error are combined in quadrature.
- <sup>19</sup> See also comment in BORIS 87B and erratum in BORIS 88.

### $\bar{\nu}$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimates of  $m_{\nu_e}^{2(eff)} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ , in many experiments, we use only KRAUS 05, LOBASHEV 99, and AKER 22 for our average.

<sup>1</sup> AKER 22 report results from the analysis of the Tritium  $\beta$  spectrum using the combined data set collected by the KATRIN experiment in the first two science runs. Supersedes AKER 19.

# Lepton Particle Listings

## Neutrino Properties

- <sup>2</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.
- <sup>3</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.
- <sup>4</sup> AKER 19 use the first month of data collected by the KATRIN experiment to determine  $m_{\nu}^2$ . The result is consistent with a neutrino mass of zero and is used to place a limit on  $m_{\nu}$ . Superseded by AKER 22.
- <sup>5</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted  $m_{\nu}^2 \approx -(20-10) \text{ eV}^2$ . This problem is attributed to a discrete spectral anomaly of about  $6 \times 10^{-11}$  intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of  $m_{\nu}^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$  which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived  $m_{\nu}^2$  limit makes unambiguous interpretation of this result difficult.
- <sup>6</sup> WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93. Using a lower temperature of the frozen tritium source eliminated the dewetting of the  $T_2$  film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable  $m_{\nu}^2$  fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.
- <sup>7</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.
- <sup>8</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.
- <sup>9</sup> STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for  $m_{\nu}^2$ . The authors acknowledge that “the negative value for the best fit of  $m_{\nu}^2$  has no physical meaning” and discuss possible explanations for this effect.
- <sup>10</sup> SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.
- <sup>11</sup> WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- <sup>12</sup> HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- <sup>13</sup> KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- <sup>14</sup> ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_{\nu}$  lies between 17 and 40 eV. However, the probability of a positive  $m_{\nu}^2$  is only 3% if statistical and systematic error are combined in quadrature.

### $\nu$ MASS (electron based)

These are measurement of  $m_{\nu}$  (in contrast to  $m_{\tau}$ , given above). The masses can be different for a Dirac neutrino in the absence of *CPT* invariance. The possible distinction between  $\nu$  and  $\bar{\nu}$  properties is usually ignored elsewhere in these Listings.

VALUE (eV)	CL%	DOCUMENT ID	TECN	COMMENT
<460	68	YASUMI 94	CNTR	<sup>163</sup> Ho decay
<225	95	SPRINGER 87	CNTR	<sup>163</sup> Ho decay

### $\nu$ MASS (muon based)

Limits given below are for the square root of  $m_{\nu_{\mu}}^{2(\text{eff})} \equiv \sum_i |U_{\tau i}|^2 m_{\nu_i}^2$ .

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the  $\pi^{\pm}$  mass and the ASSAMAGAN 96 value for the muon momentum for the  $\pi^{\pm}$  decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since  $m_{\nu_{\mu}}^{2(\text{eff})}$  is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;0.19 (CL = 90%) OUR EVALUATION</b>				
<0.17	90	1 ASSAMAGAN 96	SPEC	$m_{\nu}^2 = -0.016 \pm 0.023$

• • • We do not use the following data for averages, fits, limits, etc. • • •

<0.15		<sup>2</sup> DOLGOV 95	COSM	Nucleosynthesis
<0.48		<sup>3</sup> ENQVIST 93	COSM	Nucleosynthesis

<0.65	90	CLARK 74	ASPK	$K_{\mu 3}$ decay

<sup>1</sup> ASSAMAGAN 96 measurement of  $\rho_{\mu}$  from  $\pi^+ \rightarrow \mu^+ \nu$  at rest combined with JECKELMANN 94 Solution B pion mass yields  $m_{\nu}^2 = -0.016 \pm 0.023$  with corresponding Bayesian limit listed above. If Solution A is used,  $m_{\nu}^2 = -0.143 \pm 0.024 \text{ MeV}^2$ . Replaces ASSAMAGAN 94.

<sup>2</sup> DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

<sup>3</sup> ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1 \text{ s}$ .

<sup>4</sup> Assumes neutrino lifetime  $> 1 \text{ s}$ . For Dirac neutrinos only. See also ENQVIST 93.

<sup>5</sup> ANDERHUB 82 kinematics is insensitive to the pion mass.

### $\nu$ MASS (tau based)

The limits given below are the square roots of limits for  $m_{\nu_{\tau}}^{2(\text{eff})} \equiv \sum_i |U_{\tau i}|^2 m_{\nu_i}^2$ .

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

<sup>1</sup> BARATE 98F result based on kinematics of  $2939 \tau^- \rightarrow 2\pi^- \pi^+ \nu_{\tau}$  and  $52 \tau^- \rightarrow 3\pi^- 2\pi^+ (\pi^0) \nu_{\tau}$  decays. If possible 2.5% excited  $a_1$  decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.

<sup>2</sup> ATHANAS 00 bound comes from analysis of  $\tau^- \rightarrow \pi^- \pi^+ \pi^- \pi^0 \nu_{\tau}$  decays.

<sup>3</sup> ACKERSTAFF 98T use  $\tau^- \rightarrow 5\pi^{\pm} \nu_{\tau}$  decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using  $\tau^- \rightarrow 3h^{\pm} \nu_{\tau}$  decays to obtain quoted limit.

<sup>4</sup> AMMAR 98 limit comes from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_{\tau}$  and  $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_{\tau}$  decay modes.

<sup>5</sup> ANASTASSOV 97 derive limit by comparing their  $m_{\tau}$  measurement (which depends on  $m_{\nu_{\tau}}$ ) to BAI 96  $m_{\tau}$  threshold measurement.

<sup>6</sup> FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region  $< 0.93$  or  $> 31 \text{ MeV}$  is excluded. These bounds assume  $N_{\nu} < 4$  from nucleosynthesis; a wider excluded region occurs with a smaller  $N_{\nu}$  upper limit.

<sup>7</sup> SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for  $\tau^- \rightarrow e^- \bar{\nu}_e \nu_{\tau}, \tau^- \rightarrow \mu^- \bar{\nu}_{\mu} \nu_{\tau}, \tau^- \rightarrow \pi^- \nu_{\tau}$ , and  $\tau^- \rightarrow K^- \nu_{\tau}$ , and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO  $\tau$  mass measurement (BALEST 93) is included; see CLEO's more recent  $m_{\nu_{\tau}}$  limit (ANASTASSOV 97).

Consideration of mixing with a fourth generation heavy neutrino yields  $\sin^2 \theta_L < 0.016$  (95%CL).

See key on page 1171

# Lepton Particle Listings

## Neutrino Properties

- <sup>8</sup>ALEXANDER 96M bound comes from analyses of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow h^- h^- h^+ \nu_\tau$  decays.
- <sup>9</sup>BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.
- <sup>10</sup>HANNESTAD 96c limit is on the mass of a Majorana neutrino. This bound assumes  $N_\nu < 4$  from nucleosynthesis. A wider excluded region occurs with a smaller  $N_\nu$  upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96b.
- <sup>11</sup>SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.
- <sup>12</sup>BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of  $\tau \rightarrow 5\pi(\pi^0)\nu_\tau$  decays. Replaced by BARATE 98f.
- <sup>13</sup>DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.
- <sup>14</sup>SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between  $10^{-3}$  and  $10^8$  seconds if the decay products are predominantly  $\gamma$  or  $e^+e^-$ .
- <sup>15</sup>DODELSON 94 calculate constraints on  $\nu_\tau$  mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300s. For Dirac neutrinos limits change to  $< 0.3$  or  $> 33$ .
- <sup>16</sup>KAWASAKI 94 excluded region is for Majorana neutrino with lifetime  $> 1000$  s. Other limits are given as a function of  $\nu_\tau$  lifetime for decays of the type  $\nu_\tau \rightarrow \nu_\mu \phi$  where  $\phi$  is a Nambu-Goldstone boson.
- <sup>17</sup>PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions,  $m_3 < 70$  MeV and  $140$  MeV  $m_3 < 149$  MeV.
- <sup>18</sup>CINABRO 93 bound comes from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$  decay modes.
- <sup>19</sup>DOLGOV 93 assumes neutrino lifetime  $> 100$  s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.
- <sup>20</sup>ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1$  s.
- <sup>21</sup>ALBRECHT 92M reports measurement of a slightly lower  $\tau$  mass, which has the effect of reducing the  $\nu_\tau$  mass reported in ALBRECHT 88B. Bound is from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  mode.
- <sup>22</sup>Assumes neutrino lifetime  $> 1$  s. For Dirac neutrinos. See also ENQVIST 93.
- <sup>23</sup>KOLB 91 exclusion region is for Dirac neutrino with lifetime  $> 1$  s; other limits are given.

Revised August 2023 by K.A. Olive (University of Minnesota).

Neutrinos decouple from thermal equilibrium in the early universe at temperatures  $\mathcal{O}(1)$  MeV. The limits on low mass ( $m_\nu \lesssim 1$  MeV) neutrinos apply to  $m_{\text{tot}}$  given by

$$m_{\text{tot}} = \sum_\nu m_\nu .$$

Stable neutrinos in this mass range decouple from the thermal bath while still relativistic and make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\text{tot}} n_\nu \simeq m_{\text{tot}} (3/11) (3.045/3)^{3/4} n_\gamma ,$$

where the factor  $3/11$  is the ratio of (light) neutrinos to photons and the factor  $(3.045/3)^{3/4}$  corrects for the fact that the effective number of neutrinos in the standard model is 3.045 when taking into account  $e^+e^-$  annihilation during neutrino decoupling. Writing  $\Omega_\nu = \rho_\nu/\rho_c$ , where  $\rho_c$  is the critical energy density of the Universe, and using  $n_\gamma = 410.7 \text{ cm}^{-3}$ , we have

$$\Omega_\nu h^2 \simeq m_{\text{tot}} / (93 \text{ eV}) .$$

While an upper limit to the matter density of  $\Omega_m h^2 < 0.12$  would constrain  $m_{\text{tot}} < 11$  eV, much stronger constraints are obtained from the observations of the CMB, combined with

lensing and baryon acoustic oscillations data. These combine to give an upper limit of around 0.12 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses. The current lower bound of  $m_{\text{tot}} > 0.06$  eV implies a lower limit of  $\Omega_\nu h^2 > 6 \times 10^{-4}$ . See our review on "Neutrinos in Cosmology" for more details.

### SUM OF THE NEUTRINO MASSES, $m_{\text{tot}}$

This is a sum of the neutrino masses,  $m_{\text{tot}}$ , as defined in the above note, of effectively stable neutrinos, i.e. those with mean lifetimes on cosmological scales. When necessary, we have generalized the results reported so they apply to  $m_{\text{tot}}$ . For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85. For more information see a note on "Neutrinos in Cosmology" in this Review.

## Neutrino Properties

- <sup>4</sup> ABBOTT 21A combines Dark Energy Survey (DES) year 3 results with Planck CMB lensing measurements.
- <sup>5</sup> ALAM 21 limit on the sum of neutrino masses by the eBOSS collaboration is based on galaxy, quasar, and Lyman- $\alpha$  3D clustering data combined with Planck temperature and polarization CMB and supernovae data.
- <sup>6</sup> DI-VALENTINO 21 combines CMB temperature and polarization, SNIa luminosity distances and baryon acoustic oscillations data.
- <sup>7</sup> GARNY 21 employs a model for the Lyman- $\alpha$  flux power spectrum to set a limit using BOSS data. When combined with Planck CMB temperature and polarization data, a 95% CL range 0.10–0.13 eV is found.
- <sup>8</sup> STOCKER 21 use terrestrial and cosmological experiments to set a 95% CL range on the sum of neutrino masses of 0.058–0.139 eV for normal ordering and 0.098–0.174 eV for inverse ordering. They also set an upper limit of 0.037 eV (NO) and 0.042 eV (IO) for the lightest neutrino mass.
- <sup>9</sup> AGHANIM 20 limit on the sum of neutrino masses from Planck data combined with lensing and baryon acoustic oscillations (BAO). Without BAO, the limit relaxes to  $<0.24$  eV. Several other limits are quoted based on different combinations of data.
- <sup>10</sup> CHOUDHURY 20 combines 2018 Planck CMB temperature and polarization data plus lensing, together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS. Assumes  $\Lambda$ CDM model. The upper limit is 0.17 eV for the inverted hierarchy, and 0.12 eV for degenerate neutrinos. Limits are also derived for extended cosmological models.
- <sup>11</sup> IVANOV 20 combines 2018 Planck CMB data with baryon acoustic oscillation data from BOSS. This study is based on a full-shape likelihood for the redshift-space galaxy power spectrum of the BOSS data.
- <sup>12</sup> PALANQUE-DELABROUILLE 20 combine Lyman alpha and Planck temperature and polarization data. Limit improves to 0.09 eV when CMB lensing and baryon acoustic oscillation data are included.
- <sup>13</sup> LOUREIRO 19 combines data from large scale structure, cosmic microwave background, type Ia supernovae and big bang nucleosynthesis using physically motivated neutrino mass models.
- <sup>14</sup> UPADHYE 19 uses the shape of the BOSS redshift-space galaxy power spectrum in combination with the CMB, and supernovae data. Limit weakens to  $<0.54$  eV if the dark energy equation of state is allowed to vary.
- <sup>15</sup> CHOUDHURY 18 combines 2015 Planck CMB temperature data, information from the optical depth to reionization from Planck 2016 intermediate results together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS as well as supernovae Type Ia data from the Pantheon Sample. The limit is strengthened to 0.118 eV when high- $l$  CMB polarization data is also included.
- <sup>16</sup> SIMPSON 17 uses a combination of laboratory and cosmological measurements to determine the light neutrino masses and argue that there is strong evidence for the normal mass ordering.
- <sup>17</sup> Constrains the total mass of neutrinos using the Lyman- $\alpha$  forest power spectrum with BOSS (mid-resolution), XQ-100 (high-resolution) and CMB. Without the CMB data, the limit relaxes to 0.8 eV. Supersedes PALANQUE-DELABROUILLE 15A.
- <sup>18</sup> Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation and Planck cluster data.
- <sup>19</sup> Constrains the total mass of neutrinos from BAO data from SDSS-II/BOSS combined with CMB data from Planck. Limit quoted for normal mass hierarchy. The limit for the inverted mass hierarchy is 0.20 eV and for the degenerate mass hierarchy it is 0.15 eV.
- <sup>20</sup> ROSSI 15 sets limits on the sum of neutrino masses using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.
- <sup>21</sup> Constrains the total mass of neutrinos from Planck CMB data along with WMAP polarization, high  $l$ , and BAO data.
- <sup>22</sup> Finite neutrino mass fit to resolve discrepancy between CMB and lensing measurements.
- <sup>23</sup> Fit to the total mass of neutrinos from BOSS data along with WMAP CMB data and data from other BAO constraints and weak lensing.
- <sup>24</sup> Fit to the total mass of neutrinos from Planck CMB data along with BAO.
- <sup>25</sup> Fit based on the SPT-SZ survey combined with CMB, BAO, and  $H_0$  data.
- <sup>26</sup> Constrains the total mass of neutrinos (marginalizing over the effective number of neutrino species) from CMB, CMB lensing, BAO, and galaxy clustering data.
- <sup>27</sup> Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS, 6dFGS, SDSS, WiggleZ data on the galaxy power spectrum, and HST data on the Hubble parameter. The limit is increased to 0.25 eV if a lower bound to the sum of neutrino masses of 0.04 eV is assumed.
- <sup>28</sup> Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of  $H_0$ .
- <sup>29</sup> Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.
- <sup>30</sup> Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.
- <sup>31</sup> Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.
- <sup>32</sup> Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of  $H_0$  (SHOES), and baryon acoustic oscillation data from SDSS.
- <sup>33</sup> Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter,  $w \neq -1$ .
- <sup>34</sup> Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes  $\Lambda$ CDM model.
- <sup>35</sup> Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the  $\Lambda$ CDM model. Supersedes SPERGEL 07.

- <sup>36</sup> Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to  $0.03 < \Sigma m_\nu < 0.54$  eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes  $\Lambda$ CDM model.
- <sup>37</sup> Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state,  $w$ .
- <sup>38</sup> Constrains the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes  $\Lambda$ CDM model. Limit degrades to 0.59 eV in a more general  $w$ CDM model.
- <sup>39</sup> Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.
- <sup>40</sup> Constrains the total mass of neutrinos from recent CMB, large scale structure, SNIa, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- <sup>41</sup> Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.
- <sup>42</sup> Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SNIa data.
- <sup>43</sup> Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- <sup>44</sup> Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.
- <sup>45</sup> Constrains the total mass of neutrinos from the CMB experiments alone, assuming  $\Lambda$ CDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- <sup>46</sup> Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- <sup>47</sup> Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.
- <sup>48</sup> Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dFGRS data, and Lyman  $\alpha$  data. The limit does not noticeably change if the Lyman  $\alpha$  data are not used.
- <sup>49</sup> LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.
- <sup>50</sup> WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman  $\alpha$  forest.
- <sup>51</sup> FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale  $\sigma_8$  and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.
- <sup>52</sup> CROFT 99 result based on the power spectrum of the Ly  $\alpha$  forest. If  $\Omega_{\text{matter}} < 0.5$ , the limit is improved to  $m_\nu < 2.4 (\Omega_{\text{matter}}/0.17-1)$  eV.

### Limits on MASSES of Light Stable Right-Handed $\nu$ (with necessarily suppressed interaction strengths)

VALUE (eV)	DOCUMENT ID	TECN	COMMENT
------------	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$<100-200$	<sup>1</sup> OLIVE	82	COSM Dirac $\nu$
$<200-2000$	<sup>1</sup> OLIVE	82	COSM Majorana $\nu$

<sup>1</sup> Depending on interaction strength  $G_R$  where  $G_R < G_F$ .

### Limits on MASSES of Heavy Stable Right-Handed $\nu$ (with necessarily suppressed interaction strengths)

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
-------------	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$>10$	<sup>1</sup> OLIVE	82	COSM $G_R/G_F < 0.1$
$>100$	<sup>1</sup> OLIVE	82	COSM $G_R/G_F < 0.01$

<sup>1</sup> These results apply to heavy Majorana neutrinos and are summarized by the equation:  $m_\nu > 1.2 \text{ GeV } (G_F/G_R)$ . The bound saturates, and if  $G_R$  is too small no mass range is allowed.

### $\nu$ CHARGE

$e$  = electron charge is the unit of values listed below.

- CAPRINI 05 limit derived from the lack of a charge asymmetry in the universe. Limit assumes that charge asymmetries between particles are not anti-correlated.
- AALBERS 23A utilize the first 60 days of data collected by the LZ dark matter search to place a limit on the electric charge of solar neutrinos. Low energy electron-recoil events are utilized. This LZ-collaboration analysis supersedes that of the external authors in ATZORI-CORONA 23 because of a more complete treatment of experiment uncertainties.
- ATZORI-CORONA 23 use LUX-ZEPLIN dark matter search data published by AALBERS 23 to place a limit on neutrino millicharge.
- BONET 22A use data collected by four low-threshold Ge detectors, placed 17.1 m from one of the cores of the nuclear reactors at Brokdorf to derive this limit. A spectral analysis is performed on reactor on and off data.
- ABE 20E obtains this result by assuming that the low-energy excess events in the XMAS detector are produced by neutrino millicharge which is common for all three neutrino flavors.
- KHAN 20 performed a constrained spectral fit analysis of the excess observed in the electron recoil energy spectrum by the XENON1T experiment. This range of neutrino millicharge values is one of the possible interpretations of these excess events. For the individual flavor constraints at 90% C.L. see the original reference.
- DELLA-VALLE 16 obtain a limit on the charge of neutrinos valid for masses of less than 10 MeV. For heavier neutrinos the limit increases as a power of mass, reaching  $10^{-6} e$  for  $m = 100$  MeV.
- CHEN 14A use the Multi-Configuration RHPA method to analyze reactor  $\bar{\nu}_e$  scattering on Ge atoms with 300 eV recoil energy threshold to obtain this limit.
- STUDENIKIN 14 uses the limit on  $\mu_{\nu}$  from BEDA 13 and the 2.8 keV threshold of the electron recoil energy to obtain this limit.
- GNINENKO 07 use limit on  $\bar{\nu}_e$  magnetic moment from LI 03b to derive this result. The limit is considerably weaker than the limits on the charge of  $\nu_e$  and  $\bar{\nu}_e$  from various astrophysics considerations.
- This RAFFELT 99 limit applies to all neutrino flavors which are light enough ( $<5$  keV) to be emitted from globular-cluster red giants.
- This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough ( $<1$  keV) to be emitted from the sun.
- BABU 94 use COOPER-SARKAR 92 limit on  $\nu$  magnetic moment to derive quoted result. It applies to  $\nu_\tau$ .
- DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to  $\nu_\tau$ .
- Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to  $\nu_e$ .
- The limit applies to all flavors.

$> 3. \times 10^{-3}$	90	34 BELLOTTI	76 HLBC	$\nu$ , CERN GGM
$> 1.3 \times 10^{-2}$	90	34 BELLOTTI	76 HLBC	$\bar{\nu}$ , CERN GGM

- KRAKAUER 91 quotes the limit  $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3)$  s/eV, where  $a$  is a parameter describing the asymmetry in the neutrino decay defined as  $dN_{\nu_1}/dcos\theta = (1/2)(1 + a\cos\theta)$ . The parameter  $a = 0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).
- RAFFELT 85 limit on the radiative decay is from solar x- and  $\gamma$ -ray fluxes. Limit depends on  $\nu$  flux from  $p\bar{p}$ , now established from GALLEX and SAGE to be  $> 0.5$  of expectation.
- REINES 74 looked for  $\nu$  of nonzero mass decaying radiatively to a neutral of lesser mass  $+\gamma$ . Used liquid scintillator detector near fission reactor. Finds lab lifetime  $6 \times 10^7$  s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit  $6 \times 10^7$  s REINES 74 assumed that the full  $\bar{\nu}_e$  reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV - 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.
- IVANEZ-BALLESTROS 23 reports a limit on the lifetime-to-mass ratio of the mass eigenstates  $\nu_1$  and  $\nu_2$  for inverted mass ordering. No limit was obtained in the case of normal mass ordering.
- AHARMIM 19 quotes the limit  $\tau/m_{\nu_2}$  for invisible nonradiative decay of  $\nu_2$ . They obtained this result by analyzing the entire SNO dataset, allowing for the decay of  $\nu_2$  which would cause an energy-dependent distortion of the survival probability of electron-type solar neutrinos.
- AHARMIM 19 quotes the limit  $\tau/m_{\nu_2}$  for invisible nonradiative decay of  $\nu_2$ . They obtained this result by combining the  $\tau/m_{\nu_2}$  measurements from SNO and other solar neutrino experiments (Super-Kamiokande, KamLAND, and Borexino  $^8\text{B}$  results; Borexino and KamLAND  $^7\text{Be}$  results; the combined gallium interaction rate from GNO, GALLEX, and SAGE; and the chlorine interaction rate from Homestake). The quoted limit at 99% CL is  $> 1.04 \times 10^{-3}$ .
- ESCUDERO 19 sets limits on invisible neutrino decays using Planck 2018 data of  $\tau > 1.3-0.3 \times 10^9$  s at 95% C.L. Values in the range  $\tau = 2-16 \times 10^9$  s are preferred at 95% C.L. when Planck polarization data is included. Limits scale as  $(m_{\nu}/0.05 \text{ eV})^3$ .
- CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of  $\nu_1$  masses between  $10^{-4}$  and 0.1 eV.
- MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay  $\nu_2 \rightarrow \nu_1$  the lifetime limit is  $\lesssim 4 \times 10^{20}$  s for  $m_{\min} \lesssim 0.14$  eV. For transition with the  $|\Delta m_{31}|$  mass difference the lifetime limit is  $\sim 2 \times 10^{19}$  s for  $m_{\min} \lesssim 0.14$  eV and  $\sim 5 \times 10^{20}$  s for  $m_{\min} \gtrsim 0.14$  eV.

### $\nu$ (MEAN LIFE) / MASS

Measures  $[\sum |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$ , where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any  $\nu$  within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for  $\nu_i \rightarrow \nu_j + \gamma$

$$\text{is constrained by } \Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m^2} \mu_{ij}^2 \text{ where } \mu_{ij} \text{ is the neutrino}$$

transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

## Lepton Particle Listings

## Neutrino Properties

- <sup>10</sup> MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the  $|\Delta m_{31}|$  mass difference they obtain the lifetime limit  $\sim 10^{20}$  s for  $m_{\min} \lesssim 0.14$  eV.
- <sup>11</sup> WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3}$  eV<sup>2</sup> to obtain  $\tau_{13}/m_1^3 > 3.2 \times 10^{27}$  s/eV<sup>3</sup> for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ .
- <sup>12</sup> XIN 05 search for the  $\gamma$  from radiative decay of  $\nu_e$  produced by the electron capture on <sup>51</sup>Cr. No events were seen and the limit on  $\tau/m_\nu$  was derived. This is a weaker limit on the decay of  $\nu_e$  than KRAKAUER 91.
- <sup>13</sup> XIN 05 use their limit on the neutrino magnetic moment of  $\nu_e$  together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3}$  eV<sup>2</sup> to obtain  $\tau_{13}/m_1^3 > 1 \times 10^{23}$  s/eV<sup>3</sup> for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ . Again, this limit is specific for  $\nu_e$ .
- <sup>14</sup> AHARMIM 04 obtained these results from the solar  $\bar{\nu}_e$  flux limit set by the SNO measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \bar{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- <sup>15</sup> CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a  $\tau/m_{\nu_2}$  in  $\nu_2 \rightarrow \nu_1 \gamma$ . Limit ranges from  $\sim 100$  to  $10^7$  s/eV for  $0.01 < m_{\nu_1} < 0.1$  eV.
- <sup>16</sup> EGUCHI 04 obtained these results from the solar  $\bar{\nu}_e$  flux limit set by the KamLAND measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \bar{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- <sup>17</sup> The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for  $\nu_2$ . They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino state and  $\nu_2$  decays through nonradiative Majoron emission process,  $\nu_2 \rightarrow \bar{\nu}_1 + J$ , or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.
- <sup>18</sup> DERBIN 02b (also BACK 03b) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as  $dN_\gamma/d\cos\theta = (1/2)(1 + \alpha\cos\theta)$  with  $\alpha=0$  for a Majorana neutrino, and  $\alpha$  varying to  $-1$  to  $1$  for a Dirac neutrino. The listed bound is for the case of  $\alpha=0$ . The most conservative bound  $1.5 \times 10^{13}$  s eV<sup>-1</sup> is obtained for the case of  $\alpha=-1$ .
- <sup>19</sup> The ratio of the lifetime over the mass derived by JOSHIPURA 02b is for  $\nu_2$ . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino state and  $\nu_2$  decays through nonradiative process like Majoron emission decay,  $\nu_2 \rightarrow \nu'_1 + J$  where  $\nu'_1$  state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.
- <sup>20</sup> DOLGOV 99 places limits in the (Majorana)  $\tau$ -associated  $\nu$  mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.
- <sup>21</sup> BILLER 98 use the observed TeV  $\gamma$ -ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows  $\tau_\nu/B_\gamma > 0.15 \times 10^{21}$  s at 0.05 eV,  $> 1.2 \times 10^{21}$  s at 0.17 eV,  $> 3 \times 10^{21}$  s at 1 eV, where  $B_\gamma$  is the branching ratio to photons.
- <sup>22</sup> BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
- <sup>23</sup> Limit on the radiative decay based on nonobservation of  $\gamma$ 's in coincidence with  $\nu$ 's from SN 1987A.
- <sup>24</sup> DODELSON 92 range is for wrong-helicity keV mass Dirac  $\nu$ 's from the core of neutron star in SN 1987A decaying to  $\nu$ 's that would have interacted in KAM2 or IMB detectors.
- <sup>25</sup> GRANEK 91 considers heavy neutrino decays to  $\gamma\nu_L$  and  $3\nu_L$ , where  $m_{\nu_L} < 100$  keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into  $\gamma\nu_L$ , and  $m_{\nu_L}$ .
- <sup>26</sup> KRAKAUER 91 quotes the limit for  $\nu_e$ ,  $\tau/m_\nu > (0.3a^2 + 9.8a + 15.9)$  s/eV, where  $a$  is a parameter describing the asymmetry in the radiative neutrino decay defined as  $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$   $a=0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).
- <sup>27</sup> WALKER 90 uses SN 1987A  $\gamma$  flux limits after 289 days.
- <sup>28</sup> CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
- <sup>29</sup> RAFFELT 89 uses KYULDJIEV 84 to obtain  $\tau m^3 > 3 \times 10^{18}$  s eV<sup>3</sup> (based on  $\bar{\nu}_e e^-$  cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.
- <sup>30</sup> RAFFELT 89b analyze stellar evolution and exclude the region  $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21}$  s eV<sup>3</sup>.
- <sup>31</sup> Model-dependent theoretical analysis of SN 1987A neutrinos. Quoted limit is for  $[\sum_j |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$ , where  $\ell = \mu, \tau$ . Limit is  $3.3 \times 10^{14}$  s/eV for  $\ell = e$ .
- <sup>32</sup> OBERAUER 87 looks for photons and  $e^+e^-$  pairs from radiative decays of reactor neutrinos.

