CARRIER-FREE RADIOISOTOPES FROM CYCLOTRON TARGETS  
 I. PREPARATION AND ISOLATION OF  $\text{Sn}^{113}$  AND  $\text{In}^{114}$  FROM CADMIUM<sup>1</sup>

Roy D. Maxwell<sup>2</sup>, Herman R. Haymond, Donald R. Bomberger, Warren M. Garrison and Joseph G. Hamilton.

Crocker Laboratory, Radiation Laboratory, and Divisions of Medical Physics, Experimental Medicine, and Radiology; University of California, Berkeley and San Francisco.

The cyclotron is the only practical source of many carrier-free<sup>3</sup> radioisotopes. The preparation and radiochemical isolation of a number of these activities, produced in the 60-inch cyclotron of Crocker Laboratory, will be presented in this paper and in subsequent papers of this series. In most cases the carrier-free radioisotopes were prepared for use in biological systems and the final preparations were in the form of isotonic saline solutions at a range of pH from 5 to 8.

The present paper reports the radiochemical isolation of carrier-free  $\text{Sn}^{113}$  and  $\text{In}^{114}$  produced by bombarding cadmium with 38 Mev alpha-particles. At this energy,  $\text{Sn}^{113}$  and  $\text{In}^{114}$  are produced in a thick target by the nuclear reactions<sup>4</sup>;  $\text{Cd}^{110}(\alpha, n)\text{Sn}^{113}$ ,  $\text{Cd}^{111}(\alpha, 2n)\text{Sn}^{113}$ ,  $\text{Cd}^{112}(\alpha, 3n)\text{Sn}^{113}$ ,  $\text{Cd}^{111}(\alpha, p)\text{In}^{114}$ ,  $\text{Cd}^{112}(\alpha, pn)\text{In}^{114}$ . The shorter-lived tin and indium activities together with the possible radioisotopes of silver produced by (n,p) reactions, were allowed to decay out prior to the chemical separations.

The target, a block of C.P. cadmium metal, soft soldered to a water-cooled copper plate, was bombarded with 38 Mev alpha-particles for a total of 450  $\mu$ -hrs. at an average beam intensity of 3.4  $\mu$ a. After aging for one week, the bombarded surface was milled off and dissolved in a minimum volume of 16 N HNO<sub>3</sub>.

0.2 gm of target cadmium nitrate was dissolved in 25 ml. of water, and the tin and indium activities were carried quantitatively on 10 mg of Fe(OH)<sub>3</sub> precipitated with NH<sub>4</sub>OH. The Fe(OH)<sub>3</sub> was dissolved in 15 ml of 36 N H<sub>2</sub>SO<sub>4</sub> and transferred to an all-glass distilling flask.<sup>5,6</sup> 9 N HBr was added dropwise while a stream of CO<sub>2</sub> was bubbled through the solution at 220° C. The distillate, containing the carrier-free Sn<sup>113</sup>, HBr, Br<sub>2</sub> and traces of H<sub>2</sub>SO<sub>4</sub> was caught in a series of traps filled with 12 N HCl; the indium activity remained in the residue. Carrier-free radio-tin collected in HNO<sub>3</sub> or H<sub>2</sub>SO<sub>4</sub>, forms a radiocolloid<sup>7,8</sup> and is adsorbed onto the walls of the containing vessel. 12 N HCl keeps the radio-tin in solution presumably as the chlorostannate complex. The trap contents were treated with 5 ml. of 16 N HNO<sub>3</sub> to destroy HBr, 15 mg of citric acid were added and the solution was evaporated on a steam bath to the 1-2 ml volume of H<sub>2</sub>SO<sub>4</sub> carried over in the distillation. Citric acid prevents the formation of radiocolloid after removal of HCl.

The H<sub>2</sub>SO<sub>4</sub> solution was diluted with 25 ml of water and the radio-tin was carried down on Fe(OH)<sub>3</sub> precipitated with NH<sub>4</sub>OH. The Fe(OH)<sub>3</sub> was dissolved in 8 N HCl and iron was extracted with isopropyl ether. The aqueous phase, containing

- (8) The colloidal properties of carrier-free radio-tin are being investigated.

These results will be published elsewhere.

HCl,  $\text{Sn}^{113}$  and equilibrium amounts of the  $\text{In}^{113}$  daughter, was evaporated to dryness on 10 mg of sodium citrate. The activity dissolved quantitatively in distilled water.

The carrier-free  $\text{Sn}^{113}$  was identified by its 105-day half-life and by the 0.39 Mev conversion electron of the  $\text{In}^{113}$  daughter<sup>9</sup>. The indium fraction from a chemical separation of an equilibrium mixture using tin and indium carriers, showed the 105 min. period of  $\text{In}^{113}$ .

The residue from the tin distillation, containing  $\text{Fe}^{+++}$  and  $\text{In}^{114}$ , was neutralized with  $\text{NH}_4\text{OH}$ . The  $\text{Fe}(\text{OH})_3$  plus indium activity was dissolved in 8 N HCl, and extracted with isopropyl ether. The HCl solution of  $\text{In}^{114}$  was evaporated to dryness on 10 mg of NaCl. The activity dissolved quantitatively with the addition of distilled water. The  $\text{In}^{114}$  was identified by the assigned 48-day half-life and by the 0.19 Mev conversion electron 9,10.

The authors wish to express their appreciation to Professor G. T. Seaborg for his interest in this work, to Mr. T. Putnam and B. Rossi and the 60-inch cyclotron staff for bombardments, and to Mrs. Alberta Mozley and Mrs. Helen Haydon for technical assistance.