<sup>33</sup> BINETRUY 84 finds  $\tau < 10^8$  s for neutrinos in a radiation-dominated universe.

<sup>34</sup> These experiments look for  $\nu_k \rightarrow \nu_j \gamma$  or  $\bar{\nu}_k \rightarrow \bar{\nu}_j \gamma$ .

<sup>35</sup> STECKER 80 limit based on UV background; result given is  $\tau > 4 \times 10^{22}$  s at  $m_\nu = 20$  eV.

<sup>36</sup> FALK 78 finds lifetime constraints based on supernova energetics.

<sup>37</sup> COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require  $\tau > 10^{23}$  s for  $m_\nu \sim 1$  eV. See also COWSIK 79 and GOLDMAN 79.

 $\nu$  MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is characterized by a  $3 \times 3$  matrix  $\lambda$  of the magnetic ( $\mu$ ) and electric ( $d$ ) dipole moments ( $\lambda = \mu - id$ ). For Majorana neutrinos the matrix  $\lambda$  is antisymmetric and only transition moments are allowed, while for Dirac neutrinos  $\lambda$  is a general  $3 \times 3$  matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80)  $\mu_\nu = 3eG_F m_\nu / (8\pi^2 \sqrt{2}) = 3.2 \times 10^{-19} (m_\nu / \text{eV}) \mu_B$ , i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on  $\lambda$  are obtained via elastic  $\nu$ - $e$  scattering, where the scattered neutrino is not observed. The combinations of matrix elements of  $\lambda$  that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar  $\nu_e$  and reactor  $\bar{\nu}_e$  do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$  collider experiments.

- 1 APRILE 22b use data collected with the XENONnT dark matter detector to place a limit on an enhanced magnetic moment of solar neutrinos. Supersedes APRILE 20.
- 2 BEDA 13 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor  $\bar{\nu}_e$ .
- 3 AUERBACH 01 limit is based on the LSND  $\nu_e$  and  $\nu_\mu$  electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.
- 4 SCHWIENHORST 01 quote an experimental sensitivity of  $4.9 \times 10^{-7}$ .
- 5 AALBERS 23a utilize the first 60 days of data collected by the LZ dark matter search to place a limit on the magnetic moment of solar neutrinos. Low energy electron-recoil events are utilized. This LZ-collaboration analysis supersedes that of the external authors in ATZORI-CORONA 23 because of a more complete treatment of experiment uncertainties.
- 6 ATZORI-CORONA 23 use LUX-ZEPLIN dark matter search data published by AALBERS 23 to place a limit on an enhanced magnetic moment of solar neutrinos.
- 7 BONET 22a use data collected by four low-threshold Ge detectors, placed 17.1 m from one of the cores of the nuclear reactors at Brokdorf to derive this limit. A spectral analysis is performed on reactor on and off data.
- 8 COLOMA 22 present a re-analysis of data taken by the COHERENT and Dresden-II experiments. The combination of both experiments is used to place a limit on the magnetic moment of electron-type neutrinos. The presented value is one-sided limit as recommended by the authors; the two-sided limit is  $< 3.2 \times 10^{-10} \mu_B$  at 90% C.L. Results based on Fe and Yb quenching models are reported in the paper. The authors are not part of either collaboration.
- 9 ABE 20e observed an excess of low-energy events in the XMASS detector, which could be interpreted as a signal produced by a neutrino magnetic moment with this magnitude.
- 10 APRILE 20 observed an excess of low-energy events in the XENON1T detector, which could be interpreted as a signal produced by a neutrino magnetic moment with this magnitude.
- 11 CAPOZZI 20 obtains a limit on the neutrino dipole moment from the brightness of the tip of the red-giant branch in  $\omega$  Centauri. A similar limit of  $\mu_\nu < 1.5 \times 10^{-12} \mu_B$  is obtained in NGC 4258.
- 12 KHAN 20 performed a constrained spectral fit analysis of the excess observed in the electron recoil energy spectrum by the XENON1T experiment. This range of the  $\mu_B$  values is one of the possible interpretations of these excess events. For the individual flavor constraints at 90% C.L. see the original reference.
- 13 AGOSTINI 17a obtained this limit using the shape of the recoil electron energy spectrum from the Borexino Phase-II 1291.5 live days of solar neutrino data and the constraints on the sum of the solar neutrino fluxes from the radiochemical gallium experiments SAGE, Gallex, and GNO. Without radiochemical constraints, the 90% C.L. limit of  $< 4.0 \times 10^{-11} \mu_B$  is obtained.
- 14 ARCEO-DIAZ 15 constrains the neutrino magnetic moment from observation of the tip of the red giant branch in the globular cluster  $\omega$ -Centauri.
- 15 CORSICO 14 constrains the neutrino magnetic moment from observations of white dwarf pulsations.
- 16 MILLER-BERTOLAMI 14b constrains the neutrino magnetic moment from observations of the white dwarf luminosity function of the Galactic disk.
- 17 VIAUX 13a constrains the neutrino magnetic moment from observations of the globular cluster M5.
- 18 BEDA 10 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Superseded by BEDA 13.
- 19 DENIZ 10 observe reactor  $\bar{\nu}_e$  scattering with recoil kinetic energies 3-8 MeV using Cs(I) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  magnetic moment.
- 20 KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.
- 21 ARPESELLA 08a obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.
- 22 BEDA 07 performed search for electromagnetic  $\bar{\nu}_e$ -e scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.

- 23 WONG 07 performed search for non-standard  $\bar{\nu}_e$ -e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor  $\bar{\nu}_e$ . Supersedes LI 03b.
- 24 DARAKTCHIEVA 05 present the final analysis of the search for non-standard  $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.
- 25 XIN 05 evaluated the  $\nu_e$  flux at the Kuo-Sheng nuclear reactor and searched for non-standard  $\nu_e$ -e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor  $\bar{\nu}_e$ , but is specific to  $\nu_e$ .
- 26 GRIFOLS 04 obtained this bound using the SNO data of the solar  $^8\text{B}$  neutrino flux measured with deuteron breakup. This bound applies to  $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$ .
- 27 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments,  $\mu_{\nu 1} = \mu_{\nu 2}$ . This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- 28 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND.  $\mu_{\nu 1} = \mu_{\nu 2}$  is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- 29 BACK 03b obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios (see BEACOM 99).
- 30 DARAKTCHIEVA 03 searched for non-standard  $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.
- 31 LI 03b used Ge detector in active shield near nuclear reactor to test for nonstandard  $\bar{\nu}_e$ -e scattering.
- 32 GRIMOUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of  $6.3 \times 10^{-10} \mu_B$  is obtained.
- 33 TANIMOTO 00 combined  $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$  data from VENUS, TOPAZ, and AMY.
- 34 AYALA 99 improves the limit of BARBIERI 88.
- 35 BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios.
- 36 RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough ( $< 5$  keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 37 RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough ( $< 1$  keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 38 ACCIARRI 97q result applies to both direct and transition magnetic moments and for  $q^2=0$ .
- 39 ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
- 40 Applies to absolute value of magnetic moment.
- 41 DERBIN 93 determine the cross section for 0.6-2.0 MeV electron energy as  $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$ . However, the (reactor on - reactor off)/(reactor off) is only  $\sim 1/100$ .
- 42 COOPER-SARKAR 92 assume  $f_{D_S}/f_\pi = 2$  and  $D_S, \bar{D}_S$  production cross section =  $2.6 \mu\text{b}$  to calculate  $\nu$  flux.
- 43 VIDYAKIN 92 limit is from a  $e\bar{\nu}_e$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses  $\sin^2 \theta_W = 0.23$  as input.
- 44 DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the  $\nu$  magnetic moment is  $< 1 \times 10^{-9}$  at the 95%CL. DORENBOSCH 89 measures both  $\nu_\mu e$  and  $\bar{\nu}_e e$  elastic scattering and assume  $\mu(\nu) = \mu(\bar{\nu})$ .
- 45 KRAKAUER 90 experiment fully reported in ALLEN 93.
- 46 RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives  $< 1.4 \times 10^{-12}$ . Limit at 95%CL obtained from  $\delta M_C$ .
- 47 Significant dependence on details of stellar models.
- 48 FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by  $\mu < 10^{-16} [10^{-9} G/B_0]$  where  $B_0$  is the present-day intergalactic field strength.
- 49 GROTCH 88 combined data from MAC, ASP, CELLO, and Mark J.
- 50 For  $m_\nu = 8-200$  eV. NUSSINOV 87 examines transition magnetic moments for  $\nu_\mu \rightarrow \nu_e$  and obtain  $< 3 \times 10^{-15}$  for  $m_\nu > 16$  eV and  $< 6 \times 10^{-14}$  for  $m_\nu > 4$  eV.
- 51 We obtain above limit from SUTHERLAND 76 using their limit  $f < 1/3$ .
- 52 KIM 74 is a theoretical analysis of  $\bar{\nu}_\mu$  reaction data.

## Neutrino Properties

### NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77c), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

VALUE ( $10^{-32} \text{ cm}^2$ )	CL%	DOCUMENT ID	TECN	COMMENT
- 2.1 to 3.3	90	1 DENIZ	10 TEXO	Reactor $\bar{\nu}_e e$
- 27.5 to 3	90	2 CAEDDU	18	$\nu_\mu$ coherent scat. on CsI
- 0.53 to 0.68	90	3 HIRSCH	03	$\nu_\mu e$ scat.
- 8.2 to 9.9	90	4 HIRSCH	03	anomalous $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$
- 2.97 to 4.14	90	5 AUERBACH	01 LSND	$\nu_e e \rightarrow \nu_e e$
- 0.6 to 0.6	90	VILAIN	95B CHM2	$\nu_\mu e$ elastic scat.
0.9 $\pm$ 2.7		ALLEN	93 CNTR	LAMPF $\nu e \rightarrow \nu e$
< 2.3	95	MOURAO	92 ASTR	HOME/KAM2 $\nu$ rates
< 7.3	90	6 VIDYAKIN	92 CNTR	Reactor $\bar{\nu} e \rightarrow \bar{\nu} e$
1.1 $\pm$ 2.3		ALLEN	91 CNTR	Repl. by ALLEN 93
- 1.1 $\pm$ 1.0		7 AHRENS	90 CNTR	$\nu_\mu e$ elastic scat.
- 0.3 $\pm$ 1.5		7 DORENBOS...	89 CHR	$\nu_\mu e$ elastic scat.
		8 GRIFOLS	89B ASTR	SN 1987A

- 1 DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  charge radius.
- 2 CAEDDU 18 use the data of the COHERENT experiment, AKIMOV 18. The limit is  $\langle r_{\nu_\mu}^2 \rangle$  obtained from the time-dependent data. Weaker limits were obtained for charge radii of  $\nu_e$  and for transition charge radii. The published value was divided by 2 to conform to the convention of this table.
- 3 Based on analysis of CCFR 98 results. Limit is on  $\langle r_{\nu_\mu}^2 \rangle + \langle r_{\nu_e}^2 \rangle$ . The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radii squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as  $\nu_\mu$  charge radius it implies  $\langle r_{\nu_\mu}^2 \rangle + \langle r_{\nu_e}^2 \rangle = (4.20 \pm 1.64) \times 10^{-33} \text{ cm}^2$ .
- 4 Results of LEP-2 are interpreted as limits on the axial-vector charge radii squared of a Majorana  $\nu_\tau$ . Slightly weaker limits for both vector and axial-vector charge radii squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).
- 5 AUERBACH 01 measure  $\nu_e e$  elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.
- 6 VIDYAKIN 92 limit is from a  $e \bar{\nu}$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses  $\sin^2 \theta_W = 0.23$  as input.
- 7 Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain  $1\sigma$  errors.
- 8 GRIFOLS 89B sets a limit of  $\langle r^2 \rangle < 0.2 \times 10^{-32} \text{ cm}^2$  for right-handed neutrinos.

## Neutrino Properties, Number of Neutrino Types

### Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard  $SU(2) \times U(1)$  Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with  $m < m_Z/2$ . The limits are on the number of neutrino mass eigenstates, including  $\nu_1$ ,  $\nu_2$ , and  $\nu_3$ .

### THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised June 2020 by C.-J. Lin (LBNL). Written by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types,  $N_\nu$ , come from studies of  $Z$  production in  $e^+e^-$  collisions. The invisible partial width,  $\Gamma_{\text{inv}}$ , is determined by subtracting the measured visible partial widths, corresponding to  $Z$  decays into quarks and charged leptons, from the total  $Z$  width. The invisible width is assumed to be due to  $N_\nu$  light neutrino species each contributing the neutrino partial width  $\Gamma_\nu$  as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths,  $(\Gamma_\nu/\Gamma_\ell)_{\text{SM}} = 1.991 \pm 0.001$ , is used instead of  $(\Gamma_\nu)_{\text{SM}}$  to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\text{inv}}}{\Gamma_\ell} \left( \frac{\Gamma_\ell}{\Gamma_\nu} \right)_{\text{SM}}. \quad (1)$$

The combined result from the four LEP experiments is  $N_\nu = 2.984 \pm 0.008$  [1]. Recent analyses applied corrections to the LEP result [1] by including the effect of correlated luminosity systematics and also using an improved Bhabha cross section calculation [2,3] to obtain  $N_\nu = 2.9963 \pm 0.0074$ .

In the past, when only small samples of  $Z$  decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in  $N_\nu$  was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the  $Z$  resonance. Since this method is much more dependent on the Standard Model, the approach described above is favored.

Before SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy  $e^+e^-$  colliders by measuring the cross section of the process  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$ . The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [4], leading to a 95% CL limit of  $N_\nu < 4.8$ . This process has a much larger cross section at center-of-mass energies near the  $Z$  mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [5]. These experiments have observed several thousand such events, and the combined result is  $N_\nu = 3.00 \pm 0.08$ . The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [6]. Combined with the lower energy data, the result is  $N_\nu = 2.92 \pm 0.05$ .

Experiments at  $p\bar{p}$  colliders also placed limits on  $N_\nu$  by determining the total  $Z$  width from the observed ratio of

# Lepton Particle Listings

## Number of Neutrino Types

$W^\pm \rightarrow \ell^\pm \nu$  to  $Z \rightarrow \ell^+ \ell^-$  events [7]. This involved a calculation that assumed Standard Model values for the total  $W$  width and the ratio of  $W$  and  $Z$  leptonic partial widths, and used an estimate of the ratio of  $Z$  to  $W$  production cross sections. Now that the  $Z$  width is very precisely known from the LEP experiments, the approach is now one of those used to determine the  $W$  width.

<sup>1</sup> BRIEDEN 22 combines large scale structure data from BOSS and eBOSS including the shape of the matter power spectrum with Planck CMB data.

<sup>2</sup> KUMAR 22 combine the reconstructed galaxy power spectrum from BOSS data with Planck CMB data.

<sup>3</sup> YEH 22 combines Planck 2018 CMB data with BBN and observations of deuterium and Helium-4. Supersedes FIELDS 20.

<sup>4</sup> AGHANIM 20 best fit on number of neutrino types is based on Planck data combined with lensing and baryon acoustic oscillations (BAO). Without BAO, they find  $2.89^{+0.18}_{-0.19}$ . Several other values are quoted using different combinations of data.

<sup>5</sup> FIELDS 20 combines Planck 2018 CMB data with BBN and observations of deuterium and Helium-4.

<sup>6</sup> IVANOV 20 combines 2018 Planck CMB data with baryon acoustic oscillation data from BOSS. This study is based on a full-shape likelihood for the redshift-space galaxy power spectrum of the BOSS data.

<sup>7</sup> Uses Planck Data combined with an independent standard measure of distance to the sound horizon to set a limit on the total number of neutrinos. Only CMB and early-time information are used.

<sup>8</sup> CYBURT 16 combines Planck 2015 CMB data with BBN and observations of deuterium and Helium-4.

<sup>9</sup> ROSSI 15 sets limits on the number of neutrino types using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

<sup>10</sup> Fit to the number of neutrino degrees of freedom from Planck CMB data along with WMAP polarization, high L, and BAO data.

<sup>11</sup> Fit to the number of neutrinos degrees of freedom from Planck CMB data along with BAO, shear and cluster data.

<sup>12</sup> Fit based on the SPT-SZ survey combined with CMB, BAO, and  $H_0$  data.

<sup>13</sup> Constrains the number of neutrino degrees of freedom (marginalizing over the total mass) from CMB, CMB lensing, BAO, and galaxy clustering data.

<sup>14</sup> Limit on the number of light neutrino types from observational Hubble parameter data with seven-year WMAP data, SPT, and the most recent estimate of  $H_0$ . Best fit is  $3.45 \pm 0.65$ .

<sup>15</sup> Limit on the number of light neutrino types from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Best fit is  $4.17^{+1.62}_{-1.26}$ . Limit is relaxed to  $3.98^{+2.02}_{-1.20}$  when small scales affected by non-linearities are removed.

## Number of Neutrino Types, Double- $\beta$ Decay

- <sup>16</sup> Constrains the number of neutrino types from recent CMB and large scale structure data. No priors on other cosmological parameters are used.
- <sup>17</sup> Constrains the number of neutrino types from recent CMB, large scale structure, Lyman-alpha forest, and SNIa data. The slight preference for  $N_\nu > 3$  comes mostly from the Lyman-alpha forest data.
- <sup>18</sup> Constrains the number of neutrino types from recent CMB and large scale structure data. See also HAMANN 07.
- <sup>19</sup> Limit on the number of neutrino types based on <sup>4</sup>He and D/H abundance assuming a baryon density fixed to the WMAP data. Limit relaxes to 4.6 if D/H is not used or to 5.8 if only D/H and the CMB are used. See also CYBURT 01 and CYBURT 03.
- <sup>20</sup> Limit on the number of neutrino types based on combination of WMAP data and big-bang nucleosynthesis. The limit from WMAP data alone is 8.3. See also KNELLER 01.  $N_\nu \geq 3$  is assumed to compute the limit.
- <sup>21</sup> 95% confidence level range on the number of neutrino flavors from WMAP data combined with other CMB measurements, the 2dfGRS data, and HST data.
- <sup>22</sup> SHVARTSMAN 69 limit inferred from his equations.

Observation of neutrinoless double-beta ( $0\nu\beta\beta$ ) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of  $0\nu\beta\beta$ -decay requires a nonvanishing Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating  $0\nu\beta\beta$  decay can be obtained, independently of the actual mechanism, by assuming that one of these “new physics” possibilities dominates. These limits are listed in the Double- $\beta$  Decay Listings of the experimental measurements.

In the following we assume that the exchange of light Majorana neutrinos ( $m_{\nu_i} \leq 10$  MeV) contributes dominantly to the decay rate. Besides a dependence on the phase space ( $G^{0\nu}$ ) and the nuclear matrix element ( $M^{0\nu}$ ), the observable  $0\nu\beta\beta$ -decay rate is proportional then to the square of the effective Majorana mass  $m_{ee}$ ,  $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot m_{ee}^2$ , with  $m_{ee}^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$ . The sum contains, in general, complex CP-phases in  $U_{ei}^2$ , i.e., cancellations may occur. For three neutrino flavors there are two physical phases for Majorana neutrinos ( $\eta_1, \eta_2$ ) and one for Dirac neutrinos ( $\delta_{CP}$ ). The relevant Majorana phases affect only processes to which lepton-number changing amplitudes contribute. Given the general  $3 \times 3$  mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities,  $m_{\ell\ell'} = \sum_i U_{ei} U_{\ell'i} m_{\nu_i}$  ( $\ell$  or  $\ell' \neq e$ ). However, these are currently much less constrained than  $m_{ee}$ .

Nuclear structure calculations are needed to deduce  $m_{ee}$  from the decay rate. While  $G^{0\nu}$  can be calculated accurately, the computation of  $M^{0\nu}$  is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor  $\sim 2$ - $3$  spread in the calculated nuclear matrix elements. Nuclear structure calculation consistently overestimate Gamow-Teller (axial current) matrix elements. This inability of the nuclear models to reproduce Gamow-Teller decay rates is often parametrized in form of a modified coupling constant  $g_A$ . Many nuclear theorists interpret this shortcoming as evidence that important physics is missing in the modeling of weak nuclear transitions. It is not clear how these observed uncertainties impact  $0\nu\beta\beta$ -matrix elements. Nevertheless, this constitutes an additional element of uncertainty. Recent work, [1] shows how the discrepancy between experimental and theoretical axial current matrix elements might be resolved. However, application of this approach to the  $0\nu\beta\beta$  decay remains to be accomplished. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the conventional  $2\nu\beta\beta$  decay serve to constrain the nuclear theory models, results for this process are also given.

## Double- $\beta$ Decay

Oscillation experiments utilizing atmospheric, accelerator, solar, and reactor produced neutrinos and anti-neutrinos show that at least some neutrinos are massive. However, so far the inverted mass ordering (i.e., whether  $\Delta m_{31}^2 < 0$ ) is disfavored only by 2-3  $\sigma$  compared to the normal mass ordering (when  $\Delta m_{31}^2 > 0$ ), while the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana) remain undetermined. All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. (For values of the mixing angles and mass square differences see the corresponding tables.)

Based on the 3-neutrino analysis:

$m_{ee}^2 = |\cos^2 \theta_{13} \cos^2 \theta_{12} m_1 + e^{2i(\eta_2 - \eta_1)} \cos^2 \theta_{13} \sin^2 \theta_{12} m_2 + e^{-2i(\eta_1 + \delta_{CP})} \sin^2 \theta_{13} m_3|^2$ , valid for both mass orderings. Given the present knowledge of the neutrino oscillation parameters one can derive a relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in Figure 14.11 in the Neutrino Masses, Mixing and Oscillations review. The three mass orderings allowed by the oscillation data: normal ( $m_1 < m_2 \ll m_3$ ), inverted ( $m_3 \ll m_1 < m_2$ ), and degenerate ( $m_1 \approx m_2 \approx m_3$ ), result in different projections. The width of the colored bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases as well as the experimental errors of the oscillation parameters. The latter causes only minor broadening of the bands. Because of the overlap of the different mass scenarios, a measurement of  $m_{ee}$  would not reveal which mass ordering is applicable, provided the value of  $m_{ee}$  is in the overlapping range.

Analogous plots depict the relation of  $m_{ee}$  with the summed neutrino mass  $m_{tot} = m_1 + m_2 + m_3$ , constrained by observational cosmology, and  $m_{ee}$  as a function of the average mass  $m_{\nu_e}^{eff} = [\sum |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$  determined through the analysis of the electron energy distribution in low energy beta decays. (See Fig. 1 of [2].) The oscillation data thus allow to test whether observed values of  $m_{ee}$  and  $m_{tot}$  or  $m_{\nu_e}^{eff}$  are consistent within the 3 neutrino framework. The rather large intrinsic width of the  $\beta\beta$ -decay constraints essentially does not allow to positively identify the mass ordering, and thus the sign of  $\Delta m_{31}^2$ , even in combination with these other observables. Naturally, if a value of  $0 < m_{ee} \leq 0.01$  eV is ever established, then the normal mass ordering becomes the only possible scenario.

It should be noted that systematic uncertainties of the nuclear matrix elements and possible quenching of the axial current matrix elements are sometimes not folded into the mass limits reported by  $\beta\beta$ -decay experiments. Taking this additional uncertainty into account would further widen the projections. The plots are based on a 3-neutrino analysis. If it turns out that additional, i.e. sterile light neutrinos exist, the allowed regions would be modified substantially.

If neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses  $m_{\nu_i}$ . Unlike the direct neutrino mass measurements, however, a limit

on  $m_{ee}$  does not allow one to constrain the individual mass values  $m_{\nu_i}$  even when the mass differences  $\Delta m_{ij}^2$  are known.

Neutrino oscillation data imply the existence of a lower limit  $\sim 0.014$  eV for the Majorana neutrino mass for the inverted mass ordering pattern, while  $m_{ee}$  could, by fine tuning, vanish in the case of the normal mass ordering. Several new double-beta searches have been proposed to probe the interesting  $m_{ee}$  mass range, with the prospect of full coverage of the inverted mass ordering region within the next decade.

The  $0\nu\beta\beta$  decay mechanism discussed so far is not the only way in which the decay can occur. Numerous other possible scenarios have been proposed, however, all of them requiring new physics. It will be a challenging task to decide which mechanism was responsible once  $0\nu\beta\beta$  decay is observed. LHC experiments may reveal corresponding signatures for new physics of lepton number violation. If lepton-number violating right-handed weak current interactions exist, its strength can be characterized by the phenomenological coupling constants  $\eta$  and  $\lambda$  ( $\eta$  describes the coupling between the right-handed lepton current and left-handed quark current while  $\lambda$  describes the coupling when both currents are right-handed). The  $0\nu\beta\beta$  decay rate then depends on  $\langle \eta \rangle = \eta \sum_i U_{ei} V_{ei}$  and  $\langle \lambda \rangle = \lambda \sum_i U_{ei} V_{ei}$  that vanish for massless or unmixed neutrinos ( $V_{ij}$  is a matrix analogous to  $U_{ij}$  but describing the mixing with the hypothetical right-handed neutrinos). The observation of the single electron spectra could, in principle, allow to distinguish this mechanism of  $0\nu\beta\beta$  from the light Majorana neutrino exchange driven mode. The limits on  $\langle \eta \rangle$  and  $\langle \lambda \rangle$  are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between  $\eta$  and  $\lambda$ . In addition, see the section on Majoron searches for additional limits set by these experiments.

### Half-life $0\nu$ double- $\beta$ decay

In most cases the transitions  $(Z,A) \rightarrow (Z+2,A) + 2e^-$  to the  $0^+$  ground state of the final nucleus are listed. We also list transitions that decrease the nuclear charge ( $2e^+$ ,  $e^+$  CC and double EC) and transitions to an excited state of the final nucleus ( $0^+_i$ ,  $2^+$ , and  $2^+_i$ ). In the following Listings only the best or comparable limits for the half-lives of each transition are reported and only those with about  $T_{1/2} > 10^{23}$  years that are relevant for particle physics.

- 1 ABE 23 use the combined data set of the KamLAND-Zen 400 and 800 experiments, utilizing 745 kg of isotopically enriched xenon (90.9% <sup>136</sup>Xe), dissolved in liquid scintillator and an exposure of 970 kg-yr of <sup>136</sup>Xe, to derive this limit on 0νββ decay. A half-life sensitivity of 1.5 × 10<sup>26</sup> yr is reported.
- 2 ARNQUIST 23 use the final data set of the MAJORANA DEMONSTRATOR experiment, operating enriched in <sup>76</sup>Ge detectors, to set this limit on the 0νββ half-life of <sup>76</sup>Ge. The exposure is 64.5 kg-yr. A median sensitivity of 8.1 × 10<sup>25</sup> yr is reported.
- 3 AUGIER 23 utilize the complete data, set collected by the CUPID-Mo bolometric calorimeter with particle ID and located at the LSM, to study various double beta decays of <sup>100</sup>Mo to excited states of the daughter nucleus. An exposure of 1.47 kg-yr of <sup>100</sup>Mo is available.
- 4 NOVELLA 23 use data collected by the NEXT-White experiment to limit the 0νββ half-life of <sup>136</sup>Xe. The experiment contains 3.5 kg of enriched Xe and is based on a high-pressure gas TPC. Two different limits are reported, based on different data analysis approaches, > 5.5 × 10<sup>23</sup> yr and > 13 × 10<sup>23</sup> yr.
- 5 ADAMS 22A use the CUORE TeO<sub>2</sub> experiment with an exposure of 288.8 kg-yr of <sup>130</sup>Te to place a limit on its 0νββ decay. The median sensitivity is reported as 280 × 10<sup>23</sup> yr. Supersedes ADAMS 20A.
- 6 ADAMS 22B use the CUORE bolometric calorimeter to place a limit on the 0νββ decay half-life of <sup>128</sup>Te.
- 7 APRILE 22A use 36.16 kg yr of <sup>136</sup>Xe exposure of the XENON1T not enriched detector to establish the stated limit.
- 8 AUGIER 22 use the final data set of the CUPID-Mo cryogenic calorimeter, utilizing enriched Li<sub>2</sub><sup>100</sup>MoO<sub>4</sub> and an isotope exposure of 1.47 kg-y, to place a limit on the 0νββ decay half-life.
- 9 AZZOLINI 22 use the CUPID-0 scintillating cryogenic bolometer to set a limit on the 0νββ half-life of <sup>82</sup>Se. The analyzed isotope exposure is 8.82 kg-yr. A median sensitivity of 7 × 10<sup>24</sup> yr is reported. Supersedes AZZOLINI 19.
- 10 AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg-yr to set a limit on the 0νββ decay to the first excited 0<sup>+</sup> state.
- 11 AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg-yr to set a limit on the 0νββ decay to the first excited 2<sup>+</sup> state.
- 12 AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg-yr to set a limit on the 0νββ decay to the second excited 2<sup>+</sup> state.
- 13 ADAMS 21A et al. used 101.76 kg yr of <sup>130</sup>Te exposure of the CUORE (LNGS) bolometric detector to place a limit on the decay to the first excited state of <sup>130</sup>Xe, superseding ALDUINO 19 as the most restrictive bound on this particular decay.
- 14 ARMENGAUD 21 use the CUPID-Mo 4.2 kg array of enriched Li<sub>2</sub><sup>100</sup>MoO<sub>4</sub> scintillating bolometers, with 1.17 kg-yr exposure, to set this limit.
- 15 ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the 0νββ decay to the first excited 0<sup>+</sup> state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 39.9 × 10<sup>23</sup> yr.
- 16 ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the 0νββ decay to the first excited 2<sup>+</sup> state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 21.2 × 10<sup>23</sup> yr.

- 17 ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the 0νββ decay to the second excited 2<sup>+</sup> state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 18.6 × 10<sup>23</sup> yr.
- 18 ADAMS 20A use the CUORE detector to search for the 0νββ decay of <sup>130</sup>Te. The exposure was 372.5 kg-yr of TeO<sub>2</sub> corresponding to 103.6 kg-yr of <sup>130</sup>Te. The exclusion sensitivity is 1.7 × 10<sup>25</sup> yr. Supersedes ALDUINO 18.
- 19 AGOSTINI 20B present the final data set of the GERDA experiment, searching for 0νββ decay of <sup>76</sup>Ge with isotopically enriched, high resolution Ge detectors. A final exposure of 127.2 kg-yr is reported. The experiment reports the lowest background and longest half life limit ever achieved by any double beta decay experiment. The reported experiment sensitivity equals the limit. Supersedes AGOSTINI 19.
- 20 ALDUINO 19 use the combined data of the CUORICINO and CUORE-0 experiments to place a lower limit on the half life of the 0νββ decay of <sup>130</sup>Te to the first excited 0<sup>+</sup> state of <sup>130</sup>Xe. Supersedes ANDREOTTI 12.
- 21 ALENKOV 19 report the 0νββ decay half-life limit based on the 5.21 kg-d exposure of <sup>100</sup>Mo, of a cryogenic dual heat and light detector in the Yangyang underground laboratory. The median sensitivity is 1.1 × 10<sup>23</sup> years.
- 22 ANTON 19 uses the complete dataset of the EXO-200 detector to search for the 0νββ decay. The exposure is 234.1 kg yr. The median sensitivity is 5.0 × 10<sup>25</sup> yr. Supersedes ALBERT 18 and ALBERT 14b.
- 23 NI 19 use the PandaX-II dual phase TPC at CJPL to search for the 0νββ decay of <sup>136</sup>Xe. The half-life limit 2.4 × 10<sup>23</sup> yr is obtained from 22.2 kg yr exposure with a sensitivity of 1.9 × 10<sup>23</sup> yr.
- 24 ALDUINO 18 uses the CUORE detector to search for the 0νββ decay of <sup>130</sup>Te. The exposure is 86.3 kg-year of natural TeO<sub>2</sub> corresponding to 24.0 kg-year for <sup>130</sup>Te. The median sensitivity is 0.7 × 10<sup>25</sup> yr. The limit is obtained combining the new data from CUORE with those of CUORE0 (9.8 kg-year of <sup>130</sup>Te) and Cuoricino (19.8 kg-year of <sup>130</sup>Te).
- 25 ARNOLD 18 use the NEMO-3 tracking detector to place a limit on the 0νββ decay of <sup>82</sup>Se. This is a slightly weaker limit than in BARABASH 11A, using the same detector. Supersedes ARNOLD 05A.
- 26 BARABASH 18 use 1.162 kg of <sup>116</sup>CdWO<sub>4</sub> scintillating crystals to obtain this limit. Supersedes DANEVICH 03 with analogous source and is more sensitive than ARNOLD 17.
- 27 ALBERT 17C uses the EXO-200 detector that contains 19.098 ± 0.014% admixture of <sup>134</sup>Xe to search for the 0ν and 2νββ decay modes. The exposure is 29.6 kg-year. The median sensitivity is 1.9 × 10<sup>21</sup> years.
- 28 ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 g of enriched <sup>116</sup>Cd exposed for 5.26 yr, to determine the half-life limit. Supersedes BARABASH 11A.
- 29 ALDUINO 16 report result obtained with 9.8 kg-y of data collected with the CUORE-0 bolometer, combined with data from the CUORICINO. Supersedes ALFONSO 15.
- 30 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (<sup>136</sup>Xe 89.5 kg yr) to place a limit on the 0νββ-decay into the first excited state of the daughter nuclide.
- 31 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (<sup>136</sup>Xe 89.5 kg yr) to place a limit on the 0νββ-decay into the second excited state of the daughter nuclide.
- 32 ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (<sup>136</sup>Xe 89.5 kg yr) to place a limit on the 0νββ-decay into the third excited state of the daughter nuclide.
- 33 ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the limit of 0νββ-half life of <sup>100</sup>Mo. Supersedes ARNOLD 2005A and BARABASH 11A.
- 34 ANDREOTTI 12 use high resolution TeO<sub>2</sub> bolometric calorimeter to search for the 0νββ decay of <sup>130</sup>Te leading to the excited 0<sub>1</sub><sup>+</sup> state at 1793.5 keV.
- 35 UMEHARA 08 use CaF<sub>2</sub> scintillation calorimeter to search for double beta decay of <sup>48</sup>Ca. Limit is significantly more stringent than quoted sensitivity: 18 × 10<sup>21</sup> years.
- 36 Limit on 0ν-decay to the first excited 0<sub>1</sub><sup>+</sup>-state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.
- 37 Limit on 0ν-decay to the first excited 2<sup>+</sup>-state of daughter nucleus using NEMO-3 tracking calorimeter.
- 38 Supersedes ALESSANDRELLO 00. Array of TeO<sub>2</sub> crystals in high resolution cryogenic calorimeter. Some enriched in <sup>128</sup>Te. Ground state to ground state decay.
- 39 Limit on 0νββ decay of <sup>116</sup>Cd using enriched CdWO<sub>4</sub> scintillators. Supersedes DANEVICH 00.
- 40 AALSETH 02B limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.

Half-life measurements of the two-neutrino double-β decay

The measured half-life values for the transitions (Z,A) → (Z+2,A) + 2e<sup>-</sup> + 2ν̄<sub>e</sub> to the 0<sup>+</sup> ground state of the final nucleus are listed. We also list the transitions to an excited state of the final nucleus (0<sub>i</sub><sup>+</sup>, etc.). We report only the measurements with the smallest (or comparable) uncertainty for each transition.

- <sup>1</sup> AGOSTINI 23 report an updated value for the  $2\nu\beta\beta$  half-life of  $^{76}\text{Ge}$ ; the final result of the GERDA Phase II experiment. A subset of the data, corresponding to an exposure of 11.8 kg-yr, is utilized. This is one of the most precise measurements of  $2\nu\beta\beta$  decay reported in the literature. An effective nuclear matrix element of  $0.101 \pm 0.001$  is derived from this result.
- <sup>2</sup> AGUERRE 23 report the results of a 5.25 yr search for the  $2\nu\beta\beta$  decay to the excited  $0^+ \rightarrow 0^+_1$  state of the daughter nucleus, using the NEMO-3 tracking calorimeter. 36.6 g of  $^{150}\text{Nd}$  isotope were available for the measurement of this decay rate.
- <sup>3</sup> AUGIER 23 utilize the complete data, set collected by the CUPID-Mo bolometric calorimeter with particle ID and located at the LSM, to measure the  $^{100}\text{Mo}$   $2\nu\beta\beta$  half-life to excited  $0^+_1$  state of the daughter nucleus. An exposure of 1.47 kg-yr of  $^{100}\text{Mo}$  is available.
- <sup>4</sup> AUGIER 23A use full data set collected by the CUPID-Mo experiment to derive an improved  $2\nu\beta\beta$  g.s. to g.s. half-life of  $^{100}\text{Mo}$ . An exposure of 1.48 kg-yr of  $^{100}\text{Mo}$  is utilized. Supersedes ARMENGAUD 20.
- <sup>5</sup> AZZOLINI 23A report an improved measurement of the  $2\nu\beta\beta$  decay with an exposure of 8.82 kg-yr of  $^{82}\text{Se}$ , collected with the CUPID-0 detector. Supersedes AZZOLINI 19B.
- <sup>6</sup> NOVELLA 23 used the NEXT-White experiment, with a fiducial mass of 3.5 kg of enriched xenon, to measure the  $2\nu\beta\beta$  g.s. to g.s. half-life of  $^{136}\text{Xe}$ . The experiment is based on a high-pressure gas TPC. Supersedes NOVELLA 22.
- <sup>7</sup> ADAMS 22B derive the  $2\nu\beta\beta$  half-life of  $^{128}\text{Te}$  from data of the CUORE bolometric calorimeter and the half-life ratio for  $^{130}\text{Te} / ^{128}\text{Te}$  reported in BERNATOWICZ 92.
- <sup>8</sup> APRILE 22A report an improved  $^{124}\text{Xe}$   $2\nu\text{DEC}$  half-life measurement for  $^{124}\text{Xe}$ , using data collected by the XENONIT detector with an isotopically not enriched Xe target. The analyzed  $^{124}\text{Xe}$  exposure is 0.87 kg-yr. The statistical significance of the signal is 7.0 sigma. The stated half-life considers captures from the K shell up to the N5 shell. This result supersedes APRILE 19E, which exclusively considered captures from the K shell.
- <sup>9</sup> APRILE 22B use data collected by the XENONnT dark matter experiment to derive an improved  $^{124}\text{Xe}$   $2\nu\text{DEC}$  half-life measurement for  $^{124}\text{Xe}$ . This result supersedes APRILE 22A.
- <sup>10</sup> NOVELLA 22 report on a high-pressure gas TPC at Canfranc underground laboratory, filled with 3.5 kg (fiducial) xenon gas, used to measure the  $2\nu\beta\beta$  decay of  $^{136}\text{Xe}$ . Topological track reconstruction is utilized in the data analysis. The measurement is based on comparing runs with isotopically enriched and depleted xenon. Other measurements with smaller error exist.
- <sup>11</sup> ADAMS 21 use 102.7 kg yr of  $^{130}\text{Te}$  exposure, collected by the CUORE bolometric detector at LNGS, to perform a measurement of the  $2\nu\beta\beta$  decay of  $^{130}\text{Te}$ . The dataset is more than 10-times that collected by the CUORE-0 experiment. The result has been revised in ADAMS 23A. Supersedes ALDUINO 17.
- <sup>12</sup> APRILE 19E report first measurement of two-neutrino double electron capture in  $^{124}\text{Xe}$  using the XENONIT detector with a 0.73 t-yr exposure. An excess of  $126 \pm 29$  events is observed at  $64.3 \pm 0.6$  keV decay energy, corresponding to  $\sqrt{\Delta\chi^2} = 4.4$  with respect to the background-only hypothesis.
- <sup>13</sup> ARNOLD 19 use the NEMO-3 tracking calorimeter with 34.3 kg y exposure to determine the  $2\nu\beta\beta$  half-life of  $^{100}\text{Mo}$ . Supersedes ARNOLD 15.

- <sup>14</sup> ARNOLD 18 use the NEMO-3 tracking detector to determine the  $2\nu\beta\beta$  half-life of  $^{82}\text{Se}$ . 0.93 kg of  $^{82}\text{Se}$  was observed for 5.25 y. The half-life value was obtained based on the single-state-dominance (SSD) hypothesis, preferred in this case by about  $2\sigma$ . Supersedes ARNOLD 05A.
- <sup>15</sup> BARABASH 18 use 1.162 kg of  $^{116}\text{CdWO}_4$  scintillating crystals to obtain this value. Supersedes DANEVICH 03 with analogous source and agrees with ARNOLD 17 with the NEMO-3 detector.
- <sup>16</sup> ALBERT 17C uses the EXO-200 detector that contains  $19.098 \pm 0.014\%$  admixture of  $^{134}\text{Xe}$  to search for the  $2\nu\beta\beta$  decay mode. The exposure is 29.6 kg-year. The median sensitivity is  $1.2 \times 10^{21}$  years.
- <sup>17</sup> ALDUINO 17 use the CUORE-0 detector containing 10.8 kg of  $^{130}\text{Te}$  in 52 crystals of  $\text{TeO}_2$ . The exposure was 9.3 kg yr of  $^{130}\text{Te}$ . This is a more accurate rate determination than in ARNOLD 11 and BARABASH 11A.
- <sup>18</sup> ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 grams of enriched  $^{116}\text{Cd}$  exposed for 5.26 years, to determine the half-life value.
- <sup>19</sup> ARNOLD 16 use the NEMO-3 detector and a source of 6.99 g of  $^{48}\text{Ca}$ . The half-life is based on 36.7 g year exposure. It is consistent, although somewhat longer, than the previous determinations of the half-life. Supersedes BARABASH 11A.
- <sup>20</sup> ARNOLD 16A use the NEMO-3 tracking calorimeter, containing 36.6 g of  $^{150}\text{Nd}$  exposed for 1918.5 days, to determine the half-life. Supersedes ARGYRIADES 09.
- <sup>21</sup> AGOSTINI 15A use 17.9 kg yr exposure of the GERDA calorimeter to derive an improved measurement of the  $2\nu\beta\beta$  decay half life of  $^{76}\text{Ge}$ .
- <sup>22</sup> ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the  $2\nu\beta\beta$ -half life of  $^{100}\text{Mo}$ . Supersedes ARNOLD 05A and ARNOLD 04.
- <sup>23</sup> ALBERT 14 use the EXO-200 tracking detector for a re-measurement of the  $2\nu\beta\beta$ -half life of  $^{136}\text{Xe}$ . A nuclear matrix element of  $0.0218 \pm 0.0003 \text{ MeV}^{-1}$  is derived from this data. Supersedes ACKERMAN 11.
- <sup>24</sup> GAVRILYAK 13 use a proportional counter filled with Kr gas to search for the  $2\nu 2K$  decay of  $^{78}\text{Kr}$ . Data with the enriched and depleted Kr were used to determine signal and background. A  $2.5\sigma$  excess of events obtained with the enriched sample is interpreted as an indication for the presence of this decay.
- <sup>25</sup> GANDO 12A use a modification of the existing KamLAND detector. The  $\beta\beta$  decay source/detector is 13 tons of enriched  $^{136}\text{Xe}$ -loaded scintillator contained in an inner balloon. The  $2\nu\beta\beta$  decay rate is derived from the fit to the spectrum between 0.5 and 4.8 MeV. This result is in agreement with ACKERMAN 11.
- <sup>26</sup> ARNOLD 11 use enriched  $^{130}\text{Te}$  in the NEMO-3 detector to measure the  $2\nu\beta\beta$  decay rate. This result is in agreement with, but more accurate than ARNOLDI 03.
- <sup>27</sup> ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and identify its  $2\nu\beta\beta$  decay. The result is in agreement and supersedes ARNOLD 99.
- <sup>28</sup> BELLI 10 use enriched  $^{100}\text{Mo}$  with 4 HP Ge detectors to record the 590.8 and 539.5 keV  $\gamma$  rays from the decay of the  $0^+_1$  state in  $^{100}\text{Ru}$  both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.
- <sup>29</sup> First exclusive measurement of  $2\nu$ -decay to the first excited  $0^+_1$ -state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive ( $0\nu + 2\nu$ ) measurement of DEBRAECKELEER 01.
- <sup>30</sup> ARNOLD 05A use the NEMO-3 tracking detector to determine the  $2\nu\beta\beta$  half-life of  $^{82}\text{Se}$  with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.
- <sup>31</sup> DANEVICH 03 is calorimetric measurement of  $2\nu\beta\beta$  ground state decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.

### $\langle m_{ee} \rangle$ , The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- $\beta$ Decay

$\langle m_{ee} \rangle = |\sum U_{ei}^2 m_{\nu_i}|$ ,  $i = 1, 2, 3$ . It is assumed that  $\nu_i$  are Majorana particles and that the transition is dominated by the known (light) neutrinos. Note that  $U_{ei}^2$  and not  $|U_{ei}|^2$  occur in the sum, and that consequently cancellations are possible. The experiments obtain the limits on  $\langle m_{ee} \rangle$  from the measured ones on  $T_{1/2}$  using a range of nuclear matrix elements (NME), which is reflected in the spread of  $\langle m_{ee} \rangle$ . Different experiments may choose different NME. All assume  $g_A = 1.27$ . In the following Listings, only the best or comparable limits for each isotope are reported. When not mentioned explicitly the transition is between ground states, but transitions between excited states are also reported.

- ABE 23 utilize 745 kg of <sup>136</sup>Xe isotope exposure from the combined data set of the KamLAND-Zen 400 and 800 to derive a limit on  $\langle m_{\beta\beta} \rangle$ . The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements.
- ARNQUIST 23 use the final data set of the MAJORANA DEMONSTRATOR experiment, with 64.5 kg-yr of isotope exposure, to derive an upper limit for  $\langle m_{\beta\beta} \rangle$ . The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements.
- NOVELLA 23 use data collected with the NEXT-White experiment to derive a range of upper limits for  $\langle m_{\beta\beta} \rangle$ . The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements and both half-life limits stated in NOVELLA 23.
- ADAMS 22A use 1038.4 kg-yr of TeO<sub>2</sub> exposure collected by the CUORE experiment to determine this range of limits. The range reflects the uncertainty of nuclear matrix element calculations needed for the conversion of half-life to neutrino mass.
- APRILE 22A use data taken with the XENONIT detector to limit the Majorana neutrino mass. 36.16 kg-yr of <sup>136</sup>Xe exposure were utilized. The reported range of limits is due to uncertainties in the nuclear matrix elements.
- AUGIER 22 use the final data set of the CUPID-Mo cryogenic calorimeter with an isotope exposure of 1.47 kg-y to derive a range of neutrino mass limits. The range reflects the authors' estimate of the spread of nuclear matrix element calculations.
- AZZOLINI 22 use 8.82 kg-yr of isotopic exposure of the CPID-0 scintillating cryogenic bolometer to set this range of neutrino mass limits. The range reflects the authors' estimate of the spread of nuclear matrix element calculations.
- ARMENGAUD 21 use the CUPID-Mo demonstrator, with 1.17 kg-yr exposure of <sup>100</sup>Mo, to set this limit. The range reflects the estimated uncertainty of the calculated nuclear matrix elements.
- ADAMS 20A use the data of CUORE (372.5 kg-yr exposure of TeO<sub>2</sub>) to obtain this limit.
- AGOSTINI 20B use the final data set of the GERDA experiment, representing an exposure of 127.2 kg yr to derive an upper limit for  $\langle m_{\beta\beta} \rangle$ . Isotopically enriched Ge detectors were used. The range reflects the variability of the theoretically calculated nuclear matrix elements. Supersedes AGOSTINI 19.
- ALENKOV 19 report the range of the effective masses  $\langle m_{\beta\beta} \rangle$  corresponding to the 0ν ββ decay half-life limit. It is based on the 52.1 kg-d exposure of <sup>100</sup>Mo, in the Yangyang underground laboratory. The median sensitivity is 1.1 × 10<sup>23</sup> years. The range of  $\langle m_{\beta\beta} \rangle$  reflects the uncertainty of nuclear matrix elements.
- ANTON 19 uses the complete dataset of the EXO-200 experiment to obtain these limits. The spread reflect the uncertainty in the nuclear matrix elements. Supersedes ALBERT 18 and ALBERT 14b.
- NI 19 use the PandaX-II dual phase TPC at CJPL to search for the 0ν ββ decay of <sup>136</sup>Xe with 22.2 kg yr exposure. The range in the  $m_{\beta\beta}$  limit of 1.3-3.5 eV reflects the range of the calculated nuclear matrix elements. The sensitivity is 1.9 × 10<sup>23</sup> yr.
- ALDUINO 18 use the combined data of CUORE, CUORE0, and Cuoricino to obtain this limit.
- ARNOLD 18 use the NEMO-3 tracking detector to constrain the 0ν ββ decay of <sup>82</sup>Se. The limit on  $\langle m_{\beta\beta} \rangle$  is obtained assuming light neutrino exchange; the range reflects different calculations of the nuclear matrix elements. This is a somewhat weaker limit than in BARABASH 11A using the same detector.
- BARABASH 18 use 1.162 kg of <sup>116</sup>CdWO<sub>4</sub> scintillating crystals to obtain these limits. The spread reflects the estimated uncertainty in the nuclear matrix element. Supersedes DANEVICH 03.
- ARNOLD 17 utilize NEMO-3 data, taken with enriched <sup>116</sup>Cd to limit the effective Majorana neutrino mass. The reported range results from the use of different nuclear matrix elements. Supersedes BARABASH 11A.
- ALDUINO 16 place a limit on the effective Majorana neutrino mass using the combined data of the CUORE-0 and CUORICINO experiments. The range reflects the authors' evaluation of the variability of the nuclear matrix elements. Supersedes ALFONSO 15.
- ARNOLD 16A limit is derived from data taken with the NEMO-3 detector and <sup>150</sup>Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used. Supersedes ARGYRIADES 09.
- ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the neutrino mass limit based on the 0ν ββ-half life of <sup>100</sup>Mo. The spread range reflects different nuclear matrix elements. Supersedes ARNOLD 14 and BARABASH 11A.
- ARGYRIADES 10 use <sup>96</sup>Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.
- Limit was obtained using CaF<sub>2</sub> scintillation calorimeter to search for double beta decay of <sup>48</sup>Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.
- Limit for  $\langle m_{\nu} \rangle$  is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.

Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later.  $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$  and  $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$ , where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

- ARNOLD 18 use the NEMO03 tracking detector, with 0.93 kg of <sup>82</sup>Se mass and 5.25 y exposure to obtain the limits for the hypothetical right-handed currents. Supersedes ARNOLD 05A.
- BARABASH 18 use 1.162 kg of <sup>116</sup>CdWO<sub>4</sub> scintillating crystals to obtain this limits for the hypothetical right-handed currents in the 0ν ββ decay of <sup>116</sup>Cd.
- ARNOLD 14 is based on 34.7 kg yr of exposure of the NEMO-3 tracking calorimeter. The reported range limit on  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  reflects the nuclear matrix element uncertainty in <sup>100</sup>Mo.
- ARNOLD 07 use NEMO-3 half life limit for 0ν-decay of <sup>100</sup>Mo to the first excited 2<sup>+</sup>-state of daughter nucleus to limit the right-right handed admixture of weak currents  $\langle \lambda \rangle$ . This limit is not competitive when compared to the decay to the ground state.
- Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6σ statistical evidence for observation of 0ν-decay. Authors use matrix element of MUTO 89 to determine  $\langle \lambda \rangle$  and  $\langle \eta \rangle$ . Uncertainty of nuclear matrix element is not reflected in stated errors.
- ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on <sup>100</sup>Mo data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on <sup>82</sup>Se data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.
- ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given.
- Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.
- Limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.
- The range of the reported  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  values reflects the spread of the nuclear matrix elements. On axis value assuming  $\langle m_{\nu} \rangle = 0$  and  $\langle \lambda \rangle = \langle \eta \rangle = 0$ , respectively.
- GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.
- VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit 2.6 × 10<sup>23</sup> y at 90%CL.
- BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on  $\eta$ . Further details of the experiment are given in BERNATOWICZ 93.

### Neutrino Mixing

With the possible exceptions of "short-baseline anomalies," such as LSND, all neutrino data can be described within the framework of a  $3 \times 3$  mixing matrix between the mass eigenstates  $\nu_1$ ,  $\nu_2$ , and  $\nu_3$ , leading to the flavor eigenstates  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ , as described in the review "Neutrino masses, mixing and oscillations."

The Listings are divided in the following sections:

**(A) Neutrino fluxes and event ratios:** shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically, ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

**(B) Neutrino mixing parameters:** shows measurements of  $\sin^2(\theta_{12})$ ,  $\sin^2(\theta_{23})$ ,  $\sin^2(\theta_{13})$ ,  $\Delta m_{21}^2$ ,  $\Delta m_{32}^2$ , and  $\delta_{CP}$  as extracted from the measured data in the quoted publications in the frame of the three-neutrino mixing scheme. The quoted averages are not the result of a global fit, as in the review "Neutrino masses, mixing, and oscillations," and, as a consequence, might slightly differ from them. In some cases, measurements depend on the mass order (normal when  $\Delta m_{32}^2 > 0$  or inverted

when  $\Delta m_{32}^2 < 0$ ) or octant of  $\theta_{23}$  (lower when  $\theta_{23} < 45^\circ$  or upper when  $\theta_{23} > 45^\circ$ ).

### (C) Other neutrino mixing results:

The LSND anomaly [AGUILAR 01], reported a signal which is consistent with  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations. In a three neutrino framework, this would be a measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . This does not appear to be consistent with the interpretation of other neutrino data. It has been interpreted as evidence for a 4th "sterile" neutrino. The following listings include results which might be relevant towards understanding this observation. They include searches for  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ , sterile neutrino oscillations, and others.

### (A) Neutrino fluxes and event ratios

#### Events (observed/expected) from accelerator $\nu_\mu$ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
$1.01 \pm 0.10$	<sup>1</sup> ABE	14B T2K	$\nu_e$ rate in T2K near detect.
$0.71 \pm 0.08$	<sup>2</sup> AHN	06A K2K	K2K to Super-K
$0.64 \pm 0.05$	<sup>3</sup> MICHAEL	06 MINS	All charged current events
$0.71 \pm 0.08$ - 0.09	<sup>4</sup> ALIU	05 K2K	KEK to Super-K
$0.70 \pm 0.10$ - 0.11	<sup>5</sup> AHN	03 K2K	KEK to Super-K

<sup>1</sup> The rate of  $\nu_e$  from  $\mu$  decay was measured to be  $0.68 \pm 0.30$  compared to the predicted flux. From  $K$  decay  $1.10 \pm 0.14$  compared to the predicted flux.

<sup>2</sup> Based on the observation of 112 events when  $158.1 \pm 9.2$  were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about  $4.3 \sigma$ . Supersedes ALIU 05.

<sup>3</sup> This ratio is based on the observation of 215 events compared to an expectation of  $336 \pm 14$  without oscillations. See also ADAMSON 08.

<sup>4</sup> This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of  $151 \pm 12$ .

<sup>5</sup> This ratio is based on the observation of 56 events with an expectation of  $80.1 \pm 6.2$ .

#### Events (observed/expected) from reactor $\bar{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor  $\bar{\nu}_e$  event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels ( $^{235}\text{U}$ ,  $^{239}\text{Pu}$ ,  $^{241}\text{Pu}$ ) and on calculations for  $^{238}\text{U}$ .

A recent re-evaluation of the spectral conversion of electron to  $\bar{\nu}_e$  in MUELLER 11 results in an upward shift of the reactor  $\bar{\nu}_e$  spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

$0.89 \pm 0.15$	<sup>11</sup> BOEHM	80	$\bar{\nu}_e p \rightarrow e^+ n$

<sup>1</sup> ALMAZAN 20 use the RHF research reactor at ILL to compare their measured anti-neutrino event rate to the calculation by HUBER 11. Reported  $0.948 \pm 0.008 \pm 0.023 \pm 0.023$  measurement with uncertainties from statistics, systematic, and model. Note that this result is obtained for highly enriched  $^{235}\text{U}$  reactor fuel while most other reactor experiments utilize a low-enrichment mix of fissile nuclides.

- <sup>2</sup> ADEY 19 present a re-analysis of 1230 days of Daya Bay near detector data with reduced systematic uncertainties on the neutron detection efficiency. Note that ADEY 19 report the measured to predicted antineutrino ratio using the reactor model of MUELLER 11 (Huber-Mueller model). The ratio using the older ILL-Vogel model is  $1.001 \pm 0.015 \pm 0.027$ .
- <sup>3</sup> AN 16 use 217 days of data (338k events) to determine the neutrino flux ratio relative to the prediction of Mueller-Huber and ILL-Vogel models (see AN 16 for details). The reported flux ratios were corrected for  $\theta_{13}$  oscillation effect. The flux measurement is consistent with results from previous short-baseline reactor experiments. The measured inverse beta decay yield is  $(1.55 \pm 0.04) \times 10^{-18} \text{ cm}^2/(\text{GW day})$  or  $\sigma_f = (5.92 \pm 0.14) \times 10^{-43} \text{ cm}^2/\text{fission}$ . About  $4\sigma$  excess of events was observed in the 4–6 MeV prompt energy region.
- <sup>4</sup> DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on  $\sin^2\theta_{\text{MNSP}} = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$ .
- <sup>5</sup> Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.
- <sup>6</sup> EGUCHI 03 observe reactor neutrino disappearance at  $\sim 180 \text{ km}$  baseline to various Japanese nuclear power reactors.
- <sup>7</sup> BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.
- <sup>8</sup> APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use  $\bar{\nu}_e p \rightarrow e^+ n$  in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.
- <sup>9</sup> GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.
- <sup>10</sup> DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.
- <sup>11</sup> KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce  $\mu$ -like and  $e$ -like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as  $\mu/e$ . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The “ratio of the ratios” of experimental to theoretical  $\mu/e$ ,  $R(\mu/e)$ , or that of experimental to theoretical  $\mu/\text{total}$ ,  $R(\mu/\text{total})$  with  $\text{total} = \mu + e$ , is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured “up-down asymmetry” for  $\mu$  ( $N_{\text{up}}(\mu)/N_{\text{down}}(\mu)$ ) or  $e$  ( $N_{\text{up}}(e)/N_{\text{down}}(e)$ ) is reported. The expected “up-down asymmetry” is nearly unity if there is no neutrino oscillation.

$R(\mu/e) = (\text{Measured Ratio } \mu/e) / (\text{Expected Ratio } \mu/e)$

- <sup>1</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring  $e$ -like events with  $0.1 \text{ GeV}/c < p_e$  and  $\mu$ -like events  $0.2 \text{ GeV}/c < p_\mu$ , both having a visible energy  $< 1.33 \text{ GeV}$ . These criteria match the definition used by FUKUDA 94.
- <sup>2</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy  $> 1.33 \text{ GeV}$  and partially-contained events. All partially-contained events are classified as  $\mu$ -like.
- <sup>3</sup> SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained  $e$ -flavor and  $\mu$ -flavor events having lepton momentum  $> 0.3 \text{ GeV}/c$ .
- <sup>4</sup> FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.
- <sup>5</sup> DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report  $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$  for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.
- <sup>6</sup> FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained  $e$ -like events with  $0.1 < p_e < 1.33 \text{ GeV}/c$  and fully-contained  $\mu$ -like events with  $0.2 < p_\mu < 1.5 \text{ GeV}/c$ .

- <sup>7</sup> FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy  $> 1.33 \text{ GeV}$  and partially contained  $\mu$ -like events.
- <sup>8</sup> BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as  $0.36 \pm 0.02 \pm 0.02$ , as compared with expected fraction  $0.51 \pm 0.01 \pm 0.05$ . After cutting the energy range to the Kamiokande limits, BEIER 92 finds  $R(\mu/e)$  very close to the Kamiokande value.

$R(\nu_\mu) = (\text{Measured Flux of } \nu_\mu) / (\text{Expected Flux of } \nu_\mu)$

- <sup>1</sup> ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of  $127 \pm 13$  without oscillations.
- <sup>2</sup> AMBROSIO 01 result is based on the upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.
- <sup>3</sup> AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- <sup>4</sup> AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- <sup>5</sup> AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of  $\pm 0.13$ . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) \sim$  a few times  $10^{-3} \text{ eV}^2$ . However, the fit to the observed zenith distribution gives a maximum probability for  $\chi^2$  of only 5% for the best oscillation hypothesis.
- <sup>6</sup> CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ( $\approx \nu_\mu$  induced) fraction is  $0.41 \pm 0.03 \pm 0.02$ , as compared with expected  $0.51 \pm 0.05$  (syst).
- <sup>7</sup> AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define  $\rho = (\text{measured number of } \nu_e\text{'s})/(\text{measured number of } \nu_\mu\text{'s})$ . They report  $\rho(\text{measured}) = \rho(\text{expected}) = 0.96^{+0.32}_{-0.28}$ .
- <sup>8</sup> From this data BOLIEV 81 obtain the limit  $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$  for maximal mixing,  $\nu_\mu \leftrightarrow \nu_\mu$  type oscillation.

$R(\mu/\text{total}) = (\text{Measured Ratio } \mu/\text{total}) / (\text{Expected Ratio } \mu/\text{total})$

$0.96^{+0.38}_{-0.27} \pm 0.15$	<sup>6</sup> ADAMSON	06	MINS atmospheric $\nu$ with far detector

<sup>1</sup> ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio  $N(\mu^+)/N(\mu^-)$  represents the  $\overline{\nu}_\mu/\nu_\mu$  ratio. As far as the same oscillation parameters are used for  $\nu_s$  and  $\overline{\nu}_s$ , the expected  $\overline{\nu}_\mu/\nu_\mu$  ratio is almost entirely independent of any input oscillations.

<sup>2</sup> This result is obtained with a charge-separated sample of high resolution contained-vertex muons.

<sup>3</sup> This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.

<sup>4</sup> The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.

<sup>5</sup> ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with CPT conservation.

<sup>6</sup> ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

### Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of  $^8\text{B}$ . Solar neutrino fluxes are composed of all active neutrino species,  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ . In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes.

### $\nu_e$ Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) =  $10^{-36}$  captures per atom per second.

VALUE (SNU)	DOCUMENT ID	TECN	COMMENT

• • • We do not use the following data for averages, fits, limits, etc. • • •

$73.4^{+6.1+3.7}_{-6.0-4.1}$	<sup>1</sup> KAETHER	10	GALX reanalysis
$67.6 \pm 4.0 \pm 3.2$	<sup>2</sup> KAETHER	10	GNO+GALX reanalysis combined
$65.4^{+3.1+2.6}_{-3.0-2.8}$	<sup>3</sup> ABDURASHI...	09	SAGE $^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$62.9^{+5.5}_{-5.3} \pm 2.5$	<sup>4</sup> ALTMANN	05	GNO $^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$69.3 \pm 4.1 \pm 3.6$	<sup>5</sup> ALTMANN	05	GNO GNO + GALX combined
$77.5 \pm 6.2^{+4.3}_{-4.7}$	<sup>6</sup> HAMPEL	99	GALX $^{71}\text{Ga} \rightarrow ^{71}\text{Ge}$
$2.56 \pm 0.16 \pm 0.16$	<sup>7</sup> CLEVELAND	98	HOME $^{37}\text{Cl} \rightarrow ^{37}\text{Ar}$

<sup>1</sup> KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

<sup>2</sup> Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

<sup>3</sup> ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense  $^{51}\text{Cr}$  (twice by GALLEX and once by SAGE) and  $^{37}\text{Ar}$  (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.

<sup>4</sup> ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

<sup>5</sup> Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

<sup>6</sup> HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is  $118.4 \pm 17.8 \pm 6.6$  SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300  $^{71}\text{Ge}$  events were observed. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense  $^{51}\text{Cr}$  (twice by GALLEX and once by SAGE) and  $^{37}\text{Ar}$  (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.

<sup>7</sup> CLEVELAND 98 is a detailed report of the  $^{37}\text{Cl}$  experiment at the Homestake Mine. The average solar neutrino-induced  $^{37}\text{Ar}$  production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

### $\Phi_{ES} (^8\text{B})$

$^8\text{B}$  solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross-section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.16\sigma(\nu_e e)$ . If the  $^8\text{B}$  solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is  $\sim 0.16$  times of  $\nu_e$ .

## Neutrino Mixing

2.80 ± 0.19 ± 0.33	<sup>17</sup> FUKUDA	96	KAMI	average flux
2.70 ± 0.27	<sup>17</sup> FUKUDA	96	KAMI	day flux
2.87 +0.27 -0.26	<sup>17</sup> FUKUDA	96	KAMI	night flux

- 1 AGOSTINI 20A obtained this result from the  $\nu_e e$  elastic scattering rate over the period between January 2008 and December 2016. Uses the same data as AGOSTINI 18B, but the analysis technique is significantly improved.
- 2 ANDERSON 19 reports this result from the  $\nu_e e$  elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase. The events over the reconstructed electron kinetic energy range of 5–15 MeV were analyzed.
- 3 AGOSTINI 18B obtained this result from the  $\nu_e e$  elastic scattering rate over the period between January 2008 and December 2016.
- 4 ABE 16c reports the combined results of the four phases of the Super-Kamiokande average flux measurements. Here the revised Super-Kamiokande-III result is used.
- 5 ABE 16c reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold is total electron energy of 4.0 MeV.
- 6 ABE 16c revised the Super-Kamiokande-III average flux value reported in ABE 11. Super-Kamiokande-III results are for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron energy range has a total live time of 298 days.
- 7 ABE 11 recalculated the Super-Kamiokande-II results using <sup>8</sup>B spectrum of WINTER 06A.
- 8 ABE 11 recalculated the Super-Kamiokande-I results using <sup>8</sup>B spectrum of WINTER 06A.
- 9 ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the <sup>8</sup>B solar neutrino flux. They utilize  $\nu - e$  elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which  $157 \pm 23.6$  are assigned to background.
- 10 BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.
- 11 AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.
- 12 CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.
- 13 HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- 14 AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.
- 15 AHMAD 02 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.
- 16 AHMAD 01 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.
- 17 FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold  $E_e > 9.3$  MeV (first 449 days),  $> 7.5$  MeV (middle 794 days), and  $> 7.0$  MeV (last 836 days). These results update the HIRATA 90 result for the average <sup>8</sup>B solar-neutrino flux and HIRATA 91 result for the day-night variation in the <sup>8</sup>B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

### $\phi_{CC}$ (<sup>8</sup>B)

<sup>8</sup>B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to  $\nu_e$ .

VALUE ( $10^6 \text{ cm}^{-2}\text{s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT

- 1 MA 23A searched for <sup>8</sup>B solar neutrinos elastically scattered off xenon nuclei in the commissioning phase of the PANDAX-4T experiment with an effective exposure of 0.48 ton-yr. This experiment is dedicated to dark matter direct search using a dual-phase xenon TPC with a sensitive volume of 3.7 tons of liquid Xe.
- 2 AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the <sup>8</sup>B flux mostly comes from the NC signal, however, CC contribution is included in the fit.
- 3 AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.
- 4 AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

$5.44 \pm_{-0.99}^{+0.99}$	<sup>8</sup> AHMAD	01	Derived from SNO+SuperKam, water Cherenkov
----------------------------	--------------------	----	--

<sup>1</sup>ANDERSON 19 reports this result from the measured  $\nu_e e$  elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase, assuming the neutrino mixing parameters given in PDG 16 and a standard solar model given in BAHCALL 05.

<sup>2</sup>AGOSTINI 18B obtained this result from the measured  $\nu_e e$  elastic scattering rate over the period between January 2008 and December 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17. Assuming a high-metallicity standard solar model, the electron neutrino survival probability for the  $^8\text{B}$  solar neutrino is calculated to be  $0.37 \pm 0.08$ .

<sup>3</sup>AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the  $^8\text{B}$  flux mostly comes from the NC signal, however, CC contribution is included in the fit.

<sup>4</sup>AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total  $^8\text{B}$  neutrino flux and the energy-dependent  $\nu_e$  survival probability.

<sup>5</sup>AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the  $^8\text{B}$  shape.

<sup>6</sup>AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the  $^8\text{B}$  energy spectrum was not constrained. In the other method, the constraint of an undistorted  $^8\text{B}$  energy spectrum was added for comparison with AHMAD 02 results.

<sup>7</sup>AHMAD 02 determined the total flux of active  $^8\text{B}$  solar neutrinos by directly measuring the neutral-current reaction,  $\nu_e d \rightarrow np\nu_e$ , which is equally sensitive to  $\nu_e, \nu_\mu$ , and  $\nu_\tau$ . The complete description of the SNO Phase I data set is given in AHARMIM 07.

<sup>8</sup>AHMAD 01 deduced the total flux of active  $^8\text{B}$  solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande  $\nu_e$  elastic-scattering result (FUKUDA 01).

### Total Flux of Active CNO Solar Neutrinos

Total flux of active neutrinos ( $\nu_e, \nu_\mu, \nu_\tau$ ).

VALUE ( $10^8 \text{ cm}^{-2} \text{ s}^{-1}$ )	CL%	DOCUMENT ID	TECN	COMMENT
---	-----	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$6.7 \pm_{-0.8}^{+1.2}$		<sup>1</sup> BASILICO	23	BORX $\nu_e e$ directional + spectral information
-------------------------	--	-----------------------	----	---

$6.6 \pm_{-0.9}^{+2.0}$		<sup>2</sup> APPEL	22	BORX $\nu_e e$ scattering rate
-------------------------	--	--------------------	----	--------------------------------

$7.0 \pm_{-2.0}^{+3.0}$		<sup>3</sup> AGOSTINI	20D	BORX $\nu_e e$ scattering rate
-------------------------	--	-----------------------	-----	--------------------------------

$<7.9$	95	<sup>4</sup> AGOSTINI	18B	BORX $\nu_e e$ scattering rate
--------	----	-----------------------	-----	--------------------------------

<sup>1</sup>BASILICO 23 obtained this result by combining the newly developed Correlated Integrated Directionality (CID)-based CNO result obtained by using the complete Borexino data-taking period from 2007 to 2021, with a spectral fit of the Phase-III dataset (from July 2016 to October 2021, characterized by a thermally stable detector). Note that the directional information is independent from the spectral information on which the previous CNO solar neutrino measurements by Borexino were based. Neutrino flavor conversion was taken into account.

<sup>2</sup>APPEL 22 obtained this result from the measured  $\nu_e e$  elastic scattering rate over the period between January 2017 and October 2021, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 20A. The exposure corresponding to this data is 1431.6 days  $\times$  71.3 tons.

<sup>3</sup>AGOSTINI 20D obtained this result from the measured  $\nu_e e$  elastic scattering rate over the period between July 2016 to February 2020, assuming the MSW-LMA oscillation parameters derived by CAPOZZI 18.

<sup>4</sup>AGOSTINI 18B obtained this result from an upper limit of the  $\nu_e e$  elastic scattering rate for the CNO neutrinos over the period between December 2011 and May 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17.

### Total Flux of Active hep Solar Neutrinos

Total flux of active neutrinos ( $\nu_e, \nu_\mu, \nu_\tau$ ).

VALUE ( $10^5 \text{ cm}^{-2} \text{ s}^{-1}$ )	CL%	DOCUMENT ID	TECN	COMMENT
---	-----	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

$<1.8$	90	<sup>1</sup> AGOSTINI	20A	BORX $\nu_e e$ scattering and $^{12}\text{C}(\nu, \nu')^{12}\text{C}^*$
--------	----	-----------------------	-----	---

$<0.3$	90	<sup>2</sup> AHARMIM	20	SNO CC, NC, $\nu_e e$ scattering
--------	----	----------------------	----	----------------------------------

$<2.2$	90	<sup>3</sup> AGOSTINI	18B	BORX $\nu_e e$ scattering rate
--------	----	-----------------------	-----	--------------------------------

<sup>1</sup>AGOSTINI 20A obtained this result from an upper limit of the  $\nu_e e$  elastic scattering rate and NC-mediated inelastic scattering on carbon nuclei with 15.1 MeV deexcitation  $\gamma$ -ray for the hep neutrino. The dataset corresponds to an effective exposure of 0.745 kt-yr from November 2009 to October 2017. A FADC DAQ system, optimized for the acquisition of high-energy events was used for data collection. The MSW-LMA oscillation parameters derived by ESTEBAN 17 were assumed.

<sup>2</sup>AHARMIM 20 uses the entire SNO dataset, corresponding to 2.47 kton-yr of exposure after fiducialization. With the  $\text{D}_2\text{O}$  target, SNO was sensitive to charged current, neutral current, and elastic scattering channels.

<sup>3</sup>AGOSTINI 18B obtained this result from an upper limit of the  $\nu_e e$  elastic scattering rate for the hep neutrino using the dataset corresponding to an exposure of 0.8 kt-yr and assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17.

$0.14 \pm 0.063 \pm^{+0.015}_{-0.014}$	<sup>8</sup> AHMAD	02B	SNO	Derived from SNO $\phi_{CC}$
$0.07 \pm 0.049 \pm^{+0.013}_{-0.012}$	<sup>9</sup> AHMAD	02B	SNO	Const. of no $\phi_{NC}$ asymmetry

- <sup>1</sup> ABE 16c reports the combined day-night flux asymmetry results of the four phases of the Super-Kamiokande measurements. Amplitude fit method is used. See footnote to RENSHAW 14.
- <sup>2</sup> ABE 16c reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold for day-night flux asymmetry is recoil electron energy of 4.49 MeV (total electron energy of 5.0 MeV). Amplitude fit method is used. See footnote to RENSHAW 14.
- <sup>3</sup> RENSHAW 14 obtains this result by using the "amplitude fit" introduced in SMY 04. The data from the Super-Kamiokande(SK)-I, -II, -III, and 1306 live days of the SK-IV measurements are used. The analysis threshold is recoil-electron kinetic energy of 4.5 MeV for SK-I, and SK-IV except for 250 live days in SK-III (6.0 MeV). The analysis threshold for SK-I and SK-II is the same as in the previous reports. (Note that in the previous SK solar-neutrino results, the analysis threshold is quoted as recoil-electron total energy.) This day-night asymmetry result is consistent with neutrino oscillations for  $4 \times 10^{-5} \text{ eV}^2 < \Delta m_{21}^2 < 7 \times 10^{-5} \text{ eV}^2$  and large mixing values of  $\theta_{12}$  at the 68% CL.
- <sup>4</sup> CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV except for the first 159 live days (8.0 MeV).
- <sup>5</sup> HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- <sup>6</sup> This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via  $\nu_e$  elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of  $\pm 0.0004$  coming from uncertainty of oscillation parameters.
- <sup>7</sup> AHARMIM 05a measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the <sup>8</sup>B shape.
- <sup>8</sup> AHMAD 02b results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.
- <sup>9</sup> AHMAD 02b results are derived from the charged-current interactions, neutral-current interactions, and  $\nu_e$  elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

### $\phi_{ES}$ (<sup>7</sup>Be)

<sup>7</sup>Be solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_{\mu}, \nu_{\tau}$  due to the cross-section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the <sup>7</sup>Be solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

VALUE ( $10^8 \text{ cm}^{-2} \text{ s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT
$3.26 \pm 0.52$	<sup>1</sup> GANDO	15	KLND average flux
$3.10 \pm 0.15$	<sup>2</sup> BELLINI	11A	BORX average flux

- $\bullet \bullet \bullet$  We do not use the following data for averages, fits, limits, etc.  $\bullet \bullet \bullet$
- <sup>1</sup> GANDO 15 uses 165.4 kton-day exposure of the KamLAND liquid scintillator detector to measure the 862 keV <sup>7</sup>Be solar neutrino flux via  $\nu - e$  elastic scattering
- <sup>2</sup> BELLINI 11A reports the <sup>7</sup>Be solar neutrino flux measured via  $\nu - e$  elastic scattering. The data correspond to 740.7 live days between May 16, 2007 and May 8, 2010, and also correspond to 153.6 ton-year fiducial exposure. BELLINI 11A measured the 862 keV <sup>7</sup>Be solar neutrino flux, which is an 89.6% branch of the <sup>7</sup>Be solar neutrino flux, to be  $(2.78 \pm 0.13) \times 10^9 \text{ cm}^{-2} \text{ s}^{-1}$ . Supersedes ARPESELLA 08A.

### $\phi_{ES}$ (*pep*)

*pep* solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_{\mu}, \nu_{\tau}$  due to the cross section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the *pep* solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

VALUE ( $10^8 \text{ cm}^{-2} \text{ s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT
$1.0 \pm 0.2$	<sup>1</sup> BELLINI	12A	BORX average flux

- $\bullet \bullet \bullet$  We do not use the following data for averages, fits, limits, etc.  $\bullet \bullet \bullet$
- <sup>1</sup> BELLINI 12A reports 1.44 MeV *pep* solar-neutrino flux measured via  $\nu_e$  elastic scattering. The data were collected between January 13, 2008 and May 9, 2010, corresponding to 20,409 ton-day fiducial exposure. The listed flux value is calculated from the observed rate of *pep* solar neutrino interactions in Borexino  $(3.1 \pm 0.6 \pm 0.3 \text{ counts}/(\text{day} \cdot 100$

ton)) and the corresponding rate expected for no neutrino flavor oscillations  $(4.47 \pm 0.05 \text{ counts}/(\text{day} \cdot 100 \text{ ton}))$ , using the SSM prediction for the *pep* solar neutrino flux of  $(1.441 \pm 0.012) \times 10^8 \text{ cm}^{-2} \text{ s}^{-1}$ .

### $\phi_{ES}$ (CNO)

CNO solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_{\mu}, \nu_{\tau}$  due to the cross section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the CNO solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

VALUE ( $10^8 \text{ cm}^{-2} \text{ s}^{-1}$ )	CL%	DOCUMENT ID	TECN	COMMENT
$< 7.7$	90	<sup>1</sup> BELLINI	12A	BORX MSW-LMA solution assumed

- $\bullet \bullet \bullet$  We do not use the following data for averages, fits, limits, etc.  $\bullet \bullet \bullet$
- <sup>1</sup> BELLINI 12A reports an upper limit of the CNO solar neutrino flux measured via  $\nu_e$  elastic scattering. The data were collected between January 13, 2008 and May 9, 2010, corresponding to 20,409 ton-day fiducial exposure.

### $\phi_{ES}$ (*pp*)

*pp* solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_{\mu}, \nu_{\tau}$  due to the cross section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.3 \sigma(\nu_e e)$ . If the *pp* solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.3$  times of  $\nu_e$ .

VALUE ( $10^{10} \text{ cm}^{-2} \text{ s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT
$4.4 \pm 0.5$	<sup>1</sup> BELLINI	14A	BORX average flux

- $\bullet \bullet \bullet$  We do not use the following data for averages, fits, limits, etc.  $\bullet \bullet \bullet$
- <sup>1</sup> BELLINI 14A reports *pp* solar-neutrino flux measured via  $\nu_e$  elastic scattering. The data were collected between January 2012 and May 2013, corresponding to 408 days of data. The *pp* neutrino interaction rate in Borexino is measured to be  $144 \pm 13 \pm 10 \text{ counts}/(\text{day} \cdot 100 \text{ ton})$  by fitting the measured energy spectrum of events in the 165–590 keV recoil electron kinetic energy window with the expected signal + background spectrum. The listed flux value  $\phi_{ES}(pp)$  is calculated from the observed rate and the number of  $(3.307 \pm 0.003) \times 10^{31}$  electrons for 100 tons of the Borexino scintillator, and the  $\nu_e e$  integrated cross section over the *pp* neutrino spectrum,  $\sigma(\nu_e e) = 11.38 \times 10^{-46} \text{ cm}^2$ .

### $\phi_{CC}$ (*pp*)

*pp* solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to  $\nu_e$ .

<sup>1</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

<sup>2</sup> SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

<sup>3</sup> ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

<sup>4</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

<sup>5</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

<sup>6</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

<sup>7</sup> FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

<sup>8</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $0.304^{+0.013}_{-0.012}$  for normal and  $0.305^{+0.012}_{-0.013}$  for inverted mass ordering.

<sup>9</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>10</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

<sup>11</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>12</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND (GANDO 11) data. *CPT* invariance is assumed.

<sup>13</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.

<sup>14</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming *CPT* invariance. Supersedes GANDO 11.

<sup>15</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

<sup>16</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.

<sup>17</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

<sup>18</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and *CPT* invariance are assumed.

<sup>19</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

<sup>20</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free. *CPT* invariance is assumed.

<sup>21</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free.

<sup>22</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

<sup>23</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.

<sup>24</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

<sup>25</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

<sup>26</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>27</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

<sup>28</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>29</sup> ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2\theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.

<sup>30</sup> ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

## Neutrino Mixing

- <sup>31</sup> The result given by AHARMIM 08 is  $\theta = (34.4^{+1.3}_{-1.2})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>32</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK  $\nu_e$  data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- <sup>33</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- <sup>34</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.
- <sup>35</sup> The result given by AHARMIM 05A is  $\theta = (33.9 \pm 1.6)^\circ$ . This result is obtained by a two-neutrino oscillation analysis using SNO pure deuterium and salt phase data, SK  $\nu_e$  data, CI and Ga CC data, and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes  $\theta = (33.9^{+2.4}_{-2.2})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$ .
- <sup>36</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\tan^2 \theta = 0.45^{+0.09}_{-0.08}$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$ .
- <sup>37</sup> ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The  $1\sigma$  error shown here is translated from the number provided by the KamLAND collaboration,  $\tan^2 \theta = 0.40^{+0.07}_{-0.05}$ . The corresponding number quoted in ARAKI 05 is  $\tan^2 \theta = 0.40^{+0.10}_{-0.07}$  ( $\sin^2 2\theta = 0.82 \pm 0.07$ ), which envelops the 68% CL two-dimensional region.
- <sup>38</sup> The result given by AHMED 04A is  $\theta = (32.5^{+1.7}_{-1.6})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes  $\theta = (32.5^{+2.4}_{-2.3})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.82 \pm 0.06$ .
- <sup>39</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$ ,  $\tan^2 \theta = 0.40$  ( $\sin^2 2\theta = 0.82$ ).
- <sup>40</sup> The result given by SMY 04 is  $\tan^2 \theta = 0.44 \pm 0.08$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- <sup>41</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>42</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>43</sup> AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).
- <sup>44</sup> FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2 \theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

- <sup>1</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.
- <sup>2</sup> SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.
- <sup>3</sup> ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.
- <sup>4</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.
- <sup>5</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.
- <sup>6</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.
- <sup>7</sup> ABE 16c obtained this result by a three-neutrino oscillation analysis, with a constraint of  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$  coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.
- <sup>8</sup> FORERO 14 performs a global fit to  $\Delta m_{21}^2$  using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- <sup>9</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $(7.50^{+0.19}_{-0.17}) \times 10^{-5} \text{ eV}^2$  for normal and  $(7.50^{+0.18}_{-0.17}) \times 10^{-5} \text{ eV}^2$  for inverted mass ordering.
- <sup>10</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- <sup>11</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.
- <sup>12</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.
- <sup>13</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND data (GANDO 11). *CPT* invariance is assumed.
- <sup>14</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming *CPT* invariance. Supersedes GANDO 11.
- <sup>15</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

## Neutrino Mixing

- <sup>16</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.
- <sup>17</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.
- <sup>18</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and *CPT* invariance are assumed.
- <sup>19</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- <sup>20</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free. *CPT* invariance is assumed.
- <sup>21</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the  $^8\text{B}$  flux was left free.
- <sup>22</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.
- <sup>23</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.
- <sup>24</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- <sup>25</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>26</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- <sup>27</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>28</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.
- <sup>29</sup> ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2 \theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.
- <sup>30</sup> ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.
- <sup>31</sup> AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- <sup>32</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- <sup>33</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- <sup>34</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.
- <sup>35</sup> HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the  $1\sigma$  boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at  $\tan^2 \theta = 0.44$  because the fit depends only very weakly on it.
- <sup>36</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes  $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>37</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\Delta(m^2) = (6.5^{+4.4}_{-2.3}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>38</sup> ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The  $1\sigma$  error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05,  $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$ , envelops the 68% CL two-dimensional region.
- <sup>39</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes  $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.
- <sup>40</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$ ,  $\tan^2 \theta = 0.40$  ( $\sin^2 2\theta = 0.82$ ).

- <sup>41</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- <sup>42</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>43</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.
- <sup>44</sup> AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).
- <sup>45</sup> FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2 \theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

### $\sin^2(\theta_{23})$

The reported limits below correspond to the projection onto the  $\sin^2(\theta_{23})$  axis of the 90% CL contours in the  $\sin^2(\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL.

If an experiment reports  $\sin^2(2\theta_{23})$  we convert the value to  $\sin^2(\theta_{23})$ .

## Neutrino Mixing

0.551 <sup>+0.018</sup> <sub>-0.030</sub>	DE-SALAS	18	FIT	Inverted mass order, global fit	4	ADAMSON 20A uses the complete dataset from MINOS and MINOS+ experiments. The data were collected using a total exposure of 23.76 × 10 <sup>20</sup> protons on target and 60.75 kton-yr exposure to atmospheric neutrinos. Supersedes ADAMSON 14.
0.532 <sup>+0.061</sup> <sub>-0.087</sub>	20 ABE	17A	T2K	Normal mass ordering	5	ABE 18b uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, $\Delta m_{32}^2$ , $\sin^2(\theta_{23})$ , and $\delta$ , while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ , $\sin^2(\theta_{12}) = 0.304 \pm 0.014$ , and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$ .
0.534 <sup>+0.061</sup> <sub>-0.087</sub>	20 ABE	17A	T2K	Inverted mass ordering	6	ABE 23d uses the same dataset as ABE 23f. The measurement of $\sin^2(\theta_{23})$ is performed independently for $\nu_\mu$ and $\bar{\nu}_\mu$ .
0.51 <sup>+0.08</sup> <sub>-0.07</sub>	ABE	17C	T2K	Normal mass ordering with neutrinos	7	ABE 21a results are based on $1.49 \times 10^{21}$ POT in neutrino mode and $1.64 \times 10^{21}$ POT in antineutrino mode.
0.42 <sup>+0.25</sup> <sub>-0.07</sub>	ABE	17C	T2K	Normal mass ordering with antineutrinos	8	SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.
0.52 <sup>+0.075</sup> <sub>-0.09</sub>	ABE	17C	T2K	normal mass ordering with neutrinos and antineutrinos	9	AARTSEN 20 uses the data taken between May 2012 and April 2014 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. The reconstructed energy range is between 4 (5) and 90 (80) GeV for the main (confirmatory) analysis. Though the observed best-fit is in the lower octant for both mass orderings, a substantial range of $\sin^2(\theta_{23}) > 0.5$ is still compatible with the observed data for both mass orderings.
0.55 <sup>+0.05</sup> <sub>-0.09</sub>	20 ABE	17F	T2K	Normal mass ordering	10	ABE 20f results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of $1.49 \times 10^{21}$ ( $1.64 \times 10^{21}$ ) protons on target. Supersedes ABE 18g.
0.55 <sup>+0.05</sup> <sub>-0.08</sub>	20 ABE	17F	T2K	Inverted mass ordering	11	ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.
0.404 <sup>+0.022</sup> <sub>-0.030</sub>	21 ADAMSON	17A	NOVA	Normal mass ordering; octant I for $\theta_{23}$	12	AARTSEN 19c uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19c adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18a to measure the $\nu_\mu$ disappearance.
0.624 <sup>+0.022</sup> <sub>-0.030</sub>	21 ADAMSON	17A	NOVA	Normal mass ordering; octant II for $\theta_{23}$	13	ACERO 19 is based on a sample size of $12.33 \times 10^{20}$ protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by $1.9 \sigma$ and $\theta_{23}$ values in octant II by $1.6 \sigma$ . Supersedes ACERO 18.
0.398 <sup>+0.030</sup> <sub>-0.022</sub>	21 ADAMSON	17A	NOVA	Inverted mass ordering; octant I for $\theta_{23}$	14	Errors are from normal mass ordering and $\theta_{13}$ octant II fits.
0.618 <sup>+0.022</sup> <sub>-0.030</sub>	21 ADAMSON	17A	NOVA	Inverted mass ordering; octant II for $\theta_{23}$	15	ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.
0.45 <sup>+0.19</sup> <sub>-0.07</sub>	22 ABE	16D	T2K	$3\nu$ osc; normal mass ordering; $\bar{\nu}$ beam	16	ADAMSON 18a uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18a also reports the best fit result for the inverted mass ordering as $\Delta m_{32}^2 = -2.32 \times 10^{-3} \text{ eV}^2$ and $\sin^2(\theta_{23}) = 0.51$ . Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15a.
0.38 to 0.65	23 ADAMSON	16A	NOVA	normal mass ordering	17	ABE 18b uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, $\Delta m_{32}^2$ , $\sin^2\theta_{23}$ , $\sin^2\theta_{13}$ , and $\delta$ , while the solar parameters are fixed to $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_{12} = 0.304 \pm 0.014$ .
0.37 to 0.64	23 ADAMSON	16A	NOVA	Inverted mass ordering	18	ABE 18g data prefers normal mass ordering is with a posterior probability of 87%. Supersedes ABE 17f.
0.53 <sup>+0.09</sup> <sub>-0.12</sub>	24 AARTSEN	15A	ICCB	Normal mass ordering	19	ACERO 18 performs a joint fit to the data for $\nu_\mu$ disappearance and $\nu_e$ appearance. The overall best fit favors normal mass ordering and $\theta_{23}$ in octant II. No $1\sigma$ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.
0.51 <sup>+0.09</sup> <sub>-0.11</sub>	24 AARTSEN	15A	ICCB	Inverted mass ordering	20	Errors are from the projections of the 68% contour on 2D plot of $\Delta m^2$ versus $\sin^2(\theta_{23})$ . ABE 17f supersedes ABE 17a. Superseded by ABE 18g.
0.514 <sup>+0.055</sup> <sub>-0.056</sub>	25 ABE	14	T2K	$3\nu$ osc.; normal mass ordering	21	Superseded by ACERO 18.
0.511 $\pm$ 0.055	25 ABE	14	T2K	$3\nu$ osc.; inverted mass ordering	22	ABE 16d reports oscillation results using $\bar{\nu}_\mu$ disappearance in an off-axis beam.
0.41 <sup>+0.23</sup> <sub>-0.06</sub>	26 ADAMSON	14	MINS	Normal mass ordering	23	ADAMSON 16a obtains $\sin^2(\theta_{23})$ in the 68% C.L. range [0.38, 0.65] ([0.37, 0.64]), with two statistically degenerate best-fit values of 0.44 and 0.59 (0.44 and 0.59) for normal (inverted) mass ordering. Superseded by ADAMSON 17a.
0.41 <sup>+0.26</sup> <sub>-0.07</sub>	26 ADAMSON	14	MINS	Inverted mass ordering	24	AARTSEN 15a obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18a.
0.567 <sup>+0.032</sup> <sub>-0.128</sub>	27 FORERO	14	FIT	Normal mass ordering	25	ABE 14 results are based on $\nu_\mu$ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. Superseded by ABE 17a.
0.573 <sup>+0.025</sup> <sub>-0.043</sub>	27 FORERO	14	FIT	Inverted mass ordering	26	ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the $\nu_\mu$ disappearance and $\nu_e$ appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for first $\theta_{23}$ octant and inverted mass ordering.
0.452 <sup>+0.052</sup> <sub>-0.028</sub>	28 GONZALEZ...	14	FIT	Normal mass ordering; global fit	27	FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
0.579 <sup>+0.025</sup> <sub>-0.037</sub>	28 GONZALEZ...	14	FIT	Inverted mass ordering; global fit	28	GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.
0.24 to 0.76	29 AARTSEN	13b	ICCB	DeepCore, $2\nu$ oscillation	29	AARTSEN 13b obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
0.514 $\pm$ 0.082	30 ABE	13g	T2K	$3\nu$ osc.; normal mass ordering	30	The best fit value is $\sin^2(\theta_{23}) = 0.514 \pm 0.082$ . Superseded by ABE 14.
0.388 <sup>+0.051</sup> <sub>-0.053</sub>	31 ADAMSON	13b	MINS	Beam + Atmospheric; identical $\nu$ & $\bar{\nu}$	31	ADAMSON 13b obtained this result from $\nu_\mu$ and $\bar{\nu}_\mu$ disappearance using $\nu_\mu$ (10.71 × 10 <sup>20</sup> POT) and $\bar{\nu}_\mu$ (3.36 × 10 <sup>20</sup> POT) beams, and atmospheric (37.88kton-years) data

## Neutrino Mixing

- from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_\mu$  and  $\bar{\nu}_\mu$  oscillation parameters. Superseded by ADAMSON 14.
- <sup>32</sup> ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\sin^2(2\theta_{23}) = 0.98$ .
- <sup>33</sup> ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is  $\sin^2(2\theta_{23}) = 0.95^{+0.10}_{-0.11} \pm 0.01$ .
- <sup>34</sup> ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- <sup>35</sup> The best fit point is  $\Delta m^2 = 0.0019 \text{ eV}^2$  and  $\sin^2 2\theta = 0.99$ . The 90% single-parameter confidence interval at the best fit point is  $\sin^2 2\theta > 0.86$ .
- <sup>36</sup> The data are separated into pure samples of  $\nu_s$  and  $\bar{\nu}_s$ , and separate oscillation parameters for  $\nu_s$  and  $\bar{\nu}_s$  are fit to the data. The best fit point is  $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$  and  $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$ . The quoted result is taken from the 90% C.L. contour in the  $(\Delta m^2, \sin^2 2\theta)$  plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- <sup>37</sup> ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.
- <sup>38</sup> ABE 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between  $\nu$  and  $\bar{\nu}$ , and obtained  $\sin^2 2\theta > 0.93$  for  $\nu$  and  $\sin^2 2\theta > 0.83$  for  $\bar{\nu}$  at 90% C.L.
- <sup>39</sup> ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- <sup>40</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.407\text{--}0.583$ ) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming  $\theta_{13} = 0$  but including the solar oscillation parameters  $\Delta m_{21}^2$  and  $\sin^2 \theta_{12}$  in the fit.
- <sup>41</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.43\text{--}0.61$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- <sup>42</sup> WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.44\text{--}0.63$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- <sup>43</sup> ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- <sup>44</sup> Supersedes ALIU 05.
- <sup>45</sup> MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- <sup>46</sup> The best fit is for maximal mixing.
- <sup>47</sup> ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017 \text{ eV}^2$  and  $\sin^2(2\theta) = 0.97$ .
- <sup>48</sup> ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- <sup>49</sup> AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ ,  $N_{low}$  and  $N_{high}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{low}$  and  $N_{high}$  are the number of events with reconstructed neutrino energies  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- <sup>50</sup> ASHIE 04 obtained this result from the  $L(\text{flight length})/E(\text{estimated neutrino energy})$  distribution of  $\nu_\mu$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- <sup>51</sup> There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- <sup>52</sup> AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{low}/N_{high}$ , where  $N_{low}$  and  $N_{high}$  are the number of upward through-going muon events with reconstructed neutrino energy  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.
- <sup>53</sup> AMBROSIO 03 obtained this result by using the ratio  $R$  and the angular distribution of the upward through-going muons.  $R$  is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- <sup>54</sup> SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the  $e$ -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is  $\sin^2(2\theta) = 0.97$ .
- <sup>55</sup> AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- <sup>56</sup> AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . See the previous footnote.
- <sup>57</sup> FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold

of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is  $\sin^2(2\theta) = 0.95$ .

- <sup>58</sup> FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is to maximal mixing.
- <sup>59</sup> FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.
- <sup>60</sup> FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.
- <sup>61</sup> HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux of upward through-going muons is  $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for maximal mixing.
- <sup>62</sup> HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is  $\sin^2(2\theta) = 0.95$ .
- <sup>63</sup> FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

### $\Delta m_{32}^2$

The sign of  $\Delta m_{32}^2$  is not known at this time. If given, values are shown separately for the normal and inverted mass ordering. Unless otherwise specified, the ranges below correspond to the projection onto the  $\Delta m_{32}^2$  axis of the 90% CL contours in the  $\sin^2(2\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

<sup>1</sup> ABBASI 23 uses atmospheric neutrino data measured between 2011 and 2019 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Supersedes AARTSEN 18A.

<sup>2</sup> ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of  $1.97 \times 10^{21}$  ( $1.63 \times 10^{21}$ ) protons on target. Supersedes ABE 20F.

<sup>3</sup> ABE 23F reports  $\Delta m_{13}^2 = (2.463 \pm 0.042 \pm 0.056) \times 10^{-3} \text{ eV}^2$  for inverted mass ordering. We convert to  $\Delta m_{32}^2$  using PDG 23 value of  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ .

<sup>4</sup> AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in  $5.55 \times 10^6 \bar{\nu}_e$  candidate events. Solar oscillation parameters are fixed in the analysis to  $\sin^2(\theta_{12}) = 0.307 \pm 0.013$ ,  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$  from PDG 20. Supersedes ACERO 18A.

<sup>5</sup> ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 ( $12.5 \times 10^{20}$  POT) and Feb 6, 2014 to Mar 20, 2020 ( $13.6 \times 10^{20}$  POT). For normal mass ordering and  $\theta_{23}$  octant I (lower octant), best fit is  $0.00239 \text{ eV}^2$ ; for inverted mass ordering and octant I, best fit is  $-0.00244 \text{ eV}^2$ . Supersedes ACERO 19.

<sup>6</sup> ADAMSON 20A uses the complete dataset from MINOS and MINOS+ experiments. The data were collected using a total exposure of  $23.76 \times 10^{20}$  protons on target and  $60.75 \text{ kton-yr}$  exposure to atmospheric neutrinos. Supersedes ADAMSON 14.

<sup>7</sup> ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters,  $\Delta m_{32}^2$ ,  $\sin^2(\theta_{23})$ , and  $\delta$ , while the solar parameters and  $\sin^2(\theta_{13})$  are fixed to  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ ,  $\sin^2(\theta_{12}) = 0.304 \pm 0.014$ , and  $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$ .

<sup>8</sup> BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. We convert the results to  $\Delta m_{32}^2$  using the PDG 18 values of  $\sin^2\theta_{12} = 0.307 \pm 0.013$  and  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ . Supersedes SEO 18.

<sup>9</sup> ABE 23D uses the same dataset as ABE 23F. The measurement of  $\Delta m_{32}^2$  is performed independently for  $\nu_\mu$  and  $\bar{\nu}_\mu$ .

<sup>10</sup> ABE 21A results are based on  $1.49 \times 10^{21}$  POT in neutrino mode and  $1.64 \times 10^{21}$  POT in antineutrino mode.

<sup>11</sup> ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of  $1.49 \times 10^{21}$  ( $1.64 \times 10^{21}$ ) protons on target. Supersedes ABE 18G.

<sup>12</sup> ABE 20F reports  $\Delta m_{13}^2 = (2.43 \pm 0.07) \times 10^{-3} \text{ eV}^2$  for inverted mass ordering. We convert to  $\Delta m_{32}^2$  using PDG 20 value of  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ .

<sup>13</sup> ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

<sup>14</sup> AARTSEN 19c uses three years (April 2012 - May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy sub-detector DeepCore of the IceCube neutrino telescope. AARTSEN 19c adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the  $\nu_\mu$  disappearance.

<sup>15</sup> ACERO 19 is based on a sample size of  $12.33 \times 10^{20}$  protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by  $1.9 \sigma$  and  $\theta_{23}$  values in octant II by  $1.6 \sigma$ . Superseded by ACERO 22.

<sup>16</sup> ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

<sup>17</sup> AARTSEN 18A uses three years (April 2012 - May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy sub-detector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit values for the inverted mass ordering as  $\Delta m_{32}^2 = -2.32 \times 10^{-3} \text{ eV}^2$  and  $\sin^2(\theta_{23}) = 0.51$ . Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

<sup>18</sup> ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters,  $\Delta m_{32}^2$ ,  $\sin^2\theta_{23}$ ,  $\sin^2\theta_{13}$ , and  $\delta$ , while the solar parameters are fixed to  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$  and  $\sin^2\theta_{12} = 0.304 \pm 0.014$ .

# Lepton Particle Listings

## Neutrino Mixing

- <sup>19</sup> ABE 18c data prefers normal ordering with a posterior probability of 87%. Supersedes ABE 17f.
- <sup>20</sup> ABE 18g reports  $\Delta m_{13}^2 = (2.432 \pm 0.070) \times 10^{-3} \text{ eV}^2$  for inverted mass ordering. We convert to  $\Delta m_{32}^2$  using PDG 18 value of  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ .
- <sup>21</sup> ACERO 18 performs a joint fit to the data for  $\nu_\mu$  disappearance and  $\nu_e$  appearance. The overall best fit favors normal mass ordering and  $\theta_{23}$  in octant II. No  $1\sigma$  confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.
- <sup>22</sup> The error for octant I is taken from the result for octant II.
- <sup>23</sup> ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with  $3.9 \times 10^6 \bar{\nu}_e$  candidates. The fit to the data gives  $\Delta m_{ee}^2 = (2.522 \pm 0.068 \pm 0.076) \times 10^{-3} \text{ eV}^2$ . Solar oscillation parameters are fixed in the analysis using the global averages,  $\sin^2(\theta_{12}) = 0.307 \pm 0.013$ ,  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ , from PDG 18. Supersedes AN 17A.
- <sup>24</sup> AGAFONOVA 18 assumes maximal  $\theta_{23}$  mixing.
- <sup>25</sup> SEO 18 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to  $\theta_{13}$  and  $\Delta m_{ee}^2$  yields  $\Delta m_{ee}^2 = (2.62 \pm 0.21 \pm 0.12 \pm 0.23 \pm 0.13) \times 10^{-3} \text{ eV}^2$ . We convert the results to  $\Delta m_{32}^2$  using the PDG 18 values of  $\sin^2 \theta_{12}$  and  $\Delta m_{21}^2$ . SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.
- <sup>26</sup> ABE 17f confidence intervals are obtained using a frequentist analysis including  $\theta_{13}$  constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18g.
- <sup>27</sup> Superseded by ACERO 18.
- <sup>28</sup> AN 17A report results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than  $2.5 \times 10^6$  inverse beta-decay events with neutron capture on Gd. The fit to the data gives  $\Delta_{ee}^2 = (2.50 \pm 0.06 \pm 0.06) \times 10^{-3} \text{ eV}^2$ . Superseded by ADEY 18A.
- <sup>29</sup> ABE 16d reports oscillation results using  $\bar{\nu}_\mu$  disappearance in an off-axis beam.
- <sup>30</sup> Superseded by ADAMSON 17A.
- <sup>31</sup> CHOI 16 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to  $\theta_{13}$  and  $\Delta m_{ee}^2$  yields  $\Delta m_{ee}^2 = (2.62 \pm 0.21 \pm 0.12 \pm 0.23 \pm 0.13) \times 10^{-3} \text{ eV}^2$ . We convert the results to  $\Delta m_{32}^2$  using PDG 18 values of  $\sin^2(\theta_{12})$  and  $\Delta m_{21}^2$ .
- <sup>32</sup> AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.
- <sup>33</sup> AGAFONOVA 15A result is based on 5  $\nu_\mu \rightarrow \nu_\tau$  appearance candidates with an expected background of  $0.25 \pm 0.05$  events. The best fit is for  $\Delta m_{32}^2 = 3.3 \times 10^{-3} \text{ eV}^2$ .
- <sup>34</sup> AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of  $6.9 \times 10^5 \text{ GW}_{th}\text{-ton-days}$ . They derive  $\Delta m_{ee}^2 = (2.42 \pm 0.11) \times 10^{-3} \text{ eV}^2$ . Assuming the normal (inverted) ordering, the fitted  $\Delta m_{32}^2 = (2.37 \pm 0.11) \times 10^{-3} ((2.47 \pm 0.11) \times 10^{-3}) \text{ eV}^2$ . Superseded by AN 17A.
- <sup>35</sup> ABE 14 results are based on  $\nu_\mu$  disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as  $\Delta m_{13}^2 = (2.48 \pm 0.10) \times 10^{-3} \text{ eV}^2$  which we converted to  $\Delta m_{32}^2$  by adding PDG 14 value of  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ . Superseded by ABE 17c.
- <sup>36</sup> ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the analysis of the  $\nu_\mu$  disappearance and  $\nu_e$  appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.
- <sup>37</sup> AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive  $\Delta m_{ee}^2 = (2.59 \pm 0.19 \pm 0.20) \times 10^{-3} \text{ eV}^2$ . Assuming the normal (inverted) ordering, the fitted  $\Delta m_{32}^2 = (2.54 \pm 0.19 \pm 0.20) \times 10^{-3} ((2.64 \pm 0.19 \pm 0.20) \times 10^{-3}) \text{ eV}^2$ . Superseded by AN 15.
- <sup>38</sup> FORERO 14 performs a global fit to  $\Delta m_{31}^2$  using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- <sup>39</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $(2.460 \pm 0.046) \times 10^{-3} \text{ eV}^2$  for normal and  $(2.445 \pm 0.047 \pm 0.045) \times 10^{-3} \text{ eV}^2$  for inverted mass ordering.
- <sup>40</sup> The value for normal mass ordering is actually a measurement of  $\Delta m_{31}^2$  which differs from  $\Delta m_{32}^2$  by a much smaller value of  $\Delta m_{21}^2$ .
- <sup>41</sup> AARTSEN 13b obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
- <sup>42</sup> Based on the observation of 58  $\nu_\mu$  events with  $205 \pm 17(\text{syst})$  expected in the absence of neutrino oscillations. Superseded by ABE 14.
- <sup>43</sup> ADAMSON 13b obtained this result from  $\nu_\mu$  and  $\bar{\nu}_\mu$  disappearance using  $\nu_\mu$  ( $10.71 \times 10^{20}$  POT) and  $\bar{\nu}_\mu$  ( $3.36 \times 10^{20}$  POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_\mu$  and  $\bar{\nu}_\mu$  oscillation parameters.
- <sup>44</sup> ABE 12a obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\Delta m_{32}^2 = 2.65 \times 10^{-3} \text{ eV}^2$ .
- <sup>45</sup> ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.
- <sup>46</sup> ADAMSON 12b obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- <sup>47</sup> The 90% single-parameter confidence interval at the best fit point is  $\Delta m^2 = 0.0019 \pm 0.0004 \text{ eV}^2$ .
- <sup>48</sup> The data are separated into pure samples of  $\nu_s$  and  $\bar{\nu}_s$ , and separate oscillation parameters for  $\nu_s$  and  $\bar{\nu}_s$  are fit to the data. The best fit point is  $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$  and  $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$ . The quoted result is taken from the 90% C.L. contour in the  $(\Delta m^2, \sin^2 2\theta)$  plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- <sup>49</sup> ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.
- <sup>50</sup> ABE 11c obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is  $\Delta m^2 = 1.7\text{--}3.0 \times 10^{-3} \text{ eV}^2$ .
- <sup>51</sup> ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- <sup>52</sup> ADAMSON 11c obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- <sup>53</sup> WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- <sup>54</sup> ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- <sup>55</sup> The best fit in the physical region is for  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ .
- <sup>56</sup> Supersedes ALIU 05.
- <sup>57</sup> MICHAEL 06 best fit is  $2.74 \times 10^{-3} \text{ eV}^2$ . See also ADAMSON 08.
- <sup>58</sup> ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017 \text{ eV}^2$  and  $\sin^2 2\theta = 0.97$ .
- <sup>59</sup> ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for  $\Delta m^2 = 2.1 \times 10^{-3} \text{ eV}^2$ .
- <sup>60</sup> AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ ,  $N_{low}$  and  $N_{high}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{low}$  and  $N_{high}$  are the number of events with reconstructed neutrino energies  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for  $\Delta m^2 = 2.3 \times 10^{-3} \text{ eV}^2$ .
- <sup>61</sup> ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of  $\nu_\mu$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.4 \times 10^{-3} \text{ eV}^2$ .
- <sup>62</sup> There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ .
- <sup>63</sup> AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{low}/N_{high}$ , where  $N_{low}$  and  $N_{high}$  are the number of upward through-going muon events with reconstructed neutrino energy  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$ .
- <sup>64</sup> AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$ .
- <sup>65</sup> SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the  $e$ -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for  $\Delta m^2 = 5.2 \times 10^{-3} \text{ eV}^2$ .
- <sup>66</sup> AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- <sup>67</sup> AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . See the previous footnote.
- <sup>68</sup> FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 5.9 \times 10^{-3} \text{ eV}^2$ .
- <sup>69</sup> FUKUDA 99b obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 (\text{theoretical error})) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 3.9 \times 10^{-3} \text{ eV}^2$ .
- <sup>70</sup> FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for  $\Delta m^2 = 3.1 \times 10^{-3} \text{ eV}^2$ .

See key on page 1171

# Lepton Particle Listings

## Neutrino Mixing

<sup>71</sup>FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$ .

<sup>72</sup>HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux of upward through-going muons is  $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$ .

<sup>73</sup>HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for  $\Delta m^2 = 13 \times 10^{-3} \text{ eV}^2$ .

<sup>74</sup>FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for  $\Delta m^2 = 16 \times 10^{-3} \text{ eV}^2$ .

### $\sin^2(\theta_{13})$

At present time direct measurements of  $\sin^2(\theta_{13})$  are derived from the reactor  $\bar{\nu}_e$  disappearance at distances corresponding to the  $\Delta m_{32}^2$  value, i.e.  $L \sim 1\text{ km}$ . Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based  $\nu_\mu \rightarrow \nu_e$  experiments.

If an experiment reports  $\sin^2(2\theta_{13})$  we convert the value to  $\sin^2(\theta_{13})$ .

<sup>1</sup> ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of  $1.97 \times 10^{21}$  ( $1.63 \times 10^{21}$ ) protons on target.

<sup>2</sup> AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in  $5.55 \times 10^9 \bar{\nu}_e$  candidate events. Solar oscillation parameters are fixed in the analysis to  $\sin^2(\theta_{12}) = 0.307 \pm 0.013$ ,  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$  from PDG 20. Supersedes ADEY 18A.

<sup>3</sup> DE-KERRET 20 uses 481 days of data from single detector operation and also 384 days of data with both near and far detectors operating. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 16B.

<sup>4</sup> SHIN 20 uses the RENO detector and 1500 live days of data. The near (far) detector observed 567,690 (90,747)  $\bar{\nu}_e$  candidate events with a delayed neutron capture on hydrogen. The extracted value of  $\sin^2\theta_{13}$  is consistent with the previous analysis with neutron capture on Gd in BAK 18.

<sup>5</sup> BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. Supersedes SEO 18.

<sup>6</sup> AN 16A uses data from the eight antineutrino detectors (404 days) and six antineutrino detectors (217 days) runs to determine the mixing parameter  $\sin^2(2\theta_{13})$  using the neutron capture on H only. Supersedes AN 14B.

<sup>7</sup> ABRAHAO 21 uses 865 days of data collected in both near and far detectors with at least one reactor in operation. The analysis is based on a background model independent approach, so called Reactor Rate Modulation, to determine the mixing angle  $\theta_{13}$ . Adding the background model reduces the uncertainty to 0.0041. Supersedes ABE 16B.

<sup>8</sup> SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

<sup>9</sup> ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

<sup>10</sup> ABE 18b uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters,  $\Delta m_{32}^2$ ,  $\sin^2\theta_{23}$ ,  $\sin^2\theta_{13}$ , and  $\delta$ , while the solar parameters are fixed to  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$  and  $\sin^2\theta_{12} = 0.304 \pm 0.014$ .

<sup>11</sup> ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with  $3.9 \times 10^6 \bar{\nu}_e$  candidates. The fit to the data gives  $\Delta m_{ee}^2 = (2.522 \pm 0.068) \times 10^{-3} \text{ eV}^2$ . Solar oscillation parameters are fixed in the analysis using the global averages,  $\sin^2(\theta_{12}) = 0.307 \pm 0.013$ ,  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ , from PDG 18. Supersedes AN 17A.

<sup>12</sup> AGAFONOVA 18A reports  $\sin^2(2\theta_{13}) < 0.43$  at 90% C.L. The result on the sterile neutrino search in the context of 3+1 model is also reported. A 90% C.L. upper limit on  $\sin^2(2\theta_{1\mu e}) = 0.021$  for  $\Delta m_{41}^2 \geq 0.1 \text{ eV}^2$  is set.

## Lepton Particle Listings

## Neutrino Mixing

- <sup>13</sup> SEO 18 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.
- <sup>14</sup> Using T2K data only. For inverted mass ordering, all values of  $\theta_{13}$  are ruled out at 68% CL.
- <sup>15</sup> AN 17A reports results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than  $2.5 \times 10^6$  inverse beta-decay events with neutron capture on Gd. A simultaneous fit to  $\theta_{13}$  and  $\Delta m_{ee}^2$  is performed. Superseded by ADEY 18A.
- <sup>16</sup> ABE 16B uses 455.7 live days of data from a detector 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter  $\sin^2(2\theta_{13})$ . This analysis uses 7.15 reactor-off days for constraining backgrounds. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 14H and ABE 13C.
- <sup>17</sup> CHOI 16 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. Supersedes AHN 12.
- <sup>18</sup> AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of  $6.9 \times 10^5$  GW<sub>th</sub>-ton-days. Superseded by AN 17A.
- <sup>19</sup> ABE 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter  $\sin^2(2\theta_{13})$ . The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supersedes ABE 12B.
- <sup>20</sup> ABE 14C result is for  $\nu_e$  appearance and assumes  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\sin^2(\theta_{23}) = 0.5$ , and  $\delta = 0$ .
- <sup>21</sup> ABE 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter  $\sin^2(2\theta_{13})$ . The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Superseded by ABE 16B.
- <sup>22</sup> AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.
- <sup>23</sup> AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of  $\sim 500$  m and  $\sim 1.6$  km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only.  $\Delta m_{31}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup> is assumed. Superseded by AN 16A.
- <sup>24</sup> FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.
- <sup>25</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as  $(2.18_{-0.10}^{+0.10}) \times 10^{-2}$  eV<sup>2</sup> for normal and  $(2.19_{-0.10}^{+0.12}) \times 10^{-2}$  eV<sup>2</sup> for inverted mass ordering.
- <sup>26</sup> ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 16B.
- <sup>27</sup> ABE 13E assumes maximal  $\theta_{23}$  mixing and CP phase  $\delta = 0$ .
- <sup>28</sup> ADAMSON 13a results obtained from  $\nu_e$  appearance, assuming  $\delta = 0$ , and  $\sin^2(2\theta_{23}) = 0.957$ .
- <sup>29</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is  $\sin^2(2\theta_{13}) = (9.1_{-3.1}^{+2.9}) \times 10^{-2}$ .
- <sup>30</sup> AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the  $\overline{\nu}_e$  interaction rate ratios. Superseded by AN 14.
- <sup>31</sup> ABE 12 determines the  $\overline{\nu}_e$  interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of  $\Delta m_{31}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup> is used in the analysis. Superseded by ABE 12B.
- <sup>32</sup> ABE 12B determines the neutrino mixing angle  $\theta_{13}$  using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.
- <sup>33</sup> AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle  $\theta_{13}$ . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of  $\Delta m_{31}^2 = (2.32_{-0.08}^{+0.12}) \times 10^{-3}$  eV<sup>2</sup> was assumed in the analysis. Superseded by CHOI 16.
- <sup>34</sup> AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\overline{\nu}_e$  observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of  $\Delta m_{31}^2 = (2.32_{-0.08}^{+0.12}) \times 10^{-3}$  eV<sup>2</sup> was assumed in the analysis. Superseded by AN 13.
- <sup>35</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3}$  eV<sup>2</sup>, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of  $\sin^2\theta_{13} < 0.059$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL). The normal neutrino mass ordering and CPT invariance are assumed.
- <sup>36</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3}$  eV<sup>2</sup>, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.
- <sup>37</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass ordering. For other values of  $\delta$ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.
- <sup>38</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass ordering. For other values of  $\delta$ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.
- <sup>39</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass ordering. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.
- <sup>40</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass ordering. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.
- <sup>41</sup> FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor  $\overline{\nu}_e$  fluxes, and using these fluxes, the fitted result becomes  $0.10 \pm 0.03$ .
- <sup>42</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.020 \pm 0.016$ . This result was obtained with three-neutrino fit using the KamLAND + solar data.
- <sup>43</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.032 \pm 0.037$ . This result was obtained with three-neutrino fit using the KamLAND data only.
- <sup>44</sup> This result corresponds to the limit of  $< 0.12$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.16.
- <sup>45</sup> This result corresponds to the limit of  $< 0.20$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.21.
- <sup>46</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- <sup>47</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed. This result implies an upper bound of  $\sin^2\theta_{13} < 0.057$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL).
- <sup>48</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3}$  eV<sup>2</sup>, using global solar neutrino data.
- <sup>49</sup> WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- <sup>50</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.02 to 0.26.
- <sup>51</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.04 to 0.34.
- <sup>52</sup> FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.
- <sup>53</sup> FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.
- <sup>54</sup> FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.
- <sup>55</sup> YAMAMOTO 06 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assumes  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3}$  eV<sup>2</sup>. That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for AHN 06A. For the AHN 06A best fit value of  $2.8 \times 10^{-3}$  eV<sup>2</sup>, the  $\sin^2(2\theta_{13})$  limit is  $< 0.26$ . Supersedes AHN 04.
- <sup>56</sup> AHN 04 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assuming  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ , a limit on  $\sin^2(2\theta_{\mu e})$  is converted to a limit on  $\sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3}$  eV<sup>2</sup>. That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3}$  eV<sup>2</sup>, the  $\sin^2(2\theta_{13})$  limit is  $< 0.30$ .
- <sup>57</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3}$  eV<sup>2</sup>. That value of  $\Delta m_{32}^2$  is the 1- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3}$  eV<sup>2</sup>, the  $\sin^2 2\theta_{13}$  limit is  $< 0.19$ . In this range, the  $\theta_{13}$  limit is larger for lower values of  $\Delta m_{32}^2$ , and smaller for higher values of  $\Delta m_{32}^2$ .
- <sup>58</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3}$  eV<sup>2</sup>. That value of  $\Delta m_{32}^2$  is the 1- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3}$  eV<sup>2</sup>, the  $\sin^2 2\theta_{13}$  limit is  $< 0.23$ .
- <sup>59</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3}$  eV<sup>2</sup>. That value of  $\Delta m_{32}^2$  is the central value for ADAMSON 08. For the ADAMSON 08 1- $\sigma$  low value of  $2.30 \times 10^{-3}$  eV<sup>2</sup>,

See key on page 1171

## Neutrino Mixing

the  $\sin^2 \theta_{13}$  limit is  $< 0.16$ . See also APOLLONIO 03 for a detailed description of the experiment.

### CP violating phase

#### $\delta$ , CP violating phase

Measurements of  $\delta$  come from atmospheric and accelerator experiments looking at  $\nu_e$  appearance. We encode values between 0 and  $2\pi$ , though it is equivalent to use  $-\pi$  to  $\pi$ .

<sup>1</sup> ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of  $1.97 \times 10^{21}$  ( $1.63 \times 10^{21}$ ) protons on target. For inverted mass ordering, the quoted result is  $1.54^{+0.18}_{-0.19}$   $\pi$  rad. Supersedes ABE 20F.  
<sup>2</sup> ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 ( $12.5 \times 10^{20}$  POT) and Feb 6, 2014 to Mar 20, 2020 ( $13.6 \times 10^{20}$  POT). Results for normal and inverted mass ordering, and  $\theta_{23}$  octant I and II are presented. Supersedes ACERO 19.  
<sup>3</sup> For the octant I (lower octant), the 68% CL allowed region is discontinuous, and all delta values are allowed at 90% CL.  
<sup>4</sup> ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters,  $\Delta m_{21}^2$ ,  $\sin^2 \theta_{23}$ , and

$\delta$ , while the solar parameters and  $\sin^2 \theta_{23}$  are fixed to  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$  eV<sup>2</sup>,  $\sin^2 \theta_{12} = 0.304 \pm 0.014$ , and  $\sin^2 \theta_{13} = 0.0219 \pm 0.0012$ .  
<sup>5</sup> The inverted mass ordering is rejected at 1.0  $\sigma$ . The quoted error bars are based on the local best-fit point.  
<sup>6</sup> SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.  
<sup>7</sup> ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of  $1.49 \times 10^{21}$  ( $1.64 \times 10^{21}$ ) protons on target. For inverted mass ordering, the quoted result is  $1.56^{+0.15}_{-0.17}$   $\pi$  rad. Supersedes ABE 18G.  
<sup>8</sup> ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.  
<sup>9</sup> ACERO 19 is based on a sample size of  $1.33 \times 10^{20}$  protons on target with combined antineutrino and neutrino data. Superseded by ACERO 22.  
<sup>10</sup> ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters,  $\Delta m_{32}^2$ ,  $\sin^2 \theta_{23}$ ,  $\sin^2 \theta_{13}$ , and  $\delta$ , while the solar parameters are fixed to  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$  eV<sup>2</sup> and  $\sin^2 \theta_{12} = 0.304 \pm 0.014$ .  
<sup>11</sup> ABE 18G confidence intervals are marginalized over both mass orderings. Normal order preferred with a posterior probability of 87%. The 1-sigma result for normal mass ordering used in the average was provided by the experiment via private communications. Supersedes ABE 17F.  
<sup>12</sup> ACERO 18 performs a joint fit to the data for  $\nu_\mu$  disappearance and  $\nu_e$  appearance. The overall best fit favors normal mass ordering and  $\theta_{23}$  in octant II. No 1 $\sigma$  confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.  
<sup>13</sup> ABE 17F confidence intervals are obtained using a frequentist analysis including  $\theta_{13}$  constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.  
<sup>14</sup> Errors are projections of 68% C.L. curve of  $\delta_{CP}$  vs.  $\sin^2 \theta_{23}$ .  
<sup>15</sup> ADAMSON 16 result is based on a data sample with  $2.74 \times 10^{20}$  protons on target. The likelihood-based analysis observed 6  $\nu_e$  events with an expected background of  $0.99 \pm 0.11$  events.  
<sup>16</sup> ADAMSON 14 result is based on three-flavor formalism and  $\theta_{23} > \pi/4$ . Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  octants; all values of  $\delta$  are allowed at 90% C.L.  
<sup>17</sup> GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.  
<sup>18</sup> ADAMSON 13A result is based on  $\nu_e$  appearance in MINOS and the calculated  $\sin^2(2\theta_{23}) = 0.957$ ,  $\theta_{23} > \pi/4$ , and normal mass hierarchy. Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  octants; all values of  $\delta$  are allowed at 90% C.L.

### (C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations. In a three neutrino framework, this would be a measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . This does not appear to be consistent with most of the other neutrino data. The following listings include results from  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  appearance and  $\nu_\mu, \bar{\nu}_\mu, \nu_e$ , and  $\bar{\nu}_e$  disappearance experiments, and searches for CPT violation.

<sup>1</sup> AGUILAR-AREVALO 21 result is based on a total of  $18.75 \times 10^{20}$  POT in neutrino mode, and  $11.27 \times 10^{20}$  POT in anti-neutrino mode. Best fit at 0.043 eV<sup>2</sup>. The allowed region does not extend to large  $\Delta m^2$ . The quoted value is the entire allowed region of  $\Delta m^2$  at 90% C.L. for all values of  $\sin^2(2\theta)$ . Supersedes AGUILAR-AREVALO 18c.  
<sup>2</sup> AGUILAR-AREVALO 18c result is based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $460.5 \pm 99.0$  events; The best fit value is  $\Delta m^2 = 0.041$  eV<sup>2</sup>. Superseded by AGUILAR-AREVALO 21.  
<sup>3</sup> AGUILAR-AREVALO 13A result is based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with twoneutrino oscillations. The best fit value is  $\Delta m^2 = 3.14$  eV<sup>2</sup>.  
<sup>4</sup> MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of  $\Delta m^2$  up to 25 eV<sup>2</sup>. The best limit is 0.04 at 7 eV<sup>2</sup>.

# Lepton Particle Listings

## Neutrino Mixing

<sup>5</sup> AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight by observing beam-on electron events from  $\nu_e C \rightarrow e^- X$ . Present analysis results in  $8.1 \pm 12.2 \pm 1.7$  excess events in the  $60 < E_e < 200$  MeV energy range, corresponding to oscillation probability of  $0.10 \pm 0.16 \pm 0.04\%$ . This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

<sup>6</sup> ATHANASSOPOULOS 98 is a search for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight. The 40 observed beam-on electron events are consistent with  $\nu_e C \rightarrow e^- X$ ; the expected background is  $21.9 \pm 2.1$ . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability  $(0.26 \pm 0.10 \pm 0.05)\%$ . Although the significance is only  $2.3\sigma$ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations from  $\mu^+$  decay at rest. See also ATHANASSOPOULOS 98b.

<sup>7</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

<sup>1</sup> AGUILAR-AREVALO 21 result is based on a total of  $18.75 \times 10^{20}$  POT in neutrino mode, and  $11.27 \times 10^{20}$  POT in anti-neutrino mode. The best fit value is  $\sin^2(2\theta) = 0.807$ . The allowed region does not extend to large  $\Delta m^2$ . The quoted value is the entire allowed region of  $\sin^2(2\theta)$  at 90% C.L. for all values of  $\Delta m^2$ . Supersedes AGUILAR-AREVALO 18c.

<sup>2</sup> AGUILAR-AREVALO 18c result is based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $460.5 \pm 99.0$  events; The best fit value is  $\sin^2(2\theta) = 0.92$ . The quoted limit for the two-neutrino mixing angle  $\theta$  is valid above  $\Delta m^2 = 0.59$  eV<sup>2</sup>. Superseded by AGUILAR-AREVALO 21.

<sup>3</sup> AGUILAR-AREVALO 13a result is based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with two neutrino oscillations. The best fit value is  $\sin^2(2\theta) = 0.002$ .

<sup>4</sup> ANTONELLO 13 use the ICARUS T600 detector at LNGS and  $\sim 20$  GeV beam of  $\nu_\mu$  from CERN 730 km away to search for an excess of  $\nu_e$  events. Two events are found with  $3.7 \pm 0.6$  expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13a.

<sup>5</sup> Based on four events with a background of  $6.4 \pm 0.9$  from conventional sources with an average energy of 20 GeV and 730 km from the source of  $\nu_\mu$ .

<sup>6</sup> MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.

<sup>7</sup> The limit is  $\sin^2 2\theta < 0.9 \times 10^{-3}$  at  $\Delta m^2 = 2$  eV<sup>2</sup>. That value of  $\Delta m^2$  corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

<sup>8</sup> The limit becomes  $\sin^2 2\theta < 0.15$  at  $\Delta m^2 = 2.8 \times 10^{-3}$  eV<sup>2</sup>, the best-fit value of the  $\nu_\mu$  disappearance analysis in K2K.

<sup>9</sup> AGUILAR 01 is the final analysis of the LSND full data set of the search for the  $\nu_\mu \rightarrow \nu_e$  oscillations. See footnote in preceding table for further details.

<sup>10</sup> ATHANASSOPOULOS 98 report  $(0.26 \pm 0.10 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta m^2$  is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate  $\sin^2 2\theta$  and  $\Delta m^2$ . See also ATHANASSOPOULOS 98b.

<sup>11</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

<sup>12</sup> VILAIN 94c limit derived by combining the  $\nu_\mu$  and  $\bar{\nu}_\mu$  data assuming CP conservation.

### $\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ( $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ )

<0.14	90	10 FREEDMAN 93	CNTR	LAMPF

<sup>1</sup> Based on  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  appearance of  $78.4 \pm 28.5$  events. The best fit values are  $\Delta m^2 = 0.043$  eV<sup>2</sup> and  $\sin^2 2\theta = 0.88$ .

<sup>2</sup> CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

<sup>3</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475$  MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09b.

<sup>4</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200$  MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for  $\Delta(m^2) = 4.4$  eV<sup>2</sup>.

<sup>5</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for  $\bar{\nu}_e$ , detected by the inverse  $\beta$ -decay reaction on protons and <sup>12</sup>C. 15 candidate events are observed, and  $15.8 \pm 0.5$  background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

<sup>6</sup> AGUILAR 01 is the final analysis of the LSND full data set. It is a search for  $\bar{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20 < E_{e^+} < 60$  MeV) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $87.9 \pm 22.4 \pm 6.0$  total excess events. The observation is attributed to  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations with the oscillation probability of  $0.264 \pm 0.067 \pm 0.045\%$ , consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of  $\Delta(m^2)$  from  $0.2-2.0$  eV<sup>2</sup>. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

<sup>7</sup> ATHANASSOPOULOS 96 is a search for  $\bar{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  could come from either  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  or  $\nu_e \rightarrow \bar{\nu}_e$ ; our entry assumes the first interpretation. They are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20$  MeV  $< E_{e^+} < 60$  MeV) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $51 \pm 20 \pm 8$  total excess events over an estimated background  $12.5 \pm 2.9$ . ATHANASSOPOULOS 96b is a shorter version of this paper.

<sup>8</sup> ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34 \pm 0.20 \pm 0.16 \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

<sup>9</sup> HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

<sup>10</sup> FREEDMAN 93 is a search at LAMPF for  $\bar{\nu}_e$  generated from any of the three neutrino types  $\nu_\mu, \bar{\nu}_\mu$ , and  $\nu_e$  which come from the beam stop. The  $\bar{\nu}_e$ 's would be detected by the reaction  $\bar{\nu}_e p \rightarrow e^+ n$ . FREEDMAN 93 replaces DURKIN 88.

<sup>1</sup> ANTONELLO 13a obtained the limit by assuming  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillation from the  $\sim 2\%$  of  $\bar{\nu}_\mu$  events contamination in the CNGS beam.

<sup>2</sup> CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

<sup>3</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475$  MeV. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09b.

<sup>4</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200$  MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit value is 0.007 for  $\Delta(m^2) = 4.4$  eV<sup>2</sup>.

<sup>5</sup> This result is inconclusive with respect to small amplitude mixing suggested by LSND.

<sup>6</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

<sup>7</sup> AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is  $0.264 \pm 0.067 \pm 0.045\%$ ; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

<sup>8</sup>ATHANASSOPOULOS 96 reports  $(0.31 \pm 0.12 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

<sup>9</sup>ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34 \pm 0.20 \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

<sup>10</sup>HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

## Sterile neutrino limits

 $\Delta(m^2)$  for  $\sin^2(2\theta) = 1$  ( $\nu_\mu \rightarrow \nu_s$ )

$\nu_s$  means  $\nu_\tau$  or any sterile (noninteracting)  $\nu$ .

VALUE ( $10^{-5}$ eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT
<3000 (or <550)	90	<sup>1</sup> OYAMA	89 KAMI	Water Cherenkov
<4.2 or >54.	90	BIONTA	88 IMB	Flux has $\nu_\mu, \bar{\nu}_\mu, \nu_e$ , and $\bar{\nu}_e$

<sup>1</sup>OYAMA 89 gives a range of limits, depending on assumptions in their analysis. They argue that the region  $\Delta(m^2) = (100-1000) \times 10^{-5}$  eV<sup>2</sup> is not ruled out by any data for large mixing.

Search for  $\nu_\mu$  or  $\nu_e \rightarrow \nu_s$

<sup>1</sup>AKER 23 assume a 3+1 neutrino mixing model, use low-rate commissioning data of the KATRIN tritium  $\beta$  decay experiment to place a limit on  $\sin^2(\theta_{14})$  for a admixture sterile neutrino mass  $m_4$  of  $\sim 300$  eV.

<sup>2</sup>ALMAZAN 23 use inverse beta decay data collected by the STEREO experiment, placed 9 to 11 m from the ILL research reactor, to search for  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations. The ILL research reactor uses highly enriched <sup>235</sup>U fuel. No indication of the oscillation to sterile neutrinos is found, the stated limit on  $\sin^2(2\theta_{14})$  correspond to  $\Delta m_{41}^2 \sim 1$  eV<sup>2</sup> where the exclusion is maximal. Supersedes ALMAZAN 18.

<sup>3</sup>AKER 22A uses the first two science runs of the KATRIN tritium  $\beta$  decay neutrino mass experiment to search for an admixture of sterile neutrinos. No evidence is found for a spectral anomaly, indicating such admixture. The resulting limit is on  $\sin^2(2\theta_{14})$  for sterile neutrino masses  $m_4 < 40$  eV. It is most restrictive at  $\Delta m_{41}^2 \sim 400$  eV<sup>2</sup>. A 3+1 model is assumed.

<sup>4</sup>ATIF 22 report results from the combined analysis of the RENO (419 m) and NEOS (24 m) experiments data, collected at the Hanbit Nuclear Power Plant. Results, in terms of  $\sin^2(2\theta_{14})$ , constrain for  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations. The authors report both excluded and allowed parameter combinations. The exclusion result reported here is based on the Feldman-Cousins method and for  $\Delta m_{41}^2 \simeq 0.55$  eV<sup>2</sup>. Part of the allowed area is excluded by the STEREO and PROSPECT experiments.

<sup>5</sup>BARINOV 22A report an event deficit observed using the segmented Baksan Ga neutrino detector, exposed to a 3.4 MCi <sup>51</sup>Cr source. Equal suppression factors are observed for the inner and outer segments. The deficit is interpreted as evidence for oscillations to sterile neutrinos. The result is in terms of  $\sin^2(2\theta_{14})$ , for a best fit of  $\Delta m_{41}^2 = 3.3 \pm 2.3$  eV<sup>2</sup>. Some, but not all, of the allowed neutrino parameter space conflicts with other experiments.

<sup>6</sup>ANDRIAMIRADO 21 reports a search for  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations at the HFIR research reactor, at baselines from 6.7 to 9.2 m. The reactor has a <sup>235</sup>U core. 4 tons of <sup>6</sup>Li-doped liquid scintillator are used in a segmented detector. Oscillations into sterile neutrinos are disfavored. The stated limit for  $\sin^2(2\theta_{14})$  is for  $\Delta m_{41}^2 \sim 2$  eV<sup>2</sup> where the sensitivity is maximal.

<sup>7</sup>SEREBROV 21 searches for  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations with a moveable detector with baseline 6–12 m from the SM-3 research reactor with highly enriched <sup>235</sup>U fuel. Analyzing the  $L/E$  dependence a  $\chi^2$  minimum is found at  $\Delta m_{41}^2 = 7.3 \pm 0.13 \pm 1.16$  eV<sup>2</sup> and  $\sin^2(2\theta_{14}) = 0.36 \pm 0.12$ . The quoted limit of 0.005 for  $\sin^2(2\theta_{14})$  corresponds to  $\Delta m_{41}^2 \sim 2$  eV<sup>2</sup>. This is the result from 720 days of reactor ON and 860 days of reactor OFF measurements. The significance of the  $\chi^2$  minimum is 2.9  $\sigma$ . Supersedes SEREBROV 20, SEREBROV 19 and SEREBROV 18A.

<sup>8</sup>SKROBOVA 20 searches for  $\bar{\nu}_e - \bar{\nu}_s$  oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW<sub>th</sub> power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. No evidence for sterile neutrinos is found. The quoted limit 0.008, the smallest excluded  $\sin^2(2\theta_{14})$ , corresponds to  $\Delta m_{41}^2 \sim 1.0$  eV<sup>2</sup>. Supersedes ALEKSEEV 18.

<sup>9</sup>ALEKSEEV 18 searches for  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW<sub>th</sub> power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. The best fit point is at  $\Delta m_{41}^2 = 1.4$  eV<sup>2</sup> and  $\sin^2(2\theta_{14}) = 0.05$  with  $\Delta\chi^2 = 13.1$  (statistical errors only) compared to the fit with 3 active neutrinos only. The quoted limit of 0.01 for  $\sin^2(2\theta_{14})$  corresponds to  $\Delta m_{41}^2 \sim 1.0$  eV<sup>2</sup>. Superseded by SKROBOVA 20.

<sup>10</sup>ALMAZAN 18 searches for the  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations with baseline from 9.4 to 11.1 m from the ILL research reactor with highly enriched <sup>235</sup>U fuel. The STEREO detector consists of six separated cells with Gd loaded scintillator, with 15 m water equivalent overburden. The detected rate is  $396.3 \pm 4.7$   $\bar{\nu}_e$ /day with signal to background ratio of about 0.9. The reported results corresponds to 66 days of reactor-on. The analysis uses the relative rates normalized to the cell number 1. No indication of the oscillation to the sterile neutrinos is found, the stated limit on  $\sin^2(2\theta_{14})$  correspond to  $\Delta m_{41}^2 \sim 3.5$  eV<sup>2</sup> where the exclusion is maximal. Superseded by ALMAZAN 23.

<sup>11</sup>ASHENFELTER 18 searches for the  $\bar{\nu}_e \rightarrow \bar{\nu}_s$  oscillations at baseline from 6.7 to 9.2 m from the 85 MW research reactor with pure <sup>235</sup>U core. The segmented 4 ton <sup>6</sup>Li-doped liquid scintillator is operated with about 1 m water equivalent overburden and recorded 25461  $\pm$  283 IBD events. No indication of oscillations into sterile neutrinos was observed. The stated limit for  $\sin^2(2\theta_{14})$  is for  $\Delta m_{41}^2 \sim 2$  eV<sup>2</sup> where the sensitivity is maximal.

<sup>12</sup>AARTSEN 17B uses three years of upward-going atmospheric neutrino data in the energy range of 10–60 GeV to constrain their disappearance into light sterile neutrinos. The reported limit  $\sin^2\theta_{24} < 0.11$  at 90% C.L. is for  $\Delta m_{41}^2 = 1.0$  eV<sup>2</sup>. We convert the result to  $\sin^2 2\theta_{24}$  for the listing. AARTSEN 17B also reports  $\cos^2\theta_{24} \cdot \sin^2\theta_{34} < 0.15$  at 90% C.L. for  $\Delta m_{41}^2 = 1.0$  eV<sup>2</sup>.

<sup>13</sup>ABDURASHITOV 17 use the Troitsk nu-mass experiment to search for sterile neutrinos with mass 0.1 – 2 keV. We convert the reported limit from  $U_{e4}^2 < 0.002$  to  $\sin^2 2\theta_{14} < 0.008$  assume  $U_{e4} \sim \sin\theta_{14}$ . The stated limit corresponds to the smallest  $U_{e4}^2$ . The exclusion curve begins at  $U_{e4}^2$  of 0.02 for  $m_4 = 0.1$  keV.

<sup>14</sup>KO 17 reports on short baseline reactor oscillation search ( $\bar{\nu}_e \rightarrow \bar{\nu}_s$ ), motivated by the so-called “reactor antineutrino anomaly”. The experiment is conducted at 23.7 m from the core of unit 5 of the Hanbit Nuclear Power Complex in Korea. The reported limit on  $\sin^2(2\theta_{41})$  for sterile neutrinos was determined using the reactor antineutrino spectrum determined by the Daya Bay experiment for  $\Delta m_{14}^2$  around 0.55 eV<sup>2</sup> where the sensitivity is maximal. A fraction of the parameter space derived from the “reactor antineutrino anomaly” is excluded by this work. Compared to reactor models an event excess is observed at about 5 MeV, in agreement with other experiments.

<sup>15</sup>AARTSEN 16 use one year of upward-going atmospheric muon neutrino data in the energy range of 320 GeV to 20 TeV to constrain their disappearance into light sterile neutrinos. Sterile neutrinos are expected to produce distinctive zenith distribution for these energies for  $0.01 \leq \Delta m^2 \leq 10$  eV<sup>2</sup>. The stated limit is for  $\sin^2 2\theta_{24}$  at  $\Delta m^2$  around 0.3 eV<sup>2</sup>.

<sup>16</sup>ADAMSON 16b combine the results of AN 16B, ADAMSON 16C, and Bugey-3 reactor experiments to constrain  $\nu_\mu$  to  $\nu_e$  mixing through oscillations into light sterile neutrinos. The stated limit for  $\sin^2 2\theta_{\mu e}$  is at  $|\Delta m_{41}^2| = 1.2$  eV<sup>2</sup>.

<sup>17</sup>ADAMSON 16c use the NuMI beam and exposure of  $10.56 \times 10^{20}$  protons on target to search for the oscillation of  $\nu_\mu$  dominated beam into light sterile neutrinos with detectors at 1.04 and 735 km. The reported limit  $\sin^2(\theta_{24}) < 0.022$  at 95% C.L. is for  $|\Delta m_{41}^2| = 0.5$  eV<sup>2</sup>. We convert the result to  $\sin^2(2\theta_{24})$  for the listing.

<sup>18</sup>AN 16B utilize 621 days of data to place limits on the  $\bar{\nu}_e$  disappearance into a light sterile neutrino. The stated limit corresponds to the smallest  $\sin^2(2\theta_{14})$  at  $|\Delta m_{41}^2| \sim 3 \times 10^{-2}$  eV<sup>2</sup> (obtained from Figure 3 in AN 16B). The exclusion curve begins at  $|\Delta m_{41}^2| \sim 1.5 \times 10^{-4}$  eV<sup>2</sup> and extends to  $\sim 0.25$  eV<sup>2</sup>. The analysis assumes  $\sin^2(2\theta_{12}) = 0.846 \pm 0.021$ ,  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5}$  eV<sup>2</sup>, and  $|\Delta m_{32}^2| = (2.44 \pm 0.06) \times 10^{-3}$  eV<sup>2</sup>.

<sup>19</sup>AMBROSIO 01 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and  $\Delta m^2$  around 0.0024 eV<sup>2</sup>, the  $\nu_\mu \rightarrow \nu_s$  oscillation is disfavored with 99% confidence level with respect to the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis.

<sup>20</sup>FUKUDA 00 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the  $\Delta m^2$  and  $\sin^2 2\theta$  region preferred by the Super-Kamiokande data, the  $\nu_\mu \rightarrow \nu_s$  hypothesis is rejected at the 99% confidence level, while the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis consistently fits all of the data sample.

### Heavy Neutral Leptons, Searches for

OMITTED FROM SUMMARY TABLE

We define searches for Heavy Neutral Leptons (HNLs) as searches for Dirac or Majorana fermions with sterile neutrino quantum numbers, that are heavy enough to not disrupt the simplest Big Bang Nucleosynthesis bounds and/or unstable on cosmological timescales: Typically HNLs have mass  $\sim$  MeV or higher.

Searches for these particles generically set bounds on the mixing between the HNL and the active neutrinos, as parametrized by the extended  $3 \times 4$  PMNS matrix elements  $U_{\ell X}$  (see the "Neutrino mass, mixing and oscillations" review) where  $\ell = e, \mu$  or  $\tau$ , and we denote the HNL as  $\nu_X$ . While many measurements may be interpreted to place bounds on various combinations of these matrix elements, we quote below limits only for those cases in which one matrix element is assumed to be much larger than the other two, i.e.  $|U_{\ell X}| \gg |U_{\ell' X}|$  for  $\ell' \neq \ell$ .

Experimental searches make use of various different strategies, including e.g. resonance searches in missing mass decay distributions or specific final states, searches for lepton number violating decays, and trilepton signatures. The resulting bounds on  $U_{\ell X}$  are typically dependent on the HNL mass. The quoted limits below are either the best limit near an experimental kinematic threshold, or a characteristic value in the mass range of the experimental sensitivity.

#### Limits on heavy neutral lepton mixing parameters

##### Limits on $|U_{eX}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

- AAD 23AO search for  $W \rightarrow \nu_X e$ , for both Majorana and Dirac HNL scenarios. Also consider scenarios involving multiflavor mixing, with correspondingly weaker limits.
- Search for ionization signals in an LArTPC. Assumes the candidate particle is 100% of dark matter.
- Reanalysis of BEBC results (cf. COOPER-SARKAR 85) to update searches for  $D_s^\pm \rightarrow \nu_X e^\pm$  using a corrected formula for the HNL decay probabilities, additional production channels, and an improved fit for the charm meson distributions. Assumes a Majorana HNL.
- TUMASYAN 22AD search for  $W \rightarrow e \nu_X, \nu_X \rightarrow e \mu \nu_\mu$  and set limits for Dirac and Majorana Heavy Neutral Leptons. The data correspond to an integrated luminosity of 138 fb $^{-1}$ .
- Search in electron capture decay  ${}^7\text{Be} \rightarrow {}^7\text{Li} \nu_X$ . Kinematic threshold is  $\sim 850$  keV.
- Search for  $K^+ \rightarrow e^+ \nu_X$ . Assumes lifetime of  $\nu_X > 50$  ns.
- Limit from prompt lepton number violating trilepton search.
- $K^+ \rightarrow e^+ \nu_X$ , with  $\nu_X$  decay through  $U_{eX}$ . ABE 19B also considers bounds on  $|U_{\ell X} U_{\ell' X}|$  for combinations of lepton flavors in the  $\nu_X$  decay final state.
- Searches for a Majorana Heavy Neutral Lepton producing a  $\pi^- e^+$  resonance in the same sign dilepton decay  $D \rightarrow K \pi^- e^+ e^+$ .
- BRYMAN 19 sets best limits  $|U_{eX}|^2 < 1 \times 10^{-4} - 2 \times 10^{-7}$  in the mass range  $m_{\nu_X} \sim 2\text{--}55$  MeV, respectively, using the precision branching ratio measurement in AGUILAR-AREVALO 15. See also BRYMAN 19A.
- Search for  $\pi^+ \rightarrow e^+ \nu_X$ .
- Search for  $K^+ \rightarrow e^+ \nu_X$ .
- PARK 16 quotes an approximate limit  $B(B^+ \rightarrow e^+ \nu_X) < 3 \times 10^{-6}$  in the mass range  $m_{\nu_X} \sim 0.2\text{--}1.4$  GeV.
- Search for  $B^+ \rightarrow e^+ \nu_X$ .
- Search for prompt  $\nu_X$  decay signatures.
- Search for displaced  $\nu_X$  decay signatures.
- Searches for  $K$  or  $\pi \rightarrow e^+ \nu_X, \nu_X \rightarrow e^+ e^- \nu_e$  using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. BARANOV 93 also considers limits for  $|U_{eX} U_{\mu X}|$  from  $K$  or  $\pi \rightarrow \mu^+ \nu_X, \nu_X \rightarrow e^+ e^- \nu_e$ .
- $\pi^+ \rightarrow e^+ \nu_X$ , with  $\nu_X$  decay through  $U_{eX}$ .
- BERNARDI 88 also considers bounds on  $|U_{eX} U_{\mu X}|$ .
- $K^+ \rightarrow e^+ \nu_X$ , with  $\nu_X$  decay through  $U_{eX}$ .
- $D^+ \rightarrow e^+ \nu_X$ , with  $\nu_X \rightarrow e^- \ell^+ \nu_\ell$ .
- $D^+ \rightarrow e^+ \nu_X$ , with  $\nu_X \rightarrow e^- \ell^+ \nu_\ell$  or  $\nu_X \rightarrow e^- \pi^+$ .

##### Limits on $|U_{\mu X}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

$<1 \times 10^{-7}$  90 29 ABRATENKO 20 MBNE Superseded by ABRATENKO 22A

- AAD 23AO search for  $W \rightarrow \nu_X \mu$ , for both Majorana and Dirac HNL scenarios. Also consider scenarios involving multiflavor mixing, with correspondingly weaker limits.
- AAD 23CE search for Majorana HNLs via vector boson fusion  $W^\pm W^\pm \rightarrow \mu^\pm \mu^\pm$ . Limits set in a  $m_{\nu_X}$  mass range from 50 GeV up to 20 TeV, using the Phenomenological Type-I Seesaw model as a benchmark scenario.
- TUMASYAN 23AC search for Majorana HNLs via vector boson fusion  $W^\pm W^\pm \rightarrow \mu^\pm \mu^\pm$ . Limits set in a  $m_{\nu_X}$  mass range from 50 GeV up to 25 TeV.
- ABRATENKO 22A search for  $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu^\mp \pi^\pm$ , in the mass range  $m_{\nu_X} \sim 246\text{--}385$  MeV. Also considers limits from  $\nu_X \rightarrow \mu^- \pi^+$  only, for the case of a Dirac HNL.
- TUMASYAN 22AD search for  $W \rightarrow \mu \nu_X$ ,  $\nu_X \rightarrow \mu e \nu_e$  and set limits for Dirac and Majorana Heavy Neutral Leptons. The data correspond to an integrated luminosity of  $138 \text{ fb}^{-1}$ .
- Limit from prompt lepton number conserving  $W \rightarrow \mu \mu j$  search.
- Limit from prompt lepton number violating  $W \rightarrow \mu \mu j$  search.
- Search for  $K^+ \rightarrow \mu^+ \nu_X$ .
- Assumes a lifetime exceeding 50 ns, and searches over  $m_{\nu_X}$  range 200–384 MeV.
- Search for  $B^+ \rightarrow \mu^+ \nu_X$  in the mass range  $m_{\nu_X} \sim 0\text{--}1.5$  GeV.
- Limit from prompt lepton number violating trilepton search.
- Limit from displaced lepton violating or conserving trilepton searches.
- $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X$  decay through  $U_{\mu X}$ . ABE 19B also considers bounds on  $|U_{\ell X} U_{\ell' X}|$  for combinations of lepton flavors in the  $\nu_X$  decay final state.
- Limit requires muon kinetic energy  $> 1.2$  MeV.
- Search for  $\pi^+ \rightarrow \mu^+ \nu_X$ .
- PARK 16 quotes an approximate limit  $B(B^+ \rightarrow \mu^+ \nu_X) < 3 \times 10^{-6}$  in the mass range  $m_{\nu_X} \sim 0.2\text{--}1.4$  GeV.
- Search for  $B^+ \rightarrow \mu^+ \nu_X$ .
- DAUM 00 quotes a branching ratio bound  $B(\pi^+ \rightarrow \mu^+ \nu_X) < 6.0 \times 10^{-10}$  at 95% CL.
- $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu X$ .
- $D_s \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu X$ .
- Search for prompt  $\nu_X$  decay signatures.
- Search for displaced  $\nu_X$  decay signatures.
- Search for Heavy Neutral Leptons produced by neutral current muon neutrino interactions, with  $\nu_X \rightarrow \mu^+ \mu^- \nu_\mu$ .
- $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X$  decay through  $U_{\mu X}$  and  $m_{\nu_X} < m_\mu + m_\pi$ .
- BERNARDI 88 also considers bounds on  $|U_{eX} U_{\mu X}|$ .
- $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu^- \pi^+$ .
- $D^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu^- \ell^+ \nu_\ell$ .
- $D^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu^- \ell^+ \nu_\ell$  or  $\nu_X \rightarrow \mu^- \pi^+$ .

29  $K^+ \rightarrow \mu^+ \nu_X$ , with  $\nu_X \rightarrow \mu^- \pi^+$ , in the mass range  $m_{\nu_X} \sim 260\text{--}385$  MeV. ABRATENKO 20 also considers  $\nu_X \rightarrow \mu^+ \pi^-$  for the case of a Majorana HNL.

### Limits on $|U_{\tau X}|^2$

• • • We do not use the following data for averages, fits, limits, etc. • • •

9 LIVENTSEV 23 BELL Near  $m_{\nu_X} \sim 0.8\text{--}1.2$  GeV  
10 TUMASYAN 22H CMS  $p\bar{p}$  at 13 TeV

- Search for  $\tau^\pm \rightarrow \pi^\pm \pi^+ \pi^- \nu_X$ .
- Reanalysis of BEBC results (cf. COOPER-SARKAR 85) to include searches for  $D_s^\pm \rightarrow \nu_\tau \tau^\pm$ ,  $\tau^\pm \rightarrow \nu_X \pi^\pm$ ,  $\nu_X \rho^\pm$ , or  $\nu_X \nu_\tau \ell^\pm$  via  $U_{\tau X}$ . Assumes a Majorana HNL.
- Search for  $\nu_X \rightarrow \mu^+ \mu^- \nu$ .
- Reanalysis of CHARM results (cf. ORLOFF 02) to include searches for  $\nu_X \rightarrow \nu \ell^+ \ell^-$  decays, and including the production of HNLs from  $\tau$  decays.
- $D_s \rightarrow \tau^+ \nu_X$ , with  $\nu_X$  decay via  $U_{\tau X}$ .
- $D_s \rightarrow \nu_\tau \tau^+$ ,  $\tau^+ \rightarrow \nu_X X$ , with  $\nu_X$  decay via  $U_{\tau X}$ .
- Search for prompt  $\nu_X$  decay signatures.
- Search for displaced  $\nu_X$  decay signatures. Kinematical suppression of  $\nu_X \rightarrow \tau X$  at lower masses leads to rapid loosening of the  $|U_{\tau X}|$  bound compared to that for  $|U_{eX}|$  and  $|U_{\mu X}|$ .
- Search for  $\tau \rightarrow \pi \nu_X$ ,  $\nu_X \rightarrow \pi e$  or  $\pi \mu$  in the range 0.2–1.6 GeV. LIVENTSEV 23 reports results for the sum  $\sum_{\ell=e,\mu,\tau} |U_{\ell X}|^2$  in a model-dependent context, but which may be roughly reinterpreted as a limit  $|U_{eX} U_{\tau X}|^2 + |U_{\mu X} U_{\tau X}|^2 \lesssim 5 \times 10^{-9}$  in either Majorana or Dirac HNL scenarios.
- TUMASYAN 22H sets limits on an approximately mass-degenerate vector-like lepton SU(2) doublet coupling to the  $\tau$ . Some of the reported signal region distributions might be used to set limits for heavy neutral leptons coupled to the  $\tau$ . The data correspond to an integrated luminosity of  $138 \text{ fb}^{-1}$ .

#### Quark Masses

#### u-QUARK MASS

The  $u$ -,  $d$ -, and  $s$ -quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as  $\overline{MS}$ . The ratios  $m_u/m_d$  and  $m_s/m_d$  are extracted from pion and kaon masses using chiral symmetry. The estimates of  $d$  and  $u$  masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the  $u$  quark could be essentially massless. The  $s$ -quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the  $\overline{MS}$  masses at a renormalization scale of  $\mu = 2$  GeV. Results quoted in the literature at  $\mu = 1$  GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 2 and 3 in the "Quark masses" review.

- DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- FODOR 16 is a lattice simulation with  $n_f = 2 + 1$  dynamical flavors and includes partially quenched QED effects.
- CARRASCO 14 is a lattice QCD computation of light quark masses using  $2 + 1 + 1$  dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use  $2+1$  dynamical quark flavors.
- DAVIES 10 and MCNEILE 10 determine  $\bar{m}_c(\mu)/\bar{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $n_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses.

- Mass  $m_u$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios,  $m_s/\bar{m}$  and  $m_u/m_d$ .
- AOKI 12 is a lattice computation using  $1 + 1 + 1$  dynamical quark flavors.
  - DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $n_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual  $m_u, m_d$  values are obtained using the lattice determination of the average mass  $m_{ud}$  and of the ratio  $m_s/m_{ud}$  and the value of  $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$  as determined from  $\eta \rightarrow 3\pi$  decays.
  - BAZAVOV 10 is a lattice computation using  $2+1$  dynamical quark flavors.
  - DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .
  - DEANDREA 08 determine  $m_u - m_d$  from  $\eta \rightarrow 3\pi^0$ , and combine with the PDG 06 lattice average value of  $m_u + m_d = 7.6 \pm 1.6$  to determine  $m_u$  and  $m_d$ .
  - BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
  - JAMIN 06 determine  $m_u(2 \text{ GeV})$  by combining the value of  $m_s$  obtained from the spectral function for the scalar  $K\pi$  form factor with other determinations of the quark mass ratios.
  - MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order. The quark masses  $m_u$  and  $m_d$  were determined from their  $(m_u + m_d)/2$  measurement and AUBIN 04A  $m_u/m_d$  value.
  - NARISON 06 uses sum rules for  $e^+ e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.
  - AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.

WEIGHTED AVERAGE  
2.16±0.04 (Error scaled by 1.2)

#### d-QUARK MASS

See the comment for the  $u$  quark above.

We have normalized the  $\overline{MS}$  masses at a renormalization scale of  $\mu = 2$  GeV. Results quoted in the literature at  $\mu = 1$  GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 2 and 3 in the "Quark masses" review.

- DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- FODOR 16 is a lattice simulation with  $n_f = 2 + 1$  dynamical flavors and includes partially quenched QED effects.

# Quark Particle Listings

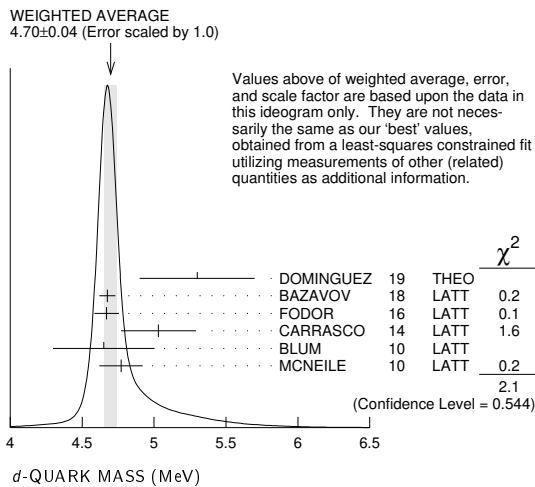

## Light Quarks (*u, d, s*)

- <sup>4</sup> CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The *u* and *d* quark masses are obtained separately by using the *K* meson mass splittings and lattice results for the electromagnetic contributions.
- <sup>5</sup> BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.
- <sup>6</sup> DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $n_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_d$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios,  $m_s/\overline{m}$  and  $m_u/m_d$ .
- <sup>7</sup> AOKI 12 is a lattice computation using 1 + 1 + 1 dynamical quark flavors.
- <sup>8</sup> DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $n_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual  $m_u, m_d$  values are obtained using the lattice determination of the average mass  $m_{ud}$  and of the ratio  $m_s/m_{ud}$  and the value of  $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$  as determined from  $\eta \rightarrow 3\pi$  decays.
- <sup>9</sup> BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.
- <sup>10</sup> DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .
- <sup>11</sup> DEANDREA 08 determine  $m_u - m_d$  from  $\eta \rightarrow 3\pi^0$ , and combine with the PDG 06 lattice average value of  $m_u + m_d = 7.6 \pm 1.6$  to determine  $m_u$  and  $m_d$ .
- <sup>12</sup> BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- <sup>13</sup> JAMIN 06 determine  $m_d(2 \text{ GeV})$  by combining the value of  $m_s$  obtained from the spectral function for the scalar *K* $\pi$  form factor with other determinations of the quark mass ratios.
- <sup>14</sup> MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate *u* and *d* quarks. Perturbative corrections were included at NNLO order. The quark masses  $m_u$  and  $m_d$  were determined from their  $(m_u + m_d)/2$  measurement and AUBIN 04A  $m_u/m_d$  value.
- <sup>15</sup> NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.
- <sup>16</sup> AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses, and one-loop perturbative renormalization constant.

- <sup>1</sup> ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with  $m_u = m_d \neq m_s \neq m_c$ , including gauge ensembles close to the physical pion point.
- <sup>2</sup> BRUNO 20 determines the light quark mass using a lattice calculation with  $n_f = 2+1$  flavors of Wilson fermions. The scale has been set from  $t_\pi$  and  $t_K$ . The tuning was done using the masses of the lightest ( $\pi$ ) and strange (*K*) pseudoscalar mesons.
- <sup>3</sup> DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.
- <sup>4</sup> YUAN 17 determine  $\overline{m}$  using QCD sum rules in the isospin  $I=0$  scalar channel. At the end of the "Numerical Results" section of YUAN 17 the authors discuss the significance of their larger value of the light quark mass compared to previous determinations.
- <sup>5</sup> CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The *u* and *d* quark masses are obtained separately by using the *K* meson mass splittings and lattice results for the electromagnetic contributions.
- <sup>6</sup> ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at  $\mu = 3 \text{ GeV}$  have been converted to  $\mu = 2 \text{ GeV}$  using conversion factors given in their paper.
- <sup>7</sup> DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $n_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- <sup>8</sup> BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $n_f=2$  dynamical twisted-mass Wilson fermions.
- <sup>9</sup> DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $n_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_d$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio,  $m_s/\overline{m}$ .
- <sup>10</sup> AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $n_f = 2 + 1$  dynamical flavors of domain wall fermions.
- <sup>11</sup> DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .
- <sup>12</sup> ALLTON 08 use a lattice computation of the  $\pi, K, \text{ and } \Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- <sup>13</sup> BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- <sup>14</sup> DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.
- <sup>15</sup> ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.
- <sup>16</sup> NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- <sup>17</sup> BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- <sup>18</sup> GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $n_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\overline{m}(2 \text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- <sup>19</sup> GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $n_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.
- <sup>20</sup> MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate *u* and *d* quarks. Perturbative corrections were included at NNLO order.
- <sup>21</sup> NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.
- <sup>22</sup> AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- <sup>23</sup> AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.
- <sup>24</sup> The errors given in AOKI 03b were  $+0.046$   
 $-0.069$ . We changed them to  $\pm 0.3$  for calculating the overall best values. AOKI 03b uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.
- <sup>25</sup> BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization.
- <sup>26</sup> CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

$$\overline{m} = (m_u + m_d)/2$$

See the comments for the *u* quark above.

We have normalized the  $\overline{m}_S$  masses at a renormalization scale of  $\mu = 2 \text{ GeV}$ . Results quoted in the literature at  $\mu = 1 \text{ GeV}$  have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 2 and 3 in the "Quark masses" review.

- 1 ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with  $m_u = m_d \neq m_s \neq m_c$ , including gauge ensembles close to the physical point.
- 2 BRUNO 20 determines the light quark mass using a lattice calculation with  $n_f = 2+1$  flavors of Wilson fermions. The scale has been set from  $f_\pi$  and  $f_K$ . The tuning was done using the masses of the lightest ( $\pi$ ) and strange ( $K$ ) pseudoscalar mesons.
- 3 BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- 4 LYTTLE 18 combined with CHAKRABORTY 2015 determine  $\overline{m}_s(3 \text{ GeV}) = 84.78 \pm 0.65$  MeV from a lattice simulation with  $n_f = 2+1+1$  flavors. They also determine the quoted value  $\overline{m}_s(2 \text{ GeV})$  for  $n_f = 4$  dynamical flavors.
- 5 ANANTHANA 16 determine  $\overline{m}_s(2 \text{ GeV}) = 106.70 \pm 9.36$  MeV and  $74.47 \pm 7.77$  MeV from fits to ALEPH and OPAL  $\tau$  decay data, respectively. We have used the weighted average of the two.
- 6 CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The *u* and *d* quark masses are obtained separately by using the *K* meson mass splittings and lattice results for the electromagnetic contributions.
- 7 ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at  $\mu = 3$  GeV have been converted to  $\mu = 2$  GeV using conversion factors given in their paper.
- 8 BODENSTEIN 13 determines  $m_s$  from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.
- 9 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $n_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- 10 CHAKRABORTY 15 is a lattice QCD computation that determines  $m_c$  and  $m_c/m_s$  using pseudoscalar meson masses tuned on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with *u/d* masses down to the physical value.
- 11 FRITZSCH 12 determine  $m_s$  using a lattice computation with  $n_f = 2$  dynamical flavors.
- 12 AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $n_f = 2 + 1$  dynamical flavors of domain wall fermions.
- 13 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $n_f=2$  dynamical twisted-mass Wilson fermions.

WEIGHTED AVERAGE

## Light Quarks (*u, d, s*)

- <sup>14</sup>BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.
- <sup>15</sup>DAVIES 10 and MCNEILE 10 determine  $\overline{m}_C(\mu)/\overline{m}_S(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $n_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_S$  is obtained from this using the value of  $m_C$  from ALLISON 08 or MCNEILE 10.
- <sup>16</sup>ALLTON 08 use a lattice computation of the  $\pi$ ,  $K$ , and  $\Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- <sup>17</sup>BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- <sup>18</sup>DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order  $\alpha_s^4$ .
- <sup>19</sup>ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.
- <sup>20</sup>NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- <sup>21</sup>BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- <sup>22</sup>CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order  $\alpha_s^4$ .
- <sup>23</sup>GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $n_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\overline{m}_S(2 \text{ GeV}) = 111 \pm 6 \pm 4 \pm 6 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- <sup>24</sup>GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $n_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.
- <sup>25</sup>JAMIN 06 determine  $\overline{m}_S(2 \text{ GeV})$  from the spectral function for the scalar  $K\pi$  form factor.
- <sup>26</sup>MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order.
- <sup>27</sup>NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$ .
- <sup>28</sup>NARISON 06 obtains the quoted range from positivity of the spectral functions.
- <sup>29</sup>BAIKOV 05 determines  $\overline{m}_S(M_\tau) = 100^{+5}_{-3} +^{17}_{-19}$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ , with an estimate of the  $\alpha_s^4$  terms. We have converted the result to  $\mu = 2 \text{ GeV}$ .
- <sup>30</sup>GAMIZ 05 determines  $\overline{m}_S(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^2$ , with an estimate of the  $\alpha_s^3$  terms.
- <sup>31</sup>GORBUNOV 05 use hadronic tau decays to N3LO, including power corrections.
- <sup>32</sup>NARISON 05 determines  $\overline{m}_S(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ .
- <sup>33</sup>AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- <sup>34</sup>AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines  $m_s = 113.8 \pm 2.3 \pm^{5.8}_{-2.9}$  using  $K$  mass as input and  $m_s = 142.3 \pm 5.8 \pm^{22}_{-0}$  using  $\phi$  mass as input. We have performed a weighted average of these values.
- <sup>35</sup>AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.
- <sup>36</sup>BEČIREVIĆ 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization. They also quote  $\overline{m}/m_s = 24.3 \pm 0.2 \pm 0.6$ .
- <sup>37</sup>CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
- <sup>38</sup>GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is chosen to satisfy CKM unitarity.
- <sup>39</sup>GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is taken from the PDG.

18 to 23	<sup>5</sup> LEUTWYLER 90B	90B	THEO

- <sup>1</sup>GAO 97 uses electromagnetic mass splittings of light mesons.
- <sup>2</sup>LEUTWYLER 96 uses a combined fit to  $\eta \rightarrow 3\pi$  and  $\psi' \rightarrow J/\psi(\pi, \eta)$  decay rates, and the electromagnetic mass differences of the  $\pi$  and  $K$ .
- <sup>3</sup>DONOGHUE 92 result is from a combined analysis of meson masses,  $\eta \rightarrow 3\pi$  using second-order chiral perturbation theory including nonanalytic terms, and  $(\psi(2S) \rightarrow J/\psi(1S)\pi)(\psi(2S) \rightarrow J/\psi(1S)\eta)$ .
- <sup>4</sup>GERARD 90 uses large  $N$  and  $\eta$ - $\eta'$  mixing.
- <sup>5</sup>LEUTWYLER 90B determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine  $L_7$ .

- <sup>1</sup>ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with  $m_u = m_d \neq m_s \neq m_c$ , including gauge ensembles close to the physical pion point.
- <sup>2</sup>BRUNO 20 determines the light quark mass using a lattice calculation with  $n_f = 2+1$  flavors of Wilson fermions. The scale has been set from  $f_\pi$  and  $f_K$ . The tuning was done using the masses of the lightest ( $\pi$ ) and strange ( $K$ ) pseudoscalar mesons.
- <sup>3</sup>BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.
- <sup>4</sup>CARRASCO 14 is a lattice QCD computation of light quark masses using 2+1+1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- <sup>5</sup>ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions.
- <sup>6</sup>DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $n_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- <sup>7</sup>AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $n_f = 2 + 1$  dynamical flavors of domain wall fermions.
- <sup>8</sup>BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $n_f = 2$  dynamical twisted-mass Wilson fermions.
- <sup>9</sup>ALLTON 08 use a lattice computation of the  $\pi$ ,  $K$ , and  $\Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- <sup>10</sup>BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- <sup>11</sup>OLLER 07A use unitarized chiral perturbation theory to order  $p^4$ .
- <sup>12</sup>Three flavor dynamical lattice calculation of pseudoscalar meson masses.

### c-QUARK MASS

The  $c$ -quark mass corresponds to the "running" mass  $m_c(\mu = m_c)$  in the  $\overline{MS}$  scheme. We have converted masses in other schemes to the  $\overline{MS}$  scheme using two-loop QCD perturbation theory with  $\alpha_s(\mu = m_c) =$

- <sup>1</sup> ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. We have converted  $\overline{m}_c(3 \text{ GeV}) = 1.036 \pm 0.017 \pm 0.015 - 0.008$  to  $\overline{m}_c(\overline{m}_c)$ . The simulations are carried out using  $2+1+1$  dynamical quarks with  $m_u = m_d \neq m_s \neq m_c$ , including gauge ensembles close to the physical pion point.
- <sup>2</sup> HEITGER 21 determines the charm quark mass using a  $n_f = 2+1$  flavor lattice QCD simulation with non-perturbatively O(a) improved Wilson fermions. They also determine  $\overline{m}_c(3 \text{ GeV}) = 1.007 \pm 0.016 \text{ GeV}$ .
- <sup>3</sup> HATTON 20 determines the charm quark mass with a lattice QCD + quenched QED simulation using the HISQ action and including  $n_f = 2+1+1$  flavors of sea quarks.  $m_c$  is tuned from the  $J/\psi$  meson mass giving  $\overline{m}_c(3 \text{ GeV}) = 0.9841 \pm 0.0051 \text{ GeV}$ .
- <sup>4</sup> NARISON 20 determines the quark mass using QCD Laplace sum rules from the  $B_c$  mass, combined with previous determinations of the QCD condensates and  $c$  and  $b$  masses.
- <sup>5</sup> ABRAMOWICZ 18 determine  $\overline{m}_c(\overline{m}_c) = 1.290 \pm 0.046 + 0.062 + 0.003$  from the production of  $c$  quarks in  $e p$  collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.
- <sup>6</sup> BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- <sup>7</sup> LYTLE 18 combined with CHAKRABORTY 15 determine  $\overline{m}_c(3 \text{ GeV}) = 0.9874(48) \text{ GeV}$  from a lattice simulation with  $n_f = 2+1+1$  flavors. They also determine the quoted value  $\overline{m}_c(\overline{m}_c)$  for  $n_f = 4$  dynamical flavors.
- <sup>8</sup> PESET 18 determine  $\overline{m}_c(\overline{m}_c)$  and  $\overline{m}_b(\overline{m}_b)$  using an N3LO calculation of the  $\eta_c, \eta_b$  and  $B_c$  masses.
- <sup>9</sup> CHETYRKIN 17 determine  $\overline{m}_c(\mu = 3 \text{ GeV}) = 0.993 \pm 0.008 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c)$  from a four-loop sum-rule computation of the cross-section for  $e^+ e^- \rightarrow$  hadrons in the charm threshold region.
- <sup>10</sup> ERLER 17 determine  $\overline{m}_c(\overline{m}_c) = 1.272 \pm 0.008 \text{ GeV}$  from a three-loop QCD sum-rule computation of the vector current correlator. This result is for fixed  $\alpha_s(M_Z) = 0.1182$ . Including an  $\alpha_s$  uncertainty of  $\pm 0.0016$ , the charm mass error increases from 8 to 9 MeV.
- <sup>11</sup> KIYO 16 determine  $\overline{m}_c(\overline{m}_c)$  from the  $J/\psi(1S)$  mass at order  $\alpha_s^3$  (N3LO).

# Quark Particle Listings

C

- 12 DEHNADI 15 determine  $\overline{m}_c(\overline{m}_c)$  using sum rules for  $e^+e^- \rightarrow$  hadrons at order  $\alpha_s^3$  (N3LO), and fitting to both experimental data and lattice results.
- 13 CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- 14 ALEKHIN 13 determines  $m_c$  from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 15 SAMOYLOV 13 determines  $m_c$  from a study of charm dimuon production in neutrino-iron scattering using the NLO QCD result for the charm quark production cross section.
- 16 BODENSTEIN 11 determine  $\overline{m}_c(3 \text{ GeV}) = 0.987 \pm 0.009 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009 \text{ GeV}$  using QCD sum rules for the charm quark vector current correlator.
- 17 LASCHKA 11 determine the  $c$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\overline{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- 18 AUBERT 10A determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{MS}$  scheme).
- 19 SIGNER 09 determines the  $c$ -quark mass using non-relativistic sum rules to analyze the  $e^+e^- \rightarrow c\overline{c}$  cross-section near threshold. Also determine the PS mass  $m_{PS}(\mu_F = 0.7 \text{ GeV}) = 1.50 \pm 0.04 \text{ GeV}$ .
- 20 NARISON 18A determines simultaneously  $\overline{m}_c(\overline{m}_c)$  and the 4-dimension gluon condensate using QCD exponential sum rules and their ratios evaluated at the optimal scale  $\mu = 2.85 \text{ GeV}$  at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6-8 in the (axial)-vector and (pseudo)-scalar charmonium channels.
- 21 NARISON 18B determines  $\overline{m}_c(\overline{m}_c)$  using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.
- 22 BERTONE 16 determine  $\overline{m}_c(\overline{m}_c)$  from HERA deep inelastic scattering data using the FONLL scheme. Also determine  $\overline{m}_c(\overline{m}_c) = 1.318 \pm 0.054 \pm 0.490 \pm 0.022$  using the fixed flavor number scheme.
- 23 CHAKRABORTY 15 is a lattice QCD computation using 2+1+1 dynamical flavors. Moments of pseudoscalar current-current correlators are matched to  $\alpha_s^3$ -accurate QCD perturbation theory with the  $\eta_c$  meson mass tuned to experiment.
- 24 ABRAMOWICZ 13c determines  $m_c$  from charm production in deep inelastic  $e p$  scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of  $\alpha_s$ , of  $\pm 0.03$ ,  $\pm 0.02$ , and  $\pm 0.02$  respectively, have been combined in quadrature.
- 25 DEHNADI 13 determines  $m_c$  using QCD sum rules for the charmonium spectrum and charm continuum to order  $\alpha_s^3$  (N3LO). The statistical and systematic experimental errors of  $\pm 0.006$  and  $\pm 0.009$  have been combined in quadrature. The theoretical uncertainties  $\pm 0.019$  from truncation of the perturbation series,  $\pm 0.010$  from  $\alpha_s$ , and  $\pm 0.002$  from the gluon condensate have been combined in quadrature.
- 26 NARISON 13 determines  $m_c$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6.
- 27 ALEKHIN 12 determines  $m_c$  from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 28 NARISON 12A determines  $m_c$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight.
- 29 ALEKHIN 11 determines  $m_c$  from heavy quark production in deep inelastic scattering using fixed target and HERA data, and approximate NNLO QCD.
- 30 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $n_f=2$  dynamical twisted-mass Wilson fermions.
- 31 BODENSTEIN 10 determines  $\overline{m}_c(3 \text{ GeV}) = 1.008 \pm 0.026 \text{ GeV}$  using finite energy sum rules for the vector current correlator. The authors have converted this to  $\overline{m}_c(\overline{m}_c)$  using  $\alpha_s(M_Z) = 0.1189 \pm 0.0020$ .
- 32 MCNEILE 10 determines  $m_c$  by comparing the order  $\alpha_s^3$  perturbative results for the pseudo-scalar current to lattice simulations with  $n_f = 2+1$  sea-quarks by the HPQCD collaboration.
- 33 NARISON 10 determines  $m_c$  from ratios of moments of vector current correlators computed to order  $\alpha_s^3$  and including the dimension-six gluon condensate.
- 34 CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+e^- \rightarrow Q\overline{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  computation of the heavy quark vacuum polarization. They also determine  $m_c(3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$ .
- 35 ALLISON 08 determine  $m_c$  by comparing four-loop perturbative results for the pseudo-scalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
- 36 KUHN 07 determine  $\overline{m}_c(\mu = 3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the charm threshold region.
- 37 BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ .
- 38 BUCHMUELLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra.
- 39 HOANG 06 determines  $\overline{m}_c(\overline{m}_c)$  from a global fit to inclusive  $B$  decay data. The  $B$  decay distributions were computed to order  $\alpha_s^2\beta_0$ , and the conversion between different  $m_c$  mass schemes to order  $\alpha_s^3$ .
- 40 AUBERT 04x obtain  $m_c$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{MS}$  value has been provided by the BABAR collaboration.
- 41 HOANG 04 determines  $\overline{m}_c(\overline{m}_c)$  from moments at order  $\alpha_s^2$  of the charm production cross-section in  $e^+e^-$  annihilation.
- 42 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
- 43 EIDEMULLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules.
- 44 ERLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules. Includes recent BES data.
- 45 ZYABLYUK 03 determines  $m_c$  by using QCD sum rules in the pseudoscalar channel and comparing with the  $\eta_c$  mass.

WEIGHTED AVERAGE  
1.2730±0.0028 (Error scaled by 1.0)

## $m_c/m_s$ MASS RATIO

The ratio is that of the  $\overline{MS}$  masses at a common scale, for four dynamical quark flavors.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with  $m_u = m_d \neq m_s \neq m_c$ , including gauge ensembles close to the physical pion point.
- 2 BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
- 3 CHAKRABORTY 15 is a lattice QCD computation on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with  $u/d$  masses down to the physical value.  $m_c$  and  $m_s$  are tuned from pseudoscalar meson masses.
- 4 CARRASCO 14 is a lattice QCD computation of light quark masses using 2 + 1 + 1 dynamical quarks, with  $m_u = m_d \neq m_s \neq m_c$ . The  $u$  and  $d$  quark masses are obtained separately by using the  $K$  meson mass splittings and lattice results for the electromagnetic contributions.
- 5 DURR 12 determine  $m_c/m_s$  using a lattice computation with  $n_f = 2$  dynamical fermions. The result is combined with other determinations of  $m_c$  to obtain  $m_s(2 \text{ GeV}) = 97.0 \pm 2.6 \pm 2.5 \text{ MeV}$ .
- 6 DAVIES 10 determine  $m_c/m_s$  from meson masses calculated on gluon fields including  $u$ ,  $d$ , and  $s$  sea quarks with lattice spacing down to 0.045 fm. The Highly Improved Staggered quark formalism is used for the valence quarks.
- 7 BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.
- 8 BLOSSIER 10 determine  $m_c/m_s$  from a computation of the hadron spectrum using  $n_f = 2$  dynamical twisted-mass Wilson fermions.

WEIGHTED AVERAGE  
11.761±0.028 (Error scaled by 1.2)

**$m_b/m_c$  MASS RATIO**

The ratio is that of the  $\overline{MS}$  masses at a common scale, for four dynamical quark flavors.

- APARISI 22 determine  $m_b$  at the Higgs mass,  $\overline{m}_b(m_H) = 2.60^{+0.36}_{-0.31}$  GeV from Higgs boson decay rates at the LHC, which is used to obtain  $\overline{m}_b(\overline{m}_b)$ .
- HATTON 21 determine  $\overline{m}_b(3 \text{ GeV}) = 4.513 \pm 0.026$  GeV using a lattice QCD + quenched QED simulation using the HISQ action and including  $n_f = 2+1+1$  flavors of sea quarks, by combining their  $\overline{m}_b/\overline{m}_c$  and  $\overline{m}_c$  determinations.
- NARISON 20 determines the quark mass using QCD Laplace sum rules from the  $B_c$  mass, combined with previous determinations of the QCD condensates and  $c$  and  $b$  masses.
- ABRAMOWICZ 18 determine  $\overline{m}_b(\overline{m}_b) = 4.049^{+0.104+0.099+0.001}_{-0.109-0.032-0.031}$  from the production of  $b$  quarks in  $ep$  collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.
- BAZAVOV 18 determine the  $b$  mass using a lattice computation with staggered fermions and five active quark flavors.
- PESET 18 determine  $\overline{m}_c(\overline{m}_c)$  and  $\overline{m}_b(\overline{m}_b)$  using an N3LO calculation of the  $\eta_c, \eta_b$  and  $B_c$  masses.
- KIYO 16 determine  $\overline{m}_b(\overline{m}_b)$  from the  $\Upsilon(1S)$  mass at order  $\alpha_s^3$  (N3LO).
- ALBERTI 15 determine  $\overline{m}_b(\overline{m}_b)$  from fits to inclusive  $B \rightarrow X_c e \overline{\nu}$  decay. They also find  $m_b^{\text{kin}}(1 \text{ GeV}) = 4.553 \pm 0.020$  GeV.
- BENEKE 15 determine  $\overline{m}_b(\overline{m}_b)$  using sum rules for  $e^+e^- \rightarrow$  hadrons at order N3LO including finite  $m_c$  effects. They find  $m_b^{\text{P}}(2 \text{ GeV}) = 4.532^{+0.013}_{-0.035}$  GeV, and  $\overline{m}_b(\overline{m}_b) = 4.193^{+0.022}_{-0.035}$  GeV. The value quoted is obtained using the four-loop conversion given in BENEKE 16.

$$J(P) = 0(\frac{1}{2}^+)$$

$$\text{Charge} = -\frac{1}{3} e \quad \text{Bottom} = -1$$

**b-QUARK MASS**

$b$ -quark mass corresponds to the "running mass"  $\overline{m}_b(\mu = \overline{m}_b)$  in the  $\overline{MS}$  scheme. We have converted masses in other schemes to the  $\overline{MS}$  mass using two-loop QCD perturbation theory with  $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$ . The value  $4.18^{+0.04}_{-0.03}$  GeV for the  $\overline{MS}$  mass corresponds to  $4.78 \pm 0.06$  GeV

# Quark Particle Listings

## *b*

- 10 COLQUHOUN 15 determine  $\overline{m}_b(\overline{m}_b)$  from moments of the vector current correlator computed with a lattice simulation using the NRQCD action.
- 11 DEHNADI 15 determine  $\overline{m}_b(\overline{m}_b)$  using sum rules for  $e^+e^- \rightarrow$  hadrons at order  $\alpha_s^3$  (N3LO), and fitting to both experimental data and lattice results.
- 12 BERNARDONI 14 determine  $m_b$  from  $n_f = 2$  lattice calculations using heavy quark effective theory non-perturbatively renormalized and matched to QCD at  $1/m$  order.
- 13 PENIN 14 determine  $\overline{m}_b(\overline{m}_b) = 4.169 \pm 0.008 \pm 0.002 \pm 0.002$  using an estimate of the order  $\alpha_s^3$   $b$ -quark vacuum polarization function in the threshold region, including finite  $m_c$  effects. The errors of  $\pm 0.008$  from theoretical uncertainties, and  $\pm 0.002$  from  $\alpha_s$  have been combined in quadrature.
- 14 LEE 13a determine  $m_b$  using lattice calculations of the  $\Upsilon$  and  $B_s$  binding energies in NRQCD, including three light dynamical quark flavors. The quark mass shift in NRQCD is determined to order  $\alpha_s^2$ , with partial  $\alpha_s^3$  contributions.
- 15 LUCHA 13 determines  $m_b$  from QCD sum rules for heavy-light currents using the lattice value for  $\Gamma_B$  of  $191.5 \pm 7.3$  GeV.
- 16 BODENSTEIN 12 determine  $m_b$  using sum rules for the vector current correlator and the  $e^+e^- \rightarrow Q\overline{Q}$  total cross-section.
- 17 DIMOPOULOS 12 determine quark masses from a lattice computation using  $n_f = 2$  dynamical flavors of twisted mass fermions.
- 18 LASCHKA 11 determine the  $b$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\overline{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- 19 AUBERT 10a determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{MS}$  scheme).
- 20 CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+e^- \rightarrow Q\overline{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  (N3LO) computation of the heavy quark vacuum polarization.
- 21 SCHWANDA 08 measure moments of the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay to determine  $m_b^{1S}$ . We have converted this to  $\overline{MS}$  scheme.
- 22 NARISON 18a determine  $\overline{m}_b(\overline{m}_b)$  as a function of  $\alpha_s$  using QCD exponential sum rules and their ratios evaluated at the optimal scale  $\mu = 9.5$  GeV at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6–8 in the (axial-)vector and (pseudo-)scalar bottomonium channels.
- 23 NARISON 18b determine  $\overline{m}_b(\overline{m}_b)$  using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.
- 24 ABRAMOWICZ 14a determine  $\overline{m}_b(\overline{m}_b) = 4.07 \pm 0.14^{+0.01+0.05+0.08}_{-0.07-0.00-0.05}$  from the production of  $b$  quarks in  $e p$  collisions at HERA. The errors due to fitting, modeling, PDF parameterization, and theoretical QCD uncertainties due to the values of  $\alpha_s$ ,  $m_c$ , and the renormalization scale  $\mu$  have been combined in quadrature.
- 25 AYALA 14a determine  $\overline{m}_b(\overline{m}_b)$  from the  $\Upsilon(1S)$  mass computed to N3LO order in perturbation theory using a renormalon subtracted scheme.
- 26 NARISON 13 determine  $m_b$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6.
- 27 NARISON 13a determine  $m_b$  using HQET sum rules to order  $\alpha_s^2$  (NNLO) and the  $B$  meson mass and decay constant.
- 28 HOANG 12 determine  $m_b$  using non-relativistic sum rules for the  $\Upsilon$  system at order  $\alpha_s^2$  (NNLO) with renormalization group improvement.
- 29 NARISON 12 determine  $m_b$  using exponential sum rules for the vector current correlator to order  $\alpha_s^2$ , including the effect of gluon condensates up to dimension eight.
- 30 Determine  $m_b$  to order  $\alpha_s^3$  (N3LO), including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12a.
- 31 NARISON 12a determine  $m_b$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight.
- 32 MCNEILE 10 determine  $m_b$  by comparing order  $\alpha_s^3$  (N3LO) perturbative results for the pseudo-scalar current to lattice simulations with  $n_f = 2+1$  sea-quarks by the HPQCD collaboration.
- 33 NARISON 10 determine  $m_b$  from ratios of moments of vector current correlators computed to order  $\alpha_s^2$  and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.
- 34 ABDALLAH 08b determine  $\overline{m}_b(M_Z) = 3.76 \pm 1.0$  GeV from a leading order study of four-jet rates at LEP.
- 35 GUAZZINI 08 determine  $\overline{m}_b(\overline{m}_b)$  from a quenched lattice simulation of heavy meson masses. The  $\pm 0.08$  is an estimate of the quenching error.
- 36 DELLA-MORTE 07 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the spin-averaged  $B$  meson mass using quenched lattice HQET at order  $1/m$ . The  $\pm 0.08$  is an estimate of the quenching error.
- 37 KUHN 07 determine  $\overline{m}_b(\mu = 10 \text{ GeV}) = 3.609 \pm 0.025$  GeV and  $\overline{m}_b(\overline{m}_b)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the bottom threshold region.
- 38 ABDALLAH 06b determine  $m_b(M_Z) = 2.85 \pm 0.32$  GeV from  $Z$ -decay three-jet events containing a  $b$ -quark.
- 39 BOUGHEZAL 06  $\overline{MS}$  scheme result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ .
- 40 BUCHMUELLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra.
- 41 PINEDA 06  $\overline{MS}$  scheme result comes from a partial NNLL evaluation (complete at order  $\alpha_s^2$  (NNLO)) of sum rules of the bottom production cross-section in  $e^+e^-$  annihilation.
- 42 GRAY 05 determine  $\overline{m}_b(\overline{m}_b)$  from a lattice computation of the  $\Upsilon$  spectrum. The simulations have 2+1 dynamical light flavors. The  $b$  quark is implemented using NRQCD.
- 43 AUBERT 04x obtain  $m_b$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{MS}$  value has been provided by the BABAR collaboration.
- 44 BAUER 04 determine  $m_b$ ,  $m_c$  and  $m_b - m_c$  by a global fit to inclusive  $B$  decay spectra.
- 45 HOANG 04 determine  $\overline{m}_b(\overline{m}_b)$  from moments at order  $\alpha_s^2$  of the bottom production cross-section in  $e^+e^-$  annihilation.
- 46 MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.
- 47 BAUER 03 determine the  $b$  quark mass by a global fit to  $B$  decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic

$B \rightarrow X_c \ell \nu_\ell$  decay, and the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay. The theoretical expressions used are of order  $1/m^3$ , and  $\alpha_s^2 \beta_0$ .

48 BORDES 03 determines  $m_b$  using QCD finite energy sum rules to order  $\alpha_s^2$ .

49 CORCELLA 03 determines  $\overline{m}_b$  using sum rules computed to order  $\alpha_s^2$ . Includes charm quark mass effects.

50 DEDIVITIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

51 EIDEMULLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules.

52 ERLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules. Includes recent BES data.

53 MAHMOOD 03 determines  $m_b^{1S}$  by a fit to the lepton energy moments in  $B \rightarrow X_c \ell \nu_\ell$  decay. The theoretical expressions used are of order  $1/m^3$  and  $\alpha_s^2 \beta_0$ . We have converted their result to the  $\overline{MS}$  scheme.

54 BRAMBILLA 02 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the  $\Upsilon(1S)$  mass to order  $\alpha_s^4$ , including finite  $m_c$  corrections.

55 PENIN 02 determine  $\overline{m}_b$  from the spectrum of the  $\Upsilon$  system.

$b$ -QUARK  $\overline{MS}$  MASS (GeV)

### $m_b/m_s$ MASS RATIO

VALUE	DOCUMENT ID	TECN
<b>53.88 ± 0.12 OUR AVERAGE</b>

Top Quark

**t-QUARK MASS**

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured  $t\bar{t}$  cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

**t-Quark Mass (Direct Measurements)**

The following measurements extract a  $t$ -quark mass from the kinematics of  $t\bar{t}$  events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

OUR AVERAGE of  $172.57 \pm 0.29$  GeV is an average of top mass measurements from LHC and Tevatron Runs. The latest Tevatron average,  $174.30 \pm 0.35 \pm 0.54$  GeV, was provided by the Tevatron Electroweak Working Group (TEVEWWG).
